- **Relevant programme documents:** GR-100/110/120/140/200; epistemic architecture; formal-semantics technical reports. Its treatment of institutional reality informs questions for GR-300/400 without establishing legal effect.
- **Supersedes / revised by:** No verified supersession; conceptually informs FM-005's epistemology.
- **Known tensions or ambiguities:** The three registers answer different analytical questions; they are not three substances, exclusive object bins, or an obligatory temporal pipeline. Relational reality can precede recognition, while a manifestation can later alter relational reality. Ontological suspension preserves weaker warranted claims and does not entail denial.
- **Notes for contributors:** Do not implement the registers as mutually exclusive record classes without a separately argued operational decision. Distinguish a target, its manifestation, a record of that manifestation, and a claim about it.

114.1.7 FM-005 — Epistemology of Generative Relational Economics

- **File:** GRE_Chapter_05_Complete_First_Draft.pdf, 196 pages.
- **Author:** Wanhong Huang, as recorded in PDF metadata.
- **Date:** Publication/manuscript date unknown.
- **Version/status:** "Complete First Draft" is the filename label; independent editorial/publication status unknown.
- **Primary concepts:** Mediated access; inverse problems; trace and evidence; performative representation; partial observation; boundary and scale; identity; generative attribution; historical reconstruction; uncertainty; epistemic justice; machine mediation; revisability.
- **Important passages:** Inverse problem (§5.2, pp. 13–20); trace/evidence (§5.4, pp. 28–36); performative representation (§5.6, pp. 44–53); generative attribution and trajectories (§§5.13–5.14, pp. 105–122); evidence and uncertainty (§§5.15–5.17, pp. 122–150); epistemic justice (§5.18, pp. 150–160); machine mediation (§5.19, pp. 160–168); revisability (§5.20, pp. 168–176).
- **Terminology and notation:** `K(y | C, E, A)` (Equation 5.1, p. 14) is an epistemically admissible compatibility set given manifestation `y`, conditions `C`, evidence `E`, and auxiliary assumptions `A`. Compatibility is not assumed to be numerical or probabilistic. Definitions 5.159–5.167 distinguish revisability, provisional maps, evidence updates, intervention-sensitive revision, historical revision, and category revision.
- **Relevant programme documents:** GR-100/110/120/140/150/160/200/210; claim/evidence, contestation, revision, and institutional praxis work in GR-400. Procedural questions inform GR-310 only with a separately identified institutional or legal basis.

- **Supersedes / revised by:** No verified supersession. Develops epistemic questions following FM-004 without replacing its distinctions.
- **Known tensions or ambiguities:** Manifestation does not uniquely identify its source; availability of a record does not establish warrant. Changes in the target world, evidence, and descriptive categories require distinguishable histories. Epistemic justice retains evidential standards while examining unequal conditions for producing, preserving, interpreting, and contesting evidence.
- **Notes for contributors:** Operational claim types and metadata are proposals to test against these distinctions, not adopted definitions of knowledge or truth. Preserve alternative explanations and the difference between discovery and intervention-produced change.

114.1.8 FM-006 — A Metamodel for Ontologically Heterogeneous Social Dynamics, Part I: The Highest Abstract Layer

- **File:** A METAMODEL FOR ONTOLOGICALLY HETEROGENEOUS SOCIAL DYNAMICS-I.pdf, 13 pages.
- **Author:** Wanhong HUANG, as displayed on the opening page.
- **Date:** Publication/manuscript date unknown.
- **Version/status:** Part I of a series; formal publication/revision status unknown.
- **Primary concepts:** Bare carrier; mechanism composition; action; congruence; collapse of distinctions; conditional irreversibility; limitations of a fixed carrier.
- **Important passages:** Primitives and axioms (§3, pp. 5–6); conditional propositions (§4, pp. 6–8); limitations (§7, pp. 10–11).
- **Terminology and notation:** Carrier S; mechanism semigroup M; action α; congruence $\sim$; collapse set $\Delta(m)$. The tilde here is a plain-text transcription of the PDF's equivalence symbol. These mathematical elements are weaker than semantically articulated Entity, State, Event, or Process records.
- **Relevant programme documents:** GR-100 architecture boundaries; metamodel/ontology comparison and formal-semantics technical reports; loss and abstraction research.
- **Supersedes / revised by:** Continued and qualified by FM-007; no wholesale replacement is inferred.
- **Known tensions or ambiguities:** A fixed carrier and congruence permit analysis of collapse but do not generate new states or distinctions (§7). Broad abstract/concluding wording about absence of identities and inverses differs from the precise axiom's "not assumed" formulation. Interpretation of congruence as preservation of socially valuable distinctions needs care; FM-007 explicitly separates mathematical preservation of equivalence from normative protection of differences.
- **Notes for contributors:** Theorems hold under stated assumptions; they are not empirical laws of every social history. Do not use the collapse construction as a complete formal definition or universal score of generativity.

114.1.9 FM-007 — A Metamodel for Ontologically Heterogeneous Social Dynamics, Part II: Modeling Six Categories of Social Facts

- **File:** A Metamodel for Ontologically Heterogeneous Social Dynamics-II.pdf, 92 pages.
- **Author:** Wanhong HUANG, as displayed on the opening page.
- **Date:** Publication/manuscript date unknown.
- **Version/status:** Explicitly marked DRAFT in the PDF; formal publication status unknown.
- **Primary concepts:** Six analytical categories; entity reidentification; relation formation; event occurrence; partial attributes; state sufficiency; process histories; continuation semantics; coordination; formation/description/uptake; regime changes; empirical revision obligations.
- **Important passages:** Scope (p. 2); precise base assumptions (§3, pp. 10–16); six categories (§§7–12, pp. 26–61); coordination (§15, pp. 71–75); philosophical scope (§16, pp. 75–78); regime changes (§17, pp. 78–83); prospective research design (§19, pp. 87–90).

- **Terminology and notation:** Entity, Relation, Event, Attribute, State, Process. Base notation includes S, M, α, ~, quotient Q, observation o, retained description ρ, appearance indices I, and identity equivalence E (Table 1, p. 13). Distinct equivalence constructions have different roles; use of the same mathematical structure does not equate them.
- **Relevant programme documents:** GR-100/110/120/150/200/210; identity, event, process, missingness, migration, and formal-semantics work; pilot design.
- **Supersedes / revised by:** Continues FM-006 with explicit assumptions and enrichments. Does not establish exhaustive formalization of emergence or empirical validity of every construction.
- **Known tensions or ambiguities:** The six categories are an overlapping selected analytical repertoire, with exhaustiveness and metaphysical priority left open (p. 2). "Attribute" differs from the programme's current "Property." Identities and inverses are permitted without being required (§3.4). Declared regime families do not by themselves account for unanticipated novelty. Equal behavior does not establish entity identity, and equal endpoints do not establish equal histories.
- **Notes for contributors:** Use the counterexamples and prospective research design to identify losses in a recording proposal. The finite examples are declared constructions, not completed empirical pilots. Record a decision before translating Attribute into Property or turning selected analytical roles into exclusive schema types.

114.1.10 3. Open source questions

1. **OPEN — Editorial chronology:** Obtain explicit version, date, and supersession declarations for the GRE chapters and both Chapter 3 files. Build timestamps alone do not settle these questions.
2. **OPEN — Comparative collation:** Document the full substantive differences between FM-002 and FM-003; preserve the verified eight/nine problem-family difference.
3. **OPEN — Property / Attribute:** Decide whether these are equivalent within a stated operational scope, different concepts, or a terminology change. Retain current programme terminology pending a recorded decision.
4. **OPEN — Formal scope:** Keep Part I's fixed-carrier limits, Part II's declared-regime extensions, and the GRE chapters' broader account of emergence distinct until a justified relationship is documented.
5. **OPEN — Preservation:** Clarify the relationship between formal preservation of equivalence, loss of a represented distinction, archival retention, and normative reasons to preserve a distinction.

Programme-level disposition belongs in open questions and, where a design choice changes architecture, a decision record. This register preserves source differences; it does not resolve them by editorial harmonization.

115 README

Original source: `foundation_manuscripts/README.md`.
Original source SHA-256: `9414901035fb732c0adef53e6591a89f40008d2f1faf1ed605221c158a579411`.

115.1 Foundation Manuscripts

This folder is the project-local source corpus for Generative Relational (GR) theory and related foundational work.

115.1.1 Purpose

Foundation manuscripts are used to:

- preserve the conceptual history of GR;
- provide source-grounded definitions, distinctions, notation, and examples;
- help agents maintain consistency across standards, manuals, technical reports, and schemas;
- expose tensions, revisions, and unresolved differences between manuscripts rather than silently smoothing them away.

115.1.2 What belongs here

Copy foundational GR works into this folder, including, where relevant:

- metamodel papers;
- ontology and relation papers;
- generativity / generativity-return works;
- trust, criticality, and relational-reality works;
- historiographical justice and archive-related works;
- political-philosophy foundations;
- theoretical notes that materially define GR terminology.

PDF, Markdown, TeX, and plain-text sources are all acceptable.

115.1.3 Source status

Foundation manuscripts are **conceptual source material**, not automatically normative standards.

A statement in a manuscript does not become a standards requirement merely because it appears here.

When developing a standard:

1. consult relevant foundation manuscripts;
2. preserve terminology and distinctions where feasible;
3. identify conflicts or historical changes;
4. record deliberate departures;
5. translate theory into normative language only through an explicit standards decision.

115.1.4 Precedence

For this repository, use the following precedence when conflicts occur:

1. applicable governance directives for process;
2. published normative standards for conformance;
3. accepted architecture decision records (ADRs);
4. foundation manuscripts for GR conceptual interpretation;
5. active working drafts and planning notes;
6. informal examples and exploratory material.

A later standard may intentionally define a narrower operational term than a foundation manuscript. Such divergence should be documented rather than hidden.

115.1.5 Indexing

After adding manuscripts, update `MANIFEST.md`.

For each manuscript, record:

- filename;
- title;
- date/version;
- status;
- principal concepts;
- notation;
- relevant standards;
- known tensions with other manuscripts;
- whether later work revises it.

115.1.6 Consistency rule

Agents should never infer that two manuscript formulations are equivalent merely because they sound similar. Preserve differences until an explicit decision resolves them.

116 directives part 1

Original source: `governance/directives_part_1.md`.
Original source SHA-256: `0e77b1a9ced1578fc09dda334da2a02b7d156d4d56bf763bd442e25aacc9a85c`.

116.1 Directives Part 1

> **Developed draft available:** Working Draft 0.3 source and compiled PDF. The Markdown outline below is retained as historical planning context; its candidate choices are not adopted. Current requirements and unresolved decisions are in the TeX draft. ### Procedures for the Development and Maintenance of Standards

Status: Skeleton
Planned clauses:

1. Scope
2. Terms and definitions
3. Organizational bodies
4. Membership and participation
5. New work proposals
6. Project approval
7. Working drafts
8. Committee review
9. Public review
10. Comment disposition
11. Consensus
12. Ballots and approval
13. Publication
14. Corrections and corrigenda
15. Amendments
16. Revision
17. Periodic review
18. Withdrawal
19. Appeals and complaints
20. Conflicts of interest
21. Records and transparency
22. Intellectual property
23. External liaison
24. Emergency and expedited procedures
25. Archival preservation of standards-development records

117 directives part 2

Original source: `governance/directives_part_2.md`.
Original source SHA-256: `34589bd9830ac4a957902c5c23b44a4821130e58d473abed2e18e5ab91f0652b`.

117.1 Directives Part 2

> **Developed draft available:** Working Draft 0.3 source and compiled PDF. The Markdown outline below is retained as historical planning context; its candidate choices are not adopted. Current requirements and unresolved decisions are in the TeX draft. ### Rules for the Structure and Drafting of Standards

Status: Skeleton
Planned clauses:

1. Scope
2. Normative language
3. Document architecture
4. Titles and numbering
5. Scope clauses
6. Terms and definitions
7. Requirements
8. Recommendations
9. Permissions
10. Notes and examples
11. Figures and tables
12. Mathematical notation
13. References
14. Normative and informative annexes
15. Conformance clauses
16. Profiles
17. Machine-readable artifacts
18. Version identifiers
19. Deprecation and supersession
20. Drafting for translatability and long-term interpretation

118 founding agreement template

Original source: `governance/founding_agreement_template.md`.
Original source SHA-256: `7ab0b232ad2cbc6d3921477eac51582eecf11d80687639fff10eebc7335c515d`.

118.1 Founding Agreement and Governance Adoption Record

Document class: Informative governance template
Status: PROVISIONAL — unsigned proposal; no adoption, appointment, or institutional commitment
Version: 0.1
Responsible editor: UNASSIGNED
Source: `governance/founding_agreement_template.md`
Historical draft basis (0.1): Standards Programme Charter, version 0.1, CH-001–CH-002 and CH-036–CH-041; Directives Part 1, version 0.1, D1-004–D1-008.

The template remains an initial 0.1 aid. The expanded 0.2 normative schedules govern any assessment against 0.2; completing this template alone does not cover their additional obligations.

This template records actual founding capacities, review, and express commitments. It neither supplies legal authority nor creates a legal entity. Draft completion, insertion of a name, or a rehearsed signature is not agreement. Actual signatories review the organizational and legal context of their commitments before execution.

118.1.1 1. Record identity and scope

- Proposed agreement identifier, version, and source revision:
- Record type: `UNSIGNED PROPOSAL` / `SYNTHETIC REHEARSAL` / actual executed record:
- Programme name and bounded publication/resource scope:
- Proposed effective date/time and time zone:
- Organizational form and jurisdictional context: `OPEN`:
- Separate legal review needed and scope:
- Custodian and public/protected locations: `UNASSIGNED`:

118.1.2 2. Founding basis and authority

Prospective signatory	Actual capacity	Resources/ functions within authority	Evidence and limits	Proposed commitment	Relevant interests
`UNASSIGNED`	`[individual/authorized representative]`	`[bounded scope]`	`[basis and unresolved matters]`	`[express commitment]`	`[disclosure]`

- Basis on which these persons can establish the proposed arrangements:
- Resources, rights, or functions needing another person's agreement:
- Institutional representation claimed and exact mandate:
- Constituencies consulted, separate from constituencies represented:
- Limits on professional, geographic, governmental, or international authority:

A signature does not bind an employer, community, institution, or rights holder beyond the signatory's actual authority. No ISO, IEC, IEEE, WTO, governmental, or international-organization endorsement is implied.

118.1.3 3. Exact governance package proposed for adoption

Instrument	Exact version/ revision	Canonical source and reviewed rendering	Integrity reference	Proposed scope/ exclusions
Programme Charter	`[version]`	`[source/PDF]`	`[hash or immutable revision]`	`[scope]`
Directives Part 1	`[version]`	`[source/PDF]`	`[reference]`	`[scope]`
Directives Part 2	`[version]`	`[source/PDF]`	`[reference]`	`[scope]`
GR/TC 1 Charter	`[version]`	`[source/PDF]`	`[reference]`	`[scope]`
Ethics, Conflict-of-Interest, and Contribution Rights Policy	`[version]`	`[source/PDF]`	`[reference]`	`[scope; unresolved rights terms]`
Supporting records/review/ maintenance arrangements	`[version]`	`[source]`	`[reference]`	`[scope]`

- Conflict/dependency review and dispositions:
- Rights basis for distributing the review package:
- Operative contribution/publication terms, or bounded treatment while OPEN:
- Artifacts excluded from adoption:
- Existing authority/status retained by plans, foundation manuscripts, and technical drafts:

Adopting this package does not automatically approve GR/NWIP-001, adopt a technical Standard, authorize an external pilot, relicense manuscripts, or establish patent assurances.

118.1.4 4. Founding review announced before execution

Prospective signatories explicitly propose to apply the review, disposition, reply, and material-change periods in the identified draft Directives Part 1 as conditions of this founding process. This declaration does not assume the draft Directives already have adopted authority.

- Notice identifier and exact package revision:
- Review administrator and accepted mandate: `UNASSIGNED`:
- Announcement and accessible draft locations:
- Public/protected comment routes, tested access, and handling limits:
- Opening and closing timestamps, with time zone:
- Duration check against D1-019 in the identified draft edition:
- Outreach to affected interests, expertise, and potential contributors:
- Access/language/accommodation requests, interruptions, extensions, and revised dates:
- Comment register and reasoned dispositions:
- Reply notices/deadlines and replies considered under D1-023:
- Material changes and re-review under D1-025–D1-026:
- Remaining objections, evidence, reasons, and effect on execution:

A synthetic review supplies rehearsal evidence; it does not complete the actual founding public review proposed in CH-036.

118.1.5 5. Rehearsal and independent assessment

- Rehearsal record and exact draft versions:
- Synthetic actors/evidence identified:
- Scenarios exercised: scoped proposal, sustained objection, recusal, protected report, appeal, material change, correction, withdrawal, and continuity:
- Failures, burdens, revisions, and remaining capacity gaps:
- Independent founding-process reviewer: `UNASSIGNED`:
- Accepted mandate, competence, involvement, interests, and independence assessment:
- Evidence examined, findings, limits, and corrective actions:
- Action owners, completion evidence, and remaining blockers:
- Readiness determination within the reviewer’s scope, separate from truth or legal-validity claims:

An unfilled reviewer field or self-review is not independent assessment.

118.1.6 6. Accepted roles and bounded delegation

Function	Proposed holder	Appointing basis/limits	Accepted mandate/ date	Term/review date	Alternate/ vacancy route	Conflicts/ management
Founding authority/ signatories	UNASSIGNED	[actual basis]	NOT ACCEPTED	[date]	[route]	[record]
Programme decision/ governance authority	UNASSIGNED	[scope]	NOT ACCEPTED	[date]	[route]	[record]
Coordinator/ records custodian/ Secretariat	UNASSIGNED	[scope]	NOT ACCEPTED	[date]	[route]	[record]
GR/TC 1 convenor	UNASSIGNED	[scope]	NOT ACCEPTED	[date]	[route]	[record]
Review chair	UNASSIGNED	[particular review]	NOT ACCEPTED	[date]	[route]	[record]
Editors/work-item leads	UNASSIGNED	[deliverable]	NOT ACCEPTED	[date]	[route]	[record]
Neutral procedural/ appeal reviewer	UNASSIGNED	[scope]	NOT ACCEPTED	[date]	[independent alternate]	[record]
Ethics contact and alternate	UNASSIGNED	[scope]	NOT ACCEPTED	[date]	[protected route]	[record]
Rights-review contact	UNASSIGNED	[scope]	NOT ACCEPTED	[date]	[route]	[record]
Release/ maintenance owners	UNASSIGNED	[artifacts]	NOT ACCEPTED	[date]	[route]	[record]

- Combined functions and resulting limits:
- Roles needed immediately versus later, with reasons:
- Appointment, renewal, response, removal, and neutral-review procedure:
- Decision authority succession/replacement route:
- Available independent-review arrangement and tested contact:
- Resources, funding/in-kind support, infrastructure control, and conditions:

118.1.7 7. Decision eligibility and appointments

- Nominations notice and closing timestamp:
- Announced competence or affected-perspective criteria:
- Expected review commitment and actual accepted roles:
- Affiliations, interests, and institutional mandates:
- Proposed roster and one-person/declared-capacity record:
- Reasons for selection/exclusion against announced criteria:
- Concentrated interests, missing perspectives, and corrective measures:
- Eligibility challenges, impartial handling, and dispositions:
- Roster freeze and subsequent correction/restart rules:

The founding agreement records express commitments by its actual signatories. Later decisions use the adopted delegation and applicable ballot rules; founding signatures do not substitute for technical approval ballots.

118.1.8 8. Disposition and reasons before signatures

Current disposition: PENDING — UNSIGNED.

□ Ready for execution of the specifically identified commitments.

□ Return for revision and further review.

□ Defer pending authority, rights, or capacity gaps.

□ Do not proceed, with reasons.

- Issue, alternatives, selected direction, and rationale:
- Remaining dissent and its treatment:
- Exact amendments and affected records:
- Evidence addressing CH-028 and CH-036–CH-041:
- Unmet conditions and effect on adoption/dependent action:
- Preliminary work that can continue:

118.1.9 9. Express agreement and actual execution

Proposed agreement text for review:

> Within the authority and limits recorded for me in this instrument, I expressly agree to the listed programme commitments and identified governance editions. My agreement extends only to that recorded scope. Effective arrangements, remaining limitations, and accepted delegated roles are those stated in this instrument. My signature represents no unrecorded institution, rights holder, or constituency.

Actual signatory	Capacity/ authority reference	Exact agreement/package revision	Agreement/ signature reference	Actual date/ time	Reservations and accepted treatment
`UNASSIGNED`	`[record]`	`[revision]`	`UNSIGNED`	`[blank until execution]`	`[scope]`

- Execution verification and responsible custodian:
- Effective date/conditions actually satisfied:
- Declined or absent agreement, without treating silence as assent:
- Public notice and protection of signature evidence:

Do not record a person’s signature, approval, or date without actual assent. Synthetic signatures remain explicitly synthetic and have no adoption effect.

118.1.10 10. Transition and accountability

- First governance review date and annual-account owner:
- Further decisions needed before formal project initiation:
- Review/appeal route for founding procedure and appointments:
- Amendment procedure and treatment of ongoing decisions:
- Existing drafts, open comments, restricted material, and contribution-term transition:
- Continuity, vacancy, suspension, and closure arrangements:
- Public links among prior drafts, reasons, executed edition, and later amendments:

Recording check: Status labels reflect actual events; unassigned roles remain visible; drafting, review, agreement, project initiation, technical adoption, and external authorization remain separately recorded.

119 standards programme charter

Original source: `governance/standards_programme_charter.md`.
Original source SHA-256: `5242f3c7c04abf30dd3929537a58cea4fabe7df6ec073d5a3593d75a0724171b`.

119.1 Standards Programme Charter

> **Developed draft available:** Working Draft 0.3 source and compiled PDF. The Markdown outline below is retained as historical planning context; its candidate choices are not adopted. Current requirements and unresolved decisions are in the TeX draft.

Status: Working outline

119.1.1 1. Mission

Develop and maintain open, rigorous, interoperable standards concerning the recording, preservation, presentation, and exchange of generativity-related information.

119.1.2 2. Principles

The programme should pursue:

- openness;
- transparency;
- procedural fairness;
- traceability;
- stakeholder participation;
- technical coherence;
- implementability;
- revisability;
- respect for privacy and access constraints.

119.1.3 3. Publications

The programme may issue:

- Standards;
- Technical Specifications;
- Technical Reports;
- Manuals and Guides;
- Schemas and validation artifacts;
- Corrigenda and Amendments.

119.1.4 4. Governance bodies

- Standards Council
- Technical Committees
- Working Groups
- Editors
- Project Leads
- Reviewers and Observers

119.1.5 5. Decision principle

Consensus is the preferred basis for technical adoption. Voting procedures, objection handling, appeals, and escalation shall be defined in Directives Part 1.

119.1.6 6. Maintenance

Published standards remain subject to review, confirmation, amendment, revision, supersession, or withdrawal.

120 technical committee charter

Original source: `governance/technical_committee_charter.md`.
Original source SHA-256: `ad24189fedf14e403ad5e3046e86ee2de2799c53093bb201f7bd74666de54624`.

120.1 GR/TC 1 Charter

> **Developed draft available:** Working Draft 0.3 source and compiled PDF. The Markdown outline below is retained as historical planning context; its candidate choices are not adopted. Current requirements and unresolved decisions are in the TeX draft. ### Generativity Records and Infrastructure

Status: Draft

120.1.1 Scope

Standardization of conceptual models, recording requirements, data models, interchange formats, presentation requirements, preservation/access rules, and conformance methods for records of generativity.

120.1.2 Exclusions

The committee does not, by default:

- define a complete metaphysics of generativity;
- certify substantive historical interpretations as true;
- require one software platform;
- require public disclosure of all recorded material.

120.1.3 Initial working groups

- WG 1 — Foundations and Ontology
- WG 2 — Recording Model
- WG 3 — Data and Interoperability
- WG 4 — Presentation and Reconstruction
- WG 5 — Ethics, Privacy, and Preservation
- WG 6 — Conformance and Implementation

121 GR M101 recording manual

Original source: `manuals/GR-M101-recording-manual.md`.
Original source SHA-256: `ccf47f80ee7966b6307d496b45f0d220208aafa64365bd77c96fb8cb9ac55b1e`.

121.1 GR-M101 — Recording Manual

Status: Placeholder

This manual will provide non-normative guidance for applying GR-110 in everyday research, collaborative projects, AI-assisted work, and institutional settings.

Planned contents:

- choosing record granularity;
- recording events without over-interpreting them;
- preserving branches;
- logging contingent encounters;
- recording uncertainty;
- recording retrospective reinterpretation;
- minimal vs deep recording;
- privacy-aware practice;
- worked examples.

122 README

Original source: `policy_proposals/README.md`.
Original source SHA-256: `64b817d2bc1dc2eec6b439986c4d4fbc2b6965e36fd944cbb5e4c2015d6824df`.

122.1 Policy Proposals Programme

This directory contains policy-oriented publications derived from the Generativity Standards Program.

122.1.1 Purpose

The standards programme may generate proposals for international organizations, public institutions, universities, archives, research funders, and other governance actors.

These documents are separate from normative technical standards.

122.1.2 Possible publication types

- Policy Brief
- Institutional Proposal
- Model Governance Framework
- Pilot Programme Proposal
- Capacity-Building Proposal
- Model Clause / Model Procedure
- Consultation Paper
- Discussion Paper

122.1.3 Relationship to standards

A policy proposal may recommend:

- piloting a GR standard;
- establishing generativity-record requirements in a programme;
- creating interoperable archival infrastructure;
- adopting provenance or contestation procedures;
- testing rights of correction or annotation;
- creating international research or cultural-preservation initiatives.

A policy proposal should identify which parts are:

- descriptive background;
- normative proposal;
- legal analysis;
- implementation option;
- unresolved question.

122.1.4 Neutrality and plurality

Policy documents should distinguish factual description, analysis, value judgments, and proposed institutional choices.

Where reasonable alternatives exist, they should be presented clearly enough for decision-makers to evaluate them.

122.1.5 Publication classes

For international-facing work, use one of the following where appropriate:

- **GR-IPP** — International Policy Proposal
- **GR-IIP** — International Institutional Proposal

These are distinct from Specifications and Standards. They are recommendatory and deliberative rather than conformance documents.

123 README

Original source: `policy_proposals/international_organizations/README.md`.
Original source SHA-256: `0368c1f17564de0b4411b1dfcef5ea1c84801c34bfa49c90f4534379b38e4782`.

123.1 International Organizations

This folder is reserved for policy proposals aimed at or relevant to international organizations.

Potential themes include:

- international standards for generativity records;
- research-integrity and AI provenance;
- cultural and scientific archives;
- institutional memory;
- transnational interoperability;
- AI-assisted decision records;
- future-generations access and preservation;
- capacity-building for under-resourced institutions;
- governance of contested records;
- model procedures for annotation, correction, and restricted access.

Proposals should be adapted to the mandate and legal authority of the intended organization rather than assuming one universal institutional model.

124 policy brief template

Original source: `policy_proposals/templates/policy_brief_template.md`.
Original source SHA-256: `0a6f8aaea14ac95ed55772b48031b8a49f72c374013f6cdd4c9cafb1f59c3b97`.

124.1 Policy Brief Template

124.1.1 Title

124.1.2 Intended institution / audience

124.1.3 Executive summary

124.1.4 Problem

124.1.5 Why the issue matters

124.1.6 Current institutional context

124.1.7 Proposed objective

124.1.8 Policy options

124.1.9 Option A

124.1.10 Option B

124.1.11 Option C

124.1.12 Comparative considerations

125 README

Original source: `publications/README.md`.

Original source SHA-256: `d40e4a76f4fceb01a0ee8e41bbe7042f9915a5f1c46e64893341eb94e86c5cfb`.

125.1 Validation-revised working-draft package

Document class: Informative publication and build guide
Status: PREPARATORY; version 0.3; 2026-09-22. All nine documents are working drafts, not adopted governance or Standards. Formal work-item approval remains pending.

The package develops the comprehensive plan into detailed requirements, responsibilities, procedures, semantic and assessment schedules, and worked examples. Read the Programme Brief for purpose and ADR-0006 for this validation-driven revision. The external model comparison explains the distinct roles of ISO, IEEE, ITU and UN guidance.

Every document has formal front matter, numbered scope/references/definitions, technical or institutional clauses, explicitly normative/informative annexes, and a bibliography. The substantive validation dossier records review of all 753 baseline IDs, bounded P0/P1 assessments, supported corrections and remaining evidence gaps. The 0.1 and 0.2 archives preserve earlier editions; the 0.2 to 0.3 change register identifies retained, revised and new provisions.

Draft	Editable source	Compiled review copy	Pages
Standards Programme Charter	TeX	PDF	19
Directives Part 1 — Development and Maintenance	TeX	PDF	28
Directives Part 2 — Structure and Drafting Rules	TeX	PDF	26
GR/TC 1 Charter	TeX	PDF	17
Ethics, Conflict-of-Interest, and Contribution Rights	TeX	PDF	22
GR-100 — Foundations and Vocabulary	TeX	PDF	30
GR-110 — Generativity Recording Requirements	TeX	PDF	28
GR-200 — Epistemic Recording Framework	TeX	PDF	32
GR-210 — Evidence, Interpretation, and Contestation	TeX	PDF	24

The TeX files are the substantive authoring sources for these editions. Earlier Markdown outlines remain preserved with links to their developed drafts. The PDF filenames are build identifiers, not new adopted publication codes. Generated files live in ignored `build/`; a fresh checkout needs compilation before the PDF links work.

The graph pilot additionally develops bounded preparatory Markdown Working Drafts GR-120, GR-130, GR-140 and GR-160, plus experimental GR-SPEC-120 and GR-SPEC-130. They are separate from this nine-document build and have not been promoted to adopted Standards or included in its 0.3 PDF assessment.

Useful accompanying material:

- P1/v2 contested-decision dossier: explicit claims, grounds, issue/action tracks, view limits and partial component results.
- Substantive review and assessment matrix; historical 0.2 review and 0.1 review.
- P0/v2 governance rehearsal: 18 executed arithmetic cases and detailed synthetic procedural traces.
- Revision regression cases and readiness/burden evidence.
- NWIP template, comment/disposition template, and founding agreement template.

- Requirement assessment template: individual applicability, evidence, results and counterexamples.
- Open questions, including actual authority, participation, rights terms, profiles and pilot capacity.

Original P0/P1 and the initial templates retain their historical 0.1 basis. New P0/v2 and P1/v2 assess the fixed 0.2 baseline; the revision cases examine the corrected 0.3 distinctions. None establishes full institutional conformance. Current normative schedules identify the information needed for an assessment of this edition.

125.1.1 Build

Requirements: Python 3.10+, `latexmk`, LuaLaTeX, and the TeX packages/fonts named in the preamble. These are available in the current `Ubuntu-24.04` WSL environment. No packages or external sources are downloaded by the build script.

From this directory's repository root, in PowerShell:

```
python tools/build_publications.py --wsl Ubuntu-24.04
```

Or inside WSL, from the repository root:

```
python3 tools/build_publications.py
```

To rebuild one document, append `--document GR-110` (repeatable). Full builds write `build/publications/build-report.json`; selected builds write `build-report-selected.json`. The reports identify source/preamble/PDF hashes, compiler outcomes, LaTeX/package warnings and nonblocking underfull-line spacing advisories. An old successful PDF can remain after a later failed build: check the current report and hashes before using it.

For source/PDF requirement coverage and report freshness, from Windows with `pypdf` installed:

```
python tools/check_publications.py
```

The checker also examines formal opening clauses, declared front matter, annex roles, local references, captions, archive hashes and retention of historical requirement IDs. To regenerate the text change register:

```
python tools/compare_publication_requirements.py --baseline 0.2
```

To check the fixed 0.2 review matrix, fixture identifiers/locators and finite ballot expectations, run `python tools/check_validation_package.py`. This does not automatically evaluate manuscript interpretation, factual warrant or procedural performance.

The build and static checks do not assess factual truth, institutional performance, legal status, user comprehension or PDF accessibility. Accessible publication targets and a tested alternative reading representation remain work before formal release. TeX sources and Markdown examples are available for review, but their availability alone establishes no accessibility conformance.

125.1.2 Suggested reading sequence

Read the Charter and Directives first, then GR-100 and GR-200, then GR-110/210 alongside P1. GR-110 and GR-210 depend on the declared GR-100/200 draft editions; GR-200 does not depend on GR-110. GR-120/130 and the Specification placeholders remain future work driven by the requirements and pilot findings. Jurisprudential and policy publications retain their separate scope and authority.

126 README

Original source: `publications/archive/0.1/README.md`.
Original source SHA-256: `5bf8846e9989ed0bf9ff8d88b53948a1916500976fca237b1d810c5412f0f7e9`.

126.1 Historical Working Draft package 0.1

Class: Source archive
Status: Historical preparatory Working Drafts; not adopted

This snapshot preserves the nine 0.1 TeX documents, their shared preamble, manifest and build/check scripts before expansion to 0.2. snapshot.json records original paths, archive paths and SHA-256 digests. The preceding review record describes the 84-page, 318-requirement package.

Sources retain their original relative paths. To reproduce this edition, run the archived build script from this archive root or use a separate copy preserving this layout. It resolves its own root and writes a separate `build/publications/` here. Do not substitute the current programme preamble: that would create a different rendering. An archived source may mention a root-level source map or manuscript that remains in the main repository; those references are documentary, not TeX inputs.

The existing local 0.1 PDFs and reports were copied to build/archive/0.1 before the current build changed. They are ignored generated artifacts, not guaranteed to be present in a fresh checkout. The new current package has a separate review and requirement change register.

127 PROGRAMME BRIEF

Original source: `publications/archive/0.2/PROGRAMME_BRIEF.md`.
Original source SHA-256: `ea14413d927e2010496c42c49066561dcb9dbee971c9b1395c8b2f349b67222a`.

127.1 Programme Brief

127.1.1 Why, What, and How We Develop the Generativity Standards

Status: Preliminary programme brief
Version: 0.4
Document class: Informative programme-level background

127.1.2 1. Purpose of this brief

This document gives a concise orientation to the Generativity Standards Program.
It answers three questions:

1. **Why** is a standards programme needed?
2. **What** is being standardized?
3. **How** will the standards be developed, reviewed, published, and maintained?

It is intended to be the first document read by new contributors, reviewers, collaborating organizations, and AI agents before they enter the more detailed governance, theoretical, or technical documents.

127.1.3 2. Why

127.1.4 2.0 Symbolic crisis, recognition, and practical action

The programme's organizing motivation is the symbolic crisis: instability in the connections among symbolic representations, their referents, institutional classifications, and practical trust. GRE Chapter 1, section 1.14, develops this diagnosis. It includes fabricated representations as well as sincere but outdated, partial, or inadequate categories. It does not imply that every representation has become unreliable.

The programme develops epistemic and practical infrastructure through which people and institutions can recognize reality, investigate factual claims, examine their grounds, contest interpretations, revise judgments and action, and preserve the trajectories through which knowledge and future possibilities develop. Archival loss and AI provenance are important components of this broader problem.

Reality, manifestation, representation, evidential warrant, institutional acceptance, and normative legitimacy remain distinguishable. Reality can precede recognition; records and classifications can also enter social relations and change what happens later. Technical conformance, authentic provenance, or institutional acceptance does not by itself establish that a substantive claim is true.

The infrastructure consequently concerns both what changes and how it becomes knowable and actionable. It also concerns who can produce evidence, challenge a classification, obtain review, and participate in shaping the conditions of future generation.

Source interpretation and proposed operational translations are recorded in the foundation traceability map. The current development proposal is the comprehensive plan.

127.1.5 2.1 The historical problem

Contemporary knowledge production increasingly leaves behind abundant outputs while preserving much less information about how those outputs became possible.

A paper may survive while the following disappear:

- the encounters that redirected the inquiry;
- the relations that enabled the work;

- the alternatives that were considered and abandoned;
- the changes in judgment that occurred over time;
- the conditions under which an idea became recognizable;
- the capacities that were created, weakened, or lost;
- the role of human, institutional, computational, and environmental contributors.

A final artifact therefore often preserves substantially less than the generative history from which it emerged.

127.1.6 2.2 The AI-era problem

AI-assisted work intensifies this problem.

A simple statement such as “AI was used” does not reveal:

- what role the AI system played;
- which materials were supplied to it;
- which outputs were selected or rejected;
- how human judgment interacted with machine-generated material;
- which later ideas depended on earlier AI-mediated encounters;
- how the trajectory changed through repeated interaction.

As automated and agentic systems become increasingly involved in research, education, policy, design, and administration, conventional provenance records may be too coarse to preserve the relevant history of generation.

127.1.7 2.3 The generativity problem

The programme is motivated by a broader GR concern: the history of a process includes more than its manifested outputs.

Of particular interest are changes in:

- available distinctions;
- relational structures;
- constraints;
- possible continuations;
- interpretive frames;
- generative capacities.

A process may produce a modest output while opening an important future trajectory. Another may produce a highly valued output while exhausting the conditions that made future generation possible.

For this reason, output history and generativity history should not be treated as equivalent.

127.1.8 2.4 The archival problem

Future observers may need to do more than retrieve an artifact.

They may need to ask:

- How did this become possible?
- Which relations mattered?
- What was known or believed at the time?
- Which alternatives were visible then?
- Which later interpretations rewrote the earlier history?
- Which possibilities remained unrealized?
- Which records are absent, restricted, lost, or destroyed?

A durable standards programme can help preserve enough structured information for later reconstruction, reinterpretation, contestation, and continuation.

127.1.9 3. What

127.1.10 3.1 Object of standardization

The programme develops standards for the recording, preservation, exchange, presentation, assessment, contestation, and revision of **generativity-related records**, and for their accountable use in inquiry and practical action.

The programme does not attempt to standardize a complete metaphysics of reality.

It develops an operational framework through which generative histories and the grounds of claims about them can be recorded in a consistent, inspectable, and interoperable form. It distinguishes changes in the situation under inquiry, changes in evidence and judgment, and changes in categories or methods of recognition.

127.1.11 3.2 Conceptual architecture

Within the wider multilayer architecture, a foundational distinction separates the following two levels.

127.1.12 Deep metamodel

The GR background emphasizes four highly abstract dimensions:

- Constraint
- Change
- Structure
- Difference

These belong to the foundational theoretical layer.

127.1.13 Operational record ontology

The standards programme currently explores six operational record classes:

- Entity
- State
- Event
- Process
- Relation
- Property

These are candidate standardized forms for recording.
They are not assumed to be ultimate ontological kinds.

127.1.14 3.3 What a generativity record may need to preserve

Depending on the profile and use case, a record may include:

- entities and participants;
- states and state changes;
- events and processes;
- relations;
- properties and observations;
- temporal information;
- provenance;
- perspective;
- epistemic status and uncertainty;
- generative conditions;
- contingent encounters;
- decisions and judgments;
- alternatives and unrealized branches;
- enabling and constraining relations;

- later reinterpretations;
- changes in available distinctions;
- changes in future possibilities;
- generativity return;
- access, privacy, restriction, and retention metadata.

127.1.15 3.4 Standards family

The programme is intended to produce a family of coordinated documents rather than one monolithic standard.

The provisional family includes:

- **GR-100 — Foundations and Vocabulary**
- **GR-110 — Generativity Recording Requirements**
- **GR-120 — Generativity Information Model**
- **GR-130 — Generativity Interchange Specification**
- **GR-140 — Generativity Presentation Requirements**
- **GR-150 — Conformance and Validation**
- **GR-160 — Preservation, Privacy, Access, and Retention**
- **GR-200 — Epistemic Recording Framework**
- **GR-210 — Evidence, Interpretation, and Contestation**
- **GR-300 — Jurisprudential Interface**
- **GR-310 — Rights, Duties, and Procedural Profiles**
- **GR-400 — Governance and Institutional Use**

These identifiers currently name preliminary standards-track projects, not adopted Standards. Their proposed coordinated scopes and dependencies appear in the comprehensive plan. Existing GR-120/130 project titles are retained; their requirements are distinguished from the implementable details in GR-SPEC-120/130. GR-SPEC-200 supports epistemic representation where draft requirements establish the need.

Supporting publications include:

- manuals;
- implementation guides;
- technical reports;
- schemas;
- validation artifacts;
- worked examples.

127.1.16 3.5 Normative and non-normative layers

The programme deliberately separates:

- **normative standards**, which define requirements, recommendations, permissions, and conformance;
- **manuals**, which provide practical guidance;
- **technical reports**, which develop theory, mathematical semantics, comparison, and experimental ideas;
- **foundation manuscripts**, which preserve GR conceptual history and source material.

This separation allows the standards to remain operational without losing contact with their theoretical foundations.

127.1.17 3A. Beyond ontology: epistemic, normative, legal, and institutional dimensions

The programme does not assume that a sufficiently detailed ontology alone can produce an adequate generativity record.

A mature framework must also specify how records are:

- known;
- evidenced;
- interpreted;
- contested;
- normatively evaluated;
- legally recognized;
- institutionally used;
- politically and economically situated.

Accordingly, the programme now treats ontology, epistemics, normativity, jurisprudence, governance, political economy, and technical implementation as interacting but distinguishable layers.

See `docs/framework/multilayer_architecture.md`.

127.1.18 3B. Dual outputs: standards and policy proposals

The programme may produce two coordinated families of public outputs:

1. **standards and technical infrastructure**, concerned with interoperable requirements, models, profiles, and conformance; and
2. **policy and institutional proposals**, concerned with how international organizations and other institutions may pilot, adopt, govern, or build capacity around these infrastructures.

Policy proposals are not themselves standards, and standards do not by themselves settle political or legal choices.

127.1.19 3C. Publication classes

The programme distinguishes three principal public-output families:

1. **Specifications** — technically precise and implementable documents that may be experimental, candidate, or stable without yet being formal Standards.
2. **Standards** — formally adopted normative publications with programme-level conformance authority.
3. **International Political / Policy Proposals** — recommendatory institutional or policy publications directed to international organizations or other transnational actors.

This distinction prevents technical precision, formal standardization, and political/institutional recommendation from being treated as the same kind of authority.

See `docs/framework/publication_taxonomy.md`.

127.1.20 4. How

127.1.21 Protocols within publication classes

A protocol describes behavior: participants, interactions, states, transitions, outcomes and failures. Protocols are technical subjects documented in Specifications or, after formal adoption, Standards. They do not create a separate publication authority class. Institutional review procedures and machine-to-machine protocols can support the same purpose while requiring different implementation and assessment methods.

127.1.22 Comparative and cross-domain development

The programme studies ISO/IEC and IEEE standards-development approaches, ITU technical publication practice, and relevant UN-system quality and institutional frameworks to inform its own proportionate procedures. The comparative study distinguishes source practices, proposed adaptations and unresolved governance choices. The drafting-model study records verified ISO, IEEE, ITU and UN sources, their different functions, and access limitations. This work does not imply affiliation, accreditation or compliance with those organizations' procedures.

The cross-domain programme connects the mission to epistemology, archival practice, jurisprudence, ethics, institutional governance, public policy, political economy and implementation. These domains contribute substantive work and review throughout development; they are not reduced to metadata fields or a final compliance check.

127.1.23 4A. Standards-first development

The default programme logic begins with the Standard.

The Standard identifies what a conforming practice should achieve. If those requirements create a need for shared technical infrastructure, the programme develops one or more Specifications.

This yields a recurring development loop:

Standard Working Draft → Specification need → Specification → pilot → revision of the Standard

The Standard and Specification may therefore co-evolve before publication.

127.1.24 4.1 Develop the standards programme before the standards

The programme first establishes the rules by which standards are created.

The initial governance layer includes:

- Standards Programme Charter;
- Directives Part 1 — Procedures for Development and Maintenance;
- Directives Part 2 — Structure and Drafting Rules;
- Technical Committee Charter;
- public review procedure;
- consensus and decision policy;
- conflict-of-interest and ethics policy;
- intellectual property policy;
- maintenance and versioning procedure;
- records and transparency policy.

This creates a defined process through which later GR standards can claim procedural consistency.

Expanded preparatory version 0.2 texts for this governance layer and GR-100/110/200/210 are available in the working-draft package, with formal document structure, detailed requirements and assessment schedules. Version 0.1 is preserved in a source archive. Drafting and compilation do not complete governance adoption or authorize formal technical project initiation. The expanded review record distinguishes completed authoring from remaining institutional and pilot evidence.

127.1.25 4.2 Development lifecycle

The provisional standards lifecycle is:

Stage	Status
00	Preliminary
10	Proposal
20	Working Draft
30	Committee Draft
40	Public Review Draft
50	Final Approval Draft
60	Published Standard
90	Review / Revision / Withdrawal

The process is intended to remain lighter than ISO while preserving comparable principles of traceability, review, versioning, and maintenance.

127.1.26 4.3 Evidence and source discipline

The programme distinguishes several kinds of authority.

- Governance directives govern the standards-development process.
- Published standards govern conformance.
- Accepted ADRs govern project architecture.
- Foundation manuscripts provide source authority for GR concepts.
- Working drafts and planning documents remain provisional.

Agents and contributors should not silently convert a theoretical statement into a normative requirement.

Where a standard intentionally narrows or operationalizes a broader GR concept, the divergence should be explicit and traceable.

127.1.27 4.4 Foundation manuscript workflow

The folder `foundation_manuscripts/` serves as the project-local GR source corpus.

When relevant manuscripts are added, contributors should:

1. index them in `foundation_manuscripts/MANIFEST.md`;
2. identify important concepts and notation;
3. record historical changes and tensions;
4. map relevant ideas to candidate standards clauses;
5. preserve disagreements and revisions;
6. create an ADR when a standards-specific interpretation materially departs from the source corpus.

127.1.28 4.5 Issue and decision traceability

Substantive changes should leave a visible record.

The preferred pattern is:

$$\text{Issue} \rightarrow \text{Alternatives} \rightarrow \text{Decision} \rightarrow \text{Rationale} \rightarrow \text{Affected documents}$$

Architecture-level decisions are recorded as ADRs.

Public-review comments should likewise record:

$$\text{Comment} \rightarrow \text{Disposition} \rightarrow \text{Rationale} \rightarrow \text{Resulting change}$$

The development process should itself exemplify the kind of generative traceability the standards seek to support.

127.1.29 4.6 Incremental implementation

The programme should avoid attempting to solve the entire conceptual problem before implementation begins.

A preferred development strategy is:

1. establish governance;
2. stabilize core vocabulary;
3. define a minimal coordinated recording, epistemic, presentation, protection and review profile;
4. test it first on bounded examples and then on appropriately governed real use cases;
5. develop the information model;
6. build exchange schemas;
7. test independent implementations;
8. revise through public and technical review;
9. refine conformance using assessment methods drafted alongside the requirements;
10. maintain the standards as the field evolves.

127.1.30 4.7 Pilot-driven development

Candidate pilots include:

- individual research;
- AI-assisted manuscript development;
- collaborative research;
- institutional decision processes;
- historical reconstruction from incomplete archives.

Pilots are used to test whether the standards are sufficiently expressive without becoming impractically burdensome.

The current planning proposal begins with the programme's own documented decision history and a synthetic contested institutional case. A complete pilot cycle includes evidence, interpretation, challenge, reasoned response or revision, protection, presentation and practical consequences. Real external pilots depend on actual institutional participation and appropriate access arrangements. No participation is presumed.

The comprehensive development plan sets out the proposed portfolio, milestone evidence, dependencies and immediate work queue. The earlier preliminary plan remains available as a historical draft. Planning does not substitute for governance adoption or work-item approval.

127.1.31 5. Design principles

The programme currently follows these principles:

- preserve trajectory, not only output;
- distinguish occurrence from interpretation;
- distinguish present validity from historical existence;
- treat relations as first-class when their own histories matter;
- preserve uncertainty rather than forcing premature certainty;
- preserve alternatives without implying equal feasibility;
- separate preservation from publicity;
- expose mediation in reconstructed presentations;
- distinguish evidence integrity from the warrant of a claim;
- support meaningful contestation and revision of action as well as correction of records;
- examine how recording and recognition affect participation and future possibilities;
- support future reinterpretation;
- maintain compatibility with GR foundations without turning philosophical theory directly into compliance language;
- allow standards to evolve while preserving their own development history.

127.1.32 6. Intended outcome

The long-term goal is a standards infrastructure that supports warranted, revisable recognition and practical action while enabling future actors to recover more than a final artifact.

A successful record should help a later observer understand, within the limits of available evidence:

- what changed;
- what relations mattered;
- what was recognized at the time;
- what alternatives were available;
- how judgments evolved;
- how the field of future possibilities changed;
- and how the recorded process may be continued or reinterpreted.

The programme therefore aims at three linked capacities:

$$\text{future re-recognizability} + \text{reinterpretability} + \text{regenerability}.$$

These capacities provide the broad orientation for the standards family while remaining subject to refinement through the formal standards-development process.

128 README

Original source: `publications/archive/0.2/README.md`.

Original source SHA-256: `d539e685ab86abf845a80897919a1799e3f9ddfef1f74df9311fe15ff2a19ac6`.

128.1 Historical Working Draft package 0.2

Class: Source and review archive
Status: Historical preparatory Working Drafts; not adopted

This snapshot preserves the nine 0.2 TeX documents, shared preamble, manifest, build/check/change-register tools, Programme Brief 0.4, expanded review and its requirement change register. snapshot.json records original paths, archived paths and SHA-256 digests. It is the fixed baseline for the substantive validation cycle.

The archived package contains 753 requirement identifiers and originally compiled to 225 pages. The local PDFs and build/check reports were copied before revision; generated artifacts are ignored and may be absent in a fresh checkout.

To reproduce PDFs, invoke this archive's `tools/build_publications.py` using the archived layout. It resolves the archive root and uses its preamble and manifest. Do not substitute the current presentation source. Contextual links to main-repository manuscripts and planning documents are documentary references, not TeX inputs. Archived comparison/check tools retain their historical behavior; the current tools support subsequent baselines and archive-integrity checking.

The original 0.2 review is preserved byte-for-byte. Its relative navigation describes its original repository location; use the main repository's historical review or the links above for navigation from this archive.

129 expanded working draft review

Original source: `publications/archive/0.2/docs/reviews/expanded_working_draft_review.md`.
Original source SHA-256: `278bf8b1e7a74b33ecfbabd3eee459f7948b00104a1bfdad3b32f36dd6578f75`.

129.1 Expanded Working Draft 0.2 review

Class: Informative editorial and artifact review record
Status: PREPARATORY; 2026-09-22
Package: Nine Working Drafts, version 0.2
Review relationship: AI-assisted drafting and cross-review in the same development session. This is not independent stakeholder review, a formal ballot or a finding of institutional conformance.

129.1.1 1. Scope and source basis

The revision responds to the need for substantive application detail and formal publication structure. It develops all five existing governance drafts and the four initial technical drafts. It does not open additional work items or adopt the instruments. The 0.1 archive preserves original sources and tools with hashes.

The external-source study distinguishes editorial models from quality frameworks and policy instruments. ISO's annotated model, accessible IEEE rules and ITU authoring guidance support publication design; UN NQAF and UNESCO AI ethics materials provide bounded institutional comparisons. Actual access and failed retrievals are recorded. The theoretical basis remains the GR manuscript corpus, with passage-level locators in each technical document.

Particular source attention was given to FM-005's generative attribution, trajectories, evidence survival, reconstruction, uncertainty, epistemic justice, machine mediation and revisability; FM-003's praxis and limits of a fixed intervention sequence; and FM-007's operational roles and conceptual evolution. These readings do not resolve the Property/Attribute question, chronology of Chapter 3 variants or stronger emergence claims beyond the formal assumptions.

129.1.2 2. Substantive changes

Document	Added depth and review purpose
Programme Charter	Actual authority and resources, delegation and reserved decisions, participation barriers, accountability, transitions, readiness and evidence
Directives Part 1	Work-item and stage dossiers, review preparation and disposition, ballots and clocks, independent appeal capacity, emergency action, maintenance and release controls
Directives Part 2	Formal architecture, definition and requirement construction, dependency precision, semantic/protocol boundaries, normative assessment records and editorial completion checks
TC Charter	Assignment, source and decision registers, multidisciplinary review, pilot preparation, failure reporting, handover and maintenance
Ethics/IP Policy	Intake, protection, investigation, response, reasoned findings, proportionate remedies, reconsideration, conflicts, impacts, contribution rights and assessment
GR-100	Numbered terminology, six operational roles with identity and temporal conditions, scale, continuity, mappings, missingness and vocabulary assessment

Document	Added depth and review purpose
GR-110	Purpose and collection planning, generative accounts and evidence, conditions/contributions/alternatives, maintenance and loss, practical effects, custody and assessment
GR-200	Claim decomposition, methods, source dependence, material survival, interpretation, uncertainty, revision, machine mediation, protection and normative semantic schedules
GR-210	Case intake and state transitions, responsible review, competing accounts, response and disposition, corrections and practical effects, review limits and assessment schedules

The requirement change register reports text-level changes against the archived edition. It preserves old and new texts and their normalized hashes. Stable IDs identify provisions independently of their new clause locations. No ID was intentionally removed or reassigned.

129.1.3 3. Cross-review findings and dispositions

Finding	Correction and remaining limit
Sole requirements appeared in Scope while D2 required a declarative scope	Relocated the relevant Charter, D1, TC and EIP provisions into application or authority clauses, preserving their identifiers
Some D2 provisions were under unrelated headings after restructuring	Moved epistemic distinctions, conformance limits, automated checks, bindings and artifact-execution rules to their corresponding clauses
Ethics acknowledgement and determination periods were described collectively as extendible targets	Revised EIP-014 to distinguish mandatory seven-day acknowledgement from the extendible determination target; this is an explicit revision of a 0.1 obligation
Temporary participation restrictions had unclear review/expiry linkage	EIP-067 expressly applies the emergency review and expiry controls, without creating additional institutional authority
Internal conduct threshold and merits reconsideration needed limits and a usable route	EIP-069 states a reasoned criterion, contrary evidence and fairness prerequisites; EIP-099–104 specify scoped reconsideration and assessment. The threshold remains a local proposal under Q-29
Some definition entries blended definitions with examples and implications	Separated explanations into notes in the core vocabulary and epistemic drafts
One result per ID could conceal failure of a component within a grouped requirement	Added component-result rules in the core assessment schedules; every applicable component needs evidence for overall fulfillment
Unknown/restricted values could be read as a waiver of essential record structure	Distinguished required identifiers, content and scope from contextual facts that can be explicitly unknown or protected; an allowed declaration does not prove the fact was examined
A timestamp example overstated proof of recording time	Qualified it by source attribution and clock/integrity/context limits
Repeated long-table headers repeated their caption labels and produced compiler warnings	Separated first-page captions from continuing column headers; checked the revised cross-references and renderings

No review finding establishes beneficial generativity, truth of a claim, legal authority or an operating institution. Shared-session AI cross-review is not the independent human review required by the proposed governance.

129.1.4 4. Artifact verification

The full build report records compiler outcomes, source/preamble/PDF hashes, warnings and tool versions. The check report records structural checks, archive integrity, retained IDs, local

reference resolution, freshness and PDF text coverage. These generated files are ignored and need regeneration after source changes.

All nine documents compiled successfully through WSL/LuaLaTeX. The checker passed with **753 requirement identifiers across 225 PDF pages**, compared with 318 identifiers and 84 pages in 0.1. There were no duplicate or unresolved identifiers, missing requirement text, stale artifact hashes, changed archive hashes, removed historical IDs, overfull boxes, missing glyphs or detected LaTeX/package warnings.

Document	0.1 pages	0.2 pages	0.1 requirements	0.2 requirements
GSP-Charter	9	19	41	85
GSP-Directives-1	13	27	58	95
GSP-Directives-2	8	26	45	95
GR-TC1-Charter	7	17	30	83
GSP-Ethics-IP	8	22	40	104
GR-100	13	30	12	26
GR-110	8	28	34	111
GR-200	11	32	26	49
GR-210	7	24	32	105

All 318 historical IDs remain: 315 requirement texts are unchanged after whitespace normalization, two advance the GR-200 dependency edition, and EIP-014 explicitly corrects the acknowledgement/target distinction. There are 435 new IDs. Clause relocation and non-requirement prose changes are not classified as requirement text changes by the CSV tool.

Formal-structure checks cover opening clauses, front matter, annex status, table captions and local references. The archive and PDF hashes were verified. Local Markdown targets resolved, and `PROJECT_INDEX.txt` lists 108 source/corpus files. These checks are artifact evidence, not fulfillment of all D2 technical and institutional assessment duties.

Visual review sampled each document?s cover, opening Scope page and first normative annex, plus D2?s assessment schedule, GR-100?s record-role and source tables, and GR-200?s assessment schedule. The 31-page selection is recorded in `build/review/v02/render-plan.json`; rendered pages and contact sheets are stored beside it. The inspected samples showed readable headings, intact tables and no observed clipping or overlap. One nonblocking underfull-line spacing advisory remains in GR-100?s source-map introduction; its rendered page was inspected. No tagged-PDF, screen-reader or affected-user comprehension assessment was performed.

The final toolchain is recorded in the build report: Python 3.12.3, latexmk 4.83 and LuaHBTeX 1.17.0 (TeX Live 2023/Debian) under Ubuntu-24.04/WSL. Builds use shell escape disabled and fetch no external dependencies. Text extraction checks use the Windows Python review environment with pypdf. Source-word counts in the machine report include TeX markup and repeated table headers, and are not represented as prose word counts.

129.1.5 5. Remaining assessment and institutional work

P0 and P1 remain historical 0.1 fixtures. Their arithmetic and authored examples do not assess newly added obligations or demonstrate performance of an actual committee, recording practice, review service or remedy. The initial templates likewise do not substitute for the 0.2 normative schedules.

Before adoption, work remains on actual founding authority, accepted appointments, representation, independent-review capacity, rights terms and a governed rehearsal. Before live operational claims, work remains on contextual legal/ethical review, burden and resource measurement, observed procedure tests, affected-user understanding, accessibility and justified profiles. Current TeX/PDF production does not certify tagged-PDF or screen-reader accessibility.

More detailed drafts expose decisions that can now be reviewed; they do not settle those decisions by their length or typography. ADR-0005 and Q-27–30 retain the proposed choices and alternatives.

130 README

Original source: `schemas/README.md`.

Original source SHA-256: `631706812e71e0c2317879ff36e920d8a610d6f43a6a227a1bb37acc76d77530`.

130.1 Schemas

The original plan deferred schemas until GR-120 stabilized. Under the accepted standards-first co-evolution procedure, the graph pilot now has an experimental packaged JSON Schema, a validator and fixtures, and GR-SPEC-120. This is a bounded profile, not the final GR information model. Structural schema checks alone do not establish semantic reference validity, authorization, verified file bytes, factual truth or whole-practice conformance.

The additive GR-SPEC-121 defines required versioned event-order and temporal-extent modules in the same packaged schema. Cross-record event-role checks, chronology consistency and temporal-cut evaluation remain semantic validator responsibilities.

Further possible artifacts:

- JSON Schema
- JSON-LD context
- RDF/OWL vocabulary
- SHACL shapes
- validation examples

131.1 GR-SPEC-120 — Experimental record graph and module model

Publication class: Specification
Maturity: EXPERIMENTAL implementation draft; not an adopted Standard
Version: 0.2
Date: 2026-09-22
Protocol identifier: `gsp-record-protocol/0.2`
Record schema: `gsp-workspace/0.2`
Initial profile: `gsp.general/0.2`

131.1.1 Foreword

This Specification supplies a bounded implementation model requested by the graph workspace. Its source interpretation is recorded in the graph semantics review, and its architectural selection in ADR-0008. This document operationalizes selected needs from Working Drafts; it neither adopts those drafts nor claims that every package using this model satisfies them.

The reference implementation is the independent Python protocol package. Its JSON Schema resource, fixtures, and semantic validator jointly describe the tested profile. The Git transaction and exchange binding belongs to GR-SPEC-130.

131.1.2 1. Scope

This document defines retained record envelopes, overlapping operational roles, relation incidence, versioned modules, material descriptors, snapshot projection, and migration from the initial workspace. It distinguishes the record graph from recording history and displayed layout.

The initial profile has one private-project reference boundary. It does not define a complete theory of reality, exhaustive target registry, complete claim/material/evidence-role model, substantive assessment method, institutional review procedure, cross-project protection system, or universal interpretation of relations. A record can retain an attributed account while the represented occurrence or identity remains disputed.

Requirements in this document constrain implementations claiming this experimental profile. **Shall** indicates a requirement, **should** a recommendation, **may** a permission, and **can** a capability. Normative identifiers `S120-*` are local to this draft and do not imply adoption.

131.1.3 2. References and dependency scope

Conceptual source references are GR-100 Working Draft 0.3, especially V100-002/005/006/007/009/010/025; GR-110 Working Draft 0.3, especially R110-006/009/011/012/020/021/025/029/093; and GR-200 Working Draft 0.3, especially E200-003/005/008/010/011/017/038. These references identify the needs being operationalized, not an automatic claim that implementing this Specification fulfills their complete obligation sets.

FM-007, sections 7–10 and 16.4, supplies conceptual background for identity, contextual incidence, overlapping analytical roles, and record/claim distinctions. Its Attribute category is not silently equated with the programme's provisional Property role.

The distributed JSON schema uses the JSON Schema Draft 2020-12 vocabulary. Request canonicalization uses RFC 8785 through the `rfc8785` library; ordinary sorted JSON encoding is not described as canonicalization under that RFC. External protocol details and source URLs are maintained in the binding's references.

131.1.4 3. Terms and structures

A **record** is an identified retained representation under a declared recording purpose. A **target** is what that representation concerns. A **snapshot** is the project manifest and record collection at an identified retained project revision. A **module** is a namespaced, versioned component of a record. A **participant incidence** identifies one role in one relation account. A **projection** is a declared rendering of a snapshot.

S120-001. An implementation shall distinguish record reference, represented-target identity, semantic connection, recording ancestry, and display position. It shall not infer factual truth, causation, legal authority, or temporal priority solely from any of those technical structures.

S120-002. A snapshot shall identify its project, source `head`, and record collection. Record identifiers shall be unique within that collection. A reference resolved under this profile shall identify a record present in that same snapshot.

The package accepts full 40- or 64-character lowercase hexadecimal revision identifiers. A particular storage binding declares its object format and accepted width. This is a locator format, not a time or authenticity guarantee.

S120-028. A declared project profile that the implementation does not support shall remain preserved and identified as an interpretation limitation during reads. Mutation, including migration, shall require a supported adapter rather than silently replacing that declaration or ignoring its additional constraints. Absence of a profile in the original legacy workspace shall not itself prevent the explicit legacy migration defined in Clause 10.

131.1.5 4. Record envelope

S120-003. A current record shall declare `schema_version: gsp-workspace/0.2`, a canonical lowercase UUID `id`, `title`, `content`, `record_type`, `record_roles`, `epistemic_mode`, `modality`, `status`, `related_records`, `modules`, and recording audit information. Creation and update actor objects shall contain `id` and `display_name`; corresponding recording times shall include an offset.

Additional descriptive fields are `attributed_to`, `method`, `evidence`, `uncertainty`, `alternatives`, `conditions`, `consequences`, and `occurred_at`. The schema and package expose their length limits. `occurred_at` is a supplied target-time description, not the server recording timestamp. Empty descriptive text means that the information was not recorded in that field; it does not establish absence, certainty, timelessness or fulfilled criteria.

S120-004. `record_type` shall identify one primary presentation role from Entity, State, Event, Process, Relation, and Property. `record_roles` shall contain one or more distinct roles from that vocabulary and include the primary role. Multiple roles shall not automatically create multiple represented targets.

S120-005. The implementation shall preserve the distinction among epistemic basis, asserted modality, and recorder-assigned disposition. The initial vocabularies are:

Field	Values	Limit
`epistemic_mode`	observed, reported, inferred, interpreted, retrospective	Primary account mode; combined contributions remain in descriptive grounds.
`modality`	realized, intended, possible, unrealized, unknown	A represented occurrence/effect qualification; not an assessment result.
`status`	unreviewed, contested, revised, withdrawn	Recorder-assigned account status; not an independent institutional finding.

S120-006. Creation and update audit values shall be supplied by the trusted application binding. A record mutation request shall not inject or overwrite creation audit identity/time. The authenticated recording account shall remain distinguishable from the attributed source described in the account.

131.1.6 5. Structured Relations

S120-007. A structured Relation shall be an ordinary independently referenceable record whose applied roles include Relation and whose `gsp.relation` module has supported version `1`. Its module data shall identify `predicate`, `participants`, and explicit boolean `participants_complete`. Optional descriptive fields are `predicate_definition`, `participant_limitations`, `context`, `identity_criterion`, and `temporal_scope`.

S120-008. Each participant incidence shall have its own UUID `id`, a local `record_id`, a nonempty descriptive `role`, `reference_scope`, and `orientation`. Incidence identifiers shall be distinct within one relation account. The same record may occupy multiple incidences, including different roles. A Relation may itself be a participant.

`reference_scope` is either `record` or `represented_target`. The former concerns the referenced retained representation; the latter concerns its described subject under the account's stated identification and limitations. Neither establishes that subject's identity or existence.

`orientation` is `in`, `out`, or `undirected`. In the canonical incidence projection, `in` points from participant to Relation, and `out` points from Relation to participant. `undirected` asserts no arrow direction. Orientation alone has no universal causal, temporal, evidential, or hierarchical meaning.

S120-009. The profile shall permit one to 32 listed incidences, including unary, cyclic, self-referential, parallel and higher-order relation structures. It shall not deduplicate Relation records by predicate and participant pattern. An empty incidence list lies outside this initial profile; this limit is not a claim about every mathematical or social relation.

S120-010. If `participants_complete` is false, the module shall contain a nonempty `participant_limitations` explanation. The listed local references can represent a known subset. The implementation shall not fabricate participant records to complete an uncertain account. An empty or unresolved identity criterion shall not be presented as fulfillment of a criterion-dependent GR obligation.

S120-011. An unstructured record with a Relation role shall remain representable and selectable. The projection shall identify the absence of interpreted incidence rather than infer participants from neutral references or prose.

131.1.7 6. Neutral references and modules

S120-012. `related_records` shall remain a set of up to 50 distinct local record identifiers used for neutral navigation. Migration or graph rendering shall not silently convert these references into typed substantive relations.

S120-013. Module keys shall be namespaced identifiers. Each envelope shall contain string `version`, boolean `required` when supplied, and object `data`. Omission of `required` means false except for the supported new temporal modules specified in S120-029 and GR-SPEC-121. This general default does not authorize rewriting an opaque historical envelope merely to insert the default.

S120-014. Optional unsupported modules or versions shall survive unrelated edits unchanged and remain identifiable as unsupported, read-only material. A required unsupported module shall block project mutation by an implementation unable to evaluate its constraints. Unsupported data shall not cause dynamic code installation or execution.

The current package introduces or edits five supported version `1` modules: `gsp.relation`, `gsp.notes`, `gsp.files`, `gsp.event_order`, and `gsp.temporal_extent`. A future domain registry needs its own implementation and compatibility evidence; this Specification does not pretend that unknown domain semantics have been checked.

S120-029. The additive temporal modules and `gsp.spacetime/1` projection shall follow GR-SPEC-121. Stored supported temporal envelopes shall require `required: true`; preparation shall supply true when omitted from a supported temporal create/set request and reject explicit false. No historical opaque module shall be rewritten to manufacture support. Existing protocol, schema and profile identifiers remain 0.2.

S120-030. Ordinary graph reading shall remain available independently of temporal scope. Introducing or reading temporal modules shall not automatically convert existing records, infer bounds from recording dates, or rewrite retained Git history. An unsupported retained event-order module shall prevent a claimed complete temporal projection; an unsupported temporal-extent module shall remain an explicit applicability limitation.

S120-015. `gsp.notes` data shall contain `text`. `gsp.files` data shall contain `items`, an array of retained material descriptors. Module absence shall remain distinguishable from an explicitly enabled empty module.

S120-016. Module mutation shall use explicit module operations. Core partial updates shall preserve omitted fields and modules. Removing a files module with linked items shall be refused until those links have been detached. Removing a current module shall not claim erasure of its retained historical versions.

131.1.8 7. Retained material descriptors

S120-017. A file descriptor shall contain `file_id`, `filename`, `media_type`, `sha256`, integer `byte_length`, `uploaded_by`, and `uploaded_at`. File identifiers shall distinguish descriptors within their owning record. Replacing material shall preserve the descriptor identity while retaining earlier versions through the binding's history.

S120-018. Filenames shall be display metadata rather than storage paths. A binding shall refuse path separators and control characters in these names and shall protect download headers and rendering independently. SHA-256 shall identify bytes; it shall not establish acquisition independence, evidence acceptance, factual truth, or permission to disclose them.

S120-019. File descriptors shall be created or changed through binding-verified file operations. A generic module update may enable an empty files module but shall not forge linked descriptors or clear existing file links. Detachment shall mean removal of the current link, without asserting historical byte erasure.

The pure package checks the declared descriptor against the metadata supplied by its caller. The binding separately verifies actual received bytes, exact part inventory, authorized source revision, stored assets, and atomic descriptor/byte publication. Consequently, a structurally valid snapshot with an unresolved or absent asset cannot be described as a verified complete archive solely because this package accepted its JSON.

131.1.9 8. Transaction preparation boundary

S120-020. The preparer shall validate the final candidate snapshot, including references to records created in the same transaction. Semantic cycles shall not be rejected because the underlying storage history has a different structure. Failure shall leave the supplied source snapshot unchanged.

S120-021. A transaction shall not contain repeated core mutations of one record or repeated mutations of one module or file descriptor. Creation followed by a distinct module or file operation is permitted. A module supplied within record creation cannot also be overwritten in that transaction. The implementation shall reject ambiguous repeated writes rather than silently selecting the last value.

The full transaction envelope, operation shapes, receipt, digest, replay and conditional-publication contract is specified by the binding. The reusable package prepares a candidate and receipt; it does not itself acquire locks, authorize a user, publish a Git reference, or verify that a retry corresponds to a prior committed receipt.

131.1.10 9. Projection and historical interpretation

S120-022. The canonical projection `gsp.incidence/1` shall expose every retained record as a selectable node, one incidence edge per interpreted participant, and distinct neutral-reference edges. Each incidence shall retain its relation identifier, participant identifier, role, scope and orientation. The projection shall identify its source `head` and disclose unstructured or unsupported material through warnings.

S120-023. Historical graph labels, relation structure and module data shall be derived from the same identified snapshot. A binding shall resolve historical material downloads under that snapshot and the applicable authorization. Substitution of current data into a historical presentation shall not be silent.

S120-024. Filtering or simplified rendering shall disclose its selection and information limits. Layout coordinates, proximity, centrality and creation order shall not automatically become substantive properties or causal claims. A future binary simplification shall preserve the underlying Relation identity and provide a route to its full participant account.

131.1.11 10. Legacy migration

S120-025. Reading `gsp-workspace/0.1` shall not perform a stored migration. A declared view adaptation may display the legacy primary role as a singleton role set and absent modules as empty. It shall retain the source schema declaration and preserve legacy references as neutral.

S120-026. Migration shall be an explicit sole `project.migrate` transaction under the `migration` change category. The new snapshot shall identify the source revision, prior schema, migration transaction, accountable actor/time and mapping limitations. Record IDs, account content and original recording attribution/time shall be retained. No relation predicate, participant role, evidential ground or unavailable file byte shall be invented.

131.1.12 11. Validation evidence and bounds

S120-027. An implementation shall distinguish structural validation, scoped semantic validation, byte/custody checks, publication guarantees and substantive assessment. A validation report shall state the applicable profile and material limitations.

The package implements JSON Schema Draft 2020-12 checks plus cross-record and module semantics. JSON values use finite RFC 8785-compatible numbers, valid Unicode and bounded nesting. Canonicalization rejects unsafe integers, nonfinite numbers and malformed surrogate text. The binding is responsible for rejecting duplicate JSON member names before an ordinary dictionary representation loses that distinction.

The reusable profile limits requests to 100 operations, projects to 1,000 records, relations to 32 incidences, and file transactions to eight parts, 10 MiB each and 20 MiB combined. Module JSON is bounded to 256 KiB, transaction JSON to 2 MiB, and snapshot JSON to 64 MiB. The initial HTTP/Git binding declares tighter JSON limits: 1 MiB transaction JSON and 32 MiB aggregate snapshot JSON. These limits are operational capacity decisions.

The executable acceptance cases include semantic cycles and higher-order relations; n-ary, parallel, unary and self relations; record/target scope; repeated roles; mode/modality/dispute coexistence; final-candidate reference checks; source immutability on failure; opaque module preservation; unsupported-profile write refusal; explicit migration; exact file-part declarations; descriptor replacement/detachment; digest invariance under member ordering; and historical label isolation. They establish bounded software behavior, not independent application interoperability or whole-GR conformance.

131.1.13 12. Unresolved extensions

OPEN: Separate claim, material, evidence-role, assessment and competing-interpretation objects; richer typed missingness; explicit role admissibility evidence; domain relation vocabularies; multiple descriptive-regime mappings; protected cross-project references; independently implemented academia mappings; governed retention and selective erasure.

DEFERRED: Semantic branch/merge resolution, externally stored large assets, executable third-party modules and automatic assessment. Availability of a generic graph or a Git DAG does not settle those matters.

132 README

Original source: `specifications/GR-SPEC-120-information-model/README.md`.
Original source SHA-256: `af21b9b32b834e2d5ee812081479a99712350a435d2c2cc73abed449c3f1f4ed`.

132.1 GR-SPEC-120 — Generativity Information Model Specification

Document class: Specification
Status: Experimental implementation draft 0.2; not an adopted Standard

The experimental record graph and module model defines a bounded record envelope, overlapping roles, first-class relation incidence, versioned modules, retained material descriptors, projection and explicit legacy migration. The independent Python package supplies JSON Schema, scoped validation, transaction preparation, graph projection, fixtures and a CLI.

Protocol `gsp-record-protocol/0.2`, schema `gsp-workspace/0.2` and profile `gsp.general/0.2` are experimental identifiers. They do not imply adoption of the GR Working Drafts or independent academia interoperability. See the publication taxonomy, implementation design, and source review for authority, scope and remaining limits.

133 GR SPEC 121

Original source: `specifications/GR-SPEC-121-event-time-projection/GR-SPEC-121.md`.
Original source SHA-256: `1bd94a7e8f767c30cf7366fa800e9bffd8d4f74d06833788e12d530f04bc6128`.

133.1 GR-SPEC-121 — Event time and spacetime projection

Publication class: Specification
Maturity: EXPERIMENTAL implementation draft; not an adopted Standard
Version: 0.1, 2026-09-22
Protocol / record schema / profile: `gsp-record-protocol/0.2` / `gsp-workspace/0.2` / `gsp.general/0.2`
Projection: `gsp.spacetime/1`

133.1.1 Foreword

This Specification defines a bounded event-order and temporal-applicability extension to GR-SPEC-120. It implements selected information and presentation needs from GR-120, GR-140 and GR-110 Working Draft 0.3, especially R110-008/049. These are draft dependencies, not adopted authorities or claims of whole-practice conformance.

The design gives the source interpretation, including FM-007 section 9.7, PDF p.42, and FM-005 sections 5.14 and 5.20.4. ADR-0011 records the alternatives and operational selection. Requirements use **shall**, recommendations **should**, permissions **may**, and capability statements **can**. Identifiers `T121-*` apply only to this experimental draft.

133.1.2 1. Scope and interpretation

This profile represents explicit event precedence, event-bounded applicability, predecessor-closed selections, and topology/trajectory projections at one recording revision. Space means the represented relational topology. A geographic location can be a State or Property account with a declared reference system; graph layout coordinates have no geographic meaning by default.

The profile does not compute physical duration, infer ordering from dates, execute event effects, prove causal influence, identify a unique true State, establish target identity, or determine which competing account is warranted. Extended-event overlap, explicit onset/completion semantics, account-selection scenarios and formal transformation composition remain outside this edition.

T121-001. An implementation shall distinguish recording revision, represented event order, event cut, temporal applicability and display layout. It shall not infer event precedence from Git ancestry, recording time, UUID order, free-text `occurred_at`, or display rank.

T121-002. An Event reference in this profile shall denote an operational boundary marker in the declared account. Its use shall not assert that every represented event is instantaneous. Availability of an Event record in a later snapshot shall not be described as continued occurrence of its target event.

133.1.3 2. Module representation and compatibility

The extension adds two version `1` modules. It does not change existing record IDs, protocol/schema/profile identifiers, transaction operation names, or Git binding tree paths. Existing records require no stored migration to remain readable.

T121-003. Stored supported `gsp.event_order` and `gsp.temporal_extent` envelopes shall contain `version: "1"`, `required: true`, and their specified `data` object. Structural schema validation shall reject explicit false and stored omission of the required flag. Preparation of a supported new/set module may supply true when the request omits it; it shall not change explicit false into true silently.

T121-004. An implementation unable to interpret a required temporal module shall apply the unsupported-required-module mutation restriction in S120-014. Successful ordinary graph rendering shall not imply support for temporal interpretation. Implementations shall expose the added module versions and projection capability.

T121-025. Any retained `gsp.event_order` module with an unsupported version shall prevent a complete temporal projection, including when its older envelope declares it optional. The result shall contain an `unsupported_event_order` diagnostic, `consistent: false`, null event ranks, and null cut/topology. An unsupported retained `gsp.temporal_extent` version shall produce an `unsupported_temporal_extent` diagnostic and indeterminate presence, unless the account is withdrawn; it shall not alone invalidate an otherwise usable known event order. Opaque data shall remain retained unchanged.

All references below use the canonical UUID form and same-snapshot reference boundary of GR-SPEC-120. Data objects have only the fields defined here. Existing envelope, module-size and snapshot limits continue to apply.

133.1.4 2.1 Event order

```
{"version":"1","required":true,"data":{"before":"<Event UUID>","after":"<Event UUID>"}}
```

The angle-bracket strings illustrate references; an actual instance uses canonical UUIDs.

T121-005. Both `before` and `after` shall resolve to records whose applied roles include Event. The owning record shall include the Relation role and supported `gsp.relation/1`. The latter shall contain exactly two incidences: the `before` target with orientation `in`, and the `after` target with orientation `out`, both with `reference_scope: represented_target`. Each incidence shall retain the ordinary independently identified, descriptively named role.

T121-006. Order records shall retain ordinary attribution, epistemic basis, modality, status, grounds and revision history. Duplicate endpoint assertions shall remain independently identifiable. Self-precedence and cyclic sets of otherwise well-formed assertions shall remain retained and receive consistency diagnostics rather than being erased as invalid archival evidence.

The module supplies strict ordering semantics. An arbitrary Relation predicate or direction does not. Temporal precedence does not by itself supply a causal or generative contribution claim.

133.1.5 2.2 Temporal extent

```
{
  "version":"1",
  "required":true,
  "data":{
    "start":{"kind":"event","event_id":"<Event UUID>"},
    "end":{"kind":"unknown"},
    "basis":"Grounds, scope and continuity assumptions of this applicability account.",
    "subject_record_id":"<optional subject UUID>"
  }
}
```

T121-007. Extent data shall contain `start`, `end` and nonblank `basis` text of at most 2,000 characters. Each boundary shall be exactly `{kind: event, event_id: UUID}`, `{kind: unknown}`, or `{kind: unbounded}`. Event-boundary references shall resolve to Event-role records in the same snapshot. Any supplied `subject_record_id` shall resolve in that snapshot.

T121-008. Unknown shall mean an unresolved boundary. Unbounded shall mean that no limiting boundary is asserted on that side within the declared account scope; it shall not be treated as missing data or universal perpetual existence. The absence of the module shall remain distinguishable from each explicit boundary form.

T121-009. Start applicability shall be inclusive and end applicability exclusive. When both bounds reference events, the active ordering shall support strict start-before-end reachability. Equal, reversed or incomparable bounds shall make that extent indeterminate and produce a diagnostic; the extent shall not implicitly add an order assertion.

T121-010. Subject grouping shall remain a supplied account whose basis explains the relevant scope and continuity judgment. Grouping shall not itself establish represented-target identity, state exclusivity or causal continuity. The projection shall preserve separately identified and potentially competing accounts.

133.1.6 3. Ordering and cuts

Let `E` contain the snapshot's Event-role records. Let `A` contain edges from understood order modules whose owning records are not withdrawn. Reachability in `A` supplies strict precedence only when the selected ordering is acyclic.

T121-011. The projection shall preserve order-account IDs, endpoints and statuses. Withdrawn order accounts shall remain inspectable with `active: false` and shall not constrain `A`. Contested and non-realized temporal accounts shall remain included with visible qualifications. An active order referring to a withdrawn Event account shall produce a warning rather than silently dropping that explicit reference.

T121-012. The projection shall identify cycle diagnostics and their involved events/order accounts. If a cycle exists, `consistent` shall be false, event ranks shall be null, and `cut` and `topology` shall be null. It shall not produce a purported admissible cut by silently dropping assertions. The ordinary record graph remains separately available. Here `consistent` means an interpretable, usable selected event order, subject also to T121-025; it is not a finding of factual truth.

T121-013. For an acyclic ordering, an explicit selection shall contain at most 1,000 distinct Event UUIDs present in the selected snapshot. Its cut shall be the predecessor closure of those IDs. A cut shall include every known predecessor of every included event.

T121-014. Omitted selection shall denote the all-event cut. An explicit empty selection shall denote the empty cut. The result shall expose the requested IDs, included closure, added predecessor IDs, and maximal included events as the frontier. All-event selection shall use `requested: null` and `derived: []`.

T121-015. Event ranks shall be display aids derived from the selected acyclic order; they shall not supply additional precedence, simultaneity, duration, or physical position. Incomparability shall mean absence of supported ordering in this account, not established simultaneity or independence.

133.1.7 4. Presence, topology and trajectories

Presence is classification of retained applicability claims at a cut, not an assertion that the record's target exists or does not exist independently of those claims.

T121-016. Presence classification shall follow this priority:

1. A withdrawn account is `withdrawn`.
2. A retained unsupported extent is `indeterminate`; complete absence of an extent is `unscoped`.
3. Absence of a usable consistent cut, or a diagnosed invalid pair of event bounds, is `indeterminate`.
4. Either bound being unknown is `indeterminate`.
5. A known event start outside the cut is `not_started`.
6. A known event end inside the cut is `ended`.
7. Otherwise the account is `active` within its declared scope.

T121-017. Unknown and unscoped accounts shall remain inspectable and excluded from active topology by default. A presenter shall disclose this omission and shall not treat it as evidence of absence. Partial knowledge of one boundary shall not silently complete the other.

T121-018. A topology shall contain the canonical incidence graph's active record nodes and only edges whose two endpoints are active, at the same source revision. An active Relation node shall remain present even when some of its participants are not established active. The projection shall emit `partial_relation_at_cut` for omitted participant incidences or an explicitly incomplete participant account, identifying omitted participant-entry IDs. It shall retain Relation identity and scope/completeness qualifications without presenting the visible subset as complete or inventing missing participants, extents, or incidences.

T121-019. Trajectory groups shall identify each supplied subject reference and the retained record IDs grouped under it. They shall not impose an additional event order, infer identity from a shared label, select one competing account as true, or calculate event outcomes. Event-order inventory, applicability extents and grouped trajectories shall remain distinguishable in presentation.

133.1.8 5. Projection response

T121-020. The pure projection shall identify `head`, `project_id`, `protocol_version`, `projection: gsp.spacetime/1`, `consistent`, `events`, `orders`, `cut`, `extents`, `trajectories`, `presence`, `topology`, `diagnostics`, and `limitations`. The HTTP binding shall additionally distinguish the currently observed project head and any legacy read adaptation.

Field	Content
`events`	ID, title, rank or null, direct predecessor/successor IDs, status, modality and descriptive `occurred_at`
`orders`	Owning Relation ID, before/after IDs, status and active flag
`cut`	Null, or requested/included/frontier/derived IDs as specified above
`extents`	Record ID, subject ID or null, start/end, basis and presence
`trajectories`	Subject ID and grouped record IDs
`presence`	Record ID and classified presence
`topology`	Null, or selected canonical nodes/edges
`diagnostics`	Code, message and applicable record/event/relation/participant identifiers
`limitations`	Declared interpretive and implementation limits

T121-021. Every result shall derive from one pinned snapshot. Historical titles, roles, orders, bounds and qualifications shall not silently resolve against the current revision. Projection shall not modify records, create receipts or commits, or perform migration.

133.1.9 6. HTTP selection binding

The binding uses `GET /api/projects/{id}/spacetime` for the all-event cut and `POST` to the same path for `{ "after": ["<Event UUID>"] }`. Both accept optional `revision=<head>` using the existing revision authorization and reachability rules.

T121-022. GET and POST shall require the existing project authorization. POST shall additionally require the application's anti-forgery protection despite being read-only. Its JSON body shall contain exactly `after`, an array of at most 1,000 distinct Event UUIDs, and shall not exceed 64 KiB. Invalid selection shall not be silently truncated or coerced into all-event selection.

T121-023. Malformed or duplicate-member JSON, unknown body fields, invalid/non-Event references and unsupported request media types shall use the binding's applicable validation/media errors. A structurally readable chronology conflict shall return an inspectable projection with `consistent: false`, not be represented as a storage failure or silently repaired.

Projection requests have no transaction ID or `expected_head` because they publish no change. Temporal module editing continues to use ordinary transactions with their expected revision, actor, reason and retained receipt under GR-SPEC-130.

133.1.10 7. Assessment and limits

T121-024. An assessment shall distinguish module/schema validation, reference validation, chronology consistency, projection behavior, authorized HTTP behavior, presentation and substantive factual warrant. It shall identify the cases actually executed and shall not equate a passing diagram or acyclic ordering with an established historical account.

Required discriminating cases for this profile include earlier events inserted after later events; unknown order; explicit empty/all-event cuts; ancestor closure; self and multi-event cycles; withdrawal and contestation; unknown/unbounded/missing extents; equal/reversed/incomparable bounds; subject grouping; incomplete relation context; historical versions; denied access; body bounds; and a check that projection leaves the accepted Git head unchanged. This is an assessment schedule, not a claim that all checks have already passed.

The reference implementation and packaged schema implement this bounded contract. Independent import compatibility, historical interpretation, accessibility and participant comprehension require separate evidence. Academia's native record protocol is not thereby aligned with this extension.

133.1.11 Annex A — Informative source comparison

The source-grounded design records exact manuscript pages, including the narrower consequential relational-event concept in FM-004 and the occurrence/attempt distinctions in FM-007. Their different scopes are preserved.

Lamport 1978, pp.559–560, supplies a comparison for partial orders and logical-clock displays. Its distributed-process assumptions are not assumed for social records. The W3C 2017 Time Ontology Recommendation, sections 3.1–3.3, supplies a comparison for instants, intervals and temporal reference systems. This profile makes no claim to implement that ontology or its complete interval calculus.

134 README

Original source: `specifications/GR-SPEC-121-event-time-projection/README.md`.
Original source SHA-256: `0af29ca674e5c799157b74fd8ebbd18420e0b06457c2d766fdccc7869b8c79cc`.

134.1 GR-SPEC-121 — Event time and spacetime projection

Publication class: Specification
Maturity: EXPERIMENTAL implementation draft 0.1; not an adopted Standard

GR-SPEC-121 specifies additive event-order and temporal-extent modules, consistent cuts, trajectory grouping, and the `gsp.spacetime/1` topology projection. Recording history remains distinct from represented occurrence order.

The specification develops temporal needs in GR-120 and GR-140. Its foundation interpretation and limits appear in the design and ADR-0011. The shared protocol package is the reference implementation; the GR-SPEC-130 binding supplies authorized, revision-pinned HTTP reading.

135 GR SPEC 130

Original source: `specifications/GR-SPEC-130-interchange/GR-SPEC-130.md`.
Original source SHA-256: `e04f0657fb3648a6390e43c25c07bacb554d2c09686490bbe6a6a980c8e037af`.

135.1 GR-SPEC-130 — Project transactions, Git binding and interchange

Document class: Specification
Status: EXPERIMENTAL technical specification; not an adopted Standard
Edition: 0.2, 2026-09-22
Protocol: `gsp-record-protocol/0.2`
General profile: `gsp.general/0.2`
Storage binding: `gsp.git/0.2`

135.1.1 Foreword

This Specification defines a bounded project-transaction and interchange binding for the experimental Generativity workspace. It develops the infrastructure need identified in the graph-workspace design and ADR-0008. Those documents record the selected alternatives and limitations. They do not establish standards adoption, institutional authority or factual warrant.

The first implementation combines an independent protocol package, an authenticated HTTP adapter and a Git storage adapter. The components have different responsibilities. Availability of a shared package does not establish that two independent applications have successfully exchanged records. Adaptation of the academia application remains subsequent work.

The requirements below use **shall** for requirements, **should** for recommendations, **may** for permission and **can** for capability. They apply within the declared experimental binding. A claim about a tested component shall identify its scope rather than imply conformance of an institution, factual claim or whole GR standards family.

135.1.2 1. Scope

This Specification covers:

- coordinated changes to a project's records, declarative modules and retained material;
- base-version comparison, committed receipts and repeated requests;
- one-repository-per-project Git serialization;
- reads of complete historical project snapshots;
- current-snapshot JSON, selected-snapshot material packages and full-history bundles;
- adaptation and explicit migration of the initial `gsp-workspace/0.1` representation;
- bounded failure behavior and evidence needed to assess implementation claims.

It does not define the full semantics of the six operational recording roles, replace the information model, supply an access policy, implement a public federation protocol or establish a universally applicable retention policy. Authentication, project ownership and disclosure checks are supplied by the application. Independent signatures, external timestamps, semantic merging, concurrent branches, selective erasure and remote object storage are outside this edition.

135.1.3 2. References and authority

The record envelope and module contract are specified in GR-SPEC-120. The additive event-order, temporal-extent and cut-projection contract is specified in GR-SPEC-121. The executable representation is distributed with the independent protocol package. These remain experimental; the additive modules do not change this binding's 0.2 identifier or retained tree layout.

This binding uses Git's documented object and reference operations. Conditional publication follows Git update-ref; blob construction and bounded object reading use Git hash-object and Git cat-file. Full-history interchange uses Git bundle.

Request-digest canonicalization uses RFC 8785, JSON Canonicalization Scheme. HTTP terminology follows RFC 9110. The body field `expected_head` is an application-level precondition; this edition does not redefine HTTP entity tags or `If-Match` semantics.

135.1.4 3. Terms and identifiers

Project snapshot: the project manifest and retained record representations obtained from one accepted project revision. A snapshot can refer to retained material without embedding its bytes in JSON.

Transaction: one proposed coordinated mutation, identified by a caller-supplied UUID, evaluated against a declared base revision and accepted through one publication operation. A storage transaction is not automatically a represented Event, institutional act or epistemic judgment.

Receipt: structured information retained in the same accepted snapshot as the transaction's effects. It identifies the request, recorder, base, reason, changes and bounded validation result.

Revision: in this Git binding, a full lowercase 40-character SHA-1 Git commit identifier. A revision identifies retained project content within the binding; it does not authenticate the represented target or establish independent time.

Asset: retained binary material addressed by its lowercase 64-character SHA-256 content digest. Its storage digest identifies bytes. A file descriptor supplies a separately identifiable acquisition and descriptive context.

Publication: successful advancement of `refs/heads/main` to the candidate commit, conditional on its preceding value. Prepared but unreachable objects are not accepted project revisions.

X130-001. Project, record, transaction and file descriptor identifiers shall use canonical UUID strings in this profile. Applications shall not derive arbitrary filesystem paths or Git revision expressions from supplied identifiers.

X130-002. A revision requested through this binding shall be a complete commit identifier reachable from the selected project's accepted `main` history. A shortened identifier, branch expression, foreign-project commit or dangling prepared commit shall not be treated as an accepted revision.

135.1.5 4. Transaction representation

A transaction contains `protocol_version`, `transaction_id`, `expected_head`, `reason`, `change_categories` and `operations`. Operation names and their field constraints are defined by GR-SPEC-120 and the package schemas. This edition supports record creation/update, module setting/removal, file attachment/replacement/detachment and an explicit project-migration operation.

X130-003. A receiver shall validate the supported protocol/profile, operation envelopes, identifiers, declared types and resource limits before accepting a mutation. Duplicate JSON members, malformed Unicode, nonfinite numbers and unrecognized operation fields shall be rejected rather than silently normalized.

X130-004. Transaction validation shall examine the complete resulting candidate snapshot. References between resources created in the same transaction shall be evaluated against that candidate, not against an arbitrarily ordered series of partially accepted resources.

X130-005. A transaction shall not publish a valid subset of its operations when another operation fails. Repeated mutations of one guarded resource shall follow the information-model rules rather than an implicit last-write-wins convention.

X130-006. Server-managed recording attribution and time shall be assigned by the receiving application. They shall remain distinguishable from supplied source attribution, represented occurrence time, assessments and acquisition descriptions.

X130-007. An implementation shall preserve unmodified optional modules it cannot interpret. It shall refuse a mutation when an unsupported required module prevents evaluation of the project's necessary constraints. Unsupported data shall not install executable code or determine server paths.

The shared package prepares a complete `{project, records}` candidate and a receipt without accessing Flask, SQLite, a repository or a filesystem. The application verifies the caller and actual uploaded material. The Git adapter enforces storage identities, resource bounds, material closure and conditional publication. Passing one layer's checks does not substitute for the others.

135.1.6 5. File transfer and material closure

An ordinary transaction can be sent as JSON. A transaction carrying files uses multipart encoding with one textual `transaction` JSON field and explicitly named binary parts. A file operation declares its part name, file descriptor ID, owning record, filename, media type, SHA-256 and byte length.

X130-008. The received binary part names shall correspond exactly to the declared attachment/replacement operations. Duplicate, missing and undeclared parts shall be rejected. Multipart boundary strings and transmission ordering shall not determine logical transaction identity.

X130-009. The receiving implementation shall compute the actual byte length and SHA-256 of each supplied file using bounded reads. A mismatch with its declared identity shall prevent publication.

X130-010. The bytes subsequently written to Git shall be the same bounded bytes whose digest was checked. An implementation shall not validate one path state and later publish different bytes through an unchecked reread.

X130-011. For every understood `gsp.files` version `1` descriptor in a candidate, the candidate tree shall contain a matching asset with the declared byte length. The adapter shall reject supplied assets that have no current understood descriptor in the accepted candidate.

X130-012. Filenames and media types shall remain descriptive metadata. Filenames shall not be used as arbitrary repository or filesystem paths, and media-type declarations shall not cause active content to execute.

X130-013. File detachment and replacement shall not be described as erasure of earlier bytes. This edition retains existing asset entries in subsequent project trees. Unsupported optional modules shall not trigger collection of material that a reader cannot interpret.

Files are initially offered as downloads with `nosniff`. This edition includes no antivirus finding, media authenticity finding or evidence-sufficiency determination. Identical retained bytes can serve different descriptors and acquisition accounts without becoming independent evidence merely because there are several references.

135.1.7 6. Request identity and committed receipts

The request digest is lowercase SHA-256 over RFC 8785 canonical JSON of:

```
{"transaction": "the logical transaction object", "files": "verified part-name metadata mapping"}
```

The displayed strings above denote objects, not literal serialization values. Each entry in `files` has its verified `sha256` and `byte_length`. Ordinary JSON requests use an empty mapping. The logical transaction includes its original base and operation ordering. Server-assigned actor/time and multipart framing are excluded from the digest; actor identity is checked separately.

X130-014. A committed receipt shall include protocol version, transaction ID, original `expected_head`, authenticated actor, recording time, reason, change categories, request digest, changed-resource summaries and the scope/limitations of structural validation.

X130-015. The receipt shall be retained at `.gsp/transactions/{transaction_id}.json` in the same tree as the accepted effects. A published receipt path shall not subsequently be overwritten through this binding.

X130-016. The resulting commit identifier shall not be embedded in the receipt whose containing tree would determine that identifier. A receipt response shall resolve the commit that introduced the immutable receipt path and distinguish it from the currently observed head.

X130-017. The application shall check a committed receipt before rejecting a request solely because its base has become old. A request with the same transaction ID, actor and logical digest shall return the original result without publishing another mutation. Reuse for a different request or actor shall be reported as a conflict.

X130-018. After a failed publication race, an application shall check whether an identical transaction was committed before reporting the request as an unrelated conflict. A client retry after an uncertain response shall retain its transaction ID and logical request.

X130-019. A receiver shall not claim that a timed-out or interrupted response proves that nothing was published. Receipt lookup or retry shall be available to recover the accepted result. An absent receipt during an ongoing race is an observation at that read, not a promise about subsequent completion.

Requests rejected before publication do not acquire a committed receipt. A materially reconciled draft uses a new transaction ID. These rules constrain accepted project effects; they do not promise exactly-once external notifications or institutional action.

135.1.8 7. Git repository binding

Each project uses an application-managed bare repository with one accepted branch. The retained tree has this structure:

```
project.json
records/<record-uuid>.json
assets/<sha256>
.gsp/protocol.json
.gsp/transactions/<transaction-uuid>.json
```

The protocol manifest identifies protocol, profile, binding, object format and record schema. New `gsp-workspace/0.2` projects initialize the manifest and empty records/assets/transactions trees. Older project manifests remain readable without being rewritten on access.

X130-020. The adapter shall prepare complete affected trees and a single commit before publishing any change. It shall advance `refs/heads/main` only if its current value equals the supplied expected parent.

X130-021. Publication failure shall not expose a partial accepted project. Unreachable prepared objects may remain in repository storage, but ordinary reads and exports of accepted history shall not treat them as published revisions.

X130-022. Repository operations shall avoid dependence on a shared working tree or index. Untrusted host Git configuration, hooks, replacement objects, transport settings and inherited `GIT_*` redirection shall not silently control the binding's record operations.

X130-023. A full-candidate storage write shall not silently omit existing records. The first profile represents withdrawal or revision through retained records rather than current-tree deletion. Existing asset entries and receipt paths shall survive subsequent accepted writes.

X130-024. Receipt resolution shall use one pinned accepted head and establish that the receipt path was introduced once without later mutation. An inconsistent or modified receipt history shall produce an error rather than a false original-result attribution.

X130-043. Before mutation, an existing `.gsp/protocol.json` shall exactly match the supported manifest's protocol version, profile, binding, object format and record schema, with no unrecognized fields. A different or extended manifest shall be preserved and mutation refused; the adapter shall not silently replace a future binding declaration with its own defaults. Read-only inspection of otherwise readable stored data does not imply support for mutation under that declaration.

The present adapter uses Git's SHA-1 repository object format and independent SHA-256 asset digests. Neither substitutes for an authenticated signature or external preservation guarantee. An authorized server administrator can rewrite references or remove repositories; this binding does not claim immutability against that administrator.

135.1.9 8. Limits, buffering and capability disclosure

The following are initial implementation limits, not requirements imposed by GR theory. A lower application transport limit also applies where declared.

Limit	Initial value	Scope
Transaction operations	100	Protocol envelope
Records	1,000	Retained project snapshot
Binary parts	8	HTTP transaction

Limit	Initial value	Scope
Individual file bytes	10 MiB	Input and retained asset
Combined incoming file bytes	20 MiB	Transaction, before deduplication in HTTP adaptation
Retained unique asset bytes	128 MiB	Asset blobs reachable from the current asset tree
JSON resource bytes	2 MiB	One stored serialized JSON resource
Project plus record JSON bytes	32 MiB	Combined stored serialized snapshot
Protocol transaction JSON	2 MiB	Shared package bound
HTTP transaction JSON	1 MiB	Initial HTTP binding
Module JSON	256 KiB	Shared profile
Returned history entries	100	One history response

The package's internal snapshot validation bound is 64 MiB. This Git binding's 32 MiB serialized bound is narrower. Storage JSON includes its chosen whitespace and therefore is not measured identically to the JCS request digest. Capabilities disclose the layer-specific limits.

X130-025. An implementation shall disclose its applicable bounds and shall fail before publication when a proposed change exceeds them. It shall not truncate records, modules or material to make a request fit.

X130-026. Snapshot reads shall inspect object kinds and sizes before materializing their bodies. Implementations shall bound per-resource and aggregate JSON reads and reject malformed or incomplete object streams.

X130-027. Attachment, download and bundle handling shall avoid requiring the complete accumulated history or bundle to reside in application memory. Temporary storage shall be closed and released on success, failure and client disconnection according to the host's supported lifecycle.

The retained-asset limit does not bound unreachable prepared objects, Git metadata, transaction-ledger size, operating-system caches or backups. Filesystem quotas, monitoring, governed collection and recovery remain hosting responsibilities. Increasing a declared bound requires capacity assessment and corresponding tests.

135.1.10 9. Snapshot-consistent reading and presentation

X130-028. A project read shall resolve its accepted revision once and obtain the manifest and all selected records from that tree. Participant names, relation modules, notes, related-record labels and file descriptors in a historical presentation shall not silently come from today's project.

X130-029. An application shall distinguish a requested historical revision from its currently observed project head. Historical views shall not silently become current editable views.

X130-030. Historical content, history, receipt and file operations shall pass the application's applicable project authorization checks. A digest or revision identifier shall not serve as a permission token. File delivery shall require a descriptor in the authorized record at the selected revision, not merely the presence of a matching retained blob.

X130-031. A bounded history listing shall disclose its limit. The Git recording sequence shall not be presented as the occurrence chronology or causal ordering of represented targets.

The storage adapter returns caller-owned binary temporary files positioned at byte zero for assets and bundles. The HTTP adapter closes these handles when responses finish or fail. The legacy `bundle()` helper remains available for small compatibility tests, but HTTP downloads use `bundle_file()`.

135.1.11 10. Export classes

Three distinct exports are supported:

Export	Included content	Excluded content
Snapshot JSON	Manifest, current-at-selected-revision record representations and source revision	File bytes, earlier versions, receipt ledger, credentials
Snapshot ZIP	Export manifest, project manifest, records and their understood referenced material at the selected revision	Earlier versions, accumulating receipts, detached/unreferenced assets, credentials
Git bundle	Accepted reference and its reachable commit/object history, including retained receipts and material	Application account/session database, authorization configuration, unreachable failed candidates

X130-032. An exporter shall identify the source project revision, declared export scope and known exclusions. It shall preserve exact stored representations rather than silently replacing them with a display adaptation.

X130-033. A selected-snapshot material package shall include the referenced bytes of understood supported file descriptors and preserve their digest-based filenames. It shall not include every retained asset or the accumulating transaction ledger merely because they occur in the current Git tree.

X130-034. A material package shall disclose unsupported modules and the limits of reconstructing material described only inside them. An exporter shall not assert complete recovery of an opaque module's dependencies.

X130-035. A full-history bundle shall preserve the accepted reachable history, including earlier replaced or detached material. Its presentation shall disclose that these bytes and earlier reasons can remain present even when a current snapshot no longer shows them.

X130-036. An export shall not be described as a complete running-service backup when it omits accounts, access configuration or other required service state. Importing a repository copy shall not itself assign ownership or authenticate its recording actors in a new service.

Current JSON and ZIP are experimental interchange representations. This edition specifies no automatic package-import endpoint. Independent import, collision handling, protected subsets, additional hash bindings and academia-profile mapping require further executable fixtures before an interoperability claim.

135.1.12 11. Legacy adaptation and migration

X130-037. Reading a `gsp-workspace/0.1` project shall not mutate its repository. Any presentation adaptation shall identify the legacy source and preserve its identifiers and original retained history.

X130-038. Migration shall be an explicit, attributed transaction with the old revision as its base and a recorded mapping/limitations account. Original commits shall remain available. A stale migration shall fail through the same publication precondition as another mutation.

X130-039. Migration shall not infer structured Relation participants, predicates, evidence judgments, acquisition records or attachment bytes from legacy navigation links and free text. An unstructured Relation account shall remain distinguishable from a structured relation.

Compatibility record endpoints can translate bounded requests into the shared transaction preparation path. Such endpoints do not provide the full caller-controlled retry guarantee when the server generates a new transaction ID for each request. They do not authorize bypassing unsupported-module or material-closure checks.

135.1.13 12. HTTP operation mapping and errors

The first application exposes these operations:

Method and path	Result
`GET /api/protocol`	Supported protocol/profile/modules and layered limits
`GET /api/projects/{project}` with optional `revision`	Snapshot and distinction between selected/current revision

Method and path	Result
`GET /api/projects/{project}/graph` with optional `revision`	Projection of that selected snapshot
`GET /api/projects/{project}/spacetime` with optional `revision`	Read-only event-order and topology projection at the all-event cut
`POST /api/projects/{project}/spacetime` with optional `revision`	Read-only projection at the predecessor closure of JSON body `after` Event IDs; anti-forgery protection applies
`POST /api/projects/{project}/transactions`	Accepted or replayed transaction result
`GET /api/projects/{project}/transactions/{transaction}`	Committed receipt, original result revision, observed head
`GET /api/projects/{project}/history`	Up to 100 project commits
`GET /api/projects/{project}/records/{record}/history` with optional `revision`	Bounded record history at the selected revision
`GET /api/projects/{project}/records/{record}/files/{file}` with optional `revision`	Authorized descriptor's retained bytes
`GET /api/projects/{project}/migration`	Informative preview without mutation
`GET /api/projects/{project}/export` with optional `revision`	Snapshot JSON
`GET /api/projects/{project}/package` with optional `revision`	Snapshot ZIP
`GET /api/projects/{project}/bundle`	Complete accepted reachable-history bundle

X130-040. State-changing HTTP requests shall require application authorization and its anti-forgery protection. A protected project or resource shall not become discoverable solely through a guessed identifier.

X130-041. The application shall distinguish malformed/unsupported input, denied access, missing authorized resources, base or request-ID conflicts, resource limits and storage unavailability. A failed request shall not discard the client's unsaved graph or imply a substantive judgment about its claims.

X130-044. Spacetime GET and POST shall resolve one authorized selected snapshot and distinguish its `head` from the currently observed `current_head`; the response shall identify legacy adaptation where applicable. The POST shall require the existing anti-forgery protection, accept only JSON `{after: [...]}` within 64 KiB and 1,000 distinct same-snapshot Event references, and follow GR-SPEC-121 selection and diagnostic rules. Both methods shall remain read-only and create no transaction receipt, commit or migration.

X130-045. Temporal module edits shall use the existing attributed transaction, expected-head and publication rules. A late-recorded earlier event shall not rewrite recording history or alter an earlier selected snapshot. The binding shall return retained chronology contradictions as inspectable projection diagnostics rather than invent an ordering to make the graph render.

The application uses `201` for a new accepted transaction, `200` for a recognized replay, `400` for validation failures, `401`/`403` for applicable authentication/anti-forgery failures, `404` for unavailable authorized resources, `409` for conflicts, `413` for binding size limits, `415` for unsupported media types and `503` for unavailable storage. Error classification does not establish whether an uncertain publication occurred; the receipt resolves that separate question.

135.1.14 13. Assessment evidence

X130-042. An implementation assessment shall identify the components, profile, limits, environment and scenarios actually exercised. Structural validation shall not be labelled factual verification, evidence sufficiency, institutional adoption or full GR conformance.

The first test set covers coordinated record/relation/material publication; no partial publication on failure; competing writers; stale bases; persistent receipt lookup after restart and advancing heads; immutable receipt paths; historical labels and file replacement/detachment; bounded snapshot batching; digest/length/material-closure failures; retained-byte budgets and deduplication; bundle reconstruction; and migration preserving legacy history without manufacturing structure.

HTTP tests additionally need same-request replay, changed-request rejection, malformed multipart and unsupported module behavior, authorization across current/historical resources, and snapshot export selection. Browser assessment needs pinned graph/inspector navigation, unsaved-draft preservation and a nonspatial interaction path. A passing storage test does not establish these additional behaviors.

Relevant implementation artifacts are Git adapter, transaction storage tests, legacy storage tests, HTTP binding and protocol package.

136 README

Original source: `specifications/GR-SPEC-130-interchange/README.md`.
Original source SHA-256: `ab2d440aef17b400189e969e5166da32a8f70720ea9e3204a76558ab158bc927`.

136.1 GR-SPEC-130 — Generativity Interchange Specification

Document class: Specification index
Status: EXPERIMENTAL edition 0.2; not an adopted Standard

The transaction, Git binding and interchange Specification defines coordinated project mutation, receipt-based retry recovery, bounded retained files, historical snapshots and distinct export classes for `gsp-record-protocol/0.2`.

Its concrete implementation need and alternatives are recorded in the graph-workspace design and ADR-0008. The independent protocol package supplies model and transaction validation; the application supplies authorization and the Git/HTTP adapters.

The broader GR-130 interchange programme remains preliminary. This experimental binding does not establish independent academia interoperability, an adopted Standard or a whole-family conformance claim. See the publication taxonomy and protocol development plan for authority and proposed dependencies.

137 README

Original source: `specifications/GR-SPEC-200-epistemic-recording/README.md`.
Original source SHA-256: `ff5d90f211b1769f0bb0b0a026a9a7b748a67c6ece45ed9a028f29ed6f940059`.

137.1 GR-SPEC-200 — Epistemic Recording Specification

Document class: Specification project outline
Status: Preliminary placeholder; not an adopted Standard

See the publication taxonomy and protocol development plan for scope, authority and proposed dependencies.

138 README

Original source: `specifications/README.md`.
Original source SHA-256: `b2664df6bed176403ec2d3f30c02b65f7c0c331a0238c4328286399b9656194b`.

138.1 Specifications

Document class: Informative publication-track overview
Status: PROVISIONAL

Specifications are technically precise publications that may be implemented or tested without necessarily having the formal status of a Standard.

See the publication taxonomy.

Initial candidate specifications include:

- GR-SPEC-120 — Generativity Information Model
- GR-SPEC-130 — Generativity Interchange
- GR-SPEC-200 — Epistemic Recording

GR-SPEC-120 and GR-SPEC-130 now have experimental implementable texts: the record/module/transaction model and Git/HTTP binding. Their reference package and generalized application exercise selected behaviors; neither is an adopted Standard or a claim of full GR conformance. GR-SPEC-200 remains a preliminary work item. The parallel GR-120/130/200 standards-track projects express semantic, interoperability and epistemic requirements; corresponding Specifications provide implementable detail when those requirements justify it. Existing identifiers and paths are retained.

Protocols describe interaction behavior within a Specification, including roles, transitions, outcomes and failures. They are not a separate publication authority class. Candidate capability allocations and development triggers are in the protocol and specification plan; the comprehensive plan coordinates requirements, pilots and review.

139.1 GR-100 — Foundations and Vocabulary

> **Developed draft available:** Working Draft 0.3 source and compiled PDF. The Markdown outline below is retained as historical planning context; its candidate choices are not adopted. Current requirements and unresolved decisions are in the TeX draft.

Document class: Standards-track project outline
Status: Preliminary; not an adopted Standard

Define the conceptual vocabulary used across the standards family.

Initial topics: - metamodel vs record ontology; - Entity, State, Event, Process, Relation, Property; - identity and persistence; - time; - provenance; - perspective; - uncertainty; - generative trajectory; - generative conditions; - contingency; - reinterpretation.

140 README

Original source SHA-256: `4b61cb00ca4c4ec15f9219448daa656590c379340bd962b7963b430ea3a370cb`.

140.1 GR-110 — Generativity Recording Requirements

> **Developed draft available:** Working Draft 0.3 source and compiled PDF. The Markdown outline below is retained as historical planning context; its candidate choices are not adopted. Current requirements and unresolved decisions are in the TeX draft.

Document class: Standards-track project outline
Status: Preliminary; not an adopted Standard
Define normative requirements for conforming generativity records.
Expected profiles: - Core; - Standard; - Deep / archival.

141 GR 120

Original source: `standards/GR-120-information-model/GR-120.md`.
Original source SHA-256: `ace0f0c1e1da605d82ad96903d1d0bb78e92ff05a0c924ba8131a189382b3b5b`.

141.1 GR-120 — Generativity information model

Publication class: Standards-track Working Draft; not an adopted Standard
Maturity: Preparatory WD 0.1, 2026-09-22; proposed requirements for review
Scope of this edition: Record identity, overlapping roles, relational incidence, modular descriptions and bounded temporal applicability
Additive revision: 2026-09-22 event-order requirements; earlier requirement IDs retained

141.1.1 Foreword

This bounded draft develops the earlier project outline in response to the graph-workspace pilot. The programme's governance, work-item approval and adoption procedures remain applicable; software implementation does not establish those approvals. The nine coordinated TeX Working Drafts remain at edition 0.3. This text introduces no new ultimate constituents of reality.

141.1.2 1. Scope

This document proposes requirements for an implementation-neutral model of retained representations and their relationships. It distinguishes a represented target, an identifiable record about that target, revisions of that record, and views derived from those revisions. It covers records acting in several operational roles and relations whose participants can themselves be relational records.

Detailed transport, canonical serialization, authentication, evidential assessment, institutional review and legal admissibility are outside this edition. Candidate technical realization is supplied separately by GR-SPEC-120.

141.1.3 2. Reference basis

The internal conceptual dependencies are GR-100 WD 0.3 and GR-110 WD 0.3; epistemic qualifications draw on GR-200 WD 0.3. These dependencies are drafts, not adopted normative authorities. The source review identifies the relevant FM-007 passages, earlier manuscript distinctions and operational narrowing. The current manuscripts take precedence over conflicting assumptions in the earlier academia application, as recorded in ADR-0008.

141.1.4 3. Terms

record identity: identity of a retained representation within a declared identification scope; it does not establish the identity of the represented target.

record role: an operational classification as Entity, State, Event, Process, Relation or Property. Several roles can apply to one record.

incidence: one participation of a referenced record or represented target in a stated relational account, distinguished by its own identifier and role.

module: a versioned, identified part of a record's information envelope. A module's technical boundary does not establish a separate source of epistemic, legal or institutional authority.

141.1.5 4. Proposed information requirements

M120-001. A model shall distinguish record identity from claims about represented-target identity and shall declare the scope in which a record identifier is resolved.

M120-002. A model shall permit more than one applicable operational role and shall distinguish any primary display role from an exclusive classification claim.

M120-003. A model shall preserve a Relation as an identifiable record when its own description, provenance, properties or history is recorded. Reduction to an anonymous pair of endpoints shall not be its sole representation.

M120-004. A structured relational account shall identify its stated relation, participating references, participant roles, and whether each reference concerns the record or its represented target.

M120-005. Distinct incidences shall remain distinguishable when they reference the same participant. A model shall declare any profile restrictions on participant cardinality, self-reference, cycles, parallel relations and relations participating in other relations.

M120-006. A structured relational account shall distinguish a stated complete participant scope from a partial scope. A partial account shall retain its known limitations without requiring invented participant records.

M120-007. A model shall distinguish an untyped navigation reference from a stated semantic relation. Migration shall not assign substantive relation meaning solely because an earlier record contained a link.

M120-008. A module envelope shall identify its module kind, version, interpretation requirement and content. Consumers shall preserve uninterpreted optional content when changing unrelated supported content, or refuse the change with an explicit limitation.

M120-009. A consumer that cannot interpret a required module shall not represent a mutation as validated against that module's requirements. Its applicable mutation boundary shall be declared.

M120-010. A model shall distinguish occurrence descriptions and modality from recording time, revision order, epistemic basis and disputed status. Changing a stored representation shall not automatically imply a change in its represented target.

M120-011. Absent descriptions of temporal scope, identity criteria or context shall not be interpreted as proof of timelessness, resolved identity or unrestricted applicability.

M120-012. A profile shall declare unsupported representation needs, including cross-scope references, mixed epistemic grounds and unresolved participant identity, without asserting that the underlying GR theory excludes them.

141.1.6 5. Assessment and infrastructure need

An assessment identifies the model version, claimed clauses and profile. Inspectable cases include a record with two roles; a three-participant relation; repeated participation; a relation participating in another relation; a partial account; a migrated neutral link; and an unknown optional and required module. Rejection of a case is assessed against the declared profile restriction, not mistaken for a philosophical impossibility.

GR-SPEC-120 supplies UUID references, versioned JSON module envelopes, one-to-32 incidence entries, supported mutation operations and a validation package. These choices operationalize this draft for a pilot; JSON and these numerical bounds are not requirements of M120-001–012. The additive requirements below identify the need for GR-SPEC-121; they do not require one serialization or physical theory of time.

141.1.7 6. Open matters

Q-05–09 and Q-36 remain relevant. Cross-project reference disclosure, participant identity revision, richer epistemic structures and loss-aware imported modules need further development. A fully articulated model of State, Event and Process identity is not completed by this graph profile.

141.1.8 7. Additive temporal information requirements

This section develops R110-008/049 and M120-010/011 following the event-spacetime source review. FM-007 section 9.7 explicitly leaves partial-order events as a modeling obligation; FM-005 section 5.14 requires warranted continuity for trajectories. The requirements remain proposed Working Draft text.

M120-013. A temporal model shall distinguish a recorded precedence assertion, ordering derived from stated assertions, and recording ancestry. It shall preserve the source and qualifications of the assertions used in a reconstruction.

M120-014. A temporal model shall distinguish unknown ordering from asserted simultaneity, overlap, independence or causation. Display ranks or deterministic tie-breaking shall not create a substantive precedence claim.

M120-015. A temporal applicability account shall distinguish stated event or time boundaries, unresolved boundaries, explicit unboundedness within a scope, and absence of scope information. Its boundary convention and grounds shall be identifiable.

M120-016. A trajectory shall identify the subject grouping, continuity criterion or unresolved continuity, observational boundary and relevant temporal resolution. Shared labels or record identifiers shall not alone establish continuing target identity or unchanged state.

M120-017. Competing or inconsistent temporal accounts shall remain distinguishable and attributable. A model shall distinguish malformed representation from a conflict among structurally expressible claims and shall disclose when its selected claims do not support the requested temporal reconstruction.

M120-018. A model using event records as temporal boundaries shall declare the operational boundary interpretation and its limits for extended events, occurrence intervals and recording retention. Retaining a record shall not imply continued occurrence or applicability of its target.

Assessment includes an earlier occurrence recorded later, unsupported order, an unknown interval bound, competing chronology assertions, changed subject descriptions under one continuity claim, and retention of an Event account after its occurrence. Q-45–48 record the remaining projection, interval and interpretation questions. These cases identify needed evidence without asserting successful execution or standards adoption.

142 README

Original source: `standards/GR-120-information-model/README.md`.
Original source SHA-256: `78ade876b362267428e63bbf34b3c65f44bc3a8102371ff31d2b61f3da596c53`.

142.1 GR-120 — Generativity Information Model

Document class: Standards-track project outline
Status: Preliminary; not an adopted Standard

The bounded Working Draft 0.1 develops record identity, overlapping roles, first-class relations and module interpretation requirements. The earlier outline below is retained. GR-SPEC-120 supplies the experimental technical realization.

Define the implementation-neutral conceptual information model.

Expected concerns: - typed records; - relations; - identifiers; - temporal semantics; - versions; - provenance; - perspectives; - uncertainty; - branching.

143 GR 130

Original source: `standards/GR-130-interchange/GR-130.md`.
Original source SHA-256: `be54f968c0fe8d2dbeab5fb6a7a5be312ddb37df9cbe52a79e4185a67b41fb85`.

143.1 GR-130 — Generativity interchange requirements

Publication class: Standards-track Working Draft; not an adopted Standard
Maturity: Preparatory WD 0.1, 2026-09-22; proposed requirements for review
Scope of this edition: Coherent changes, recoverable acceptance and explicit exchange scope

143.1.1 Foreword

The historical project outline called this work “Generativity Interchange Specification.” This Working Draft states implementation-neutral requirements under the existing GR-130 code. The technically precise Git binding belongs to GR-SPEC-130. This clarification preserves the earlier outline and follows the programme’s publication taxonomy without asserting adoption.

143.1.2 1. Scope and references

This document concerns exchanges of retained record representations, modules and associated material. It proposes requirements for coherent multi-resource changes, conflict detection, retry handling, revision selection and exchange manifests. It does not define semantic truth, a universal institutional workflow, independent identity assurance, network federation or external legal validity.

Internal draft dependencies are GR-110 WD 0.3 and the bounded GR-120 WD 0.1. GR-SPEC-120 and GR-SPEC-130 provide one experimental realization. ADR-0008 records alternatives and the separation of record graphs, storage history and display projections.

143.1.3 2. Terms

transaction: a declared set of proposed changes submitted for one acceptance decision in a stated storage scope.

accepted revision: a retrievable state published by the accepting implementation after its declared validation and authority checks.

receipt: retained information identifying an accepted request, its attribution, reason, validation scope and resulting revision by a resolvable association.

exchange package: a declared selection of records and material, accompanied by sufficient scope and version information to identify included and omitted classes of content.

143.1.4 3. Proposed interchange requirements

I130-001. An interchange profile shall identify its version, the information model and profile it carries, supported operations, interpretation rules and limits.

I130-002. A transaction shall identify its request, intended base revision, proposing actor or attributable acceptance context, change reason and declared changes. Attribution shall not be presented as independent authentication unless the claimed assurance is established separately.

I130-003. When several changes are submitted as one transaction, acceptance shall publish their coherent resulting state or publish none of them. Validation shall resolve references against that resulting state, including records introduced by the same transaction.

I130-004. A transaction shall not silently overwrite a changed base. An implementation shall reject the stale proposal or perform a separately declared, inspectable reconciliation procedure.

I130-005. A profile supporting retry shall define logical request equivalence independently of incidental transport encoding. Repeating an accepted equivalent request shall identify its original acceptance; reusing its identifier for a different request shall be rejected.

I130-006. Retry recognition shall survive ordinary service restart and later accepted revisions. A receipt shall not require a circular representation in which its content includes a digest that depends on that same content.

I130-007. An accepted transaction shall retain its reason, attribution, declared change categories and validation scope. A mechanically produced storage change shall not automatically be classified as a recorded Event.

I130-008. A receiver shall verify supplied byte lengths and content identifiers against received material before accepting references that assert those values. A content digest shall not be presented as establishing the material's truth, independence or evidential sufficiency.

I130-009. A revision-selecting exchange shall identify one coherent revision for its records, participant references, modules and associated material. Present authorization and historical content selection shall remain distinct decisions.

I130-010. An export shall identify its revision, version, scope and material omissions. A snapshot shall not be labelled a complete historical backup when earlier revisions, receipts, unreferenced retained material, account records or authority mappings are excluded.

I130-011. A migration shall identify its source format, target format, operation and limitations; it shall preserve earlier revision access within the declared preservation policy. The receiver shall not silently add substantive meaning to earlier neutral references.

I130-012. A profile shall distinguish successful acceptance, conflict, unsupported content and inability to determine acceptance. A client facing an uncertain response shall retain enough request identity to determine whether retry is equivalent.

143.1.5 4. Assessment and infrastructure need

Assessment uses complete resulting-state comparison after success, induced validation/storage failures, concurrent writers, duplicate submissions before and after restart, altered reuse of an identifier, tampered bytes and historical export inspection. A positive result applies only to the exercised binding and declared scope.

The identified infrastructure need is a reusable record transaction vocabulary and acceptance binding. GR-SPEC-120 defines the former; GR-SPEC-130 defines the first binding, using Git object preparation and conditional reference publication. Git ancestry is recording provenance, not occurrence chronology or a restriction that semantic graphs be acyclic.

143.1.6 5. Open matters

Federated identity, detached signatures, offline reconciliation, loss-aware imports, physical storage quotas and independent preservation custody remain open. No compatibility with the earlier academia application's signed transition format is claimed. A later adapter needs byte-preservation and interpretation tests before any such claim.

144 README

Original source: `standards/GR-130-interchange/README.md`.

Original source SHA-256: `287826884012d704a70c5681159cb473d01d68409f10069d8e5a4c873b0c18b4`.

144.1 GR-130 — Generativity Interchange Specification

Document class: Standards-track project outline
Status: Preliminary; not an adopted Standard

The bounded Working Draft 0.1 states implementation-neutral interchange requirements. Its title clarifies the standards-track role of GR-130; the historical outline below retains its original wording. The separate GR-SPEC-130 supplies the experimental Git/HTTP binding.

Define machine-readable interchange.

Candidate representations: - JSON-LD; - RDF; - YAML; - schema validation.

145 GR 140

Original source: `standards/GR-140-presentation/GR-140.md`.
Original source SHA-256: `61551ef7549d7a4e3dba2d217e54d3a4932effb5e0617c474d9abefbe48ff49b`.

145.1 GR-140 — Generativity presentation requirements

Publication class: Standards-track Working Draft; not an adopted Standard
Maturity: Preparatory WD 0.1, 2026-09-22; proposed requirements for review
Scope of this edition: Record-graph projection, historical consistency, inspectable interaction and bounded event-cut topology
Additive revision: 2026-09-22 event-spacetime requirements; earlier requirement IDs retained

145.1.1 1. Scope and reference basis

This bounded draft addresses how a record graph is displayed and edited without confusing its visual arrangement with claims about reality. It develops the earlier outline using GR-100/110/200 WD 0.3, GR-120 WD 0.1 and the source analysis in the graph semantics review. Section 6 adds event-cut topology needs grounded in the temporal design. Complete trajectory reconstruction, physical/interval timeline semantics, public redaction and all accessibility obligations remain outside this edition.

145.1.2 2. Terms

projection: an explicitly selected view derived from a declared record revision and display policy.

incidence view: a projection representing a Relation as an identifiable node and its participant incidences as role-labelled connections.

display state: position, zoom, selection and comparable presentation preferences that do not themselves assert a change to a represented target or record.

145.1.3 3. Proposed presentation requirements

P140-001. A presentation shall identify the revision and projection being displayed, and distinguish a historical selection from the currently published revision.

P140-002. A coherent historical view shall resolve participant labels, record content, modules and associated material from the selected revision. It shall not silently substitute current values into that historical view.

P140-003. A projection shall preserve access to the identity, description and qualifications of each represented Relation, including when a simplified binary edge is used. The projection shall disclose the treatment of unary, repeated and higher-order participation.

P140-004. A projection shall distinguish neutral navigation references from stated semantic relations. Position, proximity, colour, edge direction and size shall not imply unsupported causality, certainty, normative approval or legal status.

P140-005. A filtered view shall disclose that filtering occurred and provide an indication of omitted records or incidences. An unavailable or uninterpreted participant shall not be silently rendered as if its absence were known to be semantically immaterial.

P140-006. A partial relational account shall expose its declared incompleteness and qualifications. An unstructured Relation account shall remain inspectable without invented incidences.

P140-007. View manipulation shall be distinguished from recorded changes. A user shall be able to identify when an action merely rearranges a display and when it proposes a retained, attributed change.

P140-008. A relation-creation interface shall expose participant selection, roles, reference scope and completeness sufficiently for the user to inspect the resulting account before submission. Two clicked nodes alone shall not silently determine an unqualified substantive relation.

P140-009. A client shall preserve a pending change after a detected revision conflict and expose a review route before resubmitting it against a new base. A historical view shall not offer an ambiguous mutation that appears to edit the past.

P140-010. Important graph-inspection and creation functions shall have an alternative that does not require precise pointer manipulation of the graph canvas. The declared assessment scope shall distinguish presence of controls from demonstrated accessibility.

P140-011. Unsupported optional modules and application limitations shall remain visible as interpretation limitations. A successful diagram render shall not be presented as whole-record validation, factual confirmation or programme conformance.

145.1.4 4. Assessment and infrastructure need

Test cases compare the visible view with selected-revision records, rename a participant in a later revision, filter a participating record, inspect higher-order and repeated relations, change layout without changing history, create a connection through both pointer and form controls, and preserve a draft across conflict. Automated browser checks are useful but do not substitute for assistive-technology and participant evaluation.

GR-SPEC-120's incidence projection supplies a reference graph representation. The pilot uses a canvas renderer and a parallel record list, participant form and inspector. No particular graph library or layout algorithm is required by this draft.

145.1.5 5. Open matters

Q-14, Q-25 and Q-40 cover evaluation and accessibility. Layout stability across large revisions, comparative projections, missing/restricted cross-project participants, redaction and comprehensive generative trajectory views remain open.

145.1.6 6. Additive event-spacetime presentation requirements

P140-012. A temporal presentation shall identify both the recording revision used and its represented temporal selection. It shall distinguish an event-defined cut, a display layer and an identified physical or calendar time.

P140-013. A partial-order presentation shall disclose incomparable events without presenting them as established simultaneous occurrences. A chosen linearization, when used, shall expose its arbitrary ordering choices rather than present them as recovered facts.

P140-014. A temporal topology shall disclose its applicability rule, omitted or indeterminate records, and partially displayed relation incidences. A record excluded for missing scope shall not be presented as proof that its target was absent.

P140-015. A chronology conflict shall remain inspectable with its responsible assertions. A presenter shall not silently discard conflicting claims to produce an apparently coherent temporal graph and shall state when the selected account does not support that projection.

P140-016. A trajectory presentation shall preserve access to its grouped descriptions, continuity basis and competing qualifications. It shall distinguish its inferred or stipulated temporal connections from causal-generative attribution and from execution of a state-transition model.

P140-017. Selecting a temporal view shall remain distinguishable from changing retained accounts. A historical selection shall not alter current records or silently resolve its event boundaries through newer descriptions.

GR-SPEC-121 supplies one experimental module and cut-projection realization. Review cases include retrospective insertion, alternative incomparable cuts, cycles, unknown applicability, omitted participant incidences and historical versions. Automated checks of these cases do not establish participant comprehension, full accessibility or the truth of a reconstruction. Q-45–48 preserve those remaining questions.

Original source: `standards/GR-150-conformance/README.md`.
Original source SHA-256: `2cf0ebae05a2caee0d369dfcbf610c221377c07b31b938fc5e0bb6435102356a`.

147.1 GR-150 — Conformance and Validation

Document class: Standards-track project outline
Status: Preliminary; not an adopted Standard
Define conformance claims, validation rules, profiles, and test suites.

148 GR 160

Original source: `standards/GR-160-preservation-access/GR-160.md`.
Original source SHA-256: `df1eca7eebf50a4866aaa5e206030e3e9cb73fd729daeb25e2921a94423cf605`.

148.1 GR-160 — Preservation, privacy, access and retention

Publication class: Standards-track Working Draft; not an adopted Standard
Maturity: Preparatory WD 0.1, 2026-09-22; proposed requirements for review
Scope of this edition: Associated material, access boundaries and honest retention semantics

148.1.1 1. Scope and reference basis

This bounded draft addresses retained file material associated with record revisions and the distinction between removing a current reference and erasing historical bytes. It develops the existing project outline using GR-110 WD 0.3, the programme's separation of legal and technical authority, and GR-120/130 WD 0.1.

It does not prescribe a universal retention period, legal basis, jurisdiction, evidentiary admissibility or duty to preserve. Institutional and jurisdictional decisions need their own authority and procedures. A technically valid operation cannot create that authority.

148.1.2 2. Terms

retained material: bytes maintained within a declared custody and access scope and referenced through a recorded descriptor.

reference detachment: removal of a current record's association with retained material; it does not imply erasure of historical associations or bytes.

preservation scope: the declared revisions, bytes, descriptors and contextual information retained under an identified arrangement.

148.1.3 3. Proposed preservation and access requirements

A160-001. An implementation shall distinguish mutable working files from material retained as part of a record revision and shall identify the applicable preservation scope.

A160-002. A retained-material descriptor shall identify the bytes, their length, descriptive filename and media type, and the recorded upload attribution and time. The implementation shall distinguish asserted media type from verified content characteristics.

A160-003. A replacement shall preserve the association between the earlier descriptor and earlier retained bytes within the declared history policy. A current filename shall not determine the identity of historical material.

A160-004. Before detachment or withdrawal, a user interface shall describe whether earlier versions and bytes remain retained. The implementation shall not label detachment as erasure when bytes remain retrievable through history or exported backups.

A160-005. Access to material shall be checked within its project and selected record-revision context. Knowledge of a content identifier alone shall not establish access authority.

A160-006. Historical content selection shall not bypass present access control. An implementation shall declare how authorization changes affect earlier revisions and already released exports.

A160-007. User-supplied filenames shall be treated as descriptive metadata and shall not authorize filesystem traversal, arbitrary storage paths or executable interpretation. A presentation shall declare any active-content preview capability and its protection boundary.

A160-008. Preservation limits shall state which resource they measure, including whether they concern current references, all retained content, physical storage or exported material. A logical content limit shall not be represented as a physical storage quota.

A160-009. Export and backup instructions shall identify included and excluded material, account/authority information and historical content. Restore claims shall identify the procedure and exercised evidence supporting them.

A160-010. Where an implementation lacks restriction, erasure, independent custody or recovery procedures, it shall declare those limitations without asserting that technical retention overrides applicable institutional or legal requirements.

148.1.4 4. Assessment and infrastructure need

Assessment includes byte verification, replacement and detachment across revisions, unauthorized identifier-based access, filenames containing path syntax, excluded unreferenced bytes in snapshot packages, included history in full bundles and observed limit failures. Declared institutional retention and restoration procedures require separate review and operation evidence.

The pilot's identified infrastructure need is an atomic association between descriptors and retained bytes. GR-SPEC-120 supplies descriptors and file operations; GR-SPEC-130 supplies bounded content-addressed Git storage. The selected first binding retains previously accepted assets, even after detachment. This explicit experimental policy is not a universal preservation requirement.

148.1.5 5. Open matters

Q-11, Q-35 and Q-39 retain erasure, sealing, restriction, backups, repair and custody questions. External material stores, sensitive use, malware inspection, storage reclamation and independently tested restoration need further work before broader deployment claims.

149 README

Original source: `standards/GR-160-preservation-access/README.md`.

149.1 GR-160 — Preservation, Privacy, Access, and Retention

Document class: Standards-track project outline
Status: Preliminary; not an adopted Standard

The bounded Working Draft 0.1 develops retained-material descriptors, historical byte access, detachment/erasure distinctions and declared preservation limits. The earlier outline below remains the broader project scope.

Define preservation states, access controls, sealing, restriction, anonymization, retention, deletion, and long-term interpretability.

150 README

Original source: `standards/GR-200-epistemic-recording/README.md`.
Original source SHA-256: `fb4929b8b0d0a661fcffdc65398322f73468ff232489a95c294c842bca2130be`.

150.1 GR-200 — Epistemic Recording Framework

> **Developed draft available:** Working Draft 0.3 source and compiled PDF. The Markdown outline below is retained as historical planning context; its candidate choices are not adopted. Current requirements and unresolved decisions are in the TeX draft.

Document class: Standards-track project outline
Status: Preliminary; not an adopted Standard
Provisional scope:

- observations;
- traces;
- claims;
- evidence;
- interpretations;
- judgments;
- attribution;
- perspectives;
- uncertainty;
- contestation;
- revision.

This standard should clarify how epistemic status is represented without collapsing it into the underlying event or entity record.

151 README

Original source: `standards/GR-210-evidence-interpretation/README.md`.

151.1 GR-210 — Evidence, Interpretation, and Contestation

> **Developed draft available:** Working Draft 0.3 source and compiled PDF. The Markdown outline below is retained as historical planning context; its candidate choices are not adopted. Current requirements and unresolved decisions are in the TeX draft.

Document class: Standards-track project outline
Status: Preliminary; not an adopted Standard
Provisional scope:

- evidentiary provenance;
- direct vs inferred records;
- confidence and uncertainty;
- conflicting interpretations;
- annotation and reply;
- retrospective reinterpretation;
- evidentiary chains.

152 README

Original source: `standards/GR-300-jurisprudential-interface/README.md`.
Original source SHA-256: `9e5833527ee3edff0f0129685e1f25577b7064a2c347cea3017cafe9e2f8a604`.

152.1 GR-300 — Jurisprudential Interface

Document class: Standards-track project outline
Status: Preliminary; not an adopted Standard

This document is expected to define a standards-facing interface to legal and jurisprudential use.

Potential topics:

- legal metadata;
- evidentiary status;
- attribution;
- procedural history;
- contested records;
- correction and annotation;
- jurisdictional profiles.

It should not attempt to create substantive legal obligations by itself.

153 README

Original source: `standards/GR-310-rights-duties-procedure/README.md`.
Original source SHA-256: `1c293c90006941fdb65003658dcacce41e62d12d1155708c7d074eaafd7253cf`.

153.1 GR-310 — Rights, Duties, and Procedural Profiles

Document class: Standards-track project outline
Status: Exploratory; not an adopted Standard
Potential profiles may address:

- access;
- correction;
- annotation;
- objection;
- restriction;
- preservation;
- destruction;
- notice;
- review;
- procedural fairness.

Any jurisdiction-specific implementation should be separately profiled and legally reviewed.

154 README

Original source: `standards/GR-400-governance-institutional-use/README.md`.
Original source SHA-256: `59e3638d4ca5319bd00cd38b48bafaee573767359b85d79f799f02222366ca2d`.

154.1 GR-400 — Governance and Institutional Use

Document class: Standards-track project outline
Status: Preliminary; not an adopted Standard
Potential scope:

- institutional adoption;
- decision-process records;
- research governance;
- AI-assisted workflows;
- public-sector use;
- archival governance;
- oversight and audit;
- organizational memory.

155 GR TR101 theoretical foundations

Original source: `technical_reports/GR-TR101-theoretical-foundations.md`.
Original source SHA-256: `b286a611889f21d8c5e6327fb3e944b8adf6617f3eaf99040b34650438c121f9`.

155.1 GR-TR101 — Theoretical Foundations

Status: Placeholder

This technical report will hold philosophical and theoretical material that informs the standards but should not be embedded directly into normative requirements.

Planned topics:

- generativity and manifestation;
- relational emergence;
- recordability and historical judgment;
- future re-recognizability;
- contingency;
- generativity return;
- record absence and archival silence.

156 GR TR102 category theoretic semantics

Original source: `technical_reports/GR-TR102-category-theoretic-semantics.md`.
Original source SHA-256: `a932e5370d801ba4ad01e5dce2dfb6ed518e0f2e03a3eead7a96a7a891633054`.

156.1 GR-TR102 — Category-Theoretic Semantics

Status: EXPERIMENTAL
Candidate topics:

- categories of states and transformations;
- event generators and process composition;
- spans/cospans for first-class relations;
- profunctors and relational semantics;
- double categories for relations and transformations;
- fibrations/indexing for persistence across contexts;
- functorial observables for properties;
- evolving discrimination/equivalence structures.

The core standards should not depend on any one of these constructions until the semantics are stable.

157 ADR

Original source: `templates/ADR.md`.
Original source SHA-256: `6c4d9bba614a0268c1b92b8da207f8453942f8bbfaa983db8e2a485c4838d4ea`.

157.1 ADR-XXXX — Decision title

Status: Proposed

157.1.1 Context

157.1.2 Decision

157.1.3 Alternatives considered

157.1.4 Rationale

157.1.5 Consequences

157.1.6 Affected documents

157.1.7 Supersedes

157.1.8 Superseded by

158 new work item proposal

Original source: `templates/new_work_item_proposal.md`.
Original source SHA-256: `c4b05eafdfea2090529887685b7c293680158110127ad67fc4abd2e460f5b3bd`.

158.1 New Work Item Proposal

Document class: Informative governance template
Status: PROVISIONAL; completion does not approve work
Version: 0.2
Responsible editor: UNASSIGNED
Source: `templates/new_work_item_proposal.md`
Historical draft basis (0.1): Directives Part 1, version 0.1, D1-009–D1-013; Directives Part 2, version 0.1; GR/TC 1 Charter, version 0.1.

The template remains an initial 0.1 aid. The expanded 0.2 normative schedules govern any assessment against 0.2; completing this template alone does not cover their additional obligations.

Use supported information, `OPEN`, `UNASSIGNED`, or an explained `not applicable`. A preliminary proposal can expose missing capacity without claiming authorized project status. The actual decision authority completes the decision fields separately.

158.1.1 Identifier

- Proposal identifier: `[retain existing identifier where assigned]`
- Version, date, source location, and revision:
- Current status: `Preliminary proposal — not approved`
- Related issues and decisions:

158.1.2 Proposed title

```
[bounded work; retain existing project title where applicable]
```

158.1.3 Proposer

- Name, contact or protected-contact route, and capacity:
- Institutional representation, if claimed, and evidence of mandate:
- Relevant affiliations, funding, interests, and contribution permissions:

158.1.4 Problem statement

Describe the recognition, evidential, archival, or practical problem, affected people, baseline, and evidence. Explain its connection to symbolic crisis, warranted and revisable recognition, or generative trajectories. Distinguish demonstrated need from predicted benefit.

- Objective and observable evidence of improvement:
- Uncertainty and limits of expected effects:

158.1.5 Scope

- Bounded practices, records, actors, or interactions:
- Intended use, environment, applicable conditions, and conformance subjects:
- Relationship between changes in the situation, evidence/judgment, and categories/methods:

158.1.6 Out of scope

State exclusions, including limits on truth certification, legal determination, institutional authority, and policy choice where relevant. Identify adjacent work requiring a separate scope decision.

158.1.7 Need for standardization

- Why shared requirements are useful:
- Alternatives: existing infrastructure/practice, guidance, research, Specification, policy proposal, or deferral:
- Reasons for selected route and risks of premature standardization:

158.1.8 Intended users

- Users and expected tasks:
- People represented, evaluated, or affected:
- Readers/reviewers and resource, language, accessibility, or connectivity constraints:

158.1.9 Stakeholders

Interest or affected perspective	Contribution needed	Actual participation/ outreach evidence	Gap and response
`[interest]`	`[knowledge/experience]`	`[actual/proposed/unavailable]`	`[action and owner]`

Separate situated knowledge from a mandate to represent others. Record concentrated affiliations, funding, infrastructure control, and participation burdens.

158.1.10 Existing standards and related work

Exact source/edition and passage	Verified content/access limits	Reuse, difference, or gap	Compatibility evidence needed
`[primary source]`	`[verified/partial/unavailable]`	`[proposal]`	`[assessment]`

158.1.11 GR foundation interpretation

Manuscript identifier, file, and passage	Actual terminology/ formulation	Proposed operational use	Differences, uncertainty, and needed ADR
`[FM identifier and section/ page]`	`[source meaning]`	`[bounded interpretation]`	`[OPEN or decision reference]`

Identify new classes, changed terminology, or narrowing. Preserve differing manuscript formulations instead of declaring equivalence by assumption.

158.1.12 Proposed deliverables

A standards-track Working Draft is not an adopted Standard. A protocol is contained in a Specification or Standard, not a separate authority class.

Existing code/ proposed identifier	Title	Principal publication class and maturity	Bounded scope/ conformance subject	Editor	Dependency and evidence
`[identifier]`	`[title]`	`[class; draft status]`	`[specific contribution]`	`UNASSIGNED`	`[dependency/assessment]`

158.1.13 Specifications, protocols, and dependencies

- Draft requirement or procedural need requiring reusable infrastructure:
- Proposed Specification, alternatives, and relationship to standards-track work:
- Protocol participants, inputs, preconditions, interactions, states/transitions, outputs/effects, authority, failures/refusals, and recovery:
- Exact normative dependency versions and maturity; informative sources separately:
- Circularity, unavailable dependencies, access/rights constraints, and change coordination:
- Governance versions proposed for the decision and actual adoption record or `NOT ADOPTED`:

158.1.14 Required expertise

Review domain	Concrete question	Competence or affected perspective needed	Accepted reviewer	Gap and progression consequence
Epistemic/ conceptual	`[question]`	`[competence]`	`UNASSIGNED`	`[gap]`
Ethics/ participation	`[question]`	`[competence/perspective]`	`UNASSIGNED`	`[gap]`
Jurisprudential/ institutional	`[context/authority]`	`[relevant expertise]`	`UNASSIGNED`	`[gap]`
Political economy/ public policy	`[burden/control/options]`	`[competence/perspective]`	`UNASSIGNED`	`[gap]`
Archival/ protection/security	`[question]`	`[competence]`	`UNASSIGNED`	`[gap]`
Technical/ accessibility/ human use	`[question]`	`[competence/perspective]`	`UNASSIGNED`	`[gap]`

Explain non-applicability; keep unavailable assessment visible. Split rows where findings or reviewers differ.

158.1.15 Risks

Risk or unresolved question	Evidence/ uncertainty	Affected people/ dependencies	Alternative or mitigation	Owner/review point	Progression effect
`[risk]`	`[basis]`	`[effect]`	`[action]`	`UNASSIGNED`	`[narrow/defer/review]`

Consider recording/review burdens, exclusion, coercive visibility, privacy, misleading authority, source rights, dependency, and maintenance. Legal assertions need a named context and primary-source review; a field does not create a right or duty.

158.1.16 Expected implementation or pilot evidence

- Case/baseline; synthetic, programme history, or actual external institution:
- Actual authority, participation, access, and permissions:
- Tested draft versions and requirement identifiers:
- Positive cases, counterexamples, failures, and protected/unavailable evidence:
- Human tasks, procedural review, structural checks, and exchange tests, with separate results:
- Success/failure criteria, burdens, and evidence limits:
- Challenge, correction, stopping, repair, and feedback arrangements:
- Independent review/implementation claim and supporting evidence, if proposed:

Synthetic exercises do not establish external participation, independent validation, truth, legal validity, or restored trust.

158.1.17 Proposed project lead

- Person: `UNASSIGNED`
- Accepted mandate, interests, role combinations, resources, and substitute:

158.1.18 Proposed working group

- Existing committee or proposed bounded group:
- Actual accepted members/capacities, separate from prospective invitations:
- Reason for a new group; coordination and review/closure point:

158.1.19 Resources, milestones, and maintenance

- Work, review, accessibility, preservation, and funding/in-kind resources:
- Funding conditions and infrastructure control:
- Milestones and progression evidence:
- Contribution/publication rights decisions:
- Maintenance owner: `UNASSIGNED`
- Issue intake, review interval, continuity, and closure conditions:

158.1.20 Decision

Initial value: `PENDING — no decision entered.`

☐ Accept
☐ Revise
☐ Defer
☐ Reject

Completed by the actual authority or explicitly marked **SYNTHETIC REHEARSAL**:

- Decision identifier/date, decision maker, mandate, and authority record:
- Operative Charter/Directives versions and input proposal/evidence versions:
- Conflicts, recusals, and substitute authority:
- Review participation, gaps, objections, replies, and ballot if required:
- Precise authorized scope, deliverable classes/status, and accepted assignments:
- Resources, conditions, unresolved issues, owners, and next actions:
- Notice, procedural challenge route, and resulting project/revision record:

158.1.21 Rationale

Record issue, alternatives, selected direction, reasons, remaining dissent, and affected publications. Acceptance approves only the stated work; it does not adopt outputs as Standards or authorize an external institution’s participation.

159 public comment

Original source: `templates/public_comment.md`.
Original source SHA-256: `d5c29ce63ebaead2595d84ffdf09409f2925003b26c2e47c8d4ce0c029b53b60`.

159.1 Public Comment

Document class: Informative governance template
Status: PROVISIONAL template for comments, dispositions, and rehearsal
Version: 0.2
Responsible editor: UNASSIGNED
Source: `templates/public_comment.md`
Historical draft basis (0.1): Directives Part 1, version 0.1, D1-018–D1-028; Directives Part 2, version 0.1.

The template remains an initial 0.1 aid. The expanded 0.2 normative schedules govern any assessment against 0.2; completing this template alone does not cover their additional obligations.

Free-text comments are welcome: this form is an aid, not an eligibility test. Commenters need not supply redrafted clauses, credentials, or decision identifiers. Programme staff complete receipt, disposition, and decision fields. This template establishes no live review or appointed staff role.

159.1.1 Comment identification

- Comment ID:
- Draft: `[title, identifier, class, version, and location if known]`
- Clause: `[requirement identifier, section, or topic; approximate location is acceptable]`
- Commenter: `[name/capacity or protected-contact arrangement]`
- Stakeholder category: `[optional self-description; no mandate inferred]`
- Type: Editorial / Technical / Normative / Epistemic / Governance / Ethics / Legal-institutional / Accessibility / Privacy / Other
- Relevant affiliation, interest, or institutional mandate, if claimed:
- Preferred reply route:
- Disclosure preference: public attribution / public comment without public name / protected handling requested:
- Reason for protected handling and safe public summary, if appropriate:

Use the announced protected route for sensitive material. The receiving function explains confidentiality/access limits before treating a submission as protected. Avoid placing private contacts or restricted evidence in a public issue merely to complete this form.

159.1.2 Comment

Describe the issue, affected people/behavior, and why it matters. Distinguish evidence, source interpretation, policy proposals, and uncertainty where relevant.

- Concrete example or counterexample:
- Evidence/source locations and access limits:
- Consequences for scope, meaning, conformance, burden, protection, or use:
- Urgent protection, rights, or validity concern, if any:

159.1.3 Proposed change

Optional wording, alternative, review question, or requested outcome. A useful concern does not depend on having a complete solution.

159.1.4 Receipt and route — programme staff

- Stable identifier, actual receipt timestamp/time zone, and review notice:
- Draft version and review opening/closing timestamps:
- Acknowledgement date/reference; target calculated from operative D1-020:
- Handling owner: `UNASSIGNED`
- Disclosure/access arrangement and evidence custodian:
- Route: technical/editorial consideration / procedural appeal / ethics report / record access or correction / other:
- Assisted referral and notice if initially misrouted:
- In scope / out of scope / duplicate / late, with reasons and linked record:
- For late material: current-cycle consideration or later referral; assessment of urgent material defects:

159.1.5 Disposition

Initial value: `PENDING — no disposition entered.`

☐ Accepted (Accept)
☐ Accepted with modification (Accept with modification)
☐ Deferred (Defer)
☐ Not accepted (Reject)

Use D1 disposition labels in the maintained register. Out-of-scope or duplicate comments retain their identifiers, reasons, and linked handling record.

- Reviewers/capacities, conflicts, recusals, and substitutes:
- Evidence examined, unavailable grounds, and related/competing comments:
- If deferred: owner, next action/date, and reason the issue does or does not prevent progression:

159.1.6 Rationale

Explain alternatives considered, response to material grounds, selected direction, evidence limits, and remaining disagreement. A label or vote count alone is not a disposition reason.

159.1.7 Resulting change

- Requirement identifiers and affected artifacts:
- Before/after text or versioned change; resulting draft version:
- Editorial or substantive, with reasons:
- Effects on unchanged clauses, dependencies, conformance, and affected people:
- Re-review: none with editorial justification / material-change review / renewed scope and full review:
- Re-review notice, dates, and affected-party outreach:

159.1.8 Notification, reply, and remaining disagreement

- Notification date/route and reply deadline under operative D1-023, with time zone:
- Reply/date or `no reply received`:
- Review of reply, reasons, resulting change, and remaining objection:
- Effect on progression and communicated procedural challenge route:
- Commenter agreement if explicit; silence is not agreement:

159.1.9 Decision record

- Decision identifier/date, input versions, and actual decision authority:
- Operative governance edition, mandate, and decision rule:
- Evidence/disposition links, outcome, limits, actions, and owners:
- Public account, protected annex reference, custodian, and retention decision:

- Status: pending / disposed with reply pending / reply considered / referred / closed with reasons:

Rehearsal flag: `[actual review / SYNTHETIC REHEARSAL]`. A synthetic response does not establish an actual commenter, public review, or independent decision.

160 requirement assessment

Original source: `templates/requirement_assessment.md`.
Original source SHA-256: `2c8b41a5a43fd6f106a969c959d7e3c3601da1c407dbda70407031c087e1bcfa`.

160.1 Requirement assessment record

Document class: Informative template
Status: PROVISIONAL; version 0.1. An unfilled template is not evidence of assessment or conformance.

160.1.1 Assessment declaration

- Assessed subject and boundary: [publication / vocabulary application / package / practice / case / procedure; exact version and included population]
- Purpose and intended users: [text]
- Governing publication and dependency editions: [identifiers, versions and source/PDF hashes where applicable]
- Profile and authority: [declared profile and basis, or no adopted profile]
- Assessor, competence, relationship to authors/operator and conflicts: [actual people/roles; unresolved capacity stays explicit]
- Dates and environment: [actual assessment dates, tools, exercise conditions]
- Evidence boundary and access: [supplied material, unavailable sources, protection arrangements, selection and limitations]
- Claim permitted by this assessment: [bounded statement; partial documentary review is not full practice/procedure fulfillment]

160.1.2 Requirement ledger

Create a row for every requirement within the declared assessment boundary, including failed and unassessed requirements. A grouped narrative does not replace individual results. Separate components when a clause's recording and behavioral obligations need different evidence.

Requirement and edition	Trigger / applicability reason	Method and actual evidence locator	Result	Assessor / date	Limitation or required action
[ID]	[condition]	[document inspection, recalculation, observed exercise, user task, expert review; exact record]	[one result below]	[actual attribution]	[text]

Result meanings:

- **Fulfilled:** The supplied evidence supports the required outcome within the stated boundary; include reasons.
- **Not fulfilled:** A required outcome fails; identify the evidence and consequence.
- **Not assessed:** Assessment was not performed or required evidence cannot be examined. An unknown, inaccessible source or unobserved action is not automatically a pass.
- **Not applicable:** The requirement's declared trigger is absent; identify that trigger and grounds. Changing the assessment subject does not silently remove an obligation.

A draft can require recording a justified unknown without requiring the historical fact itself to be settled. In that case, assess the stated recording obligation, and keep uncertainty about the substantive fact distinct from the result.

160.1.3 Counterexamples and unresolved results

Case	Deliberate defect or failure condition	Expected outcome	Actually observed outcome and evidence	Follow-up
[ID]	[text]	[expectation]	[actual result, or not exercised]	[owner/action]

Include ordinary and relevant failure cases for procedure assessment. An authored successful sequence is a design fixture, not an observed run. State whether notice, receipt, independent review, enforcement, correction propagation and remedy were actually examined.

160.1.4 Report and downstream use

- Supported overall conclusion: [include failures, unassessed applicable requirements and profile limits]
- Review/objection route and decision authority: [actual arrangement or unavailable]
- Affected requirements, artifacts and known dependent uses: [identifiers]
- Correction/reassessment action and owner: [text]
- Retention, access and publication decision for this report: [contextual basis; no automatic publicity of protected evidence]

Structural validity, source authenticity, factual warrant, ethical evaluation, legal status and institutional performance are different conclusions. Report only the conclusions the evidence supports.

A Metamodel for Ontologically Heterogeneous Social Dynamics

Part I: The Highest Abstract Layer

Wanhong Huang
huangwanhong@serendip.ngo

Abstract

This is the first paper of a series. It fixes the highest abstract layer, and it goes no further.

Dynamical modeling of social systems ordinarily begins by fixing a state space. This is already a commitment, and across domains it is one that cannot be met. The states of a normative order, a power configuration, a value system, and a network of recognition inhabit no common manifold and admit no common metric—and the obstacle is not that such a space is hard to construct but that these are not objects of a kind that admit a common placement. The heterogeneity is ontological, not practical, and it is not answered by better instruments. The proposal here is to begin one layer lower, at a level where change, structure, constraint, and difference are defined but not yet realized. Four axioms are given. The carrier of states is left without structure. The mechanisms acting upon it form a semigroup: associative, without inverses, without an identity. A congruence records what any mechanism is obliged to preserve. And difference is defined—not as a residue, not as a distance—as the set of distinctions a mechanism collapses. From these, four propositions follow that were not assumed: collapse is irreversible; a group of mechanisms has no collapse at all, and hence no history; a mechanism is non-destructive exactly when it is injective modulo the congruence; and collapse accumulates monotonically under composition. The absence of inverses is shown to be the load-bearing commitment. This paper does not instantiate the metamodel, does not apply it, and derives no substantive result about any particular social system. Those belong to subsequent parts. What is established here is only what a social dynamical system must be able to say, and the price of saying it.

Keywords: dynamical systems; social dynamics; semigroup action; congruence; collapse; irreversibility; formal social theory; generative relational being.

AI usage statement: The ideas, claims, and theoretical framework of this paper originate with the author. AI tools were used as an aid in drafting, in the location and verification of sources, and in revision. The origin of each idea has been verified by the author, who takes full responsibility for the content.

Recap

The metamodel in full. $\mathcal{S}$ is a set without further structure; $\mathcal{M}$ is a semigroup, with neither identity nor inverses; $\sim$ is an equivalence relation on $\mathcal{S}$.

(Change)	$\alpha : \mathcal{M} \times \mathcal{S} \longrightarrow \mathcal{S}, \qquad (m, x) \longmapsto m(x)$
(Structure)	$\alpha(m_1 m_2,\, x) \;=\; \alpha(m_1,\, \alpha(m_2, x))$
(Constraint)	$x \sim y \implies \alpha(m, x) \sim \alpha(m, y)$
(Difference)	$\Delta(m) \;=\; \{\, (x, y) \;:\; x \not\sim y \;\wedge\; \alpha(m, x) \sim \alpha(m, y) \,\}$

Sections 1–3 give the reasons for these four lines, §4 their consequences, and §5 what they decline to settle. The consequences, which were not assumed, are that collapse is irreversible, that irreversibility requires the absence of inverses, and that a mechanism destroys nothing when it is injective modulo $\sim$.

1 Introduction

1.1 The formalism is layered; this paper gives the topmost layer

The programme to which this paper belongs proposes a formalism for social dynamics at several levels of abstraction. At the highest, one says what any model must be able to express, without saying what it expresses. Below it, one says what structures a model may draw upon—an order, a metric, an algebra—and at what cost. Below that, one exhibits models. The levels are not competing accounts of the same thing. They stand in a relation of dependence: what is settled above constrains what may be built beneath, and what is built beneath must answer to it.

This is the first paper of the series, and it gives only the highest layer. It does not instantiate the framework, does not apply it to a domain, and derives no substantive result about any particular social system. Those belong to the parts that follow.

The reason for beginning at the top, and for treating it separately, is that the commitments made at this layer are the ones that later become invisible. A model which ranks has assumed comparability; a model which measures has assumed symmetry; a model which aggregates has assumed an arithmetic. Each of these is a decision, and each, once buried inside a concrete formalism, is difficult to retrieve and impossible to contest. Isolating the highest layer is a way of making the decisions available for inspection before they are made.

1.2 Writing x already stipulates what counts as a difference

A dynamical system, in its received form, is a triple: a state space, a rule of evolution, and a parameter. The rule is written

$$\dot{x} = f(x; \theta),$$

and the reading it invites is that the left side records change and the right side records the structure from which change proceeds. That reading is correct as far as it goes. What it conceals is the cost of the first term. To write x at all is to have fixed a space in which x lives, and with

it a stipulation of what counts as a difference between one state and another: whether such differences can be measured, whether they can be compared, whether they vary continuously.

For the systems at issue here, that stipulation cannot be met. The state of a normative order is a configuration of rules and expectations; the state of a power system is a distribution of asymmetries; the state of a value system is an ordering of what matters; the state of a recognition network is a pattern of who is seen. These do not sit in a common space, and they admit no common metric.

The point requires care, because it is stronger than it may appear. The difficulty is not that a common space is hard to construct, which would be a difficulty of instruments and would be answered by better ones. It is that a rule and a dependence are not two values of one variable, and no refinement of measurement will make them so. The heterogeneity of social states is ontological rather than practical, and a heterogeneity of that kind is not overcome; it is either respected or overwritten. It is the claim that these states *are* commensurable—that some scale $m : X \to \mathbb{R}$ exists—which the theory of value pluralism has spent a century contesting, and a modeling strategy that begins by assuming the space begins by assuming away what is contested.

1.3 Change, structure, constraint, and difference need no state space

The response proposed is not to find a cleverer space. It is to descend below the point at which a space is required.

Four things must be sayable of any social dynamical system. It must be able to say how it changes. It must be able to say how its changes compose. It must be able to say what its changes are constrained to preserve. And it must be able to say what its changes destroy. These are, respectively, *change*, *structure*, *constraint*, and *difference*.

The claim of this paper is not that these four are novel. It is that they are, taken together, sufficient, and that they can be given without assuming a state space, a metric, an order, an arithmetic, or a zero. This matters, because each of those assumptions, once made, quietly decides a question the theory was meant to leave open. An order on states presumes commensurability. A metric presumes symmetry, and therefore cannot distinguish betraying from being betrayed. A zero presumes that what a transformation leaves behind is a quantity capable of being null, and so decides, in advance of any argument, that loss is a magnitude.

The metamodel given in §3 makes none of these choices. In exchange, it yields results that were not put in by hand: that collapse is irreversible, that irreversibility is possible only because mechanisms lack inverses, and that a mechanism destroys nothing exactly when it is injective modulo the congruence.

1.4 Loss precedes generativity in the order of dependence

Instantiation is deferred. So is application. So, in particular, is the formal treatment of generativity, which is the term the wider programme exists to serve and which the four axioms of this paper do not provide. What they provide is its precondition: an account of what a mechanism can destroy. A framework that cannot say what is lost cannot say what it would mean to generate. The order of exposition follows the order of dependence, and loss comes first.

2 The State Space Cannot Come First

2.1 Social states are heterogeneous in kind, not in scale

Consider four systems and the state each would require.

system	state
normative order	configuration of rules, obligations, expectations
power system	distribution of dependence and authority
value system	ordering of what is held to matter
recognition network	pattern of who is acknowledged as a subject

No embedding of these into a common vector space is available, and the ones that have been proposed are precisely the objects of critique: utility, price, and the composite index each purchase comparability at the cost of the differences they were meant to preserve.

It is worth being exact about the sense in which this heterogeneity is *ontological* and not merely practical, since the two are easily confused and only the former has consequences for the form of a theory. Practical heterogeneity would mean that a common space exists but is hard to construct—that the data are poor, the scales incommensurate in practice, the measurement instruments crude. Such a difficulty is answered by better instruments, and it licenses the modeler to proceed as though the space were there, since in principle it is.

The heterogeneity at issue is not of that kind. It is not that a common space is hard to find but that the objects to be placed in it are not of a kind that admits a common placement. A rule and a dependence are not two values of one variable measured badly; they are not two values of one variable. A pattern of recognition is not a coarse rendering of a distribution of authority. These are distinct modes of being, and the question of how far one lies from another is not a hard question but a malformed one. It is in this sense that the demand for a common state space is not a technical inconvenience but a substantive commitment—indeed an ontological one, asserted in the guise of a modeling convention—and it should not be made by default.

2.2 Order presumes commensurability, metric presumes symmetry, zero presumes magnitude

Order. A partial order on $\mathcal{S}$ furnishes suprema, and a supremum of two value states is a common measure of them. To assume a lattice is to have assumed commensurability.

Metric. A metric d on $\mathcal{S}$ satisfies $d(x, y) = d(y, x)$. Symmetry cannot represent a directed act. Under a metric, a mechanism and its reception are the same distance apart, and the asymmetry of the relational act has been erased before any question about it can be posed.

Zero. An additive structure with a zero element makes the residue of a transformation a quantity that may or may not vanish. This is a determinate philosophical position—the position on which what is lost is a magnitude, and so, in principle, restorable. The rival position holds that what is lost has no place in the new structure at all. The metamodel must be able to host both, and therefore may assume neither.

2.3 Fixing the mechanisms leaves the carrier free

The path taken here inverts the usual order of construction. Rather than fixing states and deriving the transformations that act upon them, we fix the transformations and leave the states

unstructured. This is not new; it is the one by which the algebraic approach to dynamics proceeds. Its warrant is that the structure a theory requires can be carried by the acting objects, leaving the carrier as a set on which they act.

3 Change, Structure, Constraint, and Difference Are Definable without a Structured Carrier

3.1 The carrier is a bare set; the mechanisms carry the structure

Definition 1 (Primitives). A *social dynamical metamodel* is a triple $(\mathcal{S}, \mathcal{M}, \sim)$ where

- $\mathcal{S}$ is a set, the *carrier*. It is assumed to have no further structure: no order, no metric, no algebraic operation, no distinguished element.
- $\mathcal{M}$ is a set, the *mechanisms*.
- $\sim$ is an equivalence relation on $\mathcal{S}$.

Elements of $\mathcal{S}$ are states, in the weakest sense the word can bear: whatever a given domain takes a configuration to be. Elements of $\mathcal{M}$ are mechanisms: whatever, in that domain, acts upon a configuration and yields another. Nothing is presumed about what either is made of.

3.2 The mechanisms form a semigroup, and Δ is derived from α and $\sim$

Axiom 1 (Change). There is a map

$$\alpha : \mathcal{M} \times \mathcal{S} \longrightarrow \mathcal{S}, \qquad (m, x) \longmapsto m(x).$$

A mechanism acts on a state and returns a state. This is all that change is required to be.

Axiom 2 (Structure). $\mathcal{M}$ carries an associative composition

$$\mathcal{M} \times \mathcal{M} \to \mathcal{M}, \qquad (m_1, m_2) \mapsto m_1 m_2, \qquad (m_1 m_2) m_3 = m_1 (m_2 m_3),$$

and α is an action of it:

$$\alpha(m_1 m_2,\, x) = \alpha(m_1,\, \alpha(m_2, x))\,.$$

$\mathcal{M}$ is a semigroup. It is *not* assumed to have an identity, and it is *not* assumed to have inverses.

Associativity is free: it says only that doing m_1 then m_2, and then m_3, is the same as doing m_1, and then m_2 followed by m_3. The two omissions are not free, and they are the substantive content of the axiom. Their consequences are drawn in §4.

Axiom 3 (Constraint). $\sim$ is a congruence for the action:

$$x \sim y \implies \alpha(m, x) \sim \alpha(m, y) \qquad \text{for all } m \in \mathcal{M}.$$

Read: whatever the system preserves, no mechanism may destroy. The axiom does not say what $\sim$ is. It says that a mechanism which fails to respect it is not a mechanism of this system

at all. $\sim$ is the system's law of admissibility, and its content is supplied by the domain.

Axiom 4 (Difference). For each $m \in \mathcal{M}$, the *collapse* of m is

$$\Delta(m) \;=\; \big\{\, (x,y) \in \mathcal{S} \times \mathcal{S} \;:\; x \not\sim y \;\wedge\; \alpha(m,x) \sim \alpha(m,y) \,\big\}.$$

Read: $\Delta(m)$ is the set of distinctions that m destroys. Two states that the system could tell apart become, after m has acted, states it cannot tell apart.

3.3 Difference is a lost discrimination, not a leftover element

Three familiar formalizations of difference are rejected, each because it requires structure on $\mathcal{S}$ that the metamodel declines to assume.

Not a residuum. The residuated-lattice operator, $x\backslash m(x) = \max\{c : x \cdot c \leq m(x)\}$, requires that $\mathcal{S}$ carry both a multiplication and an order. It therefore requires that states be comparable, which is what the ontological heterogeneity of social states denies.

Not a distance. The metric-induced form, $d(x, m(x))$, requires a metric, and a metric is symmetric. It cannot represent a directed act, and the acts at issue are directed.

Not a kernel. The form $\ker \pi = \{x : \pi(x) = 0\}$ requires a zero, hence an algebraic structure on $\mathcal{S}$. In a semigroup the kernel of a morphism is not a subset at all: it is a congruence. Axiom 4 takes that fact as its cue and defines difference as a relation rather than an element.

> Difference, at this layer, is not a thing that is left over. It is a discrimination that has been lost.

The three rejections share a form. Each of the discarded operators returns an *element*, and in doing so commits the metamodel to a determinate view of what a remainder is—a view on which the traditions that have thought longest about remainders do not agree. What is at stake in this is taken up in §5.
Δ is a derived object. It is not a fifth primitive: it is defined entirely from α and $\sim$, which is to say from Axioms 1 and 3.

4 Irreversibility Follows from Associativity and the Congruence Alone

The axioms are weak. They nevertheless entail results that were not stipulated. This section gives them.

4.1 Collapse is irreversible

Proposition 1 (Irreversibility of Collapse). Let $(x,y) \in \Delta(m)$. Then for every $m' \in \mathcal{M}$,

$$\alpha(m'm,\, x) \;\sim\; \alpha(m'm,\, y).$$

That is: no mechanism applied after m can restore the distinction m destroyed.

Proof. By definition of Δ, $\alpha(m, x) \sim \alpha(m, y)$. By Axiom 3, applying m' to congruent states yields congruent states, so $\alpha(m', \alpha(m, x)) \sim \alpha(m', \alpha(m, y))$. By Axiom 2, the left side is $\alpha(m'm, x)$ and the right side is $\alpha(m'm, y)$. □

The proof uses only Axioms 2 and 3. Irreversibility is therefore not an extra postulate about the social world, appended because we know from experience that some things cannot be undone. It is what the associativity of mechanisms and the preservation of the congruence, taken together, already say.

4.2 Inverses annihilate difference

Proposition 2 (Groups have no history). Suppose $\mathcal{M}$ is a group acting on $\mathcal{S}$ and $\sim$ is a congruence. Then $\Delta(m) = \emptyset$ for every $m \in \mathcal{M}$.

Proof. Suppose $(x, y) \in \Delta(m)$, so $\alpha(m, x) \sim \alpha(m, y)$ and $x \not\sim y$. Applying m^{-1} and using Axiom 3, $\alpha(m^{-1}m, x) \sim \alpha(m^{-1}m, y)$, that is $x \sim y$, a contradiction. □

The absence of inverses is not a technical weakening. It is the condition under which a system can have a history at all. Where every mechanism can be undone, nothing is destroyed, nothing is preserved against destruction, and the question of what a transformation has cost does not arise. A group of mechanisms is a world without loss.

The two propositions stand in a definite relation. Proposition 1 says that what is collapsed stays collapsed. Proposition 2 says that this is possible only because mechanisms are not invertible. Taken together they locate the exact structural commitment on which everything else in this framework depends: Axiom 2's refusal of inverses.

4.3 A mechanism destroys nothing iff it is injective modulo $\sim$

Proposition 3. $\Delta(m) = \emptyset$ if and only if the induced map $\bar{m} : \mathcal{S}/\!\sim \to \mathcal{S}/\!\sim$ is injective.

Proof. Axiom 3 guarantees that $\bar{m}$ is well defined on the quotient. $\bar{m}$ fails to be injective exactly when there are classes $[x] \neq [y]$ with $\bar{m}[x] = \bar{m}[y]$, that is, when there are states $x \not\sim y$ with $\alpha(m, x) \sim \alpha(m, y)$, that is, when $\Delta(m) \neq \emptyset$. □

The proposition supplies a criterion. A mechanism destroys nothing if and only if it is injective modulo the congruence, so it is not necessary to inspect a mechanism's effects case by case in order to know whether it is destructive. It suffices to ask whether it separates what the system could already separate.

4.4 Composition accumulates

Proposition 4 (Monotonicity of Collapse). For all $m, m' \in \mathcal{M}$,

$$\Delta(m) \subseteq \Delta(m'm).$$

Proof. Let $(x, y) \in \Delta(m)$. Then $x \not\sim y$, and by Proposition 1, $\alpha(m'm, x) \sim \alpha(m'm, y)$. Hence $(x, y) \in \Delta(m'm)$. □

Collapse, once incurred, is carried forward by every subsequent mechanism. The history of a system is thus a monotone accumulation of lost discriminations, and no mechanism in the semigroup can reduce it. This is the formal sense in which a social system does not return to a prior condition.

5 Loss Is a Magnitude Only If the Carrier Has an Arithmetic

Axiom 4 defines difference as a relation. The natural alternative would define it as an element: a residue, a remainder, a something left over when a mechanism has acted. The alternative was declined, and the reason is that the two traditions with the strongest claim on the notion of a remainder—political economy and psychoanalysis—disagree about what a remainder is. An operator that returns an element settles their disagreement, and settles it by stipulation. What follows sets out the disagreement, shows where the notation would decide it, and shows what a relation-valued Δ leaves open instead.

5.1 Surplus value is restorable; the *objet a* has no place to be restored to

The economic residue. In the analysis of value, what a mechanism leaves over is a *magnitude*. Surplus value is the difference between the value a labourer produces and the value returned to him [12]; it is a quantity, it can in principle be computed, and—this is the point on which the whole normative force of the analysis rests—it could have been returned. That it was not is the injustice. The residue is thus an element of the same order as what was given: it has a location in the value system, it is expressible in the system's terms, and its restitution is intelligible even where it is not forthcoming. A theory of exploitation requires a residue of this kind, for otherwise it could not say what was taken.

The psychoanalytic residue. In Lacan the remainder is of a different kind altogether [14, 15]. The *objet petit a* is not a quantity of satisfaction withheld; it is what falls out of symbolization itself, the residue produced by the subject's entry into the symbolic order and precisely not representable within it. It is not that the object is scarce, or that it has been taken and might be given back. It has *no place* in the order that produced it. Its whole theoretical function depends on this: were it locatable, were it a magnitude, it could in principle be supplied, and the structure of desire that it sustains would collapse [16].

> The economic residue is a magnitude that was not returned. The psychoanalytic residue is not a magnitude at all. The first can be restored. The second cannot, and the obstacle is not that restoration is difficult but that there is nothing of the right kind to restore.

5.2 An element-valued operator decides between them by notation

Suppose difference were defined, as it commonly is, by an operator returning an element:

$$\Delta(m,x) \;=\; x \backslash m(x) \qquad \text{or} \qquad \Delta(m,x) \;=\; d(x, m(x)) \qquad \text{or} \qquad \Delta(m) \;=\; \ker \pi_m = \{x : \pi_m(x) = 0\}.$$

Each of these requires structure on $\mathcal{S}$: the first an order and a multiplication, the second a metric, the third a zero. And each, in requiring it, has already chosen. An operator that returns an element of $\mathcal{S}$, or of some $\mathcal{D}$ possessing a zero, has said that what is lost is a *something*—a magnitude that may be null, that has a place, that could conceivably be supplied. It has

decided for the economic residue and against the psychoanalytic one, and it has done so not by argument but by notation.

This is the kind of commitment the highest layer exists to hold open. Whether the remainder of a social mechanism is a restorable magnitude or an unrepresentable void is a substantive question, and one on which the traditions divide. A metamodel is arguably not the place to answer it, and one that answers it in its choice of symbols has answered it without argument.

5.3 A relation-valued Δ leaves both readings open

$$\Delta(m) \;=\; \{\, (x, y) \;:\; x \not\sim y \;\wedge\; \alpha(m, x) \sim \alpha(m, y) \,\}$$

Δ returns a relation, not an element. It says which discriminations a mechanism destroyed. It does not say what, if anything, was left behind, and it requires no order, no metric, no arithmetic, and no zero in order to say what it says.

The two traditions are thereby left open, and each is recovered at instantiation rather than assumed at the outset:

- Where an instantiation supplies $\mathcal{S}$ with an additive structure, a magnitude can be associated with each collapsed pair, and the residue becomes a quantity—the economic reading. Restitution is then well posed, and one may ask whether it has been made.
- Where an instantiation supplies no such structure, $\Delta(m)$ remains a set of pairs and nothing more. Two states have become indiscernible, and nothing of the right type exists to be returned—the psychoanalytic reading. Restitution is not withheld here; it is not *formulable*.

> The metamodel is not neutral because it is empty. It is neutral because it locates the disagreement: the question of whether loss is a magnitude is the question of whether the carrier has an arithmetic. That is a decision about a particular social order, to be made and defended in the modeling of that order. It is not, so far as this paper can see, a decision about the form of social dynamics as such, and it should not be made by notation alone.

5.4 The two readings license different demands

It should be said, though it exceeds the scope of this part, that the choice is consequential. A theory of justice built on the economic residue can demand restitution: something was taken, it is of a determinate size, and it can be given back. A theory built on the psychoanalytic residue cannot make this demand, and must ask instead for a different order—one whose congruence separates what the present one has conflated.

The metamodel does not adjudicate between them. It does establish that they are different demands, that they follow from different structural assumptions about the carrier, and that a theory which has not said which assumption it makes has not yet said what it is asking for.

6 Instantiation Supplies the Structure the Axioms Withhold

The metamodel is deliberately too weak to compute with. It has no order, so it cannot rank. It has no metric, so it cannot measure. It has no arithmetic, so it cannot aggregate. Each of these is supplied only at instantiation, and each supply is a commitment. The purpose of separating the layers is to make the commitments visible, so that of any concrete model it may be asked: at which line did it assume comparability, and with what warrant.

6.1 Every instantiation is a semiflow, and its congruence carries the normative weight

To instantiate is to supply four things: a carrier $\mathcal{S}$, a semigroup $\mathcal{M}$, an action α, and a congruence $\sim$. The axioms then constrain what the instantiation may do, and the propositions of §4 hold in it automatically, without reproof.

Two constraints on instantiation follow directly from §4 and are worth stating here, since they hold for every instantiation and therefore belong to the highest layer rather than to any particular one.

Semiflows, not flows. A continuous-time flow with $t \in \mathbb{R}$ is a group action, and by Proposition 2 it has $\Delta \equiv \emptyset$. Reversible dynamics has no collapse. This is the classical fact that a Hamiltonian system loses no information, and it is here a corollary rather than an observation. Any instantiation that is to model a system with a history must therefore be a semiflow, $t \geq 0$. The restriction is not a modeling convenience; it is forced.

The congruence carries the normative weight. In any instantiation, $\sim$ is not a technical choice. It is the system's statement of what it is obliged to preserve, and it is the sole point at which normative content enters the formalism. Two configurations that a theory of justice would not have conflated are configurations that $\sim$ is required to separate. Choosing $\sim$ is therefore a substantive theoretical act, and one to be defended as such. The metamodel supplies the *form* of the obligation and none of its content.

6.2 Instantiation, application, and generativity are deferred

Three things are outside the scope of Part I, and are named so that their absence is not mistaken for an oversight.

No instantiation. No carrier, semigroup, action, or congruence is exhibited for any concrete domain. The metamodel is presented as a set of conditions on models, not as a model.

No application. The framework is not read against any substantive problem in social or political theory. Where such readings are possible—and the author holds that they are, and that they alter the description of the phenomena—they require a determinate $\sim$, and hence an instantiation, and hence a later part.

No account of generativity. The axioms describe how mechanisms act on a fixed carrier. Nothing in them produces a state that was not already in $\mathcal{S}$, nor a distinction that $\sim$ did not already admit. Collapse has been given a formal home; emergence has not. This is a genuine limitation and is returned to in §6.

> Part I establishes what a social dynamical system must be able to say. It does not say it.

7 The Axioms Cannot Judge a Collapse, Generate the New, or Evolve Their Own Congruence

The framework should be judged by what it cannot do, and four things it cannot do are named here.

It cannot say that a collapse was wrong. $\Delta(m)$ records which distinctions a mechanism destroyed. It does not say they ought to have been kept. Some collapses are innocuous, and some are necessary: a system that could distinguish every state from every other would be a system incapable of generalization. The normative weight falls entirely on $\sim$, that is, on the prior determination of what a system is obliged to preserve. The metamodel supplies the form of that determination and nothing of its content.

It cannot generate the new. The axioms describe how mechanisms act on a fixed carrier. Nothing in them produces a state that was not already in $\mathcal{S}$, and nothing produces a distinction that $\sim$ did not already admit. This is a genuine limitation for a programme whose central term is generativity. Collapse has been given a formal home; emergence has not. A candidate exists—the passage of a system into an inequivalent representation of the same algebra, where the new is not a rearrangement of the old but an accession to a sector formerly unreachable—but it requires more structure than four axioms provide, and it is not developed here.

The congruence is exogenous. Axiom 3 posits $\sim$ and does not derive it. Yet in any actual system, what counts as a preserved distinction is itself an outcome of the system's history. A sharper framework would let $\sim$ evolve, so that a mechanism could alter not only the states but the system's very capacity to discriminate among them. The immediate obstacle is that Δ is defined in terms of $\sim$, and a moving $\sim$ makes the definition circular. Resolving this is, in the author's view, the most important open problem in the framework, and it is the problem to which the next part is addressed.

It is not, by itself, a theory. A metamodel of this kind constrains the class of admissible models; it does not select among them, and it makes no prediction. Its use is diagnostic. It permits one to ask of any social model: what does it take a state to be, what does it take a mechanism to be, what does it oblige a mechanism to preserve, and what, therefore, does it permit a mechanism to destroy. A model that cannot answer the fourth question has not thereby avoided destruction. It has only declined to record it.

8 Conclusion

Four axioms have been given. A carrier without structure; a semigroup of mechanisms acting upon it, associative and without inverses; a congruence recording what the system is obliged to preserve; and a difference operator defined as the set of distinctions a mechanism collapses. From these, four propositions follow: that collapse is irreversible; that it is possible only in the absence of inverses; that a mechanism is non-destructive exactly when it is injective modulo the congruence; and that collapse accumulates monotonically under composition.

The propositions are not deep. They are three lines each. What is worth noticing is that they were not put in. The framework was constructed to be as weak as it could be made—no order, no metric, no arithmetic, no zero—and by assuming so little, it was able to obtain irreversibility as a theorem rather than posit it.

A system has a history because its mechanisms cannot be undone. It can lose what it was obliged to keep because its mechanisms can collapse distinctions the congruence required it to hold apart. These are the same fact, stated once algebraically and once normatively, and it is the burden of a formal social theory to show that they are the same.

That burden is not discharged here. This paper has established only the highest layer: what a social dynamical system must be able to say, and what it costs to say it. It has exhibited no instantiation, made no application, and given no account of the term—generativity—for the sake of which the wider programme exists.

The order of exposition, however, follows the order of dependence. A framework that cannot say what a mechanism destroys cannot say what it would mean to generate, since generation is intelligible only against the possibility of loss. Loss has now been given a form. It is a relation, not a magnitude: not a quantity that has diminished, but a discrimination the system can no longer make. What follows from that—and in particular whether a congruence can be made to evolve without circularity, so that a system might recover a distinction it had lost—is the subject of the next part.

A Metamodel for Ontologically Heterogeneous Social Dynamics

Part II: Modeling Six Categories of Social Facts

Wanhong HUANG
huangwanhong@serendip.ngo

Abstract

Social inquiry uses entities, relations, events, attributes, states, and processes to articulate different questions about a common situation. This paper develops their representations within the abstract action framework introduced in Part I, with ontological questions suspended. Each category receives a separate construction, derivation, critique, and philosophical interpretation. Indexed appearances support declared entity-reidentification criteria; incidence relations require invariance under participant identification; occurrence records preserve distinctions lost by idempotent effects; partial attributes require both value and definedness consistency; state descriptions depend on retained observation and memory; and process histories retain ordering, intermediate conditions, and segmentation beyond their composite effect. Established continuation semantics supplies a common state-consistency construction. Further conditional results concern the exact composition of collapse sets, coordination among category records, classification-mediated updates, changes of descriptive regime, finite probabilistic aggregation, and finite-horizon approximation error. A cooperative-agreement model is developed through its complete twelve-map transformation family. A graph model derives collective units and shows how a component description can support edge additions while failing under deletion. The philosophical analysis separates formation, description, and social uptake; predictive sufficiency and historical warrant; and behavioral equivalence and entity identity. A proposed case-study design states the evidence and revision conditions for each representation. The contribution is a coordinated architecture of explicit modeling commitments, with empirical adequacy and broader ontological interpretation remaining open.

Keywords: social facts; analytical categories; generative relational modeling; semigroup action; continuation equivalence

Research Paper Note

This paper continues the metamodel inquiry through a specified task: modeling six categories used in discussing social facts. The full series title retains the identity of Part I. The present argument concerns representational conditions, with ontological questions held open.

The term *social fact* identifies the subject matter of inquiry at a deliberately modest level. A description can concern an organization, a relation, an occurrence, a property, a situation, or a course of activity. The paper asks what information each description needs and how its representation interacts with the others. Establishing that a modeled description is warranted requires evidence appropriate to the inquiry.

The six categories constitute a selected analytical repertoire. Their uses can overlap within one investigation. A theory of their exhaustiveness, exclusivity, or metaphysical priority remains a separate undertaking.

The mathematical argument distinguishes conditional results from proposed interpretations. The finite example is constructed to expose assumptions and countercases. Its social labels are stipulated for illustration. A subsequent application would have to establish the relevant operations, observations, histories, and identity criteria from its own material.

1 Introduction

This paper develops a common framework for representing six categories used in discussing social facts: entity, relation, event, attribute, state, and process. Its objective is to make the modeling requirements of each category explicit and to examine their connections within a shared dynamics. The method combines conditional constructions, stepwise derivations, counterexamples, philosophical analysis, and two finite illustrations. Ontological questions remain suspended throughout.

Consider an inquiry into a cooperative agreement. Investigators may ask which organizations participate, what obligations connect them, when authorization was recorded, which resources are available, whether the agreement is operative, and how implementation developed. These questions select different aspects of the inquiry. A record of implementation may help establish an event, describe a stage of a process, and change an attributed state. The usefulness of these distinctions depends on the work they enable an account to perform.

The questions become more demanding when the records diverge. An organization can change its membership while retaining an institutional identity. An authorization can be repeated without changing the current condition. Two histories can establish the same present status through different procedures. Two arrangements can look alike under a current observation while responding differently to a later request. A completed outcome can conceal different intermediate costs or failed attempts. A common mathematical language should make these differences available for analysis.

Part I supplied an abstract framework for change and composition relative to a declared regime of distinction [3]. The continuation considered here asks how the six-category vocabulary can be represented over that framework. Its scope is intermediate between an abstract action and an empirically warranted account. It develops representational possibilities and identifies the information needed to use them.

Three levels organize the argument. A *base definition* uses the symbols and explicitly declared parameters of the underlying model. An *induced construction* builds a mathematical object, such as a quotient or a set of finite paths, from specified data. An *enrichment* supplies further information, such as an actual history, an observation rule, or a criterion for following an organization through change. Keeping these levels visible makes the commitments of a category representation available for assessment.

The distinction matters because a formalism can conceal its inputs. Writing an entity as a set of related configurations can leave the relation's justification unexamined. Writing a process as a product can conceal the history omitted by that product. Writing an attribute as a function can leave its subject, definedness, and interpretation unresolved. The paper develops each construction far enough to expose these choices and to derive the conditions under which the representation performs its intended task.

The proposed contribution is a coordinated architecture for the six categories. It includes limited positive results and discriminating counterexamples. A preserved equivalence supports quotient dynamics; a coarse current observation can fail to support them. A mechanism product determines a composite effect while omitting distinctions between possible histories. Reachability can connect configurations while leaving entity identity underdetermined. These differences matter when an inquiry moves from a mathematically possible description to a claim about a particular social situation.

The entity treatment begins with indexed appearances and a criterion of reidentification. It examines invariant descriptors, directed lineage, fission, merger, and behavioral comparison. The relation treatment distinguishes incidence among participants from historical formation and potential effects under continuations. The event treatment separates occurrence tokens from transformation types and derives the loss of occurrence counts under idempotent compression.

The attribute treatment develops predicates, value maps, and partial descriptions, including the conditions for their descent to a quotient. The state treatment examines retained memory, observation tasks, and predictive sufficiency. The process treatment follows words through their trajectories and compares the information retained by products, maps, and endpoints. Each treatment includes its own interpretation, counterconditions, and evidence requirements.

A common construction compares configurations through the observations available under all finite continuations. The resulting equivalence is preserved by the declared operations. This construction be-

DRAFT

longs to established behavioral semantics [7]; its function here is to show how a consistent state description can be derived once its inputs are declared. The six-category question retains further requirements, especially occurrence, historical warrant, attribute interpretation, and reidentification.

Two examples connect the abstract results to inspectable models. The cooperative-agreement example has eight configurations and three primitive operations. Its complete transformation family can be derived, allowing comparison of mechanism effects, occurrence histories, and observations. The relational-unit example forms collective units from connected components of finite graphs. Comparing edge addition with edge deletion shows how the adequacy of a reduced description depends on the operation repertoire.

The philosophical discussion asks what these constructions commit an investigator to. It separates formation of a social arrangement, description of that arrangement, and uptake of a classification into subsequent action. It also distinguishes predictive sufficiency from historical explanation and entity identity from behavioral equivalence. These distinctions permit substantive criticism while the ontological status of the categories remains open.

The extensions examine partial operations, transitions among declared descriptive regimes, and finite probabilistic updates. Each introduces additional inputs and a corresponding preservation obligation. A change of description can require information omitted by an earlier record. A probabilistic quotient requires equal transition mass into each target class. These results provide precise limits on transferring the deterministic construction to richer settings.

The paper's social claims remain conditional modeling proposals. The finite examples establish consequences of their displayed assumptions and supply counterexamples to broader identifications. Empirical adequacy requires evidence about operation meanings, histories, observations, identity criteria, and availability conditions. The research-design section specifies how a bounded application could examine those requirements and identify revisions.

Section 2 locates the method and verified antecedents. Section 3 states the abstract framework, and Section 4 develops its generative and relational interpretation. Section 5 introduces the category architecture. Section 6 establishes the common continuation construction before Sections 7–12 develop the six category representations separately.

Section 13 develops the cooperative-agreement model. The subsequent relational-unit and coordination sections examine collective formation and compatibility among category records. Section 16 develops the philosophical interpretation, Section 17 examines changes to the dynamics, Section 18 derives finite-horizon approximation bounds and their limits, and Section 19 specifies the research design and revision conditions. The conclusion draws together the construction's results and its remaining evidential obligations.

DRAFT

2 Methodological Commitments and Verified Antecedents

This section locates the inquiry's contribution and explains how its arguments should be evaluated. It distinguishes the supplied abstract framework, established mathematical constructions, and the proposed coordination of the six categories. It then states the role of counterexamples, finite calculations, and philosophical interpretation in the paper's method.

2.1 The Inherited Framework and the Present Construction Task

Part I supplies the abstract carrier, mechanism composition, action, and regime of distinction from which the present development begins [3]. The use of that framework creates a definite dependency: results established here assume the relevant action and preservation conditions. Their social interpretation requires an account of what the carrier, mechanisms, and distinctions represent.

The present task concerns the additional work needed to model entities, relations, events, attributes, states, and processes. A vocabulary naming these categories can suggest a unified account, yet the formal requirements differ. An event occurrence needs a way to distinguish individual happenings. An attribute

needs a subject and interpretation. An entity record needs a reidentification criterion. The argument evaluates the data required for each role.

This dependency also fixes the scope of the series continuation. The paper develops an intermediate modeling layer over Part I. It leaves the categories' ultimate ontological status suspended. A successful construction establishes that declared data support a specified representation. Further philosophical and empirical arguments would be needed to determine the broader status of that representation.

The distinction among a base definition, an induced construction, and an enrichment serves this purpose. A quotient can be constructed from an equivalence already supplied. A historically actual occurrence requires an actuality claim and relevant evidence. Both can enter one account, while their sources of warrant remain different.

2.2 Behavioral Constructions and Their Local Use

The continuation construction draws on established behavioral semantics. Rutten's account of systems and behavioral equivalence provides a verified mathematical antecedent for comparing states through their observable responses to continuations [7]. The present paper uses that machinery to derive a state description relative to declared observations and operations.

The local result is valuable because it identifies the exact information retained by the construction. Two states belong to one behavioral class when the selected continuations and readouts fail to distinguish them. Changing the observations or available operations changes the relevant comparison. Thus the quotient's meaning includes its inputs.

The six-category architecture adds questions that behavioral equivalence alone leaves open. Historically distinct occurrences can produce the same response profile. Two different organizations can occupy behaviorally equivalent positions. A formation history can answer a provenance question that a predictive state omits. These are repository applications and distinctions developed in the present argument.

The division of intellectual work should remain explicit. The mathematical existence and preservation results for behavioral descriptions have established antecedents. The proposed contribution concerns their coordination with other representational requirements in this metamodel. A broad claim of novelty for quotient-based state comparison would exceed that contribution.

2.3 Provenance Models and Historical Evidence

The W3C PROV-DM recommendation distinguishes entities, activities, agents, and relations used to represent provenance [6]. Its treatment of derivation gives an established reference point for structured historical records. The present paper uses this connection narrowly: provenance representation can organize dependence and activity records whose interpretation requires evidence.

The six categories in this paper have a different organizing purpose from the categories of that recommendation. Shared terms therefore need local definitions. An entity appearance in the present construction is an indexed subject of a proposed reidentification criterion. An occurrence is a token recorded within a declared event domain. Their relation to a provenance schema would need an explicit mapping.

This distinction helps separate documentary organization from historical warrant. A well-formed provenance record can state that one item was derived through an activity involving another. Assessing the statement requires evidence concerning the activity and its dependencies. The graph or relation structure organizes the claim; the inquiry remains responsible for establishing its application to the case.

The paper's historical examples follow the same discipline. They construct candidate histories and ask which questions a retained record can answer. A proof that several histories share a record establishes an information limit. It leaves the actual history to be identified through evidence.

2.4 Pattern Interpretation and Selective Description

Dennett's discussion of real patterns connects questions of description with compression and predictive usefulness [1]. It offers a philosophical comparison for the selection of informative descriptions. The

DRAFT

present paper retains its own analytic formulation and suspends the ontological conclusion that might be drawn from that comparison.

A selective description can gain explanatory value by preserving distinctions relevant to an inquiry while omitting others. The continuation quotient formalizes one such task under exact assumptions. An entity criterion, however, may also preserve historical continuity that has little effect on the selected predictions. A useful description therefore needs a stated purpose before its compression can be assessed.

The coexistence of several purposes gives the six-category architecture a philosophical role. Predictive economy, historical accountability, occurrence counting, and participant reidentification can demand different records. Their coordination makes those demands visible within one account. It also exposes tensions when a single compression is asked to serve incompatible tasks.

The position defended here is consequently methodological. An explicit representation can clarify what an account retains, what it omits, and which further claims require support. Its usefulness is assessed through the work it performs in a bounded inquiry. Ontological interpretation remains an additional question.

2.5 Conditional Proof and Interpretation

A conditional proof establishes a consequence of stated assumptions. The quotient action proof, for example, begins with an equivalence preserved by every mechanism and derives a representative-independent action on its classes. The proof can be complete while the empirical applicability of the preservation assumption remains open.

Interpretation supplies the connection between that mathematical result and a social question. If equivalence means equality of a proposed institutional status, the application must explain why equivalent cases respond equivalently to the declared operations. A counterexample to that empirical interpretation can reveal a missing variable or a poor choice of operations without affecting the abstract theorem.

The paper therefore places symbols and domains before definitions, assumptions before conclusions, and interpretation after the relevant formal construction. This order allows a reader to identify where a disagreement arises. The disagreement may concern a proof step, the meaning of a variable, the adequacy of a classification, or the evidence supporting an input.

An original formulation also carries a distinct research status. A proposed enrichment can be mathematically coherent and philosophically suggestive while awaiting empirical evaluation. The status of the construction should travel with it when it is used in another paper or applied to a case.

2.6 Counterexamples and the Repair of Tempting Identifications

Counterexamples perform a central part of the argument. They test claims that can appear plausible when expressed only in general language. A reachable configuration may seem to belong to the same entity's development. Overlapping forward closures show why that association requires an additional identity criterion. A mechanism product may seem to preserve a process. Repeated idempotent operations show how it can omit occurrence multiplicity.

Each counterexample has a specified target. The idempotence example refutes recovery of a positive occurrence count from the compressed product under the stated assumptions. It leaves open the use of a larger state or a richer record. The graph example shows that connected components can support addition-only updates while failing under a deletion operation. It leaves intact the component description for the restricted repertoire.

A good repair preserves the useful part of the original insight. An entity can remain a continuing unit through change, provided the continuity criterion is declared. A process product can summarize a composite effect, provided the historical information it omits is retained when required. The counterexample identifies the boundary of the formulation and the data needed to cross it.

This method also guards against excessive formalization. If a proposed symbol merely renames a social term, its contribution is limited. A useful formulation should define a comparison, expose an

DRAFT

assumption, derive a consequence, or distinguish models that would otherwise be conflated. The category sections evaluate their formulas by these functions.

2.7 Finite Calculations and Mathematical Coverage

Finite illustrations make the constructions inspectable. The cooperative-agreement model has a small carrier, a declared primitive repertoire, and a transformation family that can be derived explicitly. The relational-unit example permits comparison of component descriptions under different operation repertoires.

Enumeration checks are used to examine the finite claims and to compare independently specified constructions. Such checks can detect an omitted transformation, a mistaken partition count, or an incorrect example. The accompanying proofs explain why the claimed result follows from its assumptions.

Finite verification has a defined scope. Exhausting an eight-state example verifies claims about that example. It supplies a counterexample to a universal assertion when the assertion fails there. It supplies an illustration of a general theorem when the theorem has been proved separately. It leaves empirical correspondence to the case-study stage.

The examples are therefore analytic models. Their social labels help state the intended questions, while their transition rules are declared hypotheses of the illustration. An empirical investigation may need different states, operations, and observations.

2.8 Philosophical Discussion within the Modeling Scope

The philosophical discussion concerns the commitments made by the representations. Identity requires a rule for following a subject through change. Historical explanation requires a relation between present records and candidate histories. Potential effects require a comparison under continuations. Classification can remain descriptive or enter a response rule through actual uptake.

These questions can be developed while ontology remains suspended. Suspension sets the scope of the present argument; it leaves room for substantive claims about the adequacy, consequences, and limits of a representation. A model can be criticized for erasing a relevant history or for hiding an assumption even when its categories receive an agnostic ontological interpretation.

The same discipline governs evaluation. A greater number of reachable outcomes can serve a stated aim while making other outcomes possible as well. A more persistent relation can sustain cooperation or maintain an unwanted dependence. The mathematics identifies structural properties. Evaluation requires the aims, affected subjects, and standards relevant to the inquiry.

The paper's philosophical contribution is to articulate these commitments together with the mathematical constructions. Their coordination supports a form of criticism in which a reader can identify both the formal step and the interpretive premise on which a conclusion depends.

3 Abstract Framework for Category Modeling

This section develops the base on which the category representations depend. It explains the carrier, mechanism algebra, action, and equivalence separately; derives the quotient and the behavior of collapse under composition; and examines which additional descriptions can be defined from the base. The discussion also tests identity, reversibility, order effects, and semantic interpretation through countermodels. Its purpose is to make the assumptions perform visible work in each later derivation.

3.1 Configurations and the Scope of the Carrier

The carrier S is a nonempty set of represented configurations. A configuration can include several participants and conditions together. It can also be an abstract description whose internal structure is left unspecified. The metamodel uses this flexibility to compare forms of representation without requiring every application to begin with the same inventory of objects.

DRAFT

The choice of carrier determines which differences a model can express before any quotient is applied. A carrier containing only an activity flag cannot directly distinguish permission from resources. A carrier containing both conditions can represent their different roles. A history-enriched carrier can preserve formation information that a present-condition carrier omits. These are different models even if they share a verbal description of the case.

The distinction between a point of S and an entity is therefore essential. One point can describe an entire arrangement involving several organizations. The entity category later introduces appearance records to track individual subjects within and across such configurations. A state space whose points already stand for individuals makes another legitimate but stronger interpretation.

The carrier can include possible configurations that are unreachable from a selected seed. Their inclusion can support comparisons, counterfactual tests, or alternative initial conditions. A particular application should state whether S is intended to cover every relevant possibility or only a declared subset. A theorem over all of S inherits that choice of scope.

Changing the carrier changes the available questions. A richer carrier can distinguish histories or internal relations previously merged into one point. A smaller carrier can simplify calculation at the cost of information. Comparisons between such models need explicit maps or correspondences. The mere use of the symbol S in both models supplies no alignment.

3.2 Mechanisms and Associative Composition

The mechanism domain M is equipped with an associative multiplication. Its elements represent operations at the chosen level, including composites when the model treats them as mechanisms.

Assumption 3.1 (Mechanism semigroup)**.** The nonempty set M has a product satisfying

$$\ell(nm) = (\ell n)m \qquad (\ell, n, m \in M).$$

The product nm is read as applying m first and n second.

Associativity permits a finite sequence to have a composite independent of how its parentheses are placed. It leaves execution order intact. The equation equates two groupings of the same ordered sequence; commutativity would equate different orders and is a separate property.

Closure under composition also has a specific meaning. If m and n belong to the mechanism domain, their product belongs to it. This is an algebraic closure claim. Whether a particular execution is available in a social situation requires an admissibility rule. The later feasible-path construction retains that distinction at every intermediate step.

Mechanism labels can preserve distinctions that their visible effects omit. Two procedures can have the same action on the chosen variables while differing in their formation, purpose, or provenance. An abstract mechanism algebra can retain their labels, whereas a semigroup of transformations identifies them whenever their maps agree. The appropriate choice depends on the questions the model needs to answer.

The algebra also leaves temporal duration open. A product records composition, not how much time its enactment takes. Repeated applications can collapse to one algebraic element under an idempotent equation even when their durations or occurrence counts differ. The process category derives this information loss explicitly.

3.3 The Action and Its Interpretation

The action connects mechanisms to configurations. This subsection states its consistency condition and explains what that condition establishes.

Let $\alpha : M \times S \to S$ be total, and write $mx = \alpha(m, x)$.

Assumption 3.2 (Action law)**.** For all $m, n \in M$ and $x \in S$,

$$(nm)x = n(mx).$$

DRAFT

The law equates the effect of the composite mechanism with successive evaluation of its factors. It makes the algebra and dynamics consistent. Once a finite word and initial configuration are selected, repeated use of the law identifies the word's endpoint with the action of its product.

Totality states that each mechanism has a modeled output at each carrier point. An application can use total maps for attempted operations, including self-loops under unmet conditions. It can instead supply an admissibility rule or use partial maps for successful executability. Those interpretations require explicit definitions because they disagree about what happens outside an operation's effective domain.

The action can be nonfaithful. Distinct $m, n \in M$ can satisfy $mx = nx$ for every $x \in S$. Their algebraic identity then retains information beyond the selected dynamics. If the action is faithful, equality of maps implies equality of mechanisms. Faithfulness is an additional assumption and is unneeded for the quotient results.

An effect can also be local. Distinct maps can agree at one initial configuration while differing elsewhere. An endpoint observation at that seed therefore gives weaker information than knowledge of the entire map. The history and process constructions will distinguish these successive reductions carefully.

3.4 Equivalence and Preserved Distinctions

The base equivalence declares which configurations the model treats alike at a selected level. This subsection explains its logical and dynamic requirements.

Let $\sim$ be an equivalence relation on S. Reflexivity, symmetry, and transitivity make its classes a partition. The additional action condition is

$$x \sim y \quad \Longrightarrow \quad mx \sim my \qquad (m \in M). \tag{1}$$

The full base assumptions are summarized as follows.

Assumption 3.3 (Base action and distinction)**.** Let M be a semigroup acting totally on nonempty S, with $(nm)x = n(mx)$. Let $\sim$ be an equivalence preserved by every mechanism as in Equation (1). Identities and inverses are permitted without being required.

The condition concerns configurations already treated as equivalent. They must remain equivalent after the same action. Initially distinct configurations may become equivalent. The model therefore permits collapse of a represented distinction while preserving established equivalence.

The intended meaning of $\sim$ needs a domain argument. It can record a selected observational resolution, a theoretically relevant classification, or another declared equivalence. An observation-induced relation $\ker o$ qualifies only if the operations preserve it. A current measurement can fail that condition when it omits a future-relevant variable.

The equality relation always satisfies preservation under a function. The universal relation also satisfies it, because every pair is already equivalent. These extremes show that preservation alone does not select a useful descriptive level. A finer relation retains more distinctions; a coarser relation can simplify the description. The inquiry must justify which distinctions its task requires.

A value judgment about preserving a social distinction adds another requirement. The base permits some initially distinct cases to collapse. If an application needs to protect a particular difference, it must restrict the mechanisms or strengthen its conditions. Mathematical preservation of equivalence should not be conflated with a normative requirement to preserve all differences.

3.5 Symbols and the Four Analytical Roles

The base coordinates several roles in one formal structure. This subsection relates them without treating the verbal roles as interchangeable with every symbol.

Table 1 collects the notation used in the category constructions. The abstract framework continues Part I's treatment of change and composition [3], while stating the precise assumptions required for the present results.

DRAFT

Table 1: Symbols for the action framework and its declared enrichments

Symbol	Domain and analytical role
S	Nonempty carrier of represented configurations
$M, \cdot$	Mechanism domain with associative composition
α	Total action, written $mx = \alpha(m, x)$
$\sim$	Equivalence preserved by the action
Q, q	Quotient $S/\sim$ and projection $q : S \to Q$
B, T_b	Operation labels and their declared maps
$A(x)$	Admissible mechanisms or labels at x, with the domain specified
o, ρ	Observation and retained-description maps
I, E	Appearance indices and a declared identity equivalence

Change appears through the action. Structure appears through the composition law and any further structure supplied to the carrier. Constraint includes the requirement that equivalent configurations remain equivalent under common action. Difference appears through the selected distinction regime and the changes that operations can make to it.

These are analytical roles, not four independently measured quantities. The same mathematical component can contribute to more than one role. For example, the action both implements change and expresses a compositional consistency constraint. The collapse set defined below depends on both the action and equivalence.

Resources, permissions, values, and physical time are additional application data. They can be encoded in configurations or attached through explicit maps. Their appearance in a model requires a construction or interpretation; it does not follow merely from assigning them one of the four verbal roles.

3.6 Quotient Dynamics and Representative Independence

The quotient construction makes the preserved equivalence operational. This subsection gives both directions of its adequacy condition and derives the induced action.

Let $Q = S/\sim$ and $q(x) = [x]$. The proposed quotient update is

$$\bar{\alpha}(m, [x]) = [mx]. \tag{2}$$

The expression uses a representative x, so its value must be independent of that choice.

Proposition 3.4 (Induced quotient action)**.** *Equation* (2) *is well-defined exactly when $\sim$ is preserved by every mechanism. Under Assumption 3.3, it defines an action of M on Q.*

Proof. Suppose preservation holds. If $[x] = [y]$, then $x \sim y$, so $mx \sim my$ and $[mx] = [my]$. The quotient update is therefore representative-independent.

Conversely, if the update is well-defined and $x \sim y$, the equal inputs $[x] = [y]$ give equal outputs $[mx] = [my]$. This is preservation.

For the action law, evaluate the two proposed composite updates:

$$\bar{\alpha}(nm, [x]) = [(nm)x] = [n(mx)] = \bar{\alpha}(n, \bar{\alpha}(m, [x])).$$

The middle equality follows from the base action law. Thus the quotient maps form an action. □

The quotient can be viewed as a reduction of the configuration description. The projection commutes with each operation: $q(mx) = \bar{\alpha}(m, q(x))$. This equation is the precise relationship between the full and reduced dynamics.

If preservation fails, the same quotient class would need different outputs under one mechanism. An application can then refine the equivalence, retain additional state information, or adopt another type

DRAFT

of reduced model. The failure is informative because it identifies a specific incompatibility between description and dynamics.

Representative independence is a recurring theme in the six categories. Entity descriptors, relational incidence, attributes, and historical queries each need an analogous constancy condition when transferred to a reduced domain. The quotient proof supplies the basic pattern, while each later application has its own input and interpretive commitments.

3.7 Identity Elements and Zero-Step Continuations

An algebraic identity and an identity action are different assumptions. This subsection explains that distinction and constructs a uniform zero-step convention.

If M has an identity element e, the semigroup action law gives $\alpha(e, \alpha(e, x)) = \alpha(e, x)$. It forces the map $\alpha(e, -)$ to be idempotent. Without a unitality requirement, it need not equal id_S.

For example, take the one-element monoid $M = \{e\}$ and a carrier with at least two points. Let $\alpha(e, -)$ be a constant map. The action law holds because a constant map is idempotent, while the map differs from the identity on S. The example isolates the missing assumption.

Finite words can represent zero steps by defining $T_\epsilon = \mathrm{id}_S$ directly. This convention does not require an identity mechanism in the original semigroup. It also avoids identifying the empty word with an old algebraic identity whose action has not been checked.

A uniform algebraic repair adjoins a fresh unit 1 disjoint from M, even if M already contains an identity. Set $1m = m1 = m$ and $1 \cdot 1 = 1$, retain all original products, and define $1x = x$. Associativity in cases involving 1 follows by deleting the unit; other cases use associativity in M.

The extended action law holds for the same reason. If a factor is 1, both sides reduce to the unchanged action. If both factors belong to M, the original law applies. The extension therefore retains the earlier model while adding a valid zero-step action.

This distinction matters when a word is compressed to a product. A product representation that includes the empty word must specify which element or map represents it. Checking that convention prevents a zero-step history from acquiring an unintended effect.

3.8 Collapse of a Declared Distinction

An operation can identify configurations that the base initially distinguishes. This subsection defines that collapse and derives its persistence under common subsequent action.

For $m \in M$, define

$$\Delta_-(m) = \{(x, y) \in S^2 : x \not\sim y,\ mx \sim my\}. \tag{3}$$

The set records ordered pairs that lose their distinction under m. It is relative to the declared equivalence.

Proposition 3.5 (Persistence of common-action collapse)**.** *Under Assumption 3.3,*

$$\Delta_-(m) \subseteq \Delta_-(nm) \qquad (m, n \in M).$$

Proof. Take $(x, y) \in \Delta_-(m)$. Then $x \not\sim y$ and $mx \sim my$. Preservation under n yields $n(mx) \sim n(my)$. The action law identifies these outputs with $(nm)x$ and $(nm)y$. The initial distinction therefore also collapses under nm. □

The proof holds the equivalence fixed and applies the same subsequent mechanism to both configurations. Changing either condition changes the comparison. Different later actions can give different outputs, and a finer observation can reveal differences previously identified by $\sim$.

The result also concerns represented distinctions. A collapse relative to one quotient can leave many differences intact at a finer level. Interpreting it as physical erasure, epistemic loss, or institutional homogenization requires a domain mapping and evidence. The set formula alone leaves those meanings open.

DRAFT

The original role of difference in the metamodel is therefore retained with a precise boundary. It identifies how an operation transforms a declared regime of distinction. It supplies no automatic measure of social importance or loss.

3.9 Exact Composition of Collapse Sets

The inclusion can be sharpened into an exact identity. This subsection derives the decomposition and explains its counting implications.

Write $\alpha_m(x) = mx$.

Proposition 3.6 (Two-stage collapse decomposition)**.** *Under the base assumptions,*

$$\Delta_-(nm) = \Delta_-(m) \,\dot\cup\, (\alpha_m \times \alpha_m)^{-1}\big(\Delta_-(n)\big), \tag{4}$$

where the union is disjoint.

Proof. Take a pair in $\Delta_-(nm)$. Its inputs are initially inequivalent and its final outputs are equivalent. There are two cases.

If $mx \sim my$, the pair belongs to $\Delta_-(m)$. If $mx \not\sim my$, the intermediate pair (mx, my) belongs to $\Delta_-(n)$, so the input pair lies in the displayed inverse image.

Conversely, a pair in $\Delta_-(m)$ belongs to $\Delta_-(nm)$ by Proposition 3.5. A pair in the inverse image has $mx \not\sim my$ and $n(mx) \sim n(my)$. Its inputs must be inequivalent: $x \sim y$ would imply $mx \sim my$ by preservation. Thus it also belongs to $\Delta_-(nm)$.

The first branch requires $mx \sim my$; the second requires $mx \not\sim my$. They are disjoint, completing the proof. □

The identity separates distinctions already collapsed by the first step from those surviving it and collapsing at the second. It therefore preserves the sequence of reasoning behind the final collapse set.

For finite S, cardinalities of the two branches add. The second term is the size of an inverse image, which need not equal $|\Delta_-(n)|$. Several initial pairs can map to one intermediate pair. A simple sum of the two mechanisms' raw collapse counts can therefore misrepresent the composition.

An interpreted measure would need further choices about which pairs matter and how they are weighted. The exact set identity precedes that choice and keeps its dependence on the action visible.

3.10 Order, Reversibility, and Independent Properties

Several intuitive properties of dynamics are logically distinct. This subsection uses countermodels to prevent their meanings from being merged.

On the nonnegative integers, the shift $s(k) = k + 1$ is injective and lacks an inverse within the semigroup of positive shifts. With equality as the distinction regime, its collapse set is empty. Absence of an inverse therefore does not by itself imply collapse.

On $\{1, 2, 3\}$, let a swap 1 and 2, and let b swap 2 and 3. Both are bijective and preserve every distinction. Yet $ba(1) = 3$ and $ab(1) = 2$. Order sensitivity can occur without collapse.

On $\{0, 1\}^2$, let r_1 reset the first coordinate to zero and let r_2 reset the second. They commute, because each leaves the other's coordinate unchanged. Each also collapses pairs differing only in its reset coordinate. Collapse can therefore occur without an order effect between these operations.

These examples distinguish three questions: whether an operation can be reversed within the chosen algebra, whether it identifies a represented pair, and whether its order with another operation changes an outcome. A historical interpretation can involve any combination of the three.

History itself is another question. A sequence can have a history record even when its composite is bijective or returns a seed to its initial point. The record of what occurred belongs to the event and process representation. It is not determined by the presence of a collapse set.

DRAFT

3.11 Definitions, Constructions, and Enrichments

The category account uses several forms of mathematical development. This subsection states their differences so that a representation's contribution can be assessed.

The two-sorted base language is

$$L_0 = \{S, M, \cdot, \alpha, \sim\}.$$

An explicitly defined predicate uses a stated formula in that language, with every parameter disclosed. The order-effect predicate is one example because it refers only to mechanism products, actions, and equivalence.

A quotient is an induced set construction from a specified equivalence. A word space is constructed from a specified alphabet. These constructions are available in the mathematical setting, but treating their elements as objects of the original first-order language requires an encoding or additional sorts.

An enrichment supplies further information. An actual history, observation map, availability set, or identity criterion can be supplied in this way. The enrichment can be justified and useful while remaining distinct from a consequence of the bare base data.

An underdetermination test holds the entire base fixed and varies the proposed addition. If two permitted enrichments disagree, the fixed base does not uniquely determine that addition. This does not exclude a particular definition under stronger premises. It identifies the information that those premises must supply.

The distinction also clarifies philosophical claims of emergence. A mathematical construction can derive a pattern from specified relational data. Whether that construction explains the emergence of a social category depends on the interpretation and evidence for those data. Calling the construction generative cannot replace that argument.

3.12 Symmetry and Parameter-Free Definability

A symmetry test can expose omitted distinctions. This subsection gives the logical reasoning and its interpretive boundary.

A base automorphism consists of bijections on the two sorts that preserve multiplication, action, and equivalence. Every parameter-free first-order predicate defined in L_0 has the same truth value on a tuple and its image under such an automorphism.

The proof proceeds by induction on expressions. Variables transform by the assigned bijections. Preservation of function symbols makes term evaluation commute with the automorphism. Atomic equalities and the relation $\sim$ therefore preserve truth. Boolean connectives retain that invariance.

For an existential quantifier, a witness is sent to a witness by the automorphism. Its inverse gives the converse. Universal quantification follows by the same bijective correspondence. The induction establishes truth invariance for every formula.

Consider a carrier $\{0, 1\}$ with only identity action and ordinary equality. Swapping the two states preserves the whole base. A parameter-free unary predicate therefore cannot select just one state. A named parameter or supplied subset can make that selection, adding information that breaks the symmetry.

The symmetry test is necessary, not a general converse. Passing it does not display a defining formula. It is useful because a failed test shows that a proposed semantic distinction requires additional structure or parameters.

The same point applies to social meanings. If two interpreted cases receive identical base representations, a base-only calculation cannot recover the omitted difference. The appropriate response is an explicit encoding and justification, not a stronger verbal claim about the unchanged formula.

3.13 The Base and the Category Construction Task

The preceding results establish a common formal discipline for the rest of the paper. This subsection states how that discipline guides the six categories.

DRAFT

The base provides configurations, composition, action, and a preserved distinction regime. It supports quotient dynamics, order comparisons, and collapse calculations. The category constructions use those resources while declaring their additional domains and criteria.

Entities require reidentification across appearances. Relations require participant incidence, formation records, and potential-effect comparisons. Events require occurrence indices. Attributes require coding rules at a declared level. States require sufficient retained information for the chosen task. Processes require words, trajectories, and any grouping or time records.

The contribution is therefore a coordinated development under explicit assumptions. Some components are derived from the base, some are induced constructions, and some are justified enrichments. Each can be examined through proofs, counterexamples, and evidence without turning the category repertoire into an asserted ontology.

4 Interpretation of Generative Relational Dynamics

This section explains the generative and relational vocabulary through historical formation, future possibilities, and the conditions of realization. It constructs mechanism fibres, derives the relation between support and outcome images, and examines prefix feasibility and reachability. The philosophical discussion identifies which comparison can justify a claim of generation, expansion, or reproduction. The aim is to connect the abstract action to a research question without assigning more meaning to the algebra than its inputs support.

4.1 Historical Formation and Further Activity

A working relational interpretation concerns a relatively reidentifiable dependence with a formation history and possible effects on later activity. A relation can arise historically and participate in producing further history. The two directions connect provenance with prospective dynamics while retaining distinct information requirements.

The first direction asks how a pattern came to obtain. Its answer can involve a sequence of events, a negotiation, a maintained practice, or another specified process. The second direction asks what later activity depends on that pattern. Its answer can involve an available operation, a changed outcome, or a route whose feasibility requires the pattern to persist.

A current state can encode enough information for a selected future prediction while omitting the formation sequence. That sufficiency leaves the historical question open. Conversely, a detailed history can remain insufficient for prediction when the model lacks the relevant transition rules or current conditions. Retaining records and specifying dynamics are complementary tasks.

The potential effect can remain unrealized. An authorization can make a continuation possible even during a period in which it is never used. The model must specify the conditions and test under which the effect would appear. An observed sequence that bypasses the continuation supplies different information from a complete test of the proposed possibility.

The terms *generative* and *relational* therefore orient an inquiry. They motivate questions about formation and dependence. Their use in a title or variable name does not supply the missing history, interpretation, or evidence. Those components must be developed in the model and argument.

4.2 A Base-Definable Interaction Witness

Order sensitivity gives one interaction predicate within the abstract language. This subsection states its use before the broader relation category develops its limits.

Define

$$R_{\mathrm{ord}}(m, n, x) \quad \Longleftrightarrow \quad (nm)x \not\sim (mn)x. \tag{5}$$

The predicate compares the two orders from one seed under the same distinction regime. It requires no additional relation symbol because every component belongs to the base.

DRAFT

The calculation can reveal that one operation changes the conditions under which another operates. In the cooperative example, authorization followed by attempted activation has a different effect from the reverse order. The interpretation depends on the specified maps and conditions.

Commuting operations can also contribute jointly to an outcome. Two operations that set separate prerequisite bits commute, yet a later activity can require both bits. An order predicate therefore captures one kind of interaction and leaves other forms of dependence open.

The distinction matters to the ambition of deriving relations. A base-definable predicate establishes that one structural pattern is available in the language. A social relation requires an account of its participants, formation, and meaning. The later relation section keeps those additional commitments explicit.

4.3 Mechanism Fibres and Possible Outcomes

The generative interpretation needs a way to describe possibilities before their realization. This subsection constructs their witnesses and separates them from the image of outcomes.

Let $A(x) \subseteq M$ be a declared set of admissible composite mechanisms at x. For a quotient outcome $v \in Q$, define

$$\Pi_A(x, v) = \{m \in A(x) : q(mx) = v\}, \tag{6}$$

$$P_A(x) = \{v \in Q : \Pi_A(x, v) \neq \varnothing\}, \tag{7}$$

$$G_A(x) = P_A(x) \setminus \{q(x)\}. \tag{8}$$

Definition 4.1 (Support of a possible outcome)**.** The fibre $\Pi_A(x, v)$ retains the admissible mechanism witnesses for outcome v. Its nonemptiness establishes possibility in the declared model. The image $P_A(x)$ retains outcomes with witnesses, and $G_A(x)$ restricts that image to changed quotient outcomes.

The fibre and image answer different questions. The image states which outcomes are possible. The fibre states which admissible mechanisms support one outcome. Several witnesses can share an outcome while differing in cost, history, duration, or enabling conditions.

The definition of $G_A(x)$ makes another selection. It excludes the present quotient state. This is appropriate when the research question concerns a changed outcome at that resolution. An activity that reproduces the current state can still require effort, sustain a relation, or have historical significance. Those roles remain visible through the fibre or occurrence record.

The set $A(x)$ is additional information unless a definition derives it from represented conditions. A semigroup action alone does not determine which mechanisms are available at a particular situation. The same action can be paired with different availability rules, producing different support sets.

4.4 Support Enlargement and Outcome Enlargement

Adding mechanisms can increase routes without adding outcomes. This subsection derives the exact condition for strict image expansion.

Fix the seed and quotient, and suppose $A_1(x) \subseteq A_2(x)$. Every mechanism in $\Pi_{A_1}(x, v)$ then belongs to $\Pi_{A_2}(x, v)$. Consequently

$$P_{A_1}(x) \subseteq P_{A_2}(x).$$

Proposition 4.2 (Strict outcome expansion)**.** *The inclusion of outcome images is strict exactly when some $m \in A_2(x)$ satisfies $q(mx) \notin P_{A_1}(x)$.*

Proof. If such a mechanism exists, its image belongs to the larger outcome set and lies outside the smaller one, proving strictness.

Conversely, a member of $P_{A_2}(x) \setminus P_{A_1}(x)$ has a witnessing mechanism in $A_2(x)$ by definition. That mechanism satisfies the stated condition. □

DRAFT

An added witness for an old outcome leaves the image unchanged. It can nevertheless matter if its enabling conditions differ from those of earlier witnesses. The outcome may become available under circumstances that previously blocked every route. To analyze that change, the model must retain the route conditions.

Duplicating a label can also enlarge a syntactic catalog while adding neither an effect nor a distinct enabling structure. Raw mechanism counts therefore depend on representation. A substantive claim about expanded opportunity needs a comparison that identifies what the new witness actually changes.

For infinite sets, strict inclusion need not increase cardinality. Even in a finite model, cardinality alone omits the meaning of outcomes and the relations among routes. Set-based comparison is therefore the starting point; a numerical summary requires further choices.

The result keeps several possible claims separate: more labels, more mechanism witnesses, more feasible paths, more supported outcomes, and more valued opportunities. Each transition between them requires its own premises.

4.5 Primitive Words and Prefix Feasibility

A composite mechanism can conceal the stages needed for its enactment. This subsection retains those stages and states the feasibility condition.

Choose an operation alphabet B whose labels specify mechanisms and their maps. A word $w = b_1 \cdots b_k$ gives

$$x_0 = x, \qquad x_i = T_{b_i} x_{i-1}.$$

Let $A_{\text{prim}}(x) \subseteq B$ be the admissible primitive labels at x.

Definition 4.3 (Prefix-feasible word)**.** The word is feasible from x when

$$b_i \in A_{\text{prim}}(x_{i-1}) \qquad (1 \le i \le k). \tag{9}$$

The empty word is feasible and leaves the seed unchanged.

Every test is performed at the configuration reached by the earlier prefix. The total action can calculate the hypothetical endpoint of a word whose intermediate execution is unavailable. Prefix feasibility identifies that difference.

Primitive admissibility and composite admissibility have different domains. The former concerns the next label. The latter concerns a whole mechanism. A composite can be called feasible when at least one of its factorizations is prefix-feasible. Retaining the witness matters when the process must actually be followed.

Other factorizations of the same product can remain infeasible. An existential composite feasibility claim therefore does not establish that every word with that product can be executed. The feasible-path paper develops this factorization issue through an exact descent criterion.

The distinction is especially important when prerequisites can be consumed, withdrawn, or changed by an earlier step. An endpoint image does not record those intermediate conditions. A resource or permission model must specify their update rules.

4.6 Partial Maps and Domain-Sensitive Composition

Partial operations provide an alternative representation of availability. This subsection explains the domain law and its relation to the base algebra.

Suppose m is executable on D_m and n on D_n. Their partial composition is defined on

$$D_{n \circ m} = \{x \in D_m : mx \in D_n\}.$$

The first condition permits the initial step; the second permits the next step at its result.

DRAFT

Three successive partial maps have the same prefix conditions under either parenthesization. This establishes associativity of partial-map composition. The domain and effect together determine the partial transformation.

Arbitrary domains attached to elements of an existing total semigroup can fail to preserve its equations. A total flip can satisfy $f^2 = \mathrm{id}$, while restricting its domain to one state makes its two-step partial composition empty. The restricted product has changed meaning.

An application can retain free words until their domain compatibility is established. It can instead use the semigroup of partial transformations. Either approach records the additional structure openly and avoids silently transferring identities that no longer hold.

A blocked-state totalization offers another convention. It can make failed execution observable, but the marker and its later behavior require interpretation. The state and event sections distinguish modeled unavailability from an actual failed attempt.

4.7 Realization, Selection, and Valuation

A possible route and an actual occurrence have different statuses. This subsection separates the additional commitments needed for realization and appraisal.

Nonempty support means that a witness exists under the model's rules. It leaves open whether anyone selects the witness, whether execution occurs, and whether the modeled outcome is observed. Each claim needs an occurrence or selection account.

A probability distribution is another enrichment. The set of witnesses does not supply a canonical measure, and a uniform distribution over labels can change when labels are duplicated. A probability model must identify its sample space and justify its weights.

Intention and reasons remain distinct from a selection law. A statistical account of which route is chosen can omit the participant's understanding of the choice. A philosophical account of agency may need those reasons and the conditions under which they are formed.

Valuation adds further structure. A larger outcome set can include undesirable possibilities. Greater route robustness can sustain an arrangement that participants wish to change. A generative or reproductive effect therefore has no fixed evaluative sign in the formalism.

The model can accommodate values, preferences, or constraints when they are supplied explicitly. It should then distinguish the formal consequence of those inputs from an argument that the inputs are justified. This preserves the open relation between generation, reproduction, and evaluation.

4.8 Unrestricted Reachability in a Fixed Semigroup

A fixed semigroup already contains every finite composite of its mechanisms. This subsection derives the consequence for unrestricted future reachability.

Define the reflexive reachable set

$$\mathrm{Reach}^*(x) = \{x\} \cup \{mx : m \in M\}.$$

Proposition 4.4 (Reachability after a represented action)**.** *For every $c \in M$,*

$$\mathrm{Reach}^*(cx) \subseteq \mathrm{Reach}^*(x). \tag{10}$$

Proof. A member of the left side is either cx or $m(cx)$ for some $m \in M$. The first is reachable from x by c. The second equals $(mc)x$, and closure puts mc in M. Both therefore belong to the right side. □

The result can appear to conflict with a claim that an operation opens possibilities. Its scope resolves the apparent tension. The reachable set already includes all composites, without a finite horizon, resource budget, or changed availability rule.

DRAFT

An enabling action can make a later primitive locally effective while its composite route was already included in the unrestricted set. The cooperative example illustrates that distinction. Recording authorization changes what an immediate activation can do, even though the authorization-plus-activation word was already a represented composite.

The inclusion also leaves strict contraction possible. After an irreversible action, some earlier alternatives may no longer be reachable. Equality requires additional conditions, such as a suitable route back. The theorem itself guarantees only inclusion.

A claim of generative expansion therefore needs to identify a comparison different from this unrestricted fixed-semigroup one, or explain how the model's carrier or repertoire changes.

4.9 Horizon, Availability, and Comparison Design

Finite resources and time horizons produce different possibility comparisons. This subsection explains their relation to the unrestricted theorem.

Let $\mathrm{Reach}_h^A(x)$ contain endpoints of prefix-feasible words of length at most h under a fixed primitive admissibility rule. If c is feasible at x, then

$$\mathrm{Reach}_h^A(T_c x) \subseteq \mathrm{Reach}_{h+1}^A(x).$$

A witness word from $T_c x$ can be prefixed by c, adding one feasible step and preserving its later prefix conditions.

Comparing the same remaining horizon h before and after the enabling step resets the budget. It is therefore different from comparing two plans under one fixed total budget. A statement that more outcomes are available after the step can depend on which comparison is used.

Changing admissibility while holding the seed fixed is another comparison. If a rule makes additional primitive operations available, new feasible words can appear. Their endpoint images may or may not expand, depending on whether the new words reach new outcomes.

Changing the operation repertoire or carrier is stronger still. The old and new models need an alignment before their possibility sets can be compared. A novel label alone supplies no evidence of a novel effect.

These distinctions make the generative claim more precise. A researcher can state whether an intervention changes immediate activity, bounded routes, availability scenarios, represented outcomes, or the model's own vocabulary. The proof obligations follow that choice.

DRAFT

4.10 Interpretive Role within the Category Architecture

The generative-relational interpretation connects the base to the six categories. This subsection states that connection and the remaining philosophical task.

Entities can be formed or reidentified through changing relations. Relations can condition later activity. Events record actual applications. Attributes describe conditions and outcomes. States retain the distinctions relevant to the selected task. Processes preserve ordered formation and enactment.

The formalism supplies routes, images, and compatibility tests. Historical and social meaning enters through declared records, comparisons, and interpretations. A useful model makes those additions inspectable and demonstrates why they serve the inquiry.

This preserves the central insight that history can form the conditions of further history. It also exposes the separate questions that a comprehensive account must answer: what was formed, how it was formed, which possibilities depend on it, and what evidence warrants the interpretation.

5 Representations of Six Social-Fact Categories

This section gives entity, relation, event, attribute, state, and process distinct representational jobs within a single inquiry. After the common consistency construction, six category sections develop each con-

Table 2: Representational roles and additional commitments for six categories

Category	Representational role	Additional commitment
Entity	Reidentification across indexed appearances	Identity criterion or directed lineage
Relation	A dependence pattern with formation and possible effects	Relata, history, comparison, and domain meaning
Event	An indexed occurrence of a transition or attempt	Occurrence evidence and relevant circumstances
Attribute	A predicate or value assigned at a declared descriptive level	Coding rule, scale, and evidential interpretation
State	A configuration class under a selected distinction regime	Coverage and observation adequacy
Process	An ordered history with a trajectory	Step records, grouping, duration where relevant

struction, its derivation, and the information needed to interpret it. Table 2 summarizes these dependencies. The repertoire is a working selection for this research program; its completeness remains an open question.

Sections 7–12 treat the categories individually. Each develops its mathematical representation alongside the philosophical question that motivates it. Their formal roles overlap in one inquiry, while the evidence needed for a particular claim remains specific to the category and question.

The distinction between a representation and its interpretation governs this architecture. An equivalence class can support an entity label, but its identity criterion needs justification. A transition map can support an event description, but occurrence requires a record and warrant. An attribute can be mathematically well-defined while its classification rule remains debatable. These are explicit dependencies to investigate through the detailed constructions.

6 Consistency of State Descriptions under Continuation

This section establishes a common construction used by the category treatments that follow. Given operations and an observation, it derives the coarsest equivalence that retains the observation and supports deterministic updates. The discussion gives the full proof, examines the relation to an inherited distinction regime, derives finite refinement, and treats blocked operations. It then identifies the construction's interpretive and computational limits.

6.1 The State-Description Problem

A current observation can merge configurations that respond differently to a later operation. This subsection states the resulting problem and the information needed to repair it.

Let $o : S \to Y$ report an aspect of a configuration. Equality of o values defines an equivalence on S. That relation is sufficient for reporting the current observation. It can fail to support an update rule on observation values.

If $o(x) = o(y)$ while $o(T_b x) \neq o(T_b y)$, the same current observation would need two different successor observations under b. A deterministic update using only $o(x)$ is therefore impossible. The failure identifies information omitted by the observation.

A repair can retain the original configuration, but a smaller record may suffice. The desired relation should merge configurations only when every declared continuation leaves their observations equal. That criterion retains exactly the distinctions needed for the selected task.

The mathematical construction has an established antecedent in deterministic behavior semantics. Rutten's final-system example uses observations indexed by finite input words [7, p. 44, Example 10.2(5)]. The present application uses that construction to audit state descriptions within the six-category framework.

DRAFT

6.2 Symbols and Continuation Signatures

The construction requires explicit operations and an observation. This subsection fixes their domains and the execution convention before stating the theorem.

Assumption 6.1 (Declared observation system)**.** Let S be nonempty, let B be an operation alphabet, and let $T_b : S \to S$ be a total deterministic map for every $b \in B$. Let $o : S \to Y$ be an observation. Words execute left to right, with $T_\epsilon = \mathrm{id}_S$ and $T_{bw} = T_w \circ T_b$.

Definition 6.2 (Continuation signature)**.** For $x \in S$, define

$$\sigma_x : B^* \to Y, \qquad \sigma_x(w) = o(T_w x), \qquad x \equiv_o y \iff \sigma_x = \sigma_y. \tag{11}$$

An equivalence E is compatible with the task when $E \subseteq \ker o$ and xEy implies $T_b x \, E \, T_b y$ for every $b \in B$.

The signature includes the empty word, so it retains the current observation. Positive words record possible later observations. Equality of signatures concerns the declared test system, rather than actual execution of every test.

The alphabet is also an input. Different labels can share a map, while an omitted operation can reveal a difference that the selected repertoire leaves invisible. The scope of the resulting equivalence must therefore name the operations used.

6.3 The Greatest Compatible Equivalence

The theorem derives the desired relation through four separate properties. This subsection includes the quotient maps so that the construction's dynamic use is explicit.

Proposition 6.3 (Greatest compatible equivalence)**.** *The relation $\equiv_o$ is the greatest compatible equivalence under inclusion. Its quotient supports well-defined updates $[x] \mapsto [T_b x]$ and observation $[x] \mapsto o(x)$.*

Proof. First, equality of functions is reflexive, symmetric, and transitive, so $\equiv_o$ is an equivalence. Taking the empty word in signature equality gives $o(x) = o(y)$ whenever $x \equiv_o y$. Thus $\equiv_o \subseteq \ker o$.

Second, suppose $x \equiv_o y$ and fix $b \in B$. For every word w,

$$o(T_w T_b x) = o(T_{bw} x) = o(T_{bw} y) = o(T_w T_b y).$$

Hence $T_b x \equiv_o T_b y$, proving update preservation.

Third, let E be any compatible equivalence and suppose xEy. Induction on word length gives $T_w x \, E \, T_w y$ for every word. The empty case is the assumed pair. The induction step uses preservation by the next operation. Since $E \subseteq \ker o$, the updated observations agree. Therefore $x \equiv_o y$, proving $E \subseteq \equiv_o$.

Finally, define the quotient update by $[x] \mapsto [T_b x]$. Preservation makes its value independent of the representative. Define the quotient observation by $[x] \mapsto o(x)$. Containment in $\ker o$ makes that value representative-independent as well. □

Greatest under inclusion means coarsest as a partition. The theorem merges the largest set of pairs consistent with the specified responsibilities. It does not seek the most informative possible description.

A finer equivalence can retain additional history or identity information. A coarser one must lose either the current observation or compatibility with some declared continuation. The theorem identifies that precise boundary.

The result also supplies a positive response to underdetermination. The base alone leaves the observation and repertoire open, but once they are declared, the compatible quotient is determined by them. Its interpretive adequacy remains a separate question.

DRAFT

6.4 Inherited Distinctions and Generator Scope

A new observation task can coexist with an earlier distinction regime. This subsection derives the appropriate intersection and limits the scope of generator-based preservation.

Suppose the original equivalence $\sim$ is preserved by the same operations on the same carrier. Define

$$E^\dagger = \sim \cap \equiv_o . \tag{12}$$

The intersection is an equivalence because both factors are. Each operation preserves both factors and therefore their intersection. The relation also retains the current observation.

Any compatible equivalence contained in $\sim$ lies in $\equiv_o$ by Proposition 6.3. It therefore lies in the intersection. Thus $E^\dagger$ is the greatest compatible equivalence that also respects the inherited distinctions.

The construction uses the same carrier and operation system. An earlier equivalence need not remain preserved after new availability restrictions or new operations are introduced. Its compatibility must be checked in the revised model.

Preservation under B extends by induction to every word over B. To claim preservation under all of an ambient semigroup M, the declared maps must generate its action, or the remaining maps must be checked separately.

For a counterexample, take $S = \{0, 1, 2\}$ with $o(0) = o(1) = 0$ and $o(2) = 1$. If B contains only the identity, the continuation classes are $\{0, 1\}$ and $\{2\}$. An added map sending zero to zero and one and two to two splits the first class. The old quotient was valid for its old repertoire.

6.5 Finite Horizons and the Refinement Recursion

A finite horizon gives a bounded approximation to full continuation equality. This subsection derives its recursive form and the relation between horizons.

For $h \geq 0$, define

$$x \equiv_o^{(h)} y \quad \Longleftrightarrow \quad o(T_w x) = o(T_w y) \text{ for every } |w| \leq h. \tag{13}$$

At horizon zero, this is $\ker o$. At the next horizon,

$$x \equiv_o^{(h+1)} y \quad \Longleftrightarrow \quad o(x) = o(y) \text{ and } T_b x \equiv_o^{(h)} T_b y \text{ for every } b \in B. \tag{14}$$

To derive the recursion, separate the empty word from a nonempty word bw. The empty word tests current observation. The suffix w has length at most h after the first update. These conditions cover exactly the words of length at most $h + 1$.

The relations decrease under inclusion because a longer horizon imposes all the shorter horizon's tests. Their intersection over all finite horizons equals $\equiv_o$, since every finite word belongs to some bounded horizon.

A bounded relation need not itself be update-preserved. One initial operation can expose a distinction requiring the full remaining horizon. The stable relation, rather than an arbitrary bounded one, supplies the exact unbounded state quotient.

6.6 Finite Stabilization and Its Certificate

On a finite carrier, the refinement process reaches the full relation after a bounded number of strict splits. This subsection proves the bound and distinguishes attainment from certification.

Proposition 6.4 (Finite refinement bound)**.** *If $|S| = n < \infty$ and $\ker o$ has r_0 classes, some $h \leq n - r_0$ satisfies $\equiv_o^{(h)} = \equiv_o$. Equality of consecutive refinement relations certifies stabilization.*

Proof. Every strict refinement of an equivalence on S splits at least one class. It therefore increases the number of classes by at least one. Starting from r_0 classes, at most $n - r_0$ strict increases are possible.

If consecutive relations agree, Equation (14) applies the same operator to the same input, so every later relation also agrees. The stable relation equals the intersection of all horizons, which is $\equiv_o$. A stable value must therefore be attained by the stated depth. □

DRAFT

An implementation may compare the attained partition with one further stage to certify that it has stopped changing. The bound concerns the depth of attainment, while the additional comparison supplies the certificate.

A finite alphabet makes each refinement directly enumerable. The mathematical class-count bound can hold with an infinite alphabet, but an effective computation then needs a way to check the operation family.

The result concerns a specified model. Observing a finite number of traces from an unknown social system does not establish that its unmodeled transitions agree with the assumed maps. Model identification requires additional evidence.

6.7 Blocked Operations and Totalization

Partial availability can be represented through a fresh blocked state and observation. This subsection states that convention and examines the information it preserves.

Let T_b initially be partial with domain $D_b \subseteq S$. Adjoin a fresh state † and define

$$\widehat{T}_b(x) = \begin{cases} T_b(x), & x \in D_b, \\ \dagger, & x \in S \setminus D_b, \end{cases} \qquad \widehat{T}_b(\dagger) = \dagger.$$

Extend the observation by $\widehat{o}(\dagger) = \bot$, where $\bot$ is outside the ordinary observation range.

The totalized system satisfies the theorem's map assumptions. A word executable from one configuration and blocked from another can now distinguish them through the fresh observation. Availability becomes part of the test output.

The absorbing convention records failure of the modeled execution. It need not describe a physical state from which recovery is impossible. A repairable failure requires a different transition or a richer failure record.

The construction uses free operation words. Equations between products in an earlier total semigroup may fail after domains are restricted. Their validity must be checked before the totalized word action is compressed through that presentation.

Observable blockage, silent failure, and an unattempted operation also carry different meanings. The observation should reflect the distinctions the inquiry can justify. A convenient marker is an explicit modeling choice.

6.8 Interpretive Limits and Category Use

The continuation quotient supplies a consistent state description for a selected task. This final subsection identifies how the six categories can use it and where their requirements remain independent.

An entity can persist while its continuation profile changes. Different entities can have the same profile under a coarse observation. The quotient therefore cannot replace a separate reidentification criterion.

Event occurrences and process histories can also be merged by behavioral equality. A repeated idempotent operation can leave the same future state while adding an occurrence. A historical query can require that distinction even when the predictive task does not.

Attributes can supply the observation or contribute to a family of observations. The quotient must preserve their values if those values belong to the task. Partial attributes also require a definedness criterion, developed in the attribute section.

The construction thus provides one shared tool within the category architecture. It derives dynamic consistency from declared observations and operations, while leaving identity, occurrence, history, evidence, and evaluation visible as additional commitments. The following sections develop those commitments for each category.

DRAFT

7 Entity Reidentification and Historical Continuity

This section develops the entity category through the problem of reidentifying a participant, organization, agreement, document, or other focal object across changing appearances. It begins with configurations and appearances, constructs an identity quotient under a declared criterion, and derives consequences for attributes and lineage. It then examines orbit-based alternatives, branching, behavioral similarity, relational individuation, and evidential warrant. The objective is an entity representation whose mathematical conditions and philosophical commitments remain separately assessable.

7.1 The Reidentification Problem

An entity description lets an inquiry connect claims made at different moments or in different settings. A researcher may ask whether the group that entered an agreement is the group that later exercised its permission, whether a revised document continues an earlier document, or whether a newly configured organization carries forward an earlier commitment. These questions require a way to join appearances while allowing some of their properties to change. A catalogue of currently visible features cannot settle the question by itself, because the significance of a changed feature depends on the criterion of continuity being used.

Consider a stipulated association that changes its meeting place, replaces several participants, and modifies its procedures. A study of its historical activity might follow it through all three changes. A study of the membership cohort could treat replacement of participants as a change of its focal object. A study of the meeting practice might group several otherwise different associations together because they enact the same procedure. These descriptions can be internally coherent while answering different questions. The inquiry needs to state what is being tracked and what a claim of sameness is intended to preserve.

The word *entity* marks a representational role in this paper. It provides a subject to which claims across appearances can be attached. This role is compatible with several positions about the metaphysical status of the represented subject. Ontological suspension keeps those positions available for later argument. It also prevents a mathematical equivalence class from receiving more philosophical authority than its construction supplies.

The distinction matters for the carrier S, which represents configurations of an inquiry. A configuration can describe many participants and conditions together. Conversely, one participant can appear in many configurations. Taking every $x \in S$ to be an individual would identify the overall situation with each object discussed within it. Taking every trajectory to be an individual would import another assumption about continuity. The appearance construction provides a separate domain on which the entity question can be stated explicitly.

7.2 Appearances, Contexts, and Identification

The construction introduces the records needed for the question before assigning identity classes. This order makes additional commitments visible and permits comparison between competing criteria.

Let I be a set of indexed appearances. An appearance is a position in the representation at which a focal object is presented or referred to. It can include a time, context, document reference, or observation source when the inquiry requires those data. The index distinguishes records that would otherwise have the same description. A map

$$p : I \longrightarrow S$$

associates an appearance with a represented configuration. Its mathematical role is modest: it connects entity records to the action framework. Several appearances may have the same image, and the image may contain information about several focal objects.

The appearance domain is itself a modeling choice. It can be constructed from positions in a documented history, versions in a repository, or a declared set of possible manifestations. Each source has a different epistemic status. A possible appearance supplies a place in a model; a recorded appearance

DRAFT

supplies documentary material; an evidentially warranted appearance supports a claim about the case. The mathematics can represent each, provided the interpretation of I remains clear.

Definition 7.1 (Declared entity criterion)**.** Let E be an equivalence relation on I. The represented entity domain is $\mathcal{E} = I/E$, with projection $e : I \to \mathcal{E}$. The assertion iEj records that the inquiry reidentifies appearances i and j under its stated criterion.

Reflexivity assigns an appearance to its own class. Symmetry permits the same identification to be read from either appearance. Transitivity lets a chain of warranted identifications support a single class. These properties make a partition possible: classes either coincide or are disjoint. They also constrain interpretation. A weaker relation of influence or succession may fail symmetry or allow branching that the partition would obscure.

An equivalence can be supplied in several ways. A specified identifier may induce iEj when identifiers agree. A documentary reconstruction may establish pairwise links and assess whether they justify an equivalence closure. A formal model may stipulate classes for an illustration. The resulting partitions can have the same abstract form even when their evidential bases differ. Writing the relation as E records the criterion; its justification belongs to the accompanying argument.

A possible circularity becomes visible at this point. If the input is defined to contain all appearances of an already identified entity, identity has already been used to select the domain. The construction can organize those appearances, but presupposes their initial identification. A stronger reconstruction begins with indexed records whose grouping remains open, states admissible evidence for joining them, and examines the consequences. The framework accommodates either use and requires disclosure of which one is intended.

7.3 Invariant Descriptors and Changing Properties

The quotient provides a subject for invariant descriptions. The following result identifies the appearance-level values that can be assigned to it without dependence on the chosen representative.

Proposition 7.2 (Descent of an entity descriptor)**.** *Let $d : I \to V$ be a descriptor. A map $\bar{d} : \mathcal{E} \to V$ satisfying $d = \bar{d} \circ e$ exists exactly when*

$$iEj \quad \Longrightarrow \quad d(i) = d(j). \tag{15}$$

When it exists, it is unique.

Proof. Suppose first that $d = \bar{d} \circ e$. If iEj, then $e(i) = e(j)$. Applying $\bar{d}$ to the equal arguments gives $d(i) = d(j)$.

Conversely, suppose Equation (15) holds. For $C \in \mathcal{E}$, define $\bar{d}(C)$ to be the common d-value of its members. The class is nonempty, and the condition ensures that any two members give the same value. This proves existence and representative independence. Since $e(i)$ contains i, $\bar{d}(e(i)) = d(i)$.

Every class is the image of an appearance. Any map satisfying the factorization must send that class to its members' descriptor value. Two such maps therefore agree on all of $\mathcal{E}$, proving uniqueness. □

A descriptor that changes within an identity class cannot be an invariant function of the class alone. It can remain an appropriate attribute of the entity at a specified time or context. A change of membership, location, or resources therefore need not defeat an entity criterion. It may show that the attribute's domain needs an extra coordinate.

Let $c : I \to C$ record context and consider $(e, c) : I \to \mathcal{E} \times C$. An attribute $a : I \to V$ factors through the image of this joint map precisely when

$$e(i) = e(j) \text{ and } c(i) = c(j) \quad \Longrightarrow \quad a(i) = a(j).$$

The proof repeats the two directions above with (e, c) in place of e. The resulting value is assigned on represented entity/context pairs. Extending it to every conceivable pair requires further information. If

DRAFT

records disagree even at one such pair, the model can retain conflicting evidence, uncertainty, or a need for finer context.

This distinction blocks an indiscriminate inference from changed properties to changed identity. Such an inference needs a premise making the property identity constitutive. Conversely, an invariant identifier can continue while the object relevant to another inquiry has changed substantially. Identity and descriptive attributes constrain one another through explicit decisions. A convenient database key settles only the identity question built into that database.

Structural type and entity token also differ. A descriptor may assign the same procedural form to several entity classes. Equality of its value groups similar entities. Recovering token identity from the descriptor would require injectivity of $\bar{d}$, which the proposition never assumes. A classification can describe many objects efficiently while remaining insufficient to reidentify an individual object.

7.4 Forward Reachability and Orbit Proposals

The action framework supplies a natural family of reachable configurations. This subsection examines its contribution to continuity and the additional conditions needed for identity.

For a declared subsemigroup $N \subseteq M$, write

$$\mathrm{Orb}_N(x) = \{nx : n \in N\}, \qquad \mathrm{Orb}_N^*(x) = \{x\} \cup \mathrm{Orb}_N(x).$$

The first set collects results of at least one mechanism in N. The second retains the seed. If an identity action is available, the seed may already belong to the first set; otherwise its inclusion requires an explicit convention.

The associated reflexive reachability relation is a preorder. A zero-step continuation gives reflexivity. If $y = mx$ and $z = ny$, then $z = (nm)x$, so composition gives transitivity. These properties track where a configuration can lead. Symmetry requires a path back, which a semigroup action need not supply.

Example 7.3 (Overlapping forward closures)**.** Let $S = \{u, v, w\}$ and let k send every point to v. Then $k^2 = k$, but

$$\mathrm{Orb}_{\{k\}}^*(u) = \{u, v\}, \qquad \mathrm{Orb}_{\{k\}}^*(w) = \{w, v\}.$$

The closures intersect at v while remaining distinct.

Applying k once to either seed reaches v. Further applications stay there. The reflexive closures therefore contain their respective seeds and the common destination. Since u belongs only to the first and w only to the second, the closures differ. Equivalence classes, by contrast, coincide whenever they intersect. These forward closures fail to provide an identity partition.

Two organizations can be represented as reaching a common later configuration because the model retains only a shared outcome. Their common destination leaves several interpretations open: a merger, a coarse observation that discarded their distinction, or an actual identity claim supported by other evidence. The reachability pattern alone leaves the choice unresolved. An entity criterion needs information appropriate to its intended interpretation.

Calling N identity preserving can make the orbit a useful description of transformations undergone by an already identified entity. That description presupposes the identity judgment it might appear to derive. The construction is conditional: given a criterion and mechanisms that respect it, the orbit records reachable configurations. It can contribute to persistence analysis while leaving the criterion's justification visible.

Absence of inverses also leaves the identity question open. An injective forward shift can lack an inverse in the selected semigroup while retaining every difference between starting points. An idempotent operation can collapse distinct beginnings immediately. An entity's history can involve either behavior. Historical continuity, injectivity, reversibility, and identity preservation require separate conditions.

DRAFT

7.5 Directed Lineage, Fission, and Merger

Lineage records directional continuation between appearances and permits branching to remain visible. This subsection derives the constraints that arise when such continuity is identified with equivalence.

Let $L \subseteq I \times I$ record immediate continuation. Its reflexive transitive closure L^* connects appearances by finite lineage paths. An edge may represent organizational succession, document derivation, or another declared continuation. Its meaning remains narrower than a general identity claim unless identity is independently justified.

Proposition 7.4 (Branching consequence of equivalence)**.** *If an equivalence E satisfies iEj and iEk, then jEk. Consequently, keeping two successors in distinct identity classes prevents both from belonging to the predecessor's identity class.*

Proof. Symmetry gives jEi. Transitivity with iEk yields jEk. If the successors occupy distinct classes, at least one proposed identification with the predecessor must be revised. □

The result imposes a structural choice without prescribing a philosophical resolution of fission. An inquiry can treat a predecessor as ending and both successors as new. It can identify one successor as continuing under a privileged criterion. It can preserve shared descent in a lineage description while leaving identity undecided. Its statements must agree with the relation type chosen to represent them.

For example, take

$$I = \{r, u, v, u', v'\}, \qquad L = \{(r, u), (r, v), (u, u'), (v, v')\}.$$

The partition $\{\{r\}, \{u, u'\}, \{v, v'\}\}$ treats the predecessor as ending and two successors as continuing separately. The partition $\{\{r, u, u'\}, \{v, v'\}\}$ privileges one continuing branch. Both accompany the same lineage. Choosing between them requires a criterion beyond the directed graph.

Automatic closure operations supply further alternatives. Mutual reachability under L^* is an equivalence: reflexivity and symmetry are immediate, and concatenating forward and reverse paths proves transitivity. In this acyclic example, however, distinct appearances lack paths back to one another, so the equivalence has five singleton classes. Symmetrizing the edges and taking transitive closure gives one connected component containing all five appearances. The first construction can be too fine for continuity, the second too coarse for distinguishing branches. Mathematical availability alone leaves their adequacy unsettled.

Merger produces a corresponding issue. If two earlier entities are both identified with a common successor, equivalence identifies them with each other. An inquiry that distinguishes them before merger needs to differentiate lineage from identity. It can record the successor's multiple origins without erasing the earlier distinction. The substantive question is what continues: organization, membership, resources, commitments, or a declared combination.

Temporal indexing makes the disagreement articulable. Investigators can agree that a successor inherits something from both predecessors while disagreeing about whether either predecessor continues numerically. Lineage records inheritance directions. Identity records the stronger claim of sameness. Their coordination preserves the disagreement for argument and evidence.

7.6 Behavioral Equivalence and Entity Tokens

Continuation signatures characterize agreement under specified tests. This subsection separates that result from reidentification across appearances and explains how the two tasks can be coordinated.

Section 6 identifies configurations when every declared continuation produces the same observation. Equal signatures justify shared treatment for that prospective observation task. They can support a behavioral type or compressed predictive state. Whether the records concern one entity remains an additional question.

Two stipulated devices can have identical update rules and conditions while remaining separately indexed. Two document copies can have matching content and editing possibilities. Two associations

DRAFT

can occupy the same position in a coarse procedural model. A token-sensitive inquiry can preserve their differences through appearance or provenance records. Behavioral agreement supplies no rule for discarding those records.

The converse is equally significant. An entity can continue under a criterion while its signature changes. An association can gain permission, acquire resources, or lose facility access. If these alterations affect a continuation observation, the signature changes, even when the chosen identity criterion permits the changes. Requiring signature invariance would impose a special persistence criterion under which such changes terminate the entity.

Use separate maps to coordinate the questions. The identity projection e groups appearances by continuity. A behavior map β sends an appearance to the signature of its configuration $p(i)$. The pair (e, β) retains the entity label and behavior at each appearance. It can represent a continuing entity with changed behavior, or different entities with matching behavior, without requiring one map to determine the other.

Dennett's discussion of patterns connects descriptive usefulness with compression and prediction [1]. This comparison motivates attention to what a representation preserves. The present construction adds an independent reidentification task and leaves the metaphysical conclusions of that discussion open.

A stable pattern can contribute evidence for continuity. Making it sufficient requires explaining why this pattern, at this resolution and over this interval, settles the entity question. An account must also address equally predictive descriptions that support different token groupings. The distinction between identity and behavior exposes that obligation while allowing pattern-based theories to supply a further argument.

7.7 Relational Individuation and Boundaries

An entity can be tracked through relations to other objects and conditions. This subsection evaluates that strategy without concealing its dependence on jointly specified records.

A relational description can identify an appearance through participation, commitment, dependence, or derivation. A document's relation to an earlier version can distinguish it from a matching document with another history. An association's commitments and recognition by participants can support continuity. These are proposed forms of evidence whose relevance depends on the target.

Such descriptions encounter mutual dependence. Identifying an entity through its relations requires identifying the relations and their other participants. Identifying a relation through its participants requires tracking those participants. A joint representation can constrain these components together. The distinction is between a coherent joint specification and a claim that one component is uniquely derived from data that already presuppose it.

One approach begins with provisional appearance indices and relational records, then assesses candidate assignments of identity classes and incidence relations. A candidate fails when a required predicate becomes representative-dependent or when its grouping collapses evidentially required distinctions. Several candidates may remain. The result is then a family of admissible reconstructions. Later evidence can narrow the family without pretending that the initial formulation already settled identity.

Boundary selection changes the task. The focal object can be a participant, a group, a working arrangement, or a system including resources and procedures. An alteration internal to one boundary becomes an interaction across another. The action model can represent either choice through a suitable carrier and update maps. Explanatory relevance and evidence must supply reasons for preferring a boundary.

This permits a disciplined plurality of descriptions. Different questions can use different boundaries while each description states what its identity claims preserve. Grounds for criticism remain concrete: descriptor inconsistency, unsupported continuity links, loss of a required distinction, or failure to represent the subject of the inquiry. The availability of several representations therefore leaves substantial room for disagreement and correction.

DRAFT

7.8 Continuity, Potential Efficacy, and Explanation

The motivating intuition combines reidentifiable continuity with the capacity to matter in subsequent activity. This subsection evaluates these components separately before discussing their conjunction.

Continuity relates appearances. Potential efficacy concerns a difference under a continuation or comparison. A stable identity record can be irrelevant to the chosen future observations. A configuration difference can affect those observations while giving little guidance about which entity persisted. The two conditions therefore need distinct representations and warrants.

For a proposed efficacy test, take a defensible comparison (x, y) and a nonempty continuation w. The inequality $o(T_w x) \neq o(T_w y)$ shows that the model distinguishes the configurations under that test. Attributing the contrast to an entity requires an account of how the comparison isolates that entity or a relevant condition. Other differences in resources, rules, or participants leave the source of the effect underdetermined.

Dormant efficacy remains meaningful under an existential test. A permission-bearing organization can have a modeled route to activity that is never exercised. Its absence from an observed sequence leaves the untested potential unresolved. An interpretation depends on admissible continuations, persistence of enabling conditions, and the comparison's empirical warrant. The relation category and the companion historical paper develop those requirements in more detail.

The source intuition also links continuing appearance with withholding a commitment to independent self-subsistence. Here it functions as a research proposal. Its mathematical content concerns tracking continuity and effects through explicit records. A conclusion about the ultimate constitution of the object requires a philosophical argument beyond those records and their algebraic properties.

Historical explanation introduces further information. Explaining a present capacity requires evidence about its formation and transformation. A current identity label or signature can omit those histories. Two organizations with the same present model may have acquired capacity through different sequences. The difference can matter to a historical, causal, or normative question. Keeping current efficacy separate from formation history preserves the possibility of asking those questions.

7.9 Evidence, Revision, and Disagreement

A usable entity representation includes a way to assess its identification claims. This subsection identifies evidence problems left open by the formal construction.

An appearance record can accurately report a local feature while misidentifying its subject. Matching names need not identify one organization; different names can belong to a continuing organization. The evidence task therefore concerns both record reliability and the inference linking records. A naming convention can support that inference when its reliability is justified in the case.

Conflicting records illustrate the distinction between identifier and warrant. Attach sources to appearances and preserve competing identity assignments. The inquiry can then distinguish conclusions shared by all admissible assignments from conclusions dependent on one reconstruction. A definitive identifier assigned too early can conceal disagreement and make downstream calculations appear more certain than their premises.

Revision also differentiates a claim from a record of that claim. Evidence may justify regrouping appearances while the fact that a different grouping was previously accepted remains historically relevant. Preserving both supports inquiry into changing recognition without asserting that the earlier appearances were rewritten. Occurrence, recording, and later interpretation retain their separate roles.

An operational assessment can ask what would justify joining two classes, what would require splitting one, how the criterion handles a changed name or a gap in records, and whether it distinguishes succession from continuation when needed. It should also ask whether the criterion forces attributes to remain invariant that the inquiry needs to examine as changing. Each answer requires domain-specific decisions and a way to retain unresolved cases.

Disagreement then becomes more precise. An investigator can challenge the evidence, the criterion, the appearance domain, or the fit between the criterion and the explanatory purpose. These objections call

DRAFT

for different revisions. An unqualified claim to have derived entity identity would collapse distinctions that the formal result leaves open.

7.10 Coordination with the Other Categories

The entity construction supplies one part of the six-category framework. This subsection states how that part connects to the others and what a successful application would establish.

Entity classes can support context-sensitive attribute descriptions. Appearances can participate in relational incidence records. Event tokens can index occurrences involving those appearances. Process histories can connect successive configurations, while a state description retains conditions relevant to a declared prediction. These links let an inquiry ask several questions about a continuing subject without forcing every answer to follow from one quotient.

The formal tasks remain distinguishable. Equivalence supplies a partition. Descriptor descent identifies invariant class-level information. Lineage preserves direction and branching. Signatures retain agreement under chosen tests. Evidence supports or challenges their interpretation. A successful application coordinates those tasks and demonstrates why its criterion serves a concrete question.

Stronger philosophical theories of identity, persistence, and selfhood can propose privileged criteria or criticize this separation. Their conclusions enter through argument. The present constructions expose their consequences and countercases while keeping the original inquiry visible.

8 Historically Formed Relations and Potential Effects

This section develops the relation category through three connected questions: how participants are represented, how a dependence is historically formed, and how it can matter for later activity. It first constructs contextual incidence, then examines the base-definable order predicate and a comparative potential-effect test. The philosophical discussion concerns relational individuation, dormancy, persistence, and the evidence needed for causal interpretation. The proposed account remains a focal research criterion rather than a definition of every mathematical or social relation.

8.1 The Focal Relational Question

A mathematical relation can be any subset of a product of domains. That broad usage permits precise representation of many patterns, including similarity, order, participation, and dependence. The research question here is narrower. It concerns a relatively reidentifiable dependence that has a formation history and can affect subsequent activity.

The motivating insight joins two directions of inquiry. Relations are historically formed, and they can participate in further historical formation. The first direction asks how an arrangement came to obtain. The second asks which later possibilities depend on its presence, alteration, or removal. The two directions can interact while requiring different evidence and formal records.

A stipulated agreement illustrates the distinction. Its participants can be represented through appearance indices. Its formation can be represented by a history of proposals and authorization. Its present role can be represented by a permission condition. Its potential effect can be tested through a continuation whose availability or result depends on that condition. None of these components alone supplies the entire relational account.

The category also leaves evaluation open. A dependence can enable cooperation, sustain an unwanted arrangement, constrain a participant, or preserve an existing practice. Potential efficacy identifies a role in the declared dynamics. An appraisal requires further premises about purposes, interests, and justification. Generative and reproductive roles can each have several evaluations depending on the case.

DRAFT

8.2 Participants and Contextual Incidence

A social relation needs a representation of its participants or conditions. This subsection constructs incidence and derives the requirement for describing it at an entity level.

Let I be the appearance domain and let E be a declared identity equivalence, with projection $e : I \to \mathcal{E}$. For a fixed finite arity n, let

$$R \subseteq I^n$$

record an incidence predicate. The tuple positions can have different roles, such as issuer, recipient, or object of an authorization. Binary notation is a special case; the framework imposes no requirement that every relation have two participants.

Suppose the inquiry wants a predicate on entity classes, $\bar{R} \subseteq \mathcal{E}^n$. The intended exact descent condition is

$$R = (e^n)^{-1}(\bar{R}).$$

This says that the appearance predicate can be recovered from the entity-level predicate without losing its truth conditions.

Proposition 8.1 (Incidence descent)**.** *Such a predicate $\bar{R}$ exists exactly when coordinatewise replacement by E-equivalent appearances preserves membership in R.*

Proof. If R is the displayed inverse image, coordinatewise equivalent tuples have equal e^n projections and therefore equal membership truth.

Conversely, assume replacement invariance. Define $\bar{R}$ on a tuple of entity classes by the R-value of any representative tuple. The assumption makes the value independent of representatives. Pulling the predicate back then recovers R. □

The condition can fail for historically changing participation. One appearance of an entity may belong to an agreement and a later appearance may follow its withdrawal. An entity-only predicate would assign one value to both appearances. Retaining a time or context argument permits the relation to change while the entity criterion remains fixed.

Existential projection is another option: an entity tuple is related when some representative tuple belongs to R. This always supplies a quotient-level predicate, but its pullback can be larger than R. It changes the statement from participation at this appearance to participation at some appearance. The difference matters to claims about present authorization or historical membership.

Incidence therefore performs one clear task: it identifies participation at a declared level. Historical formation and potential effect require additional structures. An incidence table can record who stands in a relation while leaving how it arose and what it enables unresolved.

8.3 Relation Tokens and Relational Types

A relation can persist, be renewed, or recur between the same participants. This subsection distinguishes a general relational type from a particular historically tracked arrangement.

A predicate such as participation in an agreement can classify many arrangements. Two agreements between the same parties may have different formation histories, scopes, or durations. Conversely, one continuing arrangement may change some terms while remaining reidentified under a chosen criterion.

An occurrence or relation-record index can retain those distinctions. Let Λ index proposed relational arrangements and attach participant, context, and formation records to each index. A classification map can send several indices to the same relational type. The map's image retains the type while its domain retains the separate arrangements.

The indexing does not establish their identity by itself. Reidentifying one arrangement through renewal requires a criterion, just as reidentifying an entity does. The criterion might concern continuing commitments, a declared institutional record, or another warranted feature. The model can represent the criterion and test its consequences without treating it as self-evident.

DRAFT

A relation can also change arity or participant roles in an extended model. Fixed-arity incidence then captures only one stage or one selected description. A more general record can retain a role-indexed participant assignment. That extension adds flexibility while introducing new questions about comparison across stages.

These distinctions prevent a relational type from absorbing its historical tokens. Two arrangements can share an extensional participant pattern and differ in provenance. A present type description can support one prediction while leaving a historical question unanswered. The historical-relations paper develops that record-sufficiency problem directly.

8.4 Order Effects in the Abstract Base

The base action supplies an exact predicate for order-sensitive effects. This subsection derives its scope and tests a broader relational reading.

For $m, n \in M$ and $x \in S$, define

$$R_{\text{ord}}(m, n, x) \quad \Longleftrightarrow \quad (nm)x \not\sim (mn)x. \tag{16}$$

The predicate compares two orders from one seed under the same equivalence. Its symbols belong to the base language, so it is explicitly definable there.

A simple numerical example uses $a(x) = x + 1$ and $b(x) = 2x$ with ordinary equality. Then $ba(x) = 2x + 2$ and $ab(x) = 2x + 1$. The order predicate holds at every input. The calculation establishes order dependence without assigning a particular social meaning to either map.

Commuting operations give a complementary countercondition. The translations $a(x) = x + 1$ and $c(x) = x + 2$ both affect the same coordinate, yet $ca(x) = ac(x) = x + 3$. A shared target of action therefore need not produce noncommutativity. Likewise, two prerequisite-setting operations can commute while jointly enabling a later activity.

The predicate is thus neither a necessary nor a sufficient criterion for a particular social relation. It can be a useful witness when the interpretation of the maps and outcome distinction is independently supplied. It leaves friendship, authorization, dependence, or another substantive meaning open.

The locality in x also matters. Two operations can commute at one configuration and differ at another. A global statement quantifies over the carrier; a local witness concerns one selected seed. An empirical comparison must identify which configurations are relevant and accessible rather than treat a local result as a universal law.

8.5 Historical Formation and Present Representation

A relation's formation history can be compressed into present conditions for some tasks. This subsection explains why that possibility preserves the historical question rather than settling it.

Let a word $w = b_1 \cdots b_k$ represent a candidate formation sequence from a seed. Its endpoint can contain a record that the relation currently obtains. Another word can produce the same endpoint. The present state can therefore be sufficient for a future operational prediction while failing to recover which formation sequence occurred.

Consider two labels n and i with identical maps that set an authorization coordinate to 1. They can be interpreted in a stipulated example as negotiated and imposed formation. Their effects agree on the chosen carrier while the labels retain different histories. A calculation using only the common endpoint cannot recover the label.

This is an underdetermination argument. Keep the base data and endpoint fixed while varying the formation record. Any function of the fixed data returns the same value in both cases. A target query that distinguishes the histories therefore requires richer input. The result identifies a representational limit; it does not claim that formation history is always inaccessible.

Historical formation also differs from dependence on information omitted by the present state. A sufficiently rich current state can encode every condition needed for the selected future task. The ar-

DRAFT

rangement still has a history. A statement that it was historically formed therefore does not imply failure of a present state description.

The distinction supports two legitimate research directions. One can ask which historical information must be retained for future updates. One can ask what happened in the formation of an arrangement even when that information is redundant for the selected prediction. A comprehensive relational model keeps both directions available.

8.6 Potential Effects under Declared Continuations

Potential efficacy concerns a comparison of possible futures. This subsection states the relevant domains and explains the positive-length condition.

Fix total operation maps T_b, an observation $o : S \to Y$, and a set $\mathcal{C} \subseteq S^2$ of admissible comparison pairs. For a word w, write $\sigma_x(w) = o(T_w x)$.

Definition 8.2 (Comparative future-effect witness)**.** For $(x, y) \in \mathcal{C}$, a nonempty word $w \in B^+$ is a future-effect witness when

$$o(T_w x) \neq o(T_w y). \tag{17}$$

Potential efficacy under the declared tests requires at least one such witness.

The positive-length requirement separates a present distinction from a future effect. Let the observation distinguish two current states, while the only operation resets both to one common state. The present observations differ, but every nonempty continuation agrees. A definition using only current inequality would count a different property.

The condition is existential. It leaves open whether the witness is ever enacted. It also permits other continuations to erase or bypass the distinction. Requiring different outcomes under every continuation would impose a stronger criterion and exclude many dependence patterns that can matter under some relevant circumstances.

The comparison set $\mathcal{C}$ carries substantive information. It identifies which alternative configurations can be compared meaningfully. A pair that differs in many respects can witness a predictive difference without isolating the relation under study. A causal interpretation needs a justified design for the contrast.

The operation repertoire and observation likewise constrain the result. A test can fail to reveal a difference because its observation is too coarse, its repertoire omits the relevant continuation, or the relation has no effect under those declared conditions. The formal witness separates these possibilities only when the model retains the relevant distinctions.

8.7 Dormancy, Erasure, and Availability

A relation can affect access to a route or remain unused throughout an observed history. This subsection examines those cases through the declared comparison.

A permission can be represented by a condition that enables an activity. Comparing otherwise specified configurations with and without that condition can yield a distinguishing continuation. The permission's effect remains potential if the activity is never attempted. The absence of an observed enactment leaves that potential unresolved.

An erasing operation can remove the condition before the distinguishing test. The resulting actual sequence may therefore show no difference. This is compatible with an earlier potential witness. The interpretation must specify the time at which the comparison is made and the conditions that persist during the test.

Availability can itself be the relevant difference. For partial operations, let $W(x)$ contain the words whose every prefix is executable from x. Use a fresh marker $\perp$ and define

$$\widehat{\sigma}_x(w) = \begin{cases} o(T_w x), & w \in W(x), \\ \perp, & w \notin W(x). \end{cases}$$

DRAFT

A word executable in one configuration and blocked in another gives a signature difference even when every commonly executable word has matching observations.

The marker records a testing convention. It can represent modeled unavailability, not an ordinary social outcome. A physical failed attempt or observable refusal requires the corresponding transition or occurrence record. Comparing these interpretations is part of the model's adequacy audit.

An inquiry that considers only the intersection $W(x) \cap W(y)$ omits availability differences. That restriction can be appropriate for comparing outcomes under shared opportunities, but it changes the question. A relational account of access needs to preserve the difference between available and unavailable continuations explicitly.

8.8 Relational Persistence and Change

A historically formed relation can persist while some of its participants, terms, or effects change. This subsection identifies the criteria needed to describe that continuity.

Persistence is a reidentification claim. It asks whether appearances of an arrangement belong to the same tracked relation under a declared criterion. Repeating an incidence pattern can support that claim while leaving open whether the arrangement was renewed, replaced, or independently recreated.

A relation's current extension can also change while its institutional or practical continuity is retained. A group can admit a new participant or revise a permission. Whether the result is the same relation, a modified relation, or a new arrangement depends on the criterion of tracking.

The model can keep these decisions visible through relation-record indices, contextual incidence, and histories. A single invariant predicate may be too coarse when the inquiry needs changing terms. A fresh relation index after every update may be too fine when continuity is central. The appropriate representation needs an argument about the kind of persistence at issue.

Potential effects can persist, vanish, or become observable under a changed repertoire. These are different claims from relation identity. One continuing agreement can lose an operational effect; two distinct agreements can have matching effects. A comprehensive account therefore tracks relation continuity and prospective behavior through separate components.

8.9 Causal Interpretation and Evidence

An observational difference is a formal witness. This subsection explains the further work needed to interpret it causally or historically.

The comparison in Equation (17) shows that the model distinguishes two configurations after the same word. Attributing the difference to one relation requires assumptions that isolate its role. Other differences between the configurations can account for the observation.

The historical question likewise needs evidence. A present authorization record may be compatible with several formation histories. Naming a history in the model makes it available for analysis, but the claim that it occurred depends on records, testimony, or other appropriate sources.

These obligations can interact. A formation history may explain why a present condition has the efficacy assigned to it. A present effect can motivate investigation of the history. Neither direction licenses an automatic inference. The account must state which premises support the transition between historical and prospective claims.

Counterfactual tests can also depend on the stability of other conditions. Removing one relation may alter participants, rules, or resources rather than leave everything else fixed. A proposed comparison must explain why its alternative configurations are admissible for the causal question. The set $\mathcal{C}$ records the choice; evidence and theory justify it.

The formalism remains useful under this restraint because it exposes the required comparison. It distinguishes a mathematical difference, a historical reconstruction, and a causal attribution. An application can then identify which parts are established and which remain hypotheses.

DRAFT

8.10 Relational Explanation and Philosophical Scope

The relational category gives dependence a central explanatory role while retaining the conditions of that explanation. This subsection examines its philosophical implications.

A relation can help explain why a participant has a capacity in one context and lacks it in another. The explanation locates the difference in a structured arrangement rather than treating the capacity as an invariant isolated attribute. The model supports that move when its variables and comparisons represent the arrangement adequately.

The explanatory direction need not deny that participants have other properties. The same configuration can include individual conditions and relational conditions, with their interaction specified by the update rules. The question is which distinctions are required for the phenomenon being studied.

Relational individuation can also shape entity descriptions. An organization's commitments and dependencies can contribute to its reidentification. The entity and relation criteria may then be jointly specified. Coherence of the joint specification is a mathematical and conceptual requirement; uniqueness and empirical warrant require further argument.

The present account suspends the claim that relations are metaphysically prior to all relata. It permits a research program to investigate how represented units emerge or become identifiable through activity and dependence. Such an investigation must show its constructions and evidence rather than assume the desired priority in its choice of primitives.

The distinction preserves the original insight about historical formation while making it testable. A relation can be investigated through its formation record, continuity, incidence, and possible effects. Each component can be challenged, refined, or found inadequate without forcing a decision about the entire ontology.

8.11 Relation Use in the Coordinated Framework

The relation category connects participants and conditions across historical and prospective questions. This subsection states what a successful application needs to coordinate.

Entity appearances provide participant references. Events identify formation, exercise, renewal, or withdrawal occurrences. Attributes describe terms and conditions. State descriptions retain present dependencies. Process histories record how the arrangement developed. The relation account joins these records to a declared potential-effect comparison.

A successful model must specify its incidence domain, relation identity criterion, formation query, observations, operation repertoire, and admissible comparisons. It must explain which parts are given, which are constructed, and which are evidenced. Where current effects and historical identity diverge, it must preserve both questions.

This makes the relational account comprehensive at the level of its intended task. It combines a formation question with a future dependence question while retaining their distinct formal and evidential requirements.

9 Event Occurrences and Transition Descriptions

This section develops the event category by distinguishing a possible transition, an occurrence, and a record of that occurrence. It constructs the required maps, derives the loss of multiplicity under effect compression, and examines how exact counting changes an idempotent model. The later discussion concerns attempts, event boundaries, temporal resolution, and evidential revision. The objective is to represent a happening without allowing a formula for its possible effect to substitute for the claim that it occurred.

DRAFT

9.1 Happenings within an Action Framework

An action model states what a mechanism would do at a represented configuration. Given $x \in S$ and a mechanism $m \in M$, the expression mx identifies the modeled result. The triple (x, m, mx) therefore describes a candidate transition. The same base is compatible with different occurrence histories: the mechanism may be applied once, repeatedly, or remain unused. The distinction between those histories requires information beyond the action map.

Social inquiry often needs precisely that additional information. A permission may be issued, renewed, refused, or merely proposed. Several meetings may enact the same procedure. Two attempts may have matching outcomes while differing in timing, participants, and significance. A model that retains only the input and final condition can answer an effect question while leaving those occurrence questions open.

The occurrence distinction remains relevant even in a wholly stipulated example. A simulation can declare a sequence of executed labels and count its positions. A counterfactual analysis can declare several possible sequences while selecting none as actual. An empirical study can reconstruct a sequence from records. The same word notation can appear in all three settings, so its epistemic role must be stated.

An event category accordingly requires a criterion of occurrence and a criterion of individuation. The first concerns whether the happening belongs to the selected history. The second concerns whether two descriptions refer to one happening or to separate happenings. A transition formula contributes a consistency condition for the modeled effect. It leaves occurrence and individuation available for their own evidence and argument.

9.2 Occurrence Indices and Record Maps

The following construction places occurrence information alongside the base dynamics. Its domain carries token distinctions while its image records the transition description.

Fix an operation alphabet B with maps $T_b : S \to S$. Let Ω be an index set of represented occurrences. Write

$$d : \Omega \longrightarrow S \times B \times S, \qquad d(\omega) = (x_\omega, b_\omega, x'_\omega).$$

The middle coordinate identifies the represented operation. The first and third identify the initial and resulting configurations.

Definition 9.1 (Consistent execution record)**.** An occurrence record d is execution-consistent with the declared total maps when

$$x'_\omega = T_{b_\omega} x_\omega \qquad (\omega \in \Omega). \tag{18}$$

An occurrence criterion separately specifies what membership in Ω means for the inquiry.

Equation (18) can be checked by substitution. It says that the recorded transition agrees with the action model. Agreement establishes internal consistency. Establishing an actual event requires a warranted interpretation of the occurrence index and its source records. A model can consistently describe a sequence that was never enacted.

The map d need not be injective. Distinct occurrence indices can map to the same triple. This allows repeated executions to remain distinct even when their recorded conditions and effects match. Conversely, one occurrence can have several records. To represent that distinction, introduce a record domain $\mathcal{R}$ and, when warranted, a map

$$r : \mathcal{R} \longrightarrow \Omega.$$

Several documents can then refer to one occurrence. Their multiplicity belongs to $\mathcal{R}$; event multiplicity belongs to Ω.

The map r may itself be uncertain. A practical inquiry can retain candidate assignments or a relation between records and possible occurrences. Forcing a total definitive assignment would assert that each record has already been identified with a particular happening. A representation of uncertain evidence should expose that assumption or use a suitably partial or set-valued relation.

DRAFT

Times, participants, locations, and source references can be attached to ω through further maps. Each supplies a possible basis for distinguishing occurrences, but none is universally sufficient. Matching timestamps can accompany simultaneous distinct events. Different timestamps can record different stages or reports of one event. A participant list can remain unchanged across repeated enactments. The occurrence index provides a formal place to retain the intended distinction; evidence must justify its use.

9.3 Transition Types and Event Multiplicity

The image of the occurrence map classifies represented transitions. This subsection derives the information lost when only that image is retained.

Suppose a finite occurrence domain contains two distinct indices ω_1, ω_2 with

$$d(\omega_1) = d(\omega_2) = (x, b, x').$$

The image contains one transition description, while the domain contains two occurrences. A second record system containing only ω_1 has the same image. The two systems therefore agree about which transition types are represented and disagree about how often the transition occurred.

Proposition 9.2 (Multiplicity loss under image reduction)**.** *The set $d(\Omega)$ alone generally fails to determine the cardinality of a finite occurrence domain Ω or the multiplicity of a transition description within it.*

Proof. Choose any consistent transition triple t. A one-element domain and a two-element domain can each map constantly to t. Both images equal $\{t\}$, whereas their domain cardinalities and the multiplicity of t differ. Any function of the image alone would have to assign the same answer to both systems. It therefore cannot recover both counts. □

A multiset representation can preserve more information than an ordinary set image. For a finite domain, define

$$n(t) = |\{\omega \in \Omega : d(\omega) = t\}|.$$

The multiplicity function retains the count of each represented type, while still discarding the identity and other attributes of its individual occurrences. If timing or responsibility matters, the occurrence records remain necessary. There is consequently a sequence of increasingly coarse descriptions: indexed records, type multiplicities, and the set of represented types.

These reductions suit different questions. A catalogue may need only which procedures have ever been used. A workload study may need how often each procedure was used. A historical analysis may need who participated in particular enactments and in what order. The appropriate representation follows from the question. Calling each of them an event description without specifying its retained information would make their answers appear interchangeable.

The proof also shows why an elaborate notation can conceal a simple loss. Adding a symbol for the set of events to an endpoint model does little if the symbol is defined only as a set of transition types. The occurrence domain has to carry the distinctions that later questions require. Those distinctions may be supplied through recorded sequence positions, independent identifiers, or another justified indexing rule.

9.4 Repeated Applications of an Idempotent Operation

Idempotence provides a particularly sharp test because it identifies repeated effects while leaving repeated applications conceptually available. This subsection derives the incompatibility and constructs an explicit repair.

Suppose $T_b^2 = T_b$. Applying b twice has the same final effect as applying it once. A flag-setting operation is a simple example: $T_b(z) = 1$ on a Boolean carrier. One application and two applications both leave the flag at 1.

DRAFT

Let words retain application positions, with b^k denoting k applications. The count $c(b^k) = k$ distinguishes b and bb. Their effect representation identifies them:

$$T_b = T_{bb}, \qquad c(b) = 1, \quad c(bb) = 2.$$

A count function of the total effect alone would therefore receive equal arguments and need to return different values.

Proposition 9.3 (Counting and idempotent compression)**.** *If a product or effect representation identifies b with bb, exact application count fails to factor through that representation. On $S \times \mathbb{N}$, the update*

$$\widetilde{T}_b(x, n) = (T_b x, n + 1) \tag{19}$$

retains application count and projects to the old effect, but it fails the idempotent equation.

Proof. For the first statement, a factorization $c = \bar{c} \circ e$ would imply $c(b) = c(bb)$ whenever $e(b) = e(bb)$. The counts 1 and 2 contradict that implication.

For the extension, apply Equation (19) twice:

$$\widetilde{T}_b^2(x, n) = (T_b^2 x, n + 2) = (T_b x, n + 2).$$

One application gives $(T_b x, n + 1)$. The natural-number coordinates differ, so $\widetilde{T}_b^2 \neq \widetilde{T}_b$. Finally, projection pr_S satisfies

$$\mathrm{pr}_S \circ \widetilde{T}_b = T_b \circ \mathrm{pr}_S,$$

showing that the visible effect on S is preserved. □

The repair changes the information and the algebra together. Freely composed words act consistently on the enlarged carrier because each application increments the counter. Imposing the old equation $b^2 = b$ on the enlarged transformations would erase that count. The model therefore needs to distinguish an effect semigroup from a history-sensitive action. Each is coherent, and their connection is the projection that forgets count.

This example gives a general methodological lesson about enrichment. Adding a variable is mathematically consequential when the variable records distinctions previously identified by an algebraic law. A proposed enrichment should be checked against the old equations, rather than assumed to preserve them automatically. The same issue arises for duration and intermediate-state records in the process category.

The counter also remains interpretation-relative. It can count attempts, successful completions, or documented reports, depending on which updates increment it. An attempt counter and a completion counter need different update rules when an action can fail. Repeated reports can inflate a documentary counter without changing an occurrence counter. The equation records exactly what the increment rule specifies and leaves its empirical warrant open.

9.5 Quotient-Silent Events

A state description can treat an occurrence as silent when it leaves the selected observation unchanged. This subsection explains why that classification is a property of the description and event criterion.

For a quotient map $q : S \to Q$, a transition is silent at that resolution when $q(T_b x) = q(x)$. Silence means that this quotient records the same class before and after the operation. Another observation can distinguish the configurations, and an occurrence index can distinguish the application even when the carrier point itself remains fixed.

A stipulated renewal illustrates the issue. Let a Boolean flag indicate whether a permission is currently recorded. A renewal applied while the flag is 1 leaves it at 1. If the inquiry concerns current permission alone, the transition is silent. If it concerns how often the agreement was renewed, who endorsed the renewal, or when its evidential record was updated, the occurrence can be central. Those questions require additional observations or occurrence records.

DRAFT

A failed attempt can likewise matter despite an unchanged outcome. The model may record that a participant tried to activate a mechanism, that a prerequisite was absent, and that the selected outcome remained unchanged. The attempt, refusal, and unchanged state have distinct descriptive roles. A definition that counts only changed quotient outcomes selects a narrower event category. It should state that selection explicitly.

The converse also holds: a change in recorded state can reflect a revised observation rather than a newly occurring event in the target history. If an investigator corrects an earlier record, the research database changes. The target event may have occurred earlier. A model of the investigation and a model of its subject then have different carriers and update meanings. Their alignment requires explicit maps or provenance relations.

This distinction is philosophically important because event significance often depends on the question under which a happening is described. The mathematics can show that an update is silent relative to a map. It cannot establish that the occurrence is insignificant in every respect. Equally, adding a counter can make every application visible, but visibility alone supplies no criterion of social importance.

9.6 Attempts, Blocking, and Completion

An event representation needs a clear convention when an operation is unavailable or its attempt fails to achieve the target. This subsection compares three modeling choices.

A total map can encode a failed attempt by leaving the configuration unchanged. This is appropriate when the intended rule specifies a self-loop under unmet prerequisites. The self-loop remains an executed application in the model, even though the selected state is unchanged. An occurrence record or attempt counter can retain it.

A partial map can encode successful executability through its domain. For x outside that domain, the operation has no modeled result. This convention expresses unavailability, and it leaves the effect of attempting the unavailable operation unspecified. An application that needs to discuss refusal, discovery of blockage, or sanctions for an attempt must supply an additional transition or record type.

A totalized partial map introduces a special blocked marker. That marker can distinguish availability failure from an ordinary outcome. Its interpretation requires care: it may record a failed test, a terminal analysis state, or an observable refusal. Each meaning places different demands on subsequent dynamics. An absorbing marker, for example, says that later modeled operations remain blocked after the failure. That is a substantive testing convention whose adequacy must be justified for the question.

These representations can agree about successful routes while differing about failed attempts. A comparison between models should therefore identify which event class is being compared. Counting successful applications in a partial model and counting every attempted label in a totalized model can produce different totals without any mathematical inconsistency. The counts answer different questions.

A comprehensive event record can declare an outcome type such as completion, refusal, interruption, or unresolved attempt. These labels remain proposed coding choices. Their relation to observed evidence, institutional categories, and the modeled state transition must be specified separately. Adding a label for success does not prove that the intended target was achieved.

9.7 Event Boundaries and Temporal Resolution

The beginning, end, and granularity of an event determine its occurrence domain. This subsection examines how changing those boundaries affects counting and interpretation.

A meeting can be represented as one event, a sequence of agenda events, or a process containing many individual contributions. The choice depends on what the inquiry needs to distinguish. A process model retains intermediate states; an event-level compression may retain only its overall transition. The two can be coordinated by a segmentation map that groups finer occurrences into coarser units.

Such grouping adds information. An ordered sequence alone can have several segmentations, each with the same total effect. A grouping criterion might concern a common purpose, an institutional procedure, a temporal interval, or a continuous activity. Each criterion can be debated. Associativity

DRAFT

guarantees consistency of composite effects when grouping changes, while leaving the intended event boundaries undetermined.

Temporal resolution can also alter the appearance of simultaneity. Events that receive one coarse timestamp may be sequential at a finer resolution. Events known to overlap may resist a faithful representation by a single total order. A word model can impose an order for analysis, but its empirical significance requires justification when operations fail to commute.

For two operations a, b, equality $T_b T_a = T_a T_b$ can make the endpoint insensitive to their ordering. It leaves the occurrence order unresolved. The same final effect can arise from two different sequences, and the difference may matter to a historical explanation. When the operations fail to commute, uncertainty about order can imply uncertainty about the predicted endpoint as well.

A partial-order event record offers another possible extension. It can preserve known precedence constraints while leaving unrelated events unordered. To derive an endpoint from it, the model must explain how linear orders consistent with those constraints are evaluated and whether they agree. Agreement can follow from suitable commutation assumptions, but those assumptions need proof for the specified maps. This paper retains the sequential base and records the partial-order extension as an explicit modeling obligation.

9.8 Occurrence Evidence and Reconstruction

An event formula becomes part of an empirical inquiry through evidence. This subsection identifies the gap between internal consistency and warranted reconstruction.

A log entry can support the claim that a system recorded an operation. Its relation to a real-world completion depends on how the log is generated. A proposal document can support an intention without proving execution. A retrospective account can describe an event while requiring corroboration about timing or participants. These are generic evidence problems; an application must examine the particular source mechanism.

One can formalize the reconstruction task without pretending to have solved it. Let H be a declared space of candidate histories and let $\rho : H \to Z$ record the information retained by the investigation. An event-count query $g : H \to \mathbb{N}$ is exactly recoverable from ρ when it is constant on each record fibre. Different histories with the same record and different counts witness failure of exact recovery. The condition identifies the information requirement while leaving evidence about the actual history open.

A reconstruction can remain useful when exact recovery fails. The set of counts compatible with a record expresses the unresolved alternatives. Additional independent records can narrow that set when their interpretation is justified. Assigning probabilities would add another layer of assumptions; the set of alternatives alone supplies no frequency or likelihood.

The same distinction applies to event identity. Two reports may be compatible with either one jointly reported event or two matching events. A model that retains both possibilities makes the uncertainty visible. A single merged event index suppresses it. The appropriate choice depends on the evidence and the inferential purpose, not on the convenience of a compact event table.

Revision of an event reconstruction should preserve the earlier record when that record has historical relevance. Correcting a count or participant assignment changes the current representation. It also creates a new occurrence in the inquiry's own history: a correction was made on the basis of particular evidence. Keeping those levels separate supports a clear account of what changed and why.

9.9 Philosophical Role of the Event Category

The formal distinctions support a philosophical account of occurrence without settling a general metaphysics of events. This subsection states what the construction contributes and where further argument would be required.

The event category permits reference to a happening that has a place in a history. Its identity can depend on a declared boundary, a continuity criterion, and a relevant description. The action framework specifies the transformations associated with a possible happening; the occurrence domain speci-

DRAFT

fies which tokens the inquiry considers. Their combination supports claims about repetition, order, and participation that an endpoint alone cannot express.

A single occurrence can receive several descriptions. An enactment may be described through its physical procedure, its authorization role, or its effect on a record. The model can attach several attributes to one occurrence index while retaining the possibility that some descriptions refer to distinct subevents. Whether they should be joined or separated depends on the event criterion and evidence.

This creates a relation between event and process categories. An event can be analyzed internally as a process. A process can be compressed into one event for a coarser inquiry. The mathematical consistency of the compression concerns its retained effects and records. Its philosophical adequacy concerns which changes, reasons, and meanings the inquiry needs to explain. A useful event boundary is justified through those purposes and can remain revisable.

The category also clarifies the status of actuality. A possible transition, an intended action, a documented attempt, and a completed occurrence occupy different places in an argument. Moving between them requires premises. The framework exposes these transitions by giving each a distinct representational component and avoiding an automatic inference from a map's existence to its enactment.

9.10 Event Use in the Coordinated Framework

The event category contributes indexed happenings to the six-category account. This subsection connects that contribution to the rest of the model and identifies the required adequacy checks.

Entities can participate in occurrences through appearance indices. Relations can be formed, exercised, or modified through recorded events. Attributes can classify event types or report conditions at their occurrence. State descriptions specify before-and-after distinctions. Processes preserve sequences and intermediate configurations. The event domain supplies the token distinctions needed to coordinate these uses.

A successful application must declare what counts as an event, how occurrence indices are warranted, which repeated applications remain distinct, and how blocked or silent attempts are treated. It must check that any enriched variables respect the algebra it continues to use. It must also explain what information is lost when records are reduced to types, counts, or effects.

These requirements make the event category more than a transition triple. The triple remains essential for the action model, while occurrence, individuation, and evidence determine how that possible transition enters an account of social history.

DRAFT

10 Attribute Descriptions and Classification Commitments

This section develops attributes through the mathematical question of assigning a predicate or value at a declared descriptive level. It derives the condition under which an attribute descends to a quotient, extends the result to partial information, and examines overlapping classifications and numerical scales. The philosophical discussion concerns the difference between a coding rule, the constitution of a status, and the evidence for an assignment. The objective is to make the information supplied by an attribute explicit rather than conceal it in the notation.

10.1 Subjects and Descriptive Levels

An attribute says something about a subject under a description. That subject can be a configuration, an entity at a time, an event occurrence, or a process record. Its domain is therefore the first modeling decision. A value assigned to a current configuration can change while an entity continues. A value assigned to an event can remain historically fixed while later evidence about it changes. A value assigned to a process can depend on intermediate steps that its endpoint omits.

The carrier S supplies one available domain. A quotient $Q = S/\sim$ supplies a coarser domain when the inquiry treats equivalent configurations alike. An appearance domain supplies context-sensitive sub-

jects. The choice matters because a well-defined function must assign one value to each input. If the input merges cases that require distinct values, the attribute needs a finer domain or a different representation.

Consider a stipulated permission classification. A configuration may include whether a permission is recorded. A current-state attribute can read that coordinate. An entity-only attribute would additionally require the permission value to remain invariant across all appearances of the entity. An entity/time attribute can retain its variation. These representations can use similar verbal labels while making different claims about their subjects.

The six-category framework therefore treats an attribute's domain as part of its meaning. A statement that a group is authorized differs from a statement that a particular record classifies the group as authorized. The two can coincide under appropriate rules and evidence. Their coincidence is a further claim, and a model should retain enough structure to state it rather than assume it through a shared variable name.

10.2 Boolean Predicates and Value Maps

The first construction represents a declared classification on the quotient. Its simplicity makes the added information particularly clear.

For $U \subseteq Q$, define

$$a_U : S \longrightarrow \{0,1\}, \qquad a_U(x) = \mathbf{1}_U(q(x)). \tag{20}$$

The map assigns 1 to configurations whose quotient class belongs to U, and 0 to the others. It is constant on every $\sim$-class because equivalent inputs have the same quotient image.

A value-valued attribute uses a map $f : Q \to V$ and defines $a = f \circ q$. The codomain can contain names, categories, numbers, or structured values. Calling the values numbers adds arithmetic notation, but the meaningful operations on them depend on the intended scale. A set of numbered categories can still carry only a nominal distinction.

The subset U and the map f supply information. The quotient alone does not select which of its classes count as authorized, isolated, resilient, or relevant to another substantive property. A particular classification may be defined through the base language and declared parameters. A freely supplied classification is a legitimate enrichment when its origin and interpretation are stated.

This distinction affects claims of derivation. Showing that an attribute can be represented by an indicator proves a representational possibility. It leaves the membership criterion for U open. Deriving a substantive attribute requires an argument that determines its membership from specified data or rules. The indicator formula then expresses that criterion's result; it cannot replace the argument selecting the criterion.

10.3 Descent from Configurations to Quotient Classes

A proposed attribute may initially be defined on the full carrier. This subsection derives the exact condition for retaining it at the quotient level.

Proposition 10.1 (Attribute factorization)**.** *Let $a : S \to V$. There exists a map $\bar{a} : Q \to V$ satisfying $a = \bar{a} \circ q$ exactly when*

$$x \sim y \quad \Longrightarrow \quad a(x) = a(y). \tag{21}$$

The map $\bar{a}$ is unique when it exists.

Proof. If $a = \bar{a} \circ q$ and $x \sim y$, then $q(x) = q(y)$. Applying $\bar{a}$ gives $a(x) = a(y)$, proving necessity.

For sufficiency, define $\bar{a}([x]) = a(x)$. If $[x] = [y]$, Equation (21) gives $a(x) = a(y)$. The definition therefore does not depend on the representative and satisfies $\bar{a}(q(x)) = a(x)$.

Every quotient class has a representative. Any factorization must take that class to its representative's a-value. This determines $\bar{a}$ uniquely. □

DRAFT

For a Boolean attribute represented on S by a subset A, the condition says that A is a union of $\sim$-classes. If one member of a class belongs to A, every equivalent member must belong. This saturation requirement makes explicit what a quotient classification assumes.

Failure of the condition has several possible responses. The inquiry can refine the equivalence so that distinct attribute values remain separate. It can change the attribute's target, perhaps by reporting a set of possible values for a coarse class. It can retain the attribute on the full carrier alongside a coarser state description. These choices preserve different information and should be assessed against the research question.

A set-valued report can describe uncertainty introduced by aggregation:

$$A([x]) = \{a(y) : y \sim x\}.$$

The definition is representative-independent because equivalent inputs have the same class. A singleton set permits exact recovery of the attribute at that class. Several values expose the ambiguity. Replacing the set by one selected value requires an additional selection or approximation rule. The construction is useful precisely because it displays what the coarse representation leaves unresolved.

The quotient condition also disciplines changes of scale. A finer state description can support an attribute that the coarser description cannot recover. Calling both descriptions states does not make their attribute languages interchangeable. When an inquiry moves between them, it should identify which values are preserved, lost, or newly supplied.

10.4 Partial Attributes and Definedness

A classification can be incomplete. This subsection extends the descent argument to show that its domain of definedness carries information alongside its reported values.

Let $a : D \to V$ be a partial attribute, where $D \subseteq S$. An input outside D lacks a value under the declared coding. The reason may be missing evidence, an unresolved classification, or inapplicability. Those reasons can require different representations, even when a preliminary formal treatment uses one partial domain.

Proposition 10.2 (Partial-attribute descent)**.** *A partial map $\bar{a} : \bar{D} \to V$ on Q can satisfy*

$$D = q^{-1}(\bar{D}), \qquad a = \bar{a} \circ q \text{ on } D$$

exactly when D is a union of $\sim$-classes and a is constant on each class contained in D.

Proof. Suppose the partial factorization exists. If $x \sim y$, then $q(x) = q(y)$. Membership of that image in $\bar{D}$ is the same for both, so $x \in D$ exactly when $y \in D$. Thus D is saturated. For members of D, applying $\bar{a}$ to equal projections gives equal values.

Conversely, assume both conditions. Set $\bar{D} = q(D)$. If $q(x) \in q(D)$, then some $y \in D$ satisfies $q(x) = q(y)$. Saturation puts x in D, so $q^{-1}(\bar{D}) = D$. Assign $\bar{a}([x])$ the common value of the class's members. Value constancy makes this well-defined and gives the required factorization. □

A two-point counterexample isolates the domain condition. Let $S = \{x, y\}$ with $x \sim y$, and let $D = \{x\}$. Even if a has only one reported value, it cannot preserve definedness on the one-point quotient. The single class would need to be both inside and outside $\bar{D}$. Checking only equality of reported values would miss this failure.

A fresh marker can totalize the partial map:

$$\widehat{a}(x) = \begin{cases} a(x), & x \in D, \\ \perp, & x \notin D, \end{cases}$$

where $\perp$ is distinct from every value in V. Constancy of $\widehat{a}$ on quotient classes combines the two requirements in the proposition. The marker makes missingness visible; its meaning remains an interpretive choice.

DRAFT

For a Boolean attribute, the codes 0, 1, and $\perp$ can represent false, true, and unknown to the investigation. This coding does not by itself assert that the underlying proposition has three truth values. Unknown can concern evidence rather than the world's state. Likewise, inapplicability can differ from both falsehood and missing evidence. A careful application separates these meanings before aggregating or comparing observations.

10.5 Overlapping Attributes and Classification Partitions

Several attributes can apply to the same subject. This subsection distinguishes that possibility from the stronger structure of a partition.

For a family $(U_j)_{j \in J}$ of subsets of Q, the profile

$$a(x) = (\mathbf{1}_{U_j}(q(x)))_{j \in J}$$

records simultaneous Boolean classifications. A configuration may belong to several U_j, or to none. The formula imposes neither mutual exclusivity nor exhaustive coverage.

A partition requires both. Its cells must be pairwise disjoint and their union must cover Q. A single-valued map $f : Q \to V$ induces a partition by its nonempty fibres. Conversely, a partition supplies a single-valued cell assignment. The structure is suitable when the classification task explicitly requires one exhaustive alternative.

A cultural or institutional classification may need overlapping predicates. A participant can hold several roles. A practice can belong to several traditions under the inquiry's declared criteria. A configuration can be both authorized and resource-constrained. Turning these predicates into one list of mutually exclusive categories changes the task unless the list retains every relevant combination.

One can create a partition from the full Boolean profile, grouping subjects that agree on all attributes. This preserves overlap information at the cost of a potentially larger classification space. For a finite family of k Boolean attributes there are at most 2^k profiles, though some may be absent. The resulting cells represent combinations of predicates, not a discovery that the original predicates were exclusive.

The philosophical point concerns what the classification claims. Overlapping predicates organize several aspects of one subject. A partition organizes alternatives at a particular level. Both can be useful, but they impose different commitments about how descriptions fit together. The six social-fact categories are used here as overlapping analytical roles and therefore require no partition of all social facts into six disjoint kinds.

10.6 Coding Rules and Constitutive Conditions

A classification can record a pattern, implement a rule, or represent an investigator's judgment. This subsection separates those functions while permitting their interaction.

An observational coding rule maps available material to a reported value. A constitutive rule specifies conditions under which a status obtains within a stipulated practice. An interpretive judgment connects records to a substantive claim. These functions can coincide in a particular model, but their coincidence requires premises about how the practice and its records work.

For a hypothetical registry, let $c(x)$ be the current registered classification and let $g(x)$ be the substantive target of the inquiry. If the target is precisely the registry's classification, then $g = c$ by definition. If the target concerns an independently specified condition, equality is a further claim. The registry can be evidence for that condition while remaining fallible with respect to it. The formal distinction protects the investigator from changing the target silently when evidence is convenient.

A constitutive classification can also influence later dynamics. If access depends on $c(x)$, two otherwise similar configurations with different classifications may admit different operations. That effect is a modeled consequence of the rule. It leaves open whether the classification accurately describes another feature, whether its implementation is stable, and whether the rule is justified.

The formation of a category and the classification of an instance are therefore different research problems. A community may develop a classification practice, after which an investigator asks which

DRAFT

instances satisfy it. A revision of the practice can change the classification rule itself. Modeling that revision requires a rule index or a dynamic state containing the relevant rule. A fixed subset U represents one selected rule at a time.

This distinction matters for philosophical accounts of social facts. Some attributes concern statuses constituted through practices; others concern patterns that an institution attempts to record. The same function notation can represent both. Their difference lies in the interpretation and the arguments connecting the code to the subject, not in the bare mathematical form of the map.

10.7 Numerical Values and Measurement Commitments

A numerical attribute invites arithmetic operations. This subsection shows why those operations require more structure than a numerical label alone.

A nominal classification can be recoded by a bijection of labels without changing its intended distinctions. An ordinal classification can be recoded by a strictly increasing function while preserving order. A quantitative scale may permit a narrower class of transformations when differences or ratios carry meaning. Which transformations are admissible is a modeling and measurement commitment.

For an ordinal attribute a and a strictly increasing ϕ,

$$a(x) < a(y) \quad \Longleftrightarrow \quad \phi(a(x)) < \phi(a(y)).$$

The equivalence follows directly from strict monotonicity on the scale. It establishes preservation of individual comparisons. It leaves aggregate operations such as addition open.

Consider two stipulated profiles $(0, 3)$ and $(2, 2)$. Their numerical sums satisfy $3 < 4$. The increasing recoding of $\{0, 1, 2, 3\}$ to $\{0, 1, 2, 100\}$ changes the sums to $100 > 4$. Individual rank information is preserved, while the aggregate ranking reverses. A sum-based comparison therefore uses more than the ordinal information.

This counterexample does not prescribe a social ranking. It identifies an assumption that a scalar model must justify. If a score represents authorization categories, degrees of recognition, or a researcher-defined index, meaningful addition cannot be inferred from its numerical appearance. The intended interpretation of the scale must explain the operation.

Aggregation can also conceal heterogeneity. Two configurations can have the same scalar score while differing in which conditions contribute to it. Those differences may affect feasible continuations. If they do, equality of the score can fail the state-preservation condition. A scalar summary can remain useful for reporting while being inadequate as the sole predictive state variable.

10.8 Aggregate Attributes and Predictive Closure

A scalar attribute can accurately summarize a configuration while leaving its later value unrecoverable from the scalar alone. This subsection derives a complete characterization for a simple aggregation model. The example gives the earlier warning about heterogeneity a precise mathematical content: the suitability of a summary depends jointly on the aggregation map and on the update family.

Let $S = \mathbb{R}^2$, where the two coordinates represent a stipulated pair of numerical attributes, and define

$$q(x, y) = \frac{x + y}{2}.$$

The map retains the arithmetic mean. Let $f : \mathbb{R} \to \mathbb{R}$ be continuous, and apply the same update independently to both coordinates:

$$T_f(x, y) = (f(x), f(y)).$$

A closed mean description requires a map $\bar{T} : \mathbb{R} \to \mathbb{R}$ satisfying $qT_f = \bar{T}q$. This is the action-preservation question for the equivalence relation induced by the mean.

The assumptions are deliberately narrow. The coordinate values lie on a scale supporting arithmetic means. Membership and weights stay fixed. Each component receives the same deterministic update,

DRAFT

and the update depends only on that component's value. Interaction between components, changing membership, different local update rules, or a restricted carrier would change the problem. The narrow formulation allows the consequences of the chosen summary to be derived completely.

Proposition 10.3 (Mean closure for a continuous component update)**.** *Under the stated assumptions, a reduced map satisfying $qT_f = \bar{T}q$ exists exactly when f is affine: $f(t) = at + b$ for constants $a, b \in \mathbb{R}$. The reduced map then equals f.*

Proof. For each t, the diagonal point (t, t) has mean t, and its updated mean is $f(t)$. Any reduced map therefore satisfies $\bar{T}(t) = f(t)$.

For arbitrary x, y, put $m = (x+y)/2$. The points (x, y) and (m, m) have the same mean, so descent implies

$$\frac{f(x) + f(y)}{2} = f\left(\frac{x+y}{2}\right).$$

Define $g(t) = f(t) - f(0)$. Then $g(0) = 0$, and g satisfies the same midpoint equality. Substitution of $2t$ and 0 gives $g(2t) = 2g(t)$. Consequently,

$$g(x+y) = 2g\left(\frac{x+y}{2}\right) = g(x) + g(y).$$

Repeated addition yields $g(n) = ng(1)$ for nonnegative integers. Since $g(n) + g(-n) = g(0) = 0$, the same expression holds for negative integers. For an integer p and positive integer q,

$$qg(p/q) = g(p) = pg(1),$$

so $g(p/q) = (p/q)g(1)$.

Given a real number t, choose a sequence of rationals tending to t. Continuity of g implies $g(t) = tg(1)$. Thus $f(t) = at + b$, with $a = g(1)$ and $b = f(0)$.

Conversely, for $f(t) = at + b$,

$$qT_f(x, y) = \frac{ax + b + ay + b}{2} = a\,q(x, y) + b = f(q(x, y)).$$

Taking $\bar{T} = f$ supplies the required factorization. □

Continuity enters at a specific step: it transfers rational linearity to all real arguments. The proof should therefore preserve that assumption even when the substantive interpretation makes smooth changes seem natural. Its conclusion concerns the displayed carrier and update rule. A finite selected set of attribute pairs can permit additional reduced maps because fewer equal-mean pairs need to be compared.

For a direct failure, take $f(t) = t^2$. The configurations $(0, 2)$ and $(1, 1)$ both have mean 1. Their updated configurations are $(0, 4)$ and $(1, 1)$, whose means are 2 and 1. Any proposed mean-only update would need to assign two different next values to the same input 1. The disagreement establishes failed closure without relying on an estimation error or an imperfect observation.

The missing information in this example can be displayed by expanding the formula:

$$\frac{x^2 + y^2}{2} = \left(\frac{x+y}{2}\right)^2 + \frac{(x-y)^2}{4}.$$

The second term records heterogeneity omitted by the mean. It vanishes on the diagonal and is positive for unequal coordinates. Retaining the mean and this additional term would recover the next mean for the squaring update. Whether the enlarged record supports its own future updates requires another closure check.

That last qualification matters. Adding a variable that repairs one prediction can leave later predictions unresolved. The construction of an adequate state description therefore proceeds relative to an

DRAFT

update family and an intended horizon. A reporting statistic answers a present descriptive question. A state variable used for repeated prediction must additionally support the continuation requirements of the inquiry.

The mathematical distinction remains useful even where an arithmetic mean has a clear interpretation. Average resources, average reported confidence, or an average numerical performance measure may summarize the selected subjects accurately. Interpreting the average as an autonomous dynamic subject requires evidence that the omitted distributional features are irrelevant to the modeled updates. Proposition 10.3 supplies one exact test in a restricted model and demonstrates why that additional requirement can be demanding.

The result also places a limit on claims that an aggregate creates a new entity. The map q defines equivalence classes of numerical configurations. Those classes can support a closed update under the proposition's conditions. Reidentifying a collective entity across time requires the appearance and continuity records developed in Section 7. A successful mean quotient establishes a descriptive and dynamic achievement, with entity identification remaining a separately stated task.

10.9 Changing Composition and Aggregate Direction

A second aggregation problem arises when the subjects entering a summary change their relative weight. This subsection derives an exact decomposition and a numerical counterexample. The objective is to separate a change within the classified groups from a change in how those groups contribute to the reported aggregate.

For a finite set of strata indexed by j, let r_j be an earlier rate and r'_j a later rate. Let w_j and w'_j be the corresponding nonnegative weights, each family summing to one. Write

$$A = \sum_j w_j r_j, \qquad A' = \sum_j w'_j r'_j.$$

The strata, rates, denominators, and weighting rule are declared components of the representation. A stratum can be a reporting category without being an entity, and membership in it can change between observations.

Proposition 10.4 (Rate and composition decomposition)**.** *The change in the aggregate satisfies*

$$A' - A = \sum_j w'_j (r'_j - r_j) + \sum_j (w'_j - w_j) r_j. \tag{22}$$

For fixed weights, weak improvement in every stratum gives weak improvement in the aggregate.

Proof. Add and subtract $\sum_j w'_j r_j$ in the expression for $A' - A$. The first difference is $\sum_j w'_j (r'_j - r_j)$; the second is $\sum_j (w'_j - w_j) r_j$. This proves the identity. When $w'_j = w_j$ for every j, the second sum vanishes. If every rate change is nonnegative, each term in the first sum is nonnegative, proving the direction statement. □

The first term evaluates within-stratum rate changes at the later composition. The second evaluates the weight change at the earlier rates. Reversing these baseline choices gives another exact decomposition. The allocation of an interaction between changing rates and weights depends on the stated convention. The total difference remains the same.

Table 3 gives stipulated counts that make the distinction visible. In the earlier observation the high-rate stratum records 90 successes out of 100 cases, while the low-rate stratum records 1 out of 10. In the later observation the high-rate stratum records 10 out of 10, and the low-rate stratum records 20 out of 100. These counts define a mathematical illustration; they report no empirical population.

Both subgroup rates rise by $1/10$. Yet the pooled rate falls from $91/110$ to $30/110$, a change of $-61/110$. The earlier weights are $(10/11, 1/11)$ and the later weights are $(1/11, 10/11)$. The within-stratum term in (22) is $1/10 = 11/110$. The composition term is

$$-\frac{9}{11}\frac{9}{10} + \frac{9}{11}\frac{1}{10} = -\frac{72}{110}.$$

DRAFT

Table 3: Stipulated subgroup rates and changing composition in two observations. Each subgroup rate increases while the pooled rate falls.

Observation	High-rate stratum	Low-rate stratum	Pooled rate
Earlier	$90/100 = 0.9$	$1/10 = 0.1$	$91/110$
Later	$10/10 = 1$	$20/100 = 0.2$	$30/110$

Adding the terms gives $-61/110$, matching the pooled calculation.

The apparent directional conflict disappears once the two questions are stated explicitly. The subgroup comparison asks how each rate changed. The pooled comparison asks for the success fraction among the cases represented in each observation, under that observation's composition. The numerical answers can move in opposite directions because the later pool contains a much larger share of the lower-rate stratum.

A fixed-weight standardized comparison answers another declared question. Holding the weights constant removes the composition term. It can make the within-stratum change easier to compare across observations. The choice of standard weights still requires a reason: earlier composition, later composition, equal weights, and a separately chosen reference population can all answer different comparative questions. The formula cannot select the relevant population by itself.

The example also exposes a connection to entity and process records. If the research question concerns the same individuals over time, aggregate counts from changing pools are insufficient by themselves. An appearance-level link or another identification method is needed to establish which subjects persist, enter, or leave. If the question concerns a changing institution's current composition, the movement of subjects between categories may itself be part of the process under study. The required record depends on that distinction.

Interpreting a pooled decline as evidence of deteriorating practice would add a causal claim. The displayed example supplies one countercondition: a change of composition can outweigh improvement within every displayed stratum. Conversely, favorable standardized rates can coexist with a practically significant redistribution of cases toward difficult conditions. Choosing one statistic to settle the overall assessment requires an evaluative argument about which changes matter and to whom.

A comprehensive attribute record should consequently preserve the numerator, denominator, inclusion rule, stratum definitions, and weighting convention wherever those components affect interpretation. A scalar can remain the principal reported value while its construction remains recoverable. The retained detail permits criticism of the formula, comparison of alternative descriptions, and correction when the original question was expressed too coarsely.

10.10 Attribute Change and Explanatory Change

An attribute can change for several reasons. This subsection distinguishes a changed subject, a changed rule, and changed knowledge about the subject.

With a fixed map $a : S \to V$, a transition from x to mx can change the value because the represented configuration changes. With a fixed configuration, replacing a by a new map a' can change the reported value because the coding rule changes. A record can also be revised while both the target configuration and intended rule remain fixed, reflecting new evidence or correction.

These are different histories. A time-indexed report alone may combine them. To interpret the report, an inquiry can retain the configuration, rule version, and evidential record as separate components. A change in one component then has an explicit location in the model.

For example, a hypothetical practice can broaden its membership criterion. Some appearances receive a new category even when their previously recorded features remain fixed. A study of recognition may treat the reclassification itself as a social event. A study of changes in the underlying features would need to distinguish it from such changes. Both inquiries can use the same archive if its rule history is retained.

DRAFT

The metamodel can accommodate rule change through an expanded carrier that includes the rule state. It can also compare separate models with an explicit alignment. In either case, a formula developed for one fixed quotient or classification needs renewed checking when the regime changes. Equality of labels across regimes supplies little evidence of equality of meaning.

10.11 Evidence and Interpretive Disagreement

Attribute assignments require evidence appropriate to their meaning. This subsection explains how formal consistency and substantive warrant can diverge.

A coding procedure can assign one value to every record consistently and still misrepresent the target. Internal consistency concerns whether the rule is applied as specified. Warrant concerns whether the rule, evidence, and interpretation justify the substantive claim. A reliable procedure for reading a database field does not establish that the field accurately represents an independently defined social condition.

Disagreement can concern different components. Investigators may agree on the records but disagree on the category. They may agree on the category but disagree on how the records support an assignment. They may disagree about the subject's identity or context, changing the domain to which the value belongs. A representation that retains these components permits a more precise diagnosis than a single disputed number.

Partial and set-valued classifications are useful when they express this unresolved state faithfully. They should not be adopted merely to avoid difficult decisions. A study can state which evidence would reduce uncertainty, which coding changes would alter the target, and which disagreements remain conceptual rather than empirical.

A further issue concerns reflexivity. Publicly assigning an attribute can affect the subject's later opportunities or behavior in a stipulated model. The reported classification then participates in the dynamics being studied. The investigator needs to distinguish evidence about an earlier condition from effects of the public classification. That distinction can be represented through separate event and state variables when the application warrants it.

10.12 Philosophical Role of Attribute Representation

The attribute construction clarifies how a description can be precise while remaining dependent on conceptual choices. This subsection develops that implication for the broader six-category account.

An attribute map is exact relative to its domain, codomain, and rule. Exactness does not make the rule inevitable. Different rules can classify the same carrier differently, and the appropriate comparison concerns their explanatory purpose, evidential basis, and consequences. Precision makes those choices inspectable; it leaves them available for criticism.

This also clarifies the difference between discovering a pattern and supplying a useful classification. A researcher can propose a category to organize inquiry, then investigate whether its instances share relevant dynamics. Conversely, a regularity may motivate a later coding scheme. The direction of inquiry matters to claims about emergence. A supplied subset becomes a representation of an observed regularity only through an argument linking it to evidence.

The framework leaves room for disagreement about which attributes matter. Formal compatibility can show that a classification survives a quotient or supports an update. It cannot establish that the classification deserves priority in every explanatory or normative inquiry. A social model therefore needs reasons for its attribute choices in addition to proofs of their internal consistency.

Within the six-category architecture, attributes supply descriptive predicates and values. Entities supply subjects across appearances; events and processes supply historical occurrences; relations supply dependencies; states supply the current descriptive level. An attribute can apply at each of these levels when its domain and rule are explicit. This flexibility is the construction's practical strength and the reason its commitments require careful disclosure.

DRAFT

11 State Descriptions, Observation, and Retained Memory

This section develops the state category by separating a carrier configuration, an observation, and a description sufficient for a declared dynamical task. It derives the condition for deterministic updates on a reduced description, examines hidden memory and several observation tasks, and discusses actual occupancy and historical interpretation. Section 6 subsequently supplies the full continuation construction. The present section explains why that construction is needed and what its result means.

11.1 The Descriptive Role of a State

A state description records the conditions under which the model evaluates subsequent operations. In the abstract base, a point $x \in S$ has that role. The point can encode a large configuration containing participants, records, resources, and rules. It need not correspond to a single entity or to one directly observable snapshot.

The quotient point $q(x)$ supplies another descriptive level. It groups configurations according to the declared equivalence $\sim$. The action-preservation assumption ensures that equivalent configurations remain equivalent after the same mechanism, allowing the quotient to carry its own deterministic action. This is a mathematical condition on the description. Its empirical interpretation depends on what the carrier and quotient represent.

An observation map $o : S \to Y$ supplies a third object. It records the features visible or relevant to a chosen inquiry. Two configurations may have the same observation while producing different later observations under one operation. In that case, the present observation is insufficient to determine the next observation. Treating Y as a deterministic state space would require a repair or a different model.

These three objects can coincide in a simple application, but their roles remain distinct. The carrier supports the full declared dynamics. The quotient supports an agreed level of identification. The observation expresses a measurement or reporting task. A model should justify each identification between them rather than derive it from the shared word *state*.

11.2 Deterministic Updates on Reduced Descriptions

A reduced description is useful when its future values can be updated from its present value. This subsection derives the condition that makes such an update well-defined.

Let $\rho : S \to Z$ be a description and let $T_b : S \to S$ be a total operation. The question is whether a function $F_b : \rho(S) \to \rho(S)$ can satisfy

$$\rho(T_b x) = F_b(\rho(x)) \qquad (x \in S). \tag{23}$$

The function is defined on the image of ρ, because unrepresented values of Z need no arbitrary transition.

Proposition 11.1 (Reduced-update criterion)**.** *A function satisfying Equation* (23) *exists exactly when*

$$\rho(x) = \rho(y) \quad \Longrightarrow \quad \rho(T_b x) = \rho(T_b y). \tag{24}$$

If the condition holds for every operation label, the description supports the corresponding deterministic updates.

Proof. If F_b exists, equal current descriptions are equal arguments to the same function and give equal next descriptions. This proves necessity.

Conversely, assign to a represented value $z = \rho(x)$ the value $F_b(z) = \rho(T_b x)$. Whenever another representative y gives the same z, the stated condition gives the same proposed output. The assignment is therefore well-defined and satisfies the equation. □

The condition says that $\ker \rho$ is preserved by the operation. It is precisely the representative-independence needed for a quotient update. The argument applies to one operation at a time, so a repertoire of operations requires preservation under every member.

DRAFT

The result distinguishes an accurate current report from a sufficient dynamic description. A report can correctly record the present value and still omit information needed for its next value. Accuracy at one moment therefore does not establish state sufficiency. Conversely, a mathematically sufficient description may be difficult to observe or may encode variables whose interpretation remains uncertain.

11.3 Hidden Memory and a Minimal Counterexample

A finite example makes the failure and repair explicit. Its purpose is to show why the omitted information matters under a specified operation.

Let $S = \{0, 1\}^2$, write $x = (v, h)$, and observe $o(v, h) = v$. Interpret v as a current reported flag and h as a retained condition. Define

$$T_r(v, h) = (h, h).$$

The configurations $(0, 0)$ and $(0, 1)$ have the same current observation, but

$$o(T_r(0, 0)) = 0, \qquad o(T_r(0, 1)) = 1.$$

Thus no deterministic function of the current flag alone can reproduce both next observations.

Retaining the pair (v, h) repairs this failure because the transition rule is already defined on that pair. The repair is sufficient for this stipulated system. Its adequacy in an application would require evidence that h represents an available condition and that the update captures the relevant dependence.

The variable can be called memory when its interpretation records a historically formed condition. The mathematical role, however, concerns future update dependence. A latent condition can perform that role without being a person's recollection. A document archive, an authorization record, or a retained resource state can each function as memory in a model if the interpretation and update rule justify the term.

The example also shows that a failed reduction does not uniquely identify the missing variable. Another sufficient encoding can be related to (v, h) by a change of coordinates, or a richer record can retain more detail. The failure proves that the chosen current observation is too coarse for the declared update. Identifying a particular hidden cause or historical mechanism requires additional evidence.

A stochastic reduced model offers a different response. It can assign a distribution to the next observation conditional on the current report. That move requires a probability model over the omitted distinctions or transitions. The deterministic failure alone supplies no canonical probabilities. Choosing a richer state and choosing a stochastic reduction are distinct modeling decisions.

11.4 Predictive Sufficiency and Historical Sufficiency

A description can be sufficient for one purpose and insufficient for another. This subsection distinguishes future observation from historical explanation.

Suppose two configurations have identical continuation signatures for the selected observations and operations. Their distinction can be omitted without affecting that predictive task. They may nevertheless correspond to different formation histories. If the historical question asks which sequence produced the present condition, the predictive quotient can discard the answer.

A stipulated permission illustrates the distinction. Two histories can produce the same current permission and all the same modeled future opportunities. One history may involve negotiation and another an imposed rule. If the current dynamics has no variable distinguishing those histories, prediction of the chosen outcome can remain identical. The historical query still differs, provided the formation labels have been meaningfully specified and evidenced.

The same issue appears in records of completed events. A state flag recording whether an activity has ever occurred can be sufficient for a future rule that depends only on that flag. It omits the count, timing, and participants of earlier occurrences. A historical inquiry needs those records even if they are redundant for the chosen transition rule.

DRAFT

The appropriate repair is task-specific. A joint description can retain both predictive information and the historical query. If the query must remain updatable after future operations, preserving only its current value can be insufficient. The historical-relations paper develops the joint continuation construction in detail. Here the general lesson is that sufficiency belongs to a declared family of questions.

This limitation has philosophical force. A compressed state can be the right object for predicting a selected variable without being a complete account of the social situation. Explanations of formation, responsibility, recognition, and significance can require distinctions absent from that prediction. The model should state its task so that predictive success receives the appropriate evidential scope.

11.5 Coordination of Observation Tasks

A six-category inquiry can require several observations at once. This subsection derives their coordination and clarifies the meaning of the resulting refinement.

Let $o_j : S \to Y_j$ be observations indexed by $j \in J$. The product observation is

$$o_G(x) = (o_j(x))_{j \in J}.$$

For each j, let E_j identify configurations whose o_j observations agree after every finite word. Define

$$E_G = \bigcap_{j \in J} E_j. \tag{25}$$

Proposition 11.2 (Joint-task equivalence)**.** *The relation E_G is the continuation equivalence for o_G. It is the greatest update-preserved equivalence contained in every* ker o_j.

Proof. Equality of product observations under a word means equality of each coordinate under that word. Requiring this for every word gives precisely the intersection in Equation (25).

Each E_j is an update-preserved equivalence by the continuation construction proved in Section 6. Intersecting those relations retains equivalence and update preservation.

If another update-preserved equivalence retains every current observation, the greatest-property argument for each individual task places it inside each E_j. It therefore lies in their intersection. □

Adding an observation coordinate can only refine the relation, since it adds an equality requirement. Adding operation labels with the earlier maps unchanged can likewise expose more distinctions: every old word remains among the new tests. Neither change alone establishes that new underlying entities or configurations have appeared.

This distinction matters when a revised study reports more categories of state than an earlier one. The increase can reflect additional measurements or a richer repertoire of hypothetical tests. It can also reflect a changed underlying model, but that is another comparison requiring explicit alignment. A count of descriptive classes cannot distinguish the possibilities by itself.

The product construction can retain too much for a practical task. An infinite family can give an infinite record; even a finite family can be costly to measure. A researcher can therefore compare exact sufficiency, finite approximations, and selective omission. Each choice should state the errors or questions it leaves unresolved.

11.6 Actual Occupancy and Epistemic State

The action framework represents possible configurations. This subsection distinguishes those configurations from what an investigator knows about the current case.

An empirical occupancy assertion identifies the configuration or class occupied by the subject at a specified time. Such an assertion needs a mapping from evidence to the model. The existence of a state space and transition maps alone leaves the initial condition unspecified.

Incomplete evidence can be represented by a set $K \subseteq S$ of configurations compatible with the available information. This set is an epistemic record. Its elements are candidate world configurations.

DRAFT

Confusing K with a single world configuration would combine uncertainty about the case with the case's own modeled conditions.

Under a known deterministic operation T_b, the predicted compatible set is

$$T_b(K) = \{T_b x : x \in K\}.$$

A subsequent observation y can restrict it to $T_b(K) \cap o^{-1}(\{y\})$, assuming the observation model is exact. This update follows by retaining precisely the candidates that satisfy both the dynamics and the observation. Noise or uncertain execution requires further rules.

The set update can be informative without selecting one actual state. If every surviving candidate gives the same answer to a query, that answer is identified relative to the model and evidence assumptions. If candidates disagree, uncertainty remains. Assigning a probability distribution would add a measure whose justification is separate from set compatibility.

A social inquiry can also include participants' beliefs or records inside S. Those variables belong to the modeled situation, whereas the investigator's compatible set concerns knowledge of that situation. Both are legitimate, and their relation can matter dynamically. A clear model distinguishes the participant's information, the public record, and the investigator's uncertainty before drawing conclusions.

11.7 State Revision and Changes of Description

A state report can change because the world changes, because evidence changes, or because the description changes. This subsection separates those transitions.

Under a fixed carrier, observation, and operation system, a transition $x \mapsto T_b x$ is a modeled change in the subject. Under a fixed subject configuration, revising a compatible set changes the inquiry's information. Replacing the observation or equivalence changes the descriptive regime. The resulting reports can look similar while having different meanings.

For equivalences $E' \subseteq E$ on the same carrier, the finer quotient S/E' maps to the coarser quotient S/E by $[x]_{E'} \mapsto [x]_E$. Representative independence follows from the inclusion. This map gives a precise alignment between the two descriptions. It permits questions about which distinctions the coarser quotient forgets.

Arbitrary quotients need not be ordered by refinement. Two observations can preserve different features. Their joint observation provides a common refinement, but recovering one from the other requires a factorization condition. Shared numerical labels or equal numbers of classes establish little about their semantic agreement.

A change of carrier introduces another level of difficulty. An enlarged model can include newly represented participants or mechanisms. Comparing states across the models then needs an explicit embedding, projection, correspondence, or other alignment. The original quotient theorem applies within its fixed domain and does not automatically settle that comparison.

These distinctions prevent an inference from greater descriptive detail to greater generative capacity. A new classification can reveal a possibility that the old description omitted. An intervention can also create or enable a new possibility. The model must identify which kind of change its before-and-after comparison represents.

11.8 Philosophical Interpretation of State Sufficiency

The state construction answers a precise question: which distinctions must a description retain for specified updates and observations? This subsection evaluates the philosophical scope of that answer.

A sufficient state is relative to the operations and observations that define the task. It can be minimal for that task while omitting information relevant to another. The relativity is disciplined by an exact criterion and a greatest-property theorem; it permits comparisons between candidate descriptions.

The result leaves open whether the selected task captures what matters about a social situation. A prediction of activity completion can omit the manner of agreement, the participants' reasons, or a dis-

DRAFT

puted history. Those omissions can be acceptable for one calculation and serious for another inquiry. The philosophical argument must state why the chosen observations serve its purpose.

Deterministic state sufficiency also presumes that the operation repertoire captures the relevant way future developments are tested. A test set can exclude interventions that would expose an omitted distinction. Expanding the repertoire can therefore revise the equivalence. The theorem remains correct under either repertoire; the adequacy dispute concerns the choice between them.

This account gives state descriptions a constructive role without treating them as complete inventories of reality. A description organizes possible transitions, supports specified inferences, and exposes its dependence on retained information. Its philosophical value lies in making those commitments available for examination.

11.9 State Use in the Six-Category Framework

The state category coordinates current descriptions with the other analytical roles. This subsection states the connections that a complete application needs to preserve.

Entity identity can continue across changing states. Relations can be represented by conditions or incidence records that influence state transitions. Event tokens identify particular transitions or attempts. Attributes read values at the chosen level. Processes retain sequences and intermediate states. The roles are connected by maps and records, and each can preserve information that another omits.

A successful state model must declare its carrier, observations, operations, and retained equivalence. It must establish representative independence for reduced updates, identify how occupancy is warranted, and distinguish uncertainty from world configuration. Where historical or entity questions exceed predictive sufficiency, it must retain the corresponding records.

The continuation construction that follows provides one exact solution to the dynamic consistency problem. Its proof becomes philosophically useful when read together with these limits and choices, because it states both what the reduced state can do and which further questions remain outside that task.

12 Process Histories and Their Compositional Reductions

This section develops processes from ordered mechanism words and their trajectories. It derives endpoint composition, distinguishes several reductions of a history, and examines segmentation and duration. The philosophical discussion concerns what makes a sequence one process, how actual history differs from possible factorization, and how branching or overlapping activity challenges the sequential model. The aim is to preserve the reasoning carried by a process rather than retain only its final result.

12.1 Ordered Activity and Process Unity

A process description connects occurrences through an order and a criterion of unity. A sequence of operations can produce a result, sustain an arrangement, transform a relation, or end without completing a selected target. The action framework supplies an ordered composition calculus. The interpretation of the sequence as one socially meaningful process requires additional criteria.

A stipulated agreement can be formed through proposal, revision, authorization, and enactment. A record of the final authorization may leave the earlier negotiations invisible. An outcome-oriented calculation may need only the composite effect. A historical explanation may depend on the proposals that failed, the order of revisions, or the interruption of an earlier route. The representations serve different questions even when they concern the same eventual configuration.

A process also need not be goal-directed in its interpretation. An analyst can group a sequence by a recurring pattern, a causal chain, a maintained relation, or a declared interval. A participant's purpose is another possible organizing criterion, requiring its own evidence. The word representation captures order while leaving those interpretations open.

DRAFT

This distinction prevents a sequence's formal availability from being mistaken for an established history. A factorization of a mechanism shows one way its effect can be composed. Evidence is needed to claim that the corresponding operations actually occurred in that order. The process category keeps factorization and occurrence linked through explicit records.

12.2 Words and Trajectories

The construction begins with labeled operations and a seed. This subsection specifies the conventions and derives the trajectory.

Let B be an operation alphabet, with total maps $T_b : S \to S$. A finite word $w = b_1 \cdots b_k$ is executed from left to right. For a starting configuration $x_0 = x$, define

$$x_i = T_{b_i} x_{i-1} \qquad (1 \le i \le k). \tag{26}$$

The process presentation retains

$$\mathsf{Proc}(x, w) = (x_0, b_1, x_1, \ldots, b_k, x_k).$$

The empty word ϵ has zero steps and leaves the seed unchanged.

Proposition 12.1 (Trajectory determination)**.** *A seed and a finite word determine a unique trajectory under the declared deterministic maps. Its endpoint is $T_w x$, where $T_w = T_{b_k} \circ \cdots \circ T_{b_1}$ and $T_\epsilon = \mathrm{id}_S$.*

Proof. For the empty word, the unique trajectory contains only x. Suppose the first $i-1$ states have been determined. The total function T_{b_i} assigns exactly one value to x_{i-1}, determining x_i uniquely. Induction constructs the entire finite trajectory.

Repeated substitution into Equation (26) gives $x_k = T_{b_k} \cdots T_{b_1} x$, which is the stated composite-map expression. □

The proof depends on determinism and totality. A partial map requires executability at every prefix. A stochastic transition requires a distribution over possible next states. A nondeterministic relation can yield several trajectories. Those extensions can be developed, but their path objects and claims of uniqueness differ from the present construction.

The labels matter independently of their maps. Two named operations can have the same action on the selected variables. A history of negotiation and a history of imposition can therefore be represented by distinct labels with identical maps when the model deliberately retains their formation names. Interpreting those names requires evidence or stipulation beyond the endpoint formula.

12.3 Words, Products, Maps, and Endpoints

Several reductions connect a process to its outcome. This subsection isolates their different information losses.

When labels specify elements of the base semigroup, a nonempty word has a product

$$e(w) = b_k \cdots b_1.$$

The action sends that product to a transformation of S. Evaluating the transformation at one seed gives an endpoint. The sequence of reductions is

$$w \longmapsto e(w) \longmapsto T_w \longmapsto T_w x \longmapsto q(T_w x). \tag{27}$$

Each arrow answers a narrower question about the process.

Distinct words can have the same product because the semigroup satisfies equations. If $b^2 = b$, one and two applications have the same product. Distinct semigroup elements can have the same map when

DRAFT

the action is nonfaithful. Distinct maps can agree at the selected seed while differing elsewhere. Finally, distinct endpoints can belong to the same quotient class. These losses are logically independent.

A concrete seed-level example uses the identity map and a constant-zero map on $\{0, 1\}$. They agree at seed 0 and differ at seed 1. Knowing the endpoint from 0 therefore fails to identify which transformation was used. Recovering the map would require observations at enough inputs or another source of information.

Nonfaithfulness occurs at another level. A semigroup can contain distinct mechanism labels whose actions coincide on every configuration in the selected carrier. Observing all endpoints within that carrier still leaves the label distinction unrecoverable. The distinction may encode a provenance difference that the dynamics deliberately omits.

The quotient can discard still more. Two histories with different endpoints can agree on a selected outcome, such as whether a joint activity occurred. Their differences in authorization, resources, or recorded formation may remain outside the outcome class. An explanation that requires those differences must retain a richer stage of the reduction sequence.

12.4 Recovery of Process Queries

A process query can concern length, order, duration, participants, or another property of the retained history. This subsection derives a general test for recovering it after compression.

Let H be a declared set of process presentations, let $\rho : H \to Z$ be a retained record, and let $g : H \to V$ be a target query. A function $\bar{g} : \rho(H) \to V$ can recover the target exactly when

$$\rho(h) = \rho(h') \quad \Longrightarrow \quad g(h) = g(h'). \tag{28}$$

Necessity follows because equal records are equal arguments to $\bar{g}$. For sufficiency, assign each represented record the common query value of its fibre. The condition makes that value well-defined and gives $g = \bar{g} \circ \rho$. This elementary argument gives each proposed reduction a query-specific test.

The test can succeed for one query and fail for another. A composite effect determines the endpoint at a fixed seed. It can fail to determine application count under idempotence. A full word determines its ordered labels, but may fail to determine elapsed time when durations vary. A timestamped record can retain elapsed time while leaving a participant's intention open.

The result is useful because it locates a failed inference precisely. If two candidate histories share the retained record and differ in the target, exact recovery is impossible from that record alone. A richer record can repair the loss, or the inquiry can retain a set of compatible answers. A guessed answer would add information without identifying its source.

The criterion remains model-relative. It assumes that the history domain contains the relevant alternatives and that ρ correctly describes retained information. A query can be formally recoverable in an overly restrictive history domain while remaining empirically uncertain. Adequacy therefore requires scrutiny of both the compression and the candidate histories.

12.5 Segmentation and Composite Events

A process can be divided into stages or compressed into a single event. This subsection derives the endpoint consistency of segmentation and its limits.

For a nonempty word of length k, choose

$$0 = t_0 < t_1 < \cdots < t_r = k.$$

The jth block contains positions $t_{j-1}+1, \ldots, t_j$. Its subword acts on $x_{t_{j-1}}$ and yields x_{t_j} by the trajectory recursion. A segmentation therefore provides stage boundaries in addition to the underlying word.

Proposition 12.2 (Endpoint consistency of segmentation)**.** *Composing the block transformations of a segmented word gives the same transformation as the entire word. The total transformation generally leaves the segmentation unrecoverable.*

DRAFT

Proof. Each block transformation is the composition of its consecutive operation maps. Composing the blocks concatenates those maps in their original order. Associativity removes the parentheses and yields T_w.

For failure of recovery, a two-letter word bb can be treated as one block or as two. Both segmentations yield T_b^2, while their boundary records differ. A function of the total transformation alone cannot recover both boundary choices. □

The proposition justifies stage-level calculation without proving that a stage boundary is socially appropriate. A group of operations can be one negotiation phase under one criterion and several events under another. The criteria can concern purpose, institutional procedure, temporal continuity, or a change in the relevant relation.

An event-level description often uses such compression. The overall transition of a meeting can be represented by one composite mechanism while an internal process record retains its steps. Their connection is mathematically clear when the event map is the composite of the process maps. The interpretive claim that these steps form one event remains additional.

Keeping both levels can be useful. The coarse event supports comparison across cases, while the detailed process explains how particular outcomes were reached. The model should identify which conclusions survive compression and which depend on the finer history.

12.6 Duration and the Limits of Algebraic Time

Order alone does not specify duration. This subsection constructs a simple time assignment and tests whether it can survive product compression.

Let $\delta : B \to \mathbb{R}_{\geq 0}$ assign a duration to each operation label. Under an additive sequential convention,

$$\tau(\epsilon) = 0, \qquad \tau(b_1 \cdots b_k) = \sum_{i=1}^{k} \delta(b_i). \tag{29}$$

The equation treats repeated applications as separate contributions to time.

For a product representation e, duration descends to a function on $e(H)$ exactly when equal products have equal τ-values. The necessity and sufficiency proof is the fibre-constancy argument in Equation (28).

If $e(b) = e(bb)$, descent requires

$$\delta(b) = 2\delta(b),$$

so $\delta(b) = 0$. A positive duration for each application therefore fails to descend through this idempotent product equation. The total effect can forget how long its enactment took.

The assumption of a fixed label duration is itself restrictive. An operation can take different times at different configurations or under different resources. A state-dependent duration map can retain that dependence along the trajectory. Interrupted or overlapping activity needs a schedule rather than a simple sum.

The mathematical distinction corresponds to several temporal questions. Sequence position records order. Duration records elapsed time under a convention. Calendar time locates an occurrence within another temporal frame. Historical periodization groups activities by an interpretive criterion. A natural-number word index supplies the first and leaves the others open.

This prevents the semigroup law from being read as a complete temporal theory. Associativity concerns the grouping of composition. It neither assigns duration nor establishes that every social process admits one fixed sequential time scale.

12.7 Feasibility at Intermediate Stages

A composite effect can be algebraically available while a particular route to it is infeasible. This subsection identifies the role of prefix conditions in the process category.

DRAFT

Let $A(x) \subseteq B$ be the labels admissible at x. A word is feasible from seed x when

$$b_i \in A(x_{i-1}) \qquad (1 \le i \le k).$$

Every step is tested at the configuration produced by its earlier prefix. A final endpoint test alone can omit a blockage encountered earlier in the process.

For a two-state flip f with $f^2 = \mathrm{id}_S$, allow f only at state 0. From 0, the word ff would return to 0 under the total maps, but its second step is unavailable at state 1. The empty word and ff have the same total effect while differing in prefix feasibility.

The example shows why arbitrary availability domains need not respect equations among earlier total products. A process representation can preserve the words and their prefix tests. Another approach composes the partial maps themselves, so domain information participates in equality. Each approach states explicitly what the product means.

The social interpretation concerns realization conditions. A plan can specify an eventual result while requiring authorization, resources, or cooperation at intermediate stages. Those requirements are added data. The feasible-path paper develops their systematic representation and the consequences of shared conditions.

12.8 Branching, Interruption, and Open-Ended Histories

Finite words provide a clear starting point. This subsection examines cases that require a broader process representation.

Branching can represent several possible continuations from one history. A set of words retains alternative routes; a tree can make shared prefixes visible. Selecting one branch as actual requires occurrence information. A probability distribution or policy would add further assumptions about selection.

Interruption can be represented by a finite prefix that stops before the selected target. Whether it is an incomplete process, a completed attempt, or a separate event depends on the process criterion. The word alone records the performed or proposed prefix and leaves that classification to the inquiry.

Restarting can preserve some conditions while changing others. A new seed may encode retained resources, records, or commitments. Connecting the restarted activity to the earlier process requires a continuity criterion. Merely concatenating labels can conceal a gap whose significance matters historically or institutionally.

Open-ended activity requires a choice of representation. One may retain all finite prefixes, introduce infinite sequences, or use a changing process graph. Results proved for finite composition transfer only when the new structure and its limiting operations are defined. The existence of arbitrarily long finite words alone supplies no completed infinite historical object.

The possibility of generating new operation labels or units raises another issue. A fixed alphabet can encode a range of possible changes in advance. A model that changes its alphabet or carrier during execution needs an explicit comparison across stages. The base framework can motivate such an extension, while its fixed-domain theorems retain their stated scope.

12.9 Historical Actuality and Explanatory Relevance

A process record becomes an explanation through an interpretation of its steps and their evidence. This subsection distinguishes that achievement from a compositional calculation.

A factorization can show how an effect could arise. A historical explanation must support the claim that the relevant sequence occurred and that its steps have the meanings assigned to them. A sequence of labels named negotiation, agreement, and enactment does not establish those meanings without evidence or an explicit stipulated example.

Different histories can support the same final outcome and different explanations. One route may preserve participants' commitments; another may replace them. One may involve repeated failed attempts; another may reach the target immediately. The endpoint calculation can treat these routes alike for one purpose while the historical account distinguishes them.

DRAFT

A process account also selects which intermediate differences matter. A complete physical or documentary record can contain more detail than the inquiry needs. Compression is therefore unavoidable in practice. The question is whether it preserves the distinctions required by the explanatory target, and whether its losses are stated.

The factorization criterion provides a formal version of that question. It can show that a particular query is unrecoverable after a chosen compression. It leaves the importance of the query to philosophical and empirical argument. This combination makes the mathematics useful without turning every retained distinction into an equally important feature.

12.10 Philosophical Role of Process Unity

A sequence becomes one process through a criterion of connection. This subsection considers the philosophical implications of making that criterion explicit.

Causal connection, common purpose, institutional procedure, and historical narrative can each organize activity. They may overlap, but one can hold while another fails. A procedure can continue despite changed intentions. A shared purpose can persist through different procedures. A causal chain can connect events that participants never understood as one undertaking.

The model can represent those criteria through separate predicates or records. It then becomes possible to ask whether one process has several forms of unity, whether its boundary is disputed, or whether a later interpretation reorganizes earlier occurrences. A single operation word leaves those questions open rather than settling them through sequence alone.

A relational account can emphasize how processes form and modify the conditions of later processes. This proposal is compatible with the action framework when the relevant conditions are encoded and updated. The explanatory work lies in specifying those conditions and demonstrating their role. Composition alone guarantees an endpoint calculation, not a general theory of historical generation.

Within ontological suspension, the process category therefore provides a disciplined way to discuss ordered formation and transformation. It can support arguments that give processes explanatory priority in a case. A universal claim that all entities or social facts are ultimately processes requires a further philosophical argument.

12.11 Process Use in the Coordinated Framework

The process category retains the sequence and intermediate manifestations needed to connect the other five roles over time. This subsection states its contribution to a complete representation.

Entity appearances can be tracked along a process under an identity or lineage criterion. Relations can be formed, exercised, or revised by its steps. Event indices identify particular occurrences. Attributes can describe initial conditions, intermediates, or the whole history. States provide the configurations through which the process proceeds.

A successful application declares the seed, operation labels, order convention, feasibility conditions, and occurrence status. It identifies the process-unity criterion and any duration or segmentation records. It then checks which queries survive reduction to products, effects, or endpoints.

The resulting account preserves the insight that a process is more informative than its final formula. The formula records a conditional consequence of the steps. The process record retains the path by which that consequence is calculated, interpreted, and, where evidence permits, situated in history.

13 A Cooperative-Agreement Illustration

This section coordinates the six categories within one finite model. It specifies the complete Boolean action, derives its transformation normal forms, compares order effects and commuting prerequisites, and constructs the observation-relative state quotient. It then examines the additional records required for entities, relations, events, attributes, and processes. The agreement vocabulary is an analytic interpretation of stipulated rules; empirical adequacy remains open.

DRAFT

13.1 Configuration Variables and Their Scope

The example retains authorization, a resource condition, and an activity flag. This subsection defines their roles and explains which questions the small carrier can answer.

Let $S = \{0,1\}^3$, with $x = (a, r, e)$. Interpret a as a recorded authorization under a cooperative agreement, r as an available resource condition, and e as whether a focal joint activity has occurred at least once. The carrier has eight configurations.

The variables have deliberately limited meanings. Authorization is represented through a recorded condition; its recognition, validity, and practical effect require interpretation. The resource coordinate records persistent availability, rather than a consumable quantity. The activity coordinate records occurrence at least once and omits multiplicity.

Participant identities and the identity of the agreement are additional records. The three bits do not identify which organizations participate or which agreement is being tracked. They describe selected conditions of a case whose referents must be supplied separately.

The complete carrier leaves the initial configuration open. A particular inquiry can select a seed and study its reachable subset. Keeping the full carrier is useful for checking equality of transformations and continuation equivalence across all represented conditions.

13.2 Operations and the Generated Action

The maps specify how the selected variables change. This subsection gives the complete rules and the relation between words and transformations.

Define

$$\begin{aligned} c(a, r, e) &= (1, r, e), \\ k(a, r, e) &= (a, 1, e), \\ j(a, r, e) &= (a, r, e \vee (a \wedge r)). \end{aligned} \tag{30}$$

Operation c records authorization, k supplies the resource condition, and j attempts activation. Let M be the transformation semigroup generated by nonempty words over these labels.

The base equivalence is equality. The selected observation is $o(a, r, e) = e$. Equality of raw configurations is therefore finer than the current activity observation.

The maps are total. When a prerequisite is absent, j leaves the configuration unchanged. An application that distinguishes an unavailable attempt, a refusal, or a failed execution needs an availability or observation enrichment.

The resource condition remains set after activation. A consumable resource would require a different map or a quantity ledger. The current rule is suitable only for the persistent condition interpretation.

Words retain operation order and repetition. Their products in M retain only transformations of the eight configurations. The following derivation characterizes exactly what that effect compression preserves.

13.3 Normal Forms of the Transformations

The generated action contains twelve distinct nonempty-word transformations. This subsection derives that number and supplies a witness for every form.

For a word w, let C, K indicate whether c, k occur anywhere. Since neither coordinate is reset, the final first two values are $a \vee C$ and $r \vee K$.

If j never occurs, the activity flag remains e. If it occurs, let C_j, K_j indicate whether c, k occur before the last j. Successive activation attempts read prerequisite values that can only increase. Their contributions to e therefore are contained in the last contribution.

Consequently, when j occurs,

$$T_w(a, r, e) = \big(a \vee C,\ r \vee K,\ e \vee [(a \vee C_j) \wedge (r \vee K_j)]\big). \tag{31}$$

DRAFT

Table 4: Transformation normal forms in the cooperative-agreement model

Final flag C	Final flag K	Added activity term $f(a, r)$	Witness word
0	0	$a \wedge r$	j
1	0	0	c
1	0	$a \wedge r$	jc
1	0	r	cj
0	1	0	k
0	1	$a \wedge r$	jk
0	1	a	kj
1	1	0	ck
1	1	$a \wedge r$	jck
1	1	r	cjk
1	1	a	kjc
1	1	1	ckj

When it does not, the last coordinate is simply e. Table 4 lists every possible effect.

Each row denotes $(a, r, e) \mapsto (a \vee C, r \vee K, e \vee f(a, r))$. The witness column contains words read left to right. It is distinct from the left-action product notation used when maps are applied to a configuration.

Proposition 13.1 (Complete finite transformation classification)**.** *The nonempty-word action has exactly twelve transformations, represented by Table 4. The zero-step identity is a thirteenth transformation in the generated monoid.*

Proof. If $(C, K) = (0, 0)$, a nonempty word consists of j operations and has added activity term $a \wedge r$. If $(C, K) = (1, 0)$, the possible terms are zero when there is no activation, $a \wedge r$ when the last activation precedes authorization, and r when it follows authorization. The symmetric case $(0, 1)$ gives zero, $a \wedge r$, and a.

For $(C, K) = (1, 1)$, the last activation can precede both setters, follow only c, follow only k, or follow both. Together with the case containing no activation, the terms are zero, $a \wedge r$, r, a, and one. Thus at most $1 + 3 + 3 + 5 = 12$ maps occur.

The table supplies a word for every form. Different flag pairs have different first or second output functions. Within a flag pair, the listed activity terms differ on an input with $e = 0$. Hence the twelve maps are distinct.

A word containing c or k changes a corresponding zero input bit. A nonempty word containing neither consists of j and changes $(1, 1, 0)$. Thus no nonempty word induces the identity. The empty word adds that map. □

The proof explains the enumeration. It also locates the information lost by the transformation record: many histories share the same setter flags and last-activation effect. Their earlier occurrences can remain distinct in a process record.

13.4 Order Effects and Joint Prerequisites

The model exhibits order sensitivity and joint contribution by commuting operations. This subsection derives both patterns and explains why they should remain distinct.

At $x = (0, 1, 0)$, applying authorization before activation gives

$$jc(x) = (1, 1, 1),$$

while activation before authorization gives

$$cj(x) = (1, 1, 0).$$

DRAFT

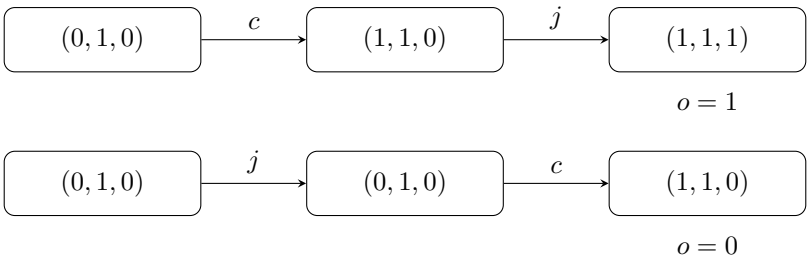

Figure 1: Two operation orders from the same resource-equipped configuration. Authorization followed by attempted activation sets the activity flag; the reverse order leaves it unset.

The expressions use left-action composition, so $jc(x)$ means $j(c(x))$. Figure 1 shows the corresponding word orders.

The order-effect predicate $R_{\text{ord}}(c, j, x)$ therefore holds. The authorization changes the result of a later activation under this stipulated comparison.

Meanwhile, $ck = kc$ on every configuration because the maps set different coordinates. Starting from $(0, 0, 0)$, either setter alone leaves one prerequisite absent. Applying both before j sets the activity flag.

The commuting setters thus jointly contribute to a later operation. Their commutation does not establish independence from every dynamic purpose. It states that their mutual order has the same effect on the chosen carrier.

The converse caution also holds. The order inequality is a mathematical property of the maps. Its interpretation as authorization dependence comes from the declared coding and update rules. Anonymous maps with the same table would satisfy the same predicate.

13.5 Occurrences and Historical Compression

Idempotence makes the difference between effects and occurrences especially clear. This subsection derives the relevant identity and identifies the records needed for repeated activity.

Boolean idempotence gives $j^2 = j$. After one activation attempt, the activity coordinate is $e \vee (a \wedge r)$. Applying the same rule again gives

$$[e \vee (a \wedge r)] \vee (a \wedge r) = e \vee (a \wedge r).$$

The first two coordinates are unchanged, proving equality of maps.

The one-step word j and the two-step word jj therefore have the same product and endpoint. Their occurrence counts differ. A process record can retain that difference through word positions or occurrence identifiers.

The activity flag adds another compression. Once $e = 1$, every later activation leaves the observed value one. A record of whether activity ever occurred cannot recover how often it occurred or how many attempts were made.

A counter extension can retain attempt count, but the extended operation then fails the old idempotence equation. One application adds one to the counter, and two applications add two. Projection to the old variables preserves the old effect. The event section derives that distinction in general.

The example therefore has two separate information losses: word-to-transformation compression and the choice of a Boolean occurrence summary. Identifying their locations makes a proposed repair precise.

13.6 Continuation Refinement

The activity observation merges states that later tests distinguish. This subsection derives the complete refinement and relates it to the common theorem.

DRAFT

Table 5: Continuation partitions for the cooperative-agreement illustration

Horizon	Classes	Distinctions retained
0	2	Current activity flag e
1	3	With $e = 0$, the configuration $(1, 1, 0)$ separates from the other three
2	5	Four singleton classes with $e = 0$; one class containing all configurations with $e = 1$
3	5	The partition is unchanged, certifying stabilization

At horizon zero, o gives two classes: the four configurations with $e = 0$ and the four with $e = 1$. The pair $(0, 1, 0)$ and $(1, 1, 0)$ belongs to the first class, yet j distinguishes it.

At horizon one, $(1, 1, 0)$ separates from the other incomplete configurations. Only this state activates immediately. The other three still give zero under every single operation.

At horizon two, the remaining incomplete states separate. The word kj distinguishes $(1, 0, 0)$ from $(0, 0, 0)$, and cj distinguishes $(0, 1, 0)$ from $(0, 0, 0)$. The word kj also distinguishes $(1, 0, 0)$ from $(0, 1, 0)$.

Every configuration with $e = 1$ continues to report one under every word. These four states therefore form one final class. The four incomplete states are singletons, giving five classes in total.

Table 5 records the horizons and the repeated stable stage. The common theorem makes that stability an exact certificate within the model.

The observation-relative quotient is coarser than the original equality regime. If the inquiry must also retain every original distinction, Equation (12) intersects with equality and keeps eight classes. The two records serve different tasks.

13.7 Coordination of the Six Categories

The same finite inquiry can use all six categories without treating them as disjoint kinds of object. This subsection states the additional commitments associated with each use.

Entity records identify the participants and the agreement across indexed appearances. Their continuity criteria can involve documents, membership, or institutional succession. None is fixed by the three Boolean coordinates.

The relation description concerns authorization and its connection to formation and possible activation. Its historical account requires a record of how the condition was established. Its potential role is represented by the activation comparison.

Event records identify particular attempts or enactments. An occurrence can leave the current state unchanged, so transition difference alone cannot supply its identity. Evidence is needed to establish that the represented attempt occurred.

Attributes select or describe conditions, such as authorization, resource availability, or completion. Their coding rules and domains determine whether they descend to a chosen quotient. An activity-only quotient can omit attribute distinctions that another task requires.

State descriptions retain selected configurational distinctions and support the corresponding updates when compatibility holds. Process records retain ordered operations and their intermediate states. The product normal form can summarize effects while the process record preserves the sequence.

The categories therefore cooperate through linked records. The question is which information each role requires and whether the links preserve it. The example supplies a common setting in which those requirements can be checked.

13.8 Limits and Verification of the Illustration

The construction is deliberately small and its rules are complete. This final subsection states what verification supports and what a substantive application must add.

DRAFT

Finite enumeration corroborates the eight configurations, twelve nonempty transformations, and horizon counts $2, 3, 5, 5$. Independent paired-state search gives the same continuation classes. The normal-form proof explains why the transformation count is complete.

The checks concern the stipulated model. They leave the interpretation of authorization, resources, and activity open. A real cooperative arrangement can involve withdrawal, consumption, uncertain responses, and disagreements about recognition.

Adding those features changes the maps or records. The existing proofs remain valid under their displayed assumptions, while the extended model requires renewed checks. Preserving that genealogy prevents a refinement from silently changing the meaning of an earlier result.

The next illustration takes a different constructive route: it derives candidate collective units from a relational graph. Together, the examples show how a common formal base can coordinate category uses while requiring different added interpretations.

14 A Constructive Model of Relational Unit Formation

This section supplies a positive construction of candidate collective units from a declared relational configuration. It derives connected components, examines their dynamics under addition and deletion, and applies the six categories to one finite history. The model also exposes a precise limit: a partition that is sufficient under one operation repertoire becomes insufficient under another. The construction is a stipulated illustration of relational unit formation, with social interpretation and temporal identity kept explicit.

14.1 Elementary Positions and Relational Configurations

The model begins with a finite set of elementary positions and a specified type of relation among them. These are declared inputs. The collective units will be constructed from their configuration, so the derivation concerns those units rather than every object appearing in the model.

Let V be finite and let

$$E_0 = \{\{u, v\} : u, v \in V,\ u \neq v\}$$

be the possible undirected edges. A configuration is $G \subseteq E_0$, and the carrier is $S = 2^{E_0}$. An edge can be interpreted in a hypothetical application as a specified cooperative connection. The model treats it as undirected and Boolean; direction, intensity, and contested meaning remain outside this illustration.

For every $e \in E_0$, define total maps

$$a_e(G) = G \cup \{e\}, \qquad d_e(G) = G \setminus \{e\}. \tag{32}$$

They add and delete the selected edge. Nonempty compositions generate a transformation semigroup acting on S. Full graph equality is the base equivalence.

Both elementary maps are idempotent. Adding an already present edge leaves the graph unchanged; deleting an absent edge does likewise. The equalities concern effects and permit separate occurrence indices for repeated applications. Thus the event distinction developed earlier is already present in this simple system.

The interpretation is intentionally bounded. Elementary positions can stand for participants only if that meaning is warranted. Edges can stand for cooperation only if the selected relation has evidence and a clear criterion. The graph construction derives groups relative to those inputs. It leaves their input justification and a broader account of individuals open.

14.2 Connected Components and Candidate Collective Units

The selected unit criterion is connectedness. This subsection proves that it gives a partition and explains the domain on which the resulting entities are represented.

DRAFT

For $u, v \in V$, define $u \simeq_G v$ when a finite undirected path in G connects them. The empty path connects each position to itself.

Proposition 14.1 (Component partition)**.** *The relation $\simeq_G$ is an equivalence on V. Its classes form a partition $\mathcal{C}(G)$, whose members are candidate collective units under the declared connectedness criterion.*

Proof. The empty path gives reflexivity. Reversing an undirected path gives a path in the opposite direction, proving symmetry. Concatenating a path from u to v with a path from v to w gives a finite walk from u to w; removing repeated segments if necessary gives a path. Thus the relation is transitive.

Every position belongs to its equivalence class. Two classes that intersect are equal by symmetry and transitivity. The classes therefore cover V and are pairwise disjoint. □

The proof establishes a mathematical partition. Interpreting each component as a socially relevant unit requires the connectedness criterion to be appropriate to the inquiry. A chain of pairwise connections may support one collective task and fail another. The unit interpretation remains a proposal to test.

There are two different equivalences in this construction. The base equivalence on S compares whole graph configurations. The relation $\simeq_G$ compares elementary positions within one configuration. Confusing these domains would identify a state class with an internal collective unit. Their distinction is essential to the six-category argument.

Define the appearance domain

$$I = \{(G, C) : G \in S,\ C \in \mathcal{C}(G)\}.$$

The map $p(G, C) = G$ connects a component appearance to its configuration. One graph can have several appearances, one for each component. In a time-indexed history, appearances can instead be (t, C), retaining repeated visits to the same graph configuration.

This is a constructive answer to part of the entity question. The units are derived from relational configurations under a specified criterion. Their identity across configurations still needs a further rule. Deriving a unit at a moment and establishing its historical continuity remain different tasks.

14.3 Component Dynamics under Edge Addition

The component partition can serve as a reduced state for a restricted repertoire. This subsection derives that positive result before examining its limitation.

Let $\pi : S \to \mathcal{P}_V$ send a graph to its partition $\mathcal{C}(G)$, where $\mathcal{P}_V$ is the set of partitions of V. For an edge $e = \{u, v\}$, consider the blocks containing u and v.

Proposition 14.2 (Addition-compatible partition)**.** *Adding $\{u, v\}$ merges the two blocks containing u and v, with no change if they are already one block. Consequently,* $\ker \pi$ *is preserved by every addition map a_e.*

Proof. If u and v lie in the same component, a path already connects them. Adding their edge creates no connection between distinct components.

If they lie in distinct components, the new edge connects those components. Any path newly connecting old components must use the added edge, because all its other edges were already present. The new connection therefore joins exactly the two endpoint components and leaves the other blocks separate.

Two graphs with the same old partition have the same blocks containing u and v. The stated merger therefore gives the same new partition in both graphs. This is preservation of $\ker \pi$. □

The partition can consequently be updated deterministically under the addition-only repertoire. Internal edge differences are irrelevant to the next component partition for those operations. The quotient is useful because its sufficiency has been proved for a declared task.

DRAFT

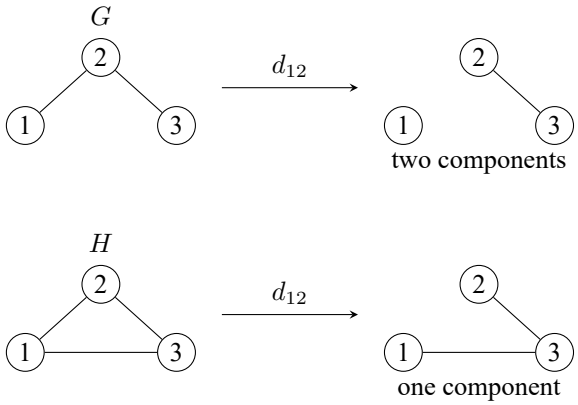

Figure 2: Edge-deletion comparison for graphs with a common initial component partition. The successor partitions expose a difference in internal relational support.

The construction also makes unit merger explicit. Adding a cross-component edge reduces the number of components by one. Adding an internal edge leaves the number fixed. Neither operation adds an elementary position. The change concerns how the fixed positions are grouped under the unit criterion.

An interpretation of merger must still explain why one new connection unifies the groups for the selected purpose. The mathematical component rule supplies that consequence once the criterion is adopted. It does not establish that every social connection should have that grouping effect.

14.4 Deletion and the Loss of Reduced-State Sufficiency

Allowing deletion changes which internal differences matter. This subsection gives a complete counterexample to partition-level sufficiency.

Take $V = \{1, 2, 3\}$ and abbreviate $\{i, j\}$ by ij in edge sets. Let

$$G = \{12, 23\}, \qquad H = \{12, 23, 13\}.$$

Both graphs are connected, so $\pi(G) = \pi(H) = \{\{1, 2, 3\}\}$. Deleting 12 gives

$$d_{12}(G) = \{23\}, \qquad d_{12}(H) = \{23, 13\}.$$

The first has components $\{1\}$ and $\{2, 3\}$. The second remains connected through the path 1–3–2. Hence their component observations differ.

Figure 2 displays the comparison. The inputs have the same group partition, while one common deletion produces different partitions.

The reduced-update criterion therefore excludes a deterministic function of the old partition alone for this deletion. The problem is located in the omitted internal structure, specifically whether another path maintains connectivity after the edge is removed.

The example gives a conditional account of robustness. The triangle retains connectivity after this deletion, whereas the path loses it. The component partition records current unity and omits this difference in its support. A model of persistence under withdrawal needs a richer description.

The result also explains why entity formation and entity persistence can demand different information. Connectedness identifies a present unit. Predicting whether it remains connected after a change can require the detailed arrangement of its relations. The unit label alone leaves that prediction unresolved.

14.5 Continuation Tests and Internal Structure

The enlarged repertoire can distinguish every graph in this finite model. This subsection derives the exact result and states its testing assumptions.

DRAFT

Table 6: Graph configurations and component observations on three positions

Present edges	Component partition
$\varnothing$	$\{\{1\},\{2\},\{3\}\}$
$\{12\}$	$\{\{1,2\},\{3\}\}$
$\{13\}$	$\{\{1,3\},\{2\}\}$
$\{23\}$	$\{\{2,3\},\{1\}\}$
$\{12,13\}$	$\{\{1,2,3\}\}$
$\{12,23\}$	$\{\{1,2,3\}\}$
$\{13,23\}$	$\{\{1,2,3\}\}$
$\{12,13,23\}$	$\{\{1,2,3\}\}$

Proposition 14.3 (Graph separation by deletion words)**.** *With component observation π and all edge deletions available, distinct graph configurations have different continuation signatures. Their full continuation equivalence is therefore equality.*

Proof. Let $G \neq H$. Choose an edge e that belongs to exactly one of them. Apply a word that deletes every edge in $E_0 \setminus \{e\}$. The word is finite because V is finite.

These deletions leave e unchanged and remove all other edges. One resulting graph is $\{e\}$; the other is empty. The endpoints of e lie in one component only in the first graph. The final component observations therefore differ.

Every distinct pair has such a witness. Equal configurations trivially have equal observations under every word. Thus signature equality is graph equality. □

The theorem concerns exact tests in a stipulated system. It assumes the full deletion repertoire, a fixed edge universe, and exact component observation. Restricted access to operations or observations can leave some internal differences unresolved.

It also leaves the desirability of the tests open. Deleting connections can be a destructive intervention in an interpreted case. The proof uses hypothetical continuations to characterize information; it supplies no recommendation to perform them.

The addition-only and deletion-enriched models therefore give different continuation quotients on the same carrier. The difference follows from their test repertoires. It does not require a different underlying configuration to have appeared.

This demonstrates the constructive and critical roles of the continuation method. It can justify a coarse state when the task permits one, and prove that the same state is inadequate after the task changes.

14.6 Complete Three-Position Enumeration

The three-position case makes the construction fully inspectable. This subsection enumerates the states, observation classes, and transformation structure.

There are three possible edges, so the carrier has $2^3 = 8$ graphs. Table 6 lists every configuration and its component partition. Four graphs share the connected partition, giving five distinct current observations.

Under addition alone, graphs with the same partition remain equivalent under every word by Proposition 14.2. The empty word distinguishes different current partitions, so the full quotient has exactly five classes. Under addition and deletion, Proposition 14.3 gives eight classes.

The appearance domain I has thirteen members in this case. The empty graph contributes three component appearances. Each one-edge graph contributes two, giving six more. Each of the four connected graphs contributes one, giving four more. Thus $3 + 6 + 4 = 13$.

The full nonempty transformation semigroup has twenty-six elements. Each edge coordinate can be left unchanged, set to zero, or set to one. In a word, the last operation on that coordinate determines its constant value. There are 3^3 such coordinate descriptions, including the identity.

DRAFT

A nonempty word sets at least one coordinate and therefore cannot be the all-unchanged identity. Every other description is realized by setting its constant coordinates once. The number is therefore $3^3 - 1 = 26$. The empty word remains available in the word calculus as the zero-step identity map.

A finite verification program enumerates these objects and independently compares paired configurations under the operation repertoires. Its results agree with the five-class and eight-class calculations. The checks concern the stipulated model; the displayed proofs provide the general conditional reasoning.

14.7 Formation, Merger, Fission, and Reappearance

A selected history gives the components temporal appearances. This subsection uses one history to distinguish group formation from identity across changes.

Begin with the empty graph and apply

$$a_{12},\ a_{23},\ a_{13},\ d_{12},\ d_{13},\ a_{12}.$$

The component history starts with three singletons, joins 1 and 2, then joins all three positions. Adding 13 changes internal structure without changing the component partition.

Deleting 12 from the triangle leaves all three positions connected through 13 and 23. Deleting 13 then leaves $\{1\}$ and $\{2, 3\}$. Adding 12 reunites all three positions. The graph trajectory records formation, internal reinforcement, fission, and reappearance under the connectedness criterion.

Whether the final three-position group is the same entity as the earlier one requires another criterion. Equality of membership sets would identify them. A criterion requiring uninterrupted connected continuity would distinguish the two intervals. Both can be represented, and the graph history makes their disagreement explicit.

A directed lineage can link components at consecutive steps when their vertex sets overlap. At fission, one component overlaps two successors. At merger, a successor overlaps several predecessors. The lineage therefore preserves directional continuation without satisfying the identity equivalence implied by treating all such links as sameness.

This history shows why a derived unit criterion does not settle every entity question. It constructs components at each configuration. The interpretation of their temporal continuity remains an additional commitment that can be tested against the purpose of the inquiry.

14.8 Coordination of the Six Categories

The same graph case can represent all six analytical roles. This subsection makes their connections and differences explicit.

The entity representation consists of component appearances and a declared continuity criterion. The relation representation includes direct edges and derived path connectivity. These differ: two positions can be connected without a direct edge between them.

Events are indexed applications of additions and deletions. Adding a present edge can be a silent graph transition and still remain one application in the history. Exact event count requires retaining positions or a counter, because the update maps are idempotent.

Attributes can concern edge presence, component size, or connectivity of a selected pair. Edge presence fails to descend to the component partition, because connected graphs can have different edges. Pairwise connectivity does descend: it is determined by whether the pair occupies one block.

States can be full graphs or reduced partitions when the repertoire permits. The addition-only case proves that a reduced state can be exact for a task. The deletion counterexample proves its limit.

Processes are operation words and graph trajectories. Their products can forget repeated applications and intermediate partitions. The selected history therefore retains information needed for formation and continuity questions that the final graph omits.

These coordinated uses establish representability under declared commitments. They leave open whether the social meaning of a graph component is appropriate in a particular case. The formal clarity helps locate that remaining question.

DRAFT

14.9 Philosophical Interpretation and Alternative Unit Criteria

Connectedness is one possible way to derive a collective unit. This subsection evaluates its strengths and limitations without giving it universal authority.

The criterion has a clear construction and definite consequences. It can identify groups from relations among supplied positions, explain mergers through new links, and describe fission through loss of connections. It also supports precise questions about which internal differences matter to persistence.

A social unit can require more than connectedness. A chain may connect participants whose commitments are incompatible. A single weak link may join otherwise independent groups. An institution may recognize a group despite sparse interaction, or participants may coordinate across a structure that this graph omits.

Alternative criteria can therefore use direction, thresholds, shared procedures, repeated interaction, or institutional records. Each criterion changes the unit construction and its evidence requirements. A thresholded graph, for example, needs a scale and a threshold whose meaning must be argued.

The model's philosophical contribution is narrower and constructive. It shows how a relational configuration can support derived units without taking those collective units as initial carrier elements. It also shows that the chosen relation structure and criterion are indispensable inputs.

This leaves ontology suspended. The result concerns a representational and explanatory strategy. An argument that all entities are ultimately relational formations would need to extend the reasoning beyond the fixed elementary positions and this specific grouping criterion.

The case nevertheless advances the original question beyond an inventory of limitations. It provides a workable construction, proves its dynamical adequacy under stated conditions, and demonstrates exactly where a richer representation becomes necessary.

15 Coordination of the Six Category Records

This section develops a joint representation in which the six categories can cooperate without losing their different roles. It specifies the domains for appearances, occurrences, states, and processes; derives the coherence of event chains with the action; and examines which quotient maps should commute. A central countercondition is that a continuing entity can occupy different states. Requiring every record to descend through every quotient would therefore impose an unjustified identity criterion.

15.1 Distinct Domains in a Common Inquiry

The category treatments introduced several kinds of record. Their coordination begins by preserving their domains. This subsection collects the necessary maps and explains why a single undifferentiated carrier of descriptions would obscure their responsibilities.

Retain a configuration carrier S, labeled operations T_b, and an action-compatible quotient $q : S \to Q$. Add an appearance domain I with anchor $p : I \to S$. The anchor associates an appearance with its represented configuration. Let E_{id} be a separate equivalence on I, with quotient $e : I \to I/E_{\mathrm{id}}$.

Add an occurrence domain Ω with source, target, and label maps

$$\mathrm{src}, \mathrm{tgt} : \Omega \to S, \qquad \mathrm{lab} : \Omega \to B.$$

These maps describe how an occurrence record relates to the operation model. The occurrence itself remains independently indexed.

A process record can retain a seed and an ordered chain of occurrences. Attributes can be attached to configurations, appearances, occurrences, or processes according to the question. Incidence relations likewise need a declared participant domain and context.

The collection is an enriched construction. An inquiry can use only the components it needs. The purpose is to expose their relationships, rather than to require a maximal record for every social fact.

DRAFT

15.2 Occurrence Coherence with the Action

An occurrence described as an instance of a modeled transition should agree with that transition's source and target. This subsection states the condition and its evidential status.

For the relevant transition occurrences, require

$$\mathrm{tgt}(\omega) = T_{\mathrm{lab}(\omega)}\big(\mathrm{src}(\omega)\big). \tag{33}$$

The equation links the occurrence description to the action model. It is a coherence assumption about the representation.

The assumption does not establish that the occurrence happened. A hypothetical event record can satisfy it, and an actual record can fail it because the model, coding, or evidence is incomplete. The failure needs interpretation before it becomes a historical conclusion.

An attempted operation can leave source and target equal. The equation permits such a record when the map fixes the source. A blocked attempt requires an availability or failure convention. An unattempted operation is a possibility in the model, rather than an occurrence record by default.

Several occurrence tokens can share the same source, label, and target. Repeated idempotent attempts supply a direct example. The coherence equation therefore need not make the description map injective.

The distinction protects occurrence identity from effect compression. A record system can retain the token, its evidential status, and its transition description separately. Each component can be revised without silently replacing the others.

15.3 Event Chains and Process Endpoints

Compatible occurrence records can be assembled into a process chain. This subsection derives the relation between the chain's endpoint and the composite action of its labels.

Let a process record be $h = (x, \omega_1, \dots, \omega_k)$, where the seed satisfies $\mathrm{src}(\omega_1) = x$ when $k > 0$, and adjacent occurrences satisfy

$$\mathrm{tgt}(\omega_i) = \mathrm{src}(\omega_{i+1}).$$

The empty chain retains its seed explicitly.

Proposition 15.1 (Coherence of process endpoints)**.** *If every occurrence in the chain satisfies Equation* (33)*, then its final endpoint is*

$$T_{\mathrm{lab}(\omega_k)} \cdots T_{\mathrm{lab}(\omega_1)} x.$$

Applying q gives the same outcome as successively applying the induced quotient operations to $q(x)$.

Proof. For one occurrence, the endpoint formula is exactly the coherence equation. Suppose it holds for the first i occurrences. Adjacency identifies their endpoint with the source of ω_{i+1}. The next coherence equation applies the next labeled map to that endpoint. Induction proves the first statement.

For the quotient statement, action compatibility gives $q(T_b z) = \bar{T}_b(q(z))$ at every step. Substituting this equality successively through the endpoint formula gives the quotient trajectory. The empty chain has endpoint x and quotient endpoint $q(x)$. □

The proof identifies the exact role of chain completeness. If two recorded occurrences have mismatched endpoints, an unrecorded intermediate step may be needed. Silently joining them would assert a transition that the record has not represented.

A process can also have a coarser segmentation whose stages contain several occurrences. Associativity preserves the endpoint when the underlying chain is coherent. It leaves the segment boundaries and their meaning to a separate record.

The result coordinates event, process, and state descriptions while preserving their different information. A shared endpoint does not recover the chain, and a coherent chain does not establish actual occurrence without evidence.

DRAFT

15.4 Entity Identity and State Anchors

Entity identity and state equivalence occupy different domains. This subsection examines their relationship and proves why state constancy should not be imposed on identity by default.

The relation E_{id} is a subset of $I \times I$. The state relation $\ker q$ is a subset of $S \times S$. A direct intersection has no intended role in this typed construction. A set-theoretic operation on their encodings would not supply the missing domain alignment.

The anchor permits a pullback:

$$uE_{\text{state}}v \quad \Longleftrightarrow \quad q(p(u)) = q(p(v)).$$

This is an equivalence on appearances. Its intersection with E_{id} is mathematically defined, but it adds state agreement to the identity criterion.

Proposition 15.2 (State assignment to an entity class)**.** *The map $q \circ p : I \to Q$ factors through the entity quotient e if and only if*

$$uE_{\text{id}}v \implies q(p(u)) = q(p(v)). \tag{34}$$

Proof. If $q \circ p = \bar{p} \circ e$, equal entity classes receive the same value under $\bar{p}$, proving necessity. Conversely, if the displayed condition holds, assign to each entity class the common state class of its appearances. The value is representative-independent and gives the required factorization. □

A continuing organization can have appearances before and after authorization, resource acquisition, or activity. Those appearances can belong to different state classes. The factorization condition then fails even when the identity criterion is appropriate.

The failure is not a defect in tracking change. It shows that current state is generally a property of an entity appearance or an entity at a context, rather than a timeless function of entity identity alone.

The pair record

$$u \longmapsto \big(e(u), q(p(u))\big)$$

retains both answers on the appearance domain. One entity can appear in several states. Repeated appearances with the same pair can still require an occurrence or time index. The pair is not automatically a complete appearance identifier.

15.5 Attributes and Incidence across Records

Attributes and relations can be transferred between record levels only under their own descent conditions. This subsection coordinates those conditions with identity and state.

A state attribute $a : S \to V$ descends through q precisely when it is constant on state classes. An appearance attribute descends through e precisely when it is constant on identity classes. The two tests concern different domains and can have different answers.

A changing attribute can be retained on appearances or on entity-context pairs. Requiring it to be constant over the entity's entire history would replace a dynamic attribute with a timeless one. That change needs an explicit research purpose.

For incidence at a configuration, let $I_s = p^{-1}(s)$ and $R_s \subseteq I_s^n$. A relation on reidentified participants requires saturation under the restricted identity criterion in each coordinate. The relation section derives that condition.

Context matters because the same participants can enter or leave a relation over time. A timeless relation on their global identity classes can merge those changes unless the context is retained in the predicate or its domain.

The compatibility tests should therefore follow the question. Some maps should commute because they report the same target through different records. Other maps should remain distinct because their targets change through time or belong to different analytical roles.

DRAFT

15.6 Shared Subjects and Category Overlap

One subject can support several category uses in a single inquiry. This subsection explains that overlap without reducing all roles to one identity criterion.

An agreement can be tracked as a continuing referent, described through obligations, located in signing or revision occurrences, assigned attributes, reported in a state, and reconstructed through a process. The records answer different questions about the same inquiry.

A process can itself become a referent in another question. An investigator can track a negotiation across stages while also using its internal occurrences to explain an outcome. The entity-like tracking role and the process role can coexist through different maps.

A relation can likewise be named, revised, or entered into another relation. A finite model can add records of those relation instances to an appropriate participant domain. The enrichment should state the new roles and their identity criteria.

Such overlap creates no requirement that every object occupy one exclusive category. An exclusive classification would be an additional theoretical proposal whose usefulness needs argument.

The six-category repertoire also remains open to challenge. A research question can expose a missing role or an inadequate distinction within a current role. The appropriate response is to specify the missing information and test a revised construction.

15.7 A Compatibility Audit for a Joint Model

A joint model can be checked through a small set of explicit obligations. This subsection organizes them by the map whose use is being claimed.

For operation-to-state transfer, verify that the state equivalence is preserved. For occurrence-to-transition transfer, verify the source, label, and target equation. For process construction, verify adjacency or state the convention for unrecorded gaps.

For attributes and incidence, check the appropriate fibre constancy and saturation conditions. For historical queries, check the record factorization criterion. For entity tracking, state the continuity criterion independently of the dynamic observation quotient.

The audit should also identify conditions that are intentionally not imposed. A continuing entity need not occupy one state. A quotient-silent event need not disappear from the occurrence record. A process with the same endpoint need not share a formation history.

A failed coherence check has several possible causes. The model can omit a relevant variable, the records can refer to different contexts, or the proposed transfer can be inappropriate for the question. The failure should be investigated at that level.

This method provides a constructive alternative to a single grand equation for all six categories. It specifies the maps and conditions that coordinate their particular uses, while preserving the distinctions that the inquiry needs.

15.8 Representation and Factual Warrant

The coherence results concern a model and its records. This final subsection states the additional requirement for a claim about social facts.

An internally coherent occurrence chain can be hypothetical or incorrectly recorded. An entity criterion can be consistently applied and still poorly suited to the practice under study. An attribute can descend through a quotient while its coding rule remains disputed.

Factual warrant requires a connection between the representation and the case. Sources, observation, interpretation, and comparison design supply that connection. The formal audit identifies where they enter.

The distinction permits a model to remain useful during disagreement. Several candidate histories or identity criteria can be represented and their consequences compared. The research state can preserve the alternatives until evidence or argument supports a refinement.

DRAFT

The coordinated category account therefore combines mathematical discipline with epistemic openness. Its maps make commitments explicit, its proofs establish conditional consequences, and its records retain the questions that those consequences leave unresolved.

16 Philosophical Scope and Factual Warrant

This section examines the philosophical commitments of the category representations and the evidence needed for their use in social inquiry. It develops ontological suspension, distinguishes formation from description and classificatory uptake, and considers historical explanation, identity, and evaluation. The aim is to preserve the questions that the formal constructions clarify without allowing their mathematical consistency to decide those questions by itself.

16.1 Ontological Suspension and Analytical Commitment

The six categories serve analytical roles in an inquiry about social facts. This subsection explains what ontological suspension permits and what it leaves the modeler responsible for.

The framework can ask how an entity is reidentified, how a relation is formed, how an occurrence is recorded, how an attribute is assigned, how a state supports updates, and how a process is reconstructed while leaving ultimate ontological priority unsettled. The questions concern representational and explanatory commitments that can be investigated within a declared scope.

Suspension does not make every modeling choice neutral. Selecting a carrier, identity criterion, or observation can privilege some distinctions and obscure others. Those choices can shape the conclusions of an inquiry even when the author withholds a metaphysical claim about what fundamentally exists.

The appropriate response is to make the choices inspectable. The entity section states its continuity criterion. The attribute section states its coding and scale. The state section states its observation and update responsibilities. The process section retains the relation between a sequence and its compressed effect.

The inherited series title connects this paper to Part I. The present subtitle and argument specify the narrower task of modeling six categories of social facts. A successful construction establishes an analytical possibility under its assumptions. An argument about the ultimate nature of social reality would require further premises.

The suspension therefore has a positive methodological role. It allows competing representations to be developed and criticized without deciding their metaphysical hierarchy in advance. Their adequacy can first be tested through the questions they answer and the distinctions they preserve.

16.2 Formation, Description, and Uptake

A pattern can form, become distinguishable in a description, and enter subsequent action through recognition or classification. This subsection separates those achievements and examines their possible interaction.

Formation concerns the development of the practice, organization, or dependence pattern being studied. Description concerns a record through which an investigator or participant distinguishes it. Uptake concerns the use of that description in further activity.

These achievements can occur in different orders. A practice can persist before an official category recognizes it. A proposed category can precede the organization it is intended to support. A description can become consequential when an institution uses it to allocate access or select a procedure.

The graph illustration derives a candidate unit from a declared connectivity rule. That construction identifies a partition of a relational configuration. A claim that participants recognize those components or act through them requires an additional uptake model and evidence.

The distinction prevents two opposite shortcuts. A new description need not create a new social organization. A description can nevertheless contribute to later formation when participants respond to it. The response must be represented explicitly before its effects are inferred.

DRAFT

A comprehensive account can therefore connect the three roles without identifying them. It can record a formation history, a descriptive rule, and a response process, then examine their dependencies and disagreements. The next subsection gives one conditional representation of the response process.

16.3 Classification-Mediated Updates

A classification can enter dynamics through a rule selecting subsequent operations. This subsection defines that enrichment and derives its compatibility with a state quotient.

Let $o : S \to Y$ be a classification or observation, and let $\pi : Y \to B$ be a deterministic response rule. Define

$$U_\pi(x) = T_{\pi(o(x))}(x). \tag{35}$$

The rule selects an operation from the observed value and applies it to the configuration.

Proposition 16.1 (Compatibility of an observation-mediated response)**.** *If an equivalence E is preserved by every T_b and $E \subseteq \ker o$, then E is preserved by U_π. The response therefore has a well-defined induced update on S/E.*

Proof. If xEy, containment in $\ker o$ gives $o(x) = o(y)$. The response rule selects the same label $b = \pi(o(x)) = \pi(o(y))$. Preservation by that map gives $T_b x \, E \, T_b y$, which is the required relation between $U_\pi(x)$ and $U_\pi(y)$. □

The theorem is conditional on uptake. The classification o and response rule π are additional inputs. A description's existence does not establish that an actor uses it, nor does a formal response rule establish its legitimacy or empirical accuracy.

The response map can lie outside the original semigroup generated by the primitive maps. On $\{0, 1\}$, let the primitives be identity and flip. Observe the state, choose flip at zero and identity at one. The response sends both states to one, while every old primitive composition is a bijection.

The example shows that conditional selection can introduce a noninvertible global update even when every selected primitive is invertible. The selection rule is part of the enlarged mechanism. The result supplies no contradiction to an earlier theorem about one fixed semigroup.

This construction provides a limited formal account of classificatory uptake. A substantive study must identify the classification, the responding actors, their information, and the actions through which the description becomes consequential.

16.4 Social Facts and Assertions About Them

A representation can encode a claim about a social condition without establishing that condition. This subsection separates the record, its asserted content, and the warrant for that content.

A database can contain an authorization entry. That is a fact about the record under a suitable evidential description. The proposition that authorization holds under the relevant practice is another claim. A disagreement can concern the entry's accuracy, the coding rule, or the governing criterion.

The same separation applies to events. An occurrence record can assert that an agreement was signed or an activity attempted. Its presence in the model supplies a representation of that claim. Evidence is needed to connect it to an actual episode.

Identity claims can also be recorded without being settled. Two sources can disagree about whether an organization continues through a change. The model can preserve both criteria and compare their consequences. A single identifier should not silently resolve the dispute.

PROV-DM offers a useful comparison through its separate treatment of entities, activities, and derivation records [6, Sections 2.1 and 5.2.1]. The present framework has its own category commitments. A translation between the schemes requires an account of the meanings and information preserved.

Huang's conformance specification likewise emphasizes declared encodings and partitions in reconstructing generative structure [4]. The category audit adds a complementary responsibility: identify the base data, added records, and interpretive premises on which each claim depends.

DRAFT

16.5 Historical Explanation and Predictive Sufficiency

A record sufficient for future observation can remain inadequate for historical explanation. This subsection examines why both uses can be legitimate and how they should be coordinated.

Two histories can reach the same configuration and agree under all selected future observations. A query about formation mode, contribution, or an earlier alternative can still distinguish them. Predictive equivalence therefore leaves historical questions open unless their information is included in the task.

A historical explanation can seek why the present arrangement arose, which processes sustained it, or how participants understood a transition. Those questions can require records that a compressed predictor omits. Their relevance needs a substantive argument beyond future-output difference.

Conversely, a detailed history can contain distinctions irrelevant to a selected forecast. The framework permits a smaller operational record while preserving the larger history in an archive. The relation between the records should remain traceable.

If a later operation consults a historical field, the predictive problem changes. The sufficient state must retain that field or equivalent information. The historical-relations companion paper develops this dynamic coordination in a finite example.

The philosophical lesson is that historicity has several roles. A process can produce a present condition, a record can preserve its formation, and later activity can respond to that record. The roles can interact without becoming one unqualified claim that history determines every future difference.

16.6 Identity, Behavior, and the Boundary of Selfhood

The entity construction tracks appearances through a declared equivalence or lineage. This subsection states what such tracking can contribute to identity questions and where further philosophical work is needed.

Behavioral equality can hold between separately identified entities. A continuing entity can also change its behavior. The continuation quotient therefore cannot replace every identity criterion. Its equivalence concerns a selected observation task.

A lineage records directional continuity through change and can branch through fission or merge through combination. Turning that relation into numerical identity requires additional choices. Undirected connectivity can join branches that the inquiry needs to distinguish.

The same caution applies to a model of a self. Embodied continuity, first-person appropriation, social recognition, and practical responsibility can disagree. A causal chain or an observation profile can contribute to an account of those questions while leaving their resolution open.

A commitment to a future self can matter precisely because future preferences or abilities may change. A model that identifies identity with unchanged behavior would miss that possibility. The relevant continuity criterion needs an independent philosophical argument.

The present metamodel supplies formal preparation for such an inquiry. It distinguishes appearance, state, history, and lineage and identifies their information requirements. An account of lived selfhood remains a further research project.

16.7 Evaluation and the Selection of Descriptions

Descriptive choices can influence what an inquiry evaluates, while the formal results leave evaluative standards open. This subsection examines that relation.

An observation of whether activity occurred differs from an observation of its distribution, burden, or meaning. A quotient preserving the first can merge distinctions needed by the others. Selecting the observation therefore shapes the questions the model can answer.

The choice can be justified by a bounded purpose. A completion flag can be sufficient for one technical calculation. Its use becomes problematic when the result is extended to a broader judgment without retaining the missing dimensions.

DRAFT

Generative and reproductive roles also remain evaluatively open. Formation of a new route can support or undermine participants' aims. Maintenance of an existing relation can preserve cooperation or sustain an unwanted dependency. The formal role alone supplies no fixed ranking.

A plural description can retain several observations and their joint continuation requirements. That construction preserves the selected information but does not decide how conflicting values should be weighed.

The framework therefore separates a formal measure from the reasons for using it. Cardinality, robustness, and predictive sufficiency can inform an evaluation when their relevance is argued. They should remain linked to the standards and participants that give the comparison its meaning.

16.8 Adequacy through Explicit Revision

The metamodel's adequacy depends on its capacity to support and survive criticism in a specified inquiry. This final subsection identifies the kinds of revision that the preceding distinctions permit.

A failed update prediction can expose an omitted condition or an overly coarse state. A disputed identity can expose an inadequate continuity criterion. A history collision can expose insufficient records for a target query. These failures belong to different parts of the representation.

A revised construction should retain the earlier formulation and explain the change. Adding a variable, refining a quotient, or changing an operation repertoire can repair one problem while introducing new assumptions. Those assumptions should remain visible.

The category framework is useful when it makes the repair more precise. It should help identify which record needs enrichment, which proof needs rechecking, and which interpretive claim remains unsupported.

Its philosophical contribution is therefore a disciplined coordination of questions. The six categories organize different responsibilities within social inquiry, and the formal constructions show how some of those responsibilities can be met under declared assumptions. The remaining tensions continue to guide research.

17 Changes of Regime and Extensions of the Dynamics

This section examines changes to the mathematical setting that the six category representations may require. The discussion first treats transitions between declared regimes of description. It then introduces a finite probabilistic extension and derives its consistency condition. Partial availability, concurrent activity, and history-dependent responses complete the comparison. Each extension identifies its additional inputs and the conclusions that survive under those inputs.

The fixed action supplies a controlled starting point. A more detailed inquiry can reveal a changing classification, a restricted operation domain, uncertain outcomes, or several activities occurring during an overlapping interval. These discoveries pose different mathematical problems. Treating them all through a larger carrier can sometimes produce a formally unified representation. The substantive value of that representation depends on the interpretation of its new coordinates and on the evidence available for their updates.

17.1 A Declared Family of Descriptive Regimes

A regime can specify a vocabulary of observations, a criterion for following entities, or an operation repertoire. To represent anticipated changes among such regimes, the model must retain which regime is active and how a transition alters the represented situation. The following construction makes those commitments explicit.

Let $\mathcal{R}$ be a set of regime labels. For each $r \in \mathcal{R}$, let S_r be a carrier and let E_r be an equivalence on that carrier. The tagged union

$$X = \coprod_{r \in \mathcal{R}} \{r\} \times S_r$$

DRAFT

keeps the regime and its state together. A point (r, x) records a state under a specified regime. Define

$$(r, x)\, E\, (s, y) \quad \Longleftrightarrow \quad r = s \text{ and } x\, E_r\, y.$$

This definition compares states within a common regime. It leaves cross-regime alignments to an additional construction.

A primitive operation can now be a partial map $U_b : X \rightharpoonup X$. Whenever it is defined, write

$$U_b(r, x) = \big(\kappa_b(r, x), F_b(r, x)\big), \qquad F_b(r, x) \in S_{\kappa_b(r,x)}.$$

The map κ_b chooses the successor regime, while F_b supplies the successor state in its corresponding carrier. This typing matters: a state code valid under one regime may lack a declared interpretation under another. Even when the carriers happen to use the same numerical codes, their alignment requires a modeling decision.

Proposition 17.1 (Descent across declared regimes)**.** *A partial operation U_b induces a partial operation on X/E if and only if E-related inputs have the same definedness and, whenever their outputs are defined, the outputs have equal regime tags and equivalent state coordinates under that common successor regime.*

Proof. A partial quotient operation needs a domain consisting of whole E-classes. Thus definedness must agree for related representatives. For an admitted class, its successor class must also be independent of the representative. By the definition of E, this requires equality of the successor regime tags and equivalence of the successor state coordinates under that tag. These requirements are necessary. Conversely, their satisfaction defines an unambiguous domain on X/E and one successor class for each admitted input class. The resulting partial map is the required quotient operation. □

Internal consistency of each regime supplies only part of this condition. A regime can preserve its own state distinctions under its ordinary operations while a transition to another regime separates states previously identified. The transition therefore deserves its own proof. This distinction is relevant whenever a modeling account proposes to accommodate changing institutions simply by allowing its parameters to change. The parameter change can alter the very distinctions needed to determine a successor.

17.2 Refinement of Descriptions and Recovery of Omitted Information

A common-carrier example isolates the cost of moving to a finer description. Suppose $S_c = S_f = S$, where c and f name coarse and fine regimes. Let a regime switch preserve the raw coordinate:

$$U(c, x) = (f, x).$$

Related inputs in the coarse regime have xE_cy. Their outputs are related in the fine regime exactly when xE_fy. Consequently the switch descends precisely under

$$E_c \subseteq E_f.$$

The direction of this inclusion deserves attention. A finer description has smaller equivalence classes, so its equivalence typically satisfies $E_f \subseteq E_c$. A strict refinement therefore generally violates the condition needed to compute the switch from a coarse class alone.

For example, take $S = \{0, 1\}$. The coarse regime identifies both points, while the fine regime distinguishes them. The unique coarse class supplies insufficient information to choose between the two fine classes. A raw-state model retaining x can execute the switch without difficulty. Its ability comes from information retained in that model. The coarse record cannot acquire the missing bit merely through a change of notation.

DRAFT

This example separates three tasks in the interpretation of social change. A descriptive revision can introduce a distinction already represented in the raw data. An evidential revision can recover a distinction through additional observation or historical records. A substantive transition can change the represented situation itself. The three tasks can coincide in a case, yet their justification differs. A revised institutional classification may use archived information, require new documentation, and affect future action. Each component should receive its own update or evidential account.

The construction also clarifies the status of anticipated novelty. A regime catalog can include several possible successor vocabularies and explicit transitions between them. Such a catalog models revision within its declared possibilities. An account of how investigators or participants develop a previously unrepresented vocabulary requires additional work. Including a symbol named *new regime* leaves the content and interpretation of that regime to be supplied.

Cross-regime entity identity raises a related issue. The tagged equivalence above keeps regimes separate because it serves a state description. An organization may remain the same organization under two descriptions. A cross-regime alignment can represent that continuity through matched entity appearances, documentary succession, or another declared criterion. Merging regime tags in the state quotient would conflate this identity question with the consistency of the descriptive dynamics.

17.3 Finite Probabilistic Transitions

Some inquiries seek probabilities of successor states. A stochastic transition model adds information beyond deterministic reachability. The finite case permits a complete statement of the exact aggregation condition and a direct comparison with the quotient action.

Let S be finite and let K be a stochastic matrix, with $K(x, y) \geq 0$ and $\sum_{y \in S} K(x, y) = 1$. Let $q : S \to Q$ be a surjective description. For a quotient value $C \in Q$, its block is $q^{-1}(C)$. The probability of entering this block from x is

$$K(x, q^{-1}(C)) = \sum_{y : q(y) = C} K(x, y).$$

An exact quotient transition must assign the same block probability to every state receiving the same current description.

This requirement is the classical finite-state lumpability condition. Kemeny and Snell give the block-sum criterion and its proof in Theorem 6.3.2 of *Finite Markov Chains* [5]. The result is used here as an established antecedent. Its role is to specify the added consistency obligation when a category description is asked to support probabilistic prediction.

Proposition 17.2 (Exact finite probabilistic aggregation)**.** *A representative-independent quotient transition matrix exists for every initial distribution if and only if*

$$q(x) = q(x') \implies \sum_{y : q(y) = C} K(x, y) = \sum_{y : q(y) = C} K(x', y) \quad (C \in Q).$$

Under this condition,

$$\bar{K}(q(x), C) = \sum_{y : q(y) = C} K(x, y).$$

For a distribution μ on S, write $\mu_q(C) = \sum_{q(x) = C} \mu(x)$. Then

$$(\mu K)_q = \mu_q \bar{K}.$$

Proof. Initial distributions concentrated at two representatives of the same block induce the same quotient initial distribution. A common quotient transition therefore requires equal probabilities into each

DRAFT

target block, proving necessity. Under the stated condition, the displayed formula defines $\bar{K}$ independently of the representative. Its entries are nonnegative, and its row sums equal one because the blocks partition S. Finally,

$$\begin{aligned}(\mu K)_q(C) &= \sum_x \mu(x) \sum_{y:q(y)=C} K(x,y) \\ &= \sum_{A\in Q} \sum_{x:q(x)=A} \mu(x)\bar{K}(A,C) \\ &= \sum_{A\in Q} \mu_q(A)\bar{K}(A,C).\end{aligned}$$

This is the required commutation identity. □

The hypothesis concerns every initial distribution. A successful aggregation under one selected distribution can depend on how probability is distributed among hidden states inside each block. The proposition gives a stronger guarantee: the quotient transition remains valid independently of that hidden mixture. A project using a weaker guarantee should state the relevant initial distributions and the resulting restriction of scope.

17.4 Possible Successors and Their Probability Distributions

A small counterexample shows why possible successor classes give insufficient information for probabilistic aggregation. Let $S = \{0, 1, 2\}$, with blocks $A = \{0, 1\}$ and $B = \{2\}$, and set

$$K = \begin{pmatrix} 4/5 & 0 & 1/5 \\ 1/5 & 0 & 4/5 \\ 0 & 0 & 1 \end{pmatrix}.$$

From either state 0 or state 1, the possible successor blocks are A and B. Their probabilities of reaching B are $1/5$ and $4/5$, respectively. The current description A therefore preserves the set of possible successor blocks while omitting a distinction essential to the next-step probability.

For social interpretation, the difference concerns the claim made by a model. An account can state that two arrangements permit the same classes of outcome. An account can also state that those outcomes have equal probabilities under specified conditions. The second statement demands further information. The deterministic architecture supplies a disciplined language for the first kind of possibility comparison; it leaves the probability assignment to an enrichment with its own evidence.

A family of primitive kernels K_b supports finite operation sequences when the same block condition holds for each primitive. Applying the commutation identity successively gives the quotient distribution after any declared finite word. This sequential result presumes that the kernel assigned to the next primitive is appropriate to the represented state. If unrecorded history changes the next-step probabilities, the chosen state is incomplete for that model.

The deterministic case appears as a special instance. For a map $T_b : S \to S$, define

$$K_b(x, y) = \mathbf{1}_{\{T_b(x)=y\}}.$$

Its mass in a target block is one exactly when the deterministic successor belongs to that block. Equality of block masses is therefore equivalent to equality of successor descriptions. The probabilistic condition recovers preservation of $\ker q$. This relation explains the common structural role of the two criteria while keeping their empirical inputs distinct.

17.5 Partial Availability and the Meaning of Failed Operations

An operation may be executable only on part of the state space. Representing it by a partial map makes availability visible in the domain. A quotient partial operation then requires both constant definedness

DRAFT

within each class and a common successor class whenever execution is available. These are distinct requirements. Equivalent outcomes following successful execution leave open whether execution is possible at each representative.

A total-map representation can encode failure by adding failure states or by declaring that an unavailable operation leaves the state unchanged. Either convention can be useful for a specified question. Their meanings differ. A failed attempt can consume resources, produce a documentary record, alter expectations, or trigger a sanction. A self-loop on the original state can represent such an attempt only if those consequences are outside the declared state question or are retained elsewhere.

The occurrence record is particularly valuable here. Two situations may have the same resulting state while differing in whether an operation was attempted. An event ledger can retain that difference even when the state dynamics compress it. If future responses depend on the attempt, its record must also enter the information available to subsequent updates. The category architecture identifies the relevant coordination obligation without forcing every event detail into every state description.

The feasible-path model developed separately in the paper portfolio supplies more detailed conditions involving permissions, resources, and execution prefixes. The present partial-map discussion establishes the simpler point: availability has a formal location, and that location must be preserved by the description when the description is used to determine executable operations.

17.6 Concurrent Activity and Temporal Resolution

A word orders its primitive occurrences. That order can represent an observed sequence, an imposed scheduling convention, or an approximation at a chosen temporal resolution. Concurrent activity requires an interpretation of how the sequential description relates to overlapping occurrences.

Commutation of two state transformations gives a limited result. If $T_a T_b = T_b T_a$, reversing their order preserves their composite effect on every state in the declared carrier. The equation concerns transformation effects. Occurrence times, exposure intervals, participants' knowledge, and temporary resource conflicts may still differ. A representation retaining only the composite transformation omits those questions.

Conversely, two operations can overlap in clock time while their effective dependencies impose an order on particular subevents. An authorization may be issued during a resource transfer yet become usable only after a confirmation step. A sequential approximation must specify which events it treats as atomic and which timing relations it suppresses. The choice is assessed against the outcome or historical query.

A fuller concurrent model would need an explicit account of compatible occurrences, temporal constraints, and composition. The present architecture supplies two starting resources: occurrence-level records preserve individual executions, and process-level records preserve their organization. The exact relation between such records and the semigroup action remains a research obligation when concurrency carries substantive content.

17.7 History-Dependent Responses and Expanded State

History dependence can be represented by storing a record that determines the information used in the next update. The resulting state might include the current condition, the most recent formation mode, and a selected event summary. This strategy is useful when the retained record has an explicit update rule and a clear relation to the questions being answered.

The cost of the strategy appears in the size and interpretation of the record. A history coordinate can contain an entire sequence, yielding an exact but large state space. A finite summary needs a preservation proof for the selected future and historical readouts. Sufficiency for one query gives a local achievement. Adding another query or operation can require refinement.

The same issue affects institutional learning or classificatory uptake. A response may depend on a participant's remembered experience, an institution's archive, or an investigator's classification. Each

DRAFT

is a different information source. A response function $\pi(o(x))$ gives a compact model only when the observation o contains the information actually used by the response rule.

These extensions support a common methodological conclusion. Enlarging the mathematics should make an additional commitment explicit and testable. A larger carrier, a stochastic kernel, or a regime tag gains explanatory value through its interpretation and the questions it helps answer. The six-category architecture organizes those commitments while leaving the choice of an adequate empirical model open.

18 Approximate Descriptions and Finite-Horizon Error

This section develops a quantified alternative to exact descriptive consistency. It introduces a metric on reduced descriptions, derives trajectory error from local approximation residuals, and examines the consequences for threshold classifications. It then explains why numerical tolerance differs from an equivalence relation and identifies the evidence needed to use an approximate model.

The exact quotient construction provides a clear baseline: equivalent configurations have equivalent successors under each declared operation. An empirical or computational model can aim for a controlled approximation when exact preservation is too demanding. That change requires a measure of discrepancy and a statement of how error propagates. A phrase such as *approximately the same state* leaves these commitments unresolved.

18.1 Metric Structure and the Meaning of Approximation

A metric supplies a nonnegative distance between descriptions, with zero distance identifying equal points, symmetry, and the triangle inequality. The triangle inequality will perform the main work in the derivation. The interpretation of the distance remains an additional modeling choice.

For numerical attributes, a distance can compare values expressed in declared units. For a vector of attributes, a distance can also combine differences across coordinates. Such a combination needs justification. Changing a unit or a coordinate weight can alter which descriptions count as close. The attribute analysis therefore remains relevant to the approximate state model.

A categorical difference may resist a useful graded interpretation. An occurrence can be correctly or incorrectly identified; two organizations can be assigned different identity claims. A numerical distance between their codes has meaning only through an independently specified comparison. The introduction of a metric should follow the question it is meant to answer.

Girard and Pappas develop a broader framework of metric comparisons and approximate simulation and bisimulation for transition systems [2]. That work provides an established antecedent for quantified approximation. The present section proves a narrower elementary bound for two deterministic evolutions following the same label sequence. It leaves a full comparison with the broader framework to later investigation.

18.2 Reduced Updates and Local Residuals

Let $T_b : S \to S$ be the declared operations of the detailed model. Let $q : S \to Q$ be a description map, where (Q, d) is a metric space. Proposed reduced updates are maps $\widehat{T}_b : Q \to Q$. Surjectivity of q is unnecessary for the following bound.

The local residual compares two ways of taking one step: update the detailed configuration and then describe it, or describe the configuration and apply the reduced update. Assume that, for each b,

$$d\big(q(T_b x), \widehat{T}_b(qx)\big) \le \delta_b \qquad (x \in S). \tag{36}$$

The parameter $\delta_b \ge 0$ is a uniform upper bound on that discrepancy.

Also assume that the reduced update satisfies

$$d\big(\widehat{T}_b u, \widehat{T}_b v\big) \le \lambda_b d(u, v) \qquad (u, v \in Q), \tag{37}$$

DRAFT

with $\lambda_b \geq 0$. This condition controls how a discrepancy already present in the reduced description can change under the next operation.

The two assumptions address different sources of error. The residual is introduced even when the reduced input exactly equals qx. The Lipschitz factor governs propagation of an earlier discrepancy. Their combination gives a bound over a finite sequence.

Both assumptions require support. A fitted model can have small residuals on observed configurations while behaving differently elsewhere. The displayed uniform inequalities are mathematical premises. A finite sample becomes evidence for them only through a separate estimation, coverage, or structural argument.

18.3 Derivation of the Trajectory Bound

Fix a word $w = b_1 \cdots b_n$. Let the detailed and reduced evolutions be

$$x_i = T_{b_i} x_{i-1}, \qquad z_i = \widehat{T}_{b_i} z_{i-1}.$$

Their discrepancy at step i is

$$e_i = d(qx_i, z_i).$$

The initialization can itself be approximate, so e_0 is retained in the general result.

Proposition 18.1 (Propagation of local description error)**.** *Under* (36) *and* (37)*,*

$$e_n \leq \left(\prod_{j=1}^{n} \lambda_{b_j} \right) e_0 + \sum_{i=1}^{n} \delta_{b_i} \prod_{j=i+1}^{n} \lambda_{b_j}. \tag{38}$$

An empty product equals one.

Proof. Insert $\widehat{T}_{b_i}(qx_{i-1})$ between the two descriptions being compared. The triangle inequality gives

$$\begin{aligned} e_i &\leq d\big(q(T_{b_i} x_{i-1}), \widehat{T}_{b_i}(qx_{i-1})\big) \\ &\quad + d\big(\widehat{T}_{b_i}(qx_{i-1}), \widehat{T}_{b_i}(z_{i-1})\big) \\ &\leq \delta_{b_i} + \lambda_{b_i} e_{i-1}. \end{aligned}$$

The first term uses the local residual bound and the second uses the Lipschitz condition. For one step, the product-sum formula is exactly this inequality. Suppose the formula holds at $n-1$. Substituting it into $e_n \leq \delta_{b_n} + \lambda_{b_n} e_{n-1}$ extends every earlier product by λ_{b_n} and adds the new residual with an empty trailing product. Induction proves (38). □

The formula retains the order of the operations. A residual introduced early is multiplied by the sensitivity factors of subsequent updates. A large factor late in the word can amplify several earlier errors. A small residual bound for each primitive therefore has to be interpreted together with the continuation.

The initialization term matters for uncertain current records. Even an exact reduced update can propagate initial discrepancy. Conversely, exact initialization removes that term while leaving the residuals introduced by the approximation itself.

18.4 Uniform Bounds and Horizon Dependence

Suppose $\delta_b \leq \delta$, $\lambda_b \leq \lambda$, and $e_0 = 0$. Since all factors are nonnegative, the general bound yields

$$e_n \leq \delta \sum_{k=0}^{n-1} \lambda^k.$$

DRAFT

The finite sum has the explicit form

$$e_n \leq \begin{cases} n\delta, & \lambda = 1, \\ \delta \dfrac{\lambda^n - 1}{\lambda - 1}, & \lambda \neq 1. \end{cases} \tag{39}$$

For $\lambda \neq 1$, multiplication of the finite sum by $\lambda - 1$ cancels its intermediate powers and leaves $\lambda^n - 1$. For $\lambda = 1$, the sum has n unit terms.

When $0 \leq \lambda < 1$, the bound is at most $\delta/(1 - \lambda)$. The reduced dynamics contract earlier discrepancies enough to bound their accumulation. When $\lambda = 1$, the bound grows linearly with the number of steps. When $\lambda > 1$, the bound can grow geometrically.

These are properties of the declared metric model. A claim of approximation adequate for one horizon therefore needs to specify the horizon. A longer continuation can cross the permissible error threshold even when each individual update appears accurate.

The distinction also affects model comparison. One reduced model can have smaller local residuals and larger sensitivity factors than another. The preferred model for a long horizon can differ from the preferred model for a single step. The derived expression makes the tradeoff available for inspection.

18.5 An Example Attaining the Growth Bound

The geometric expression can be attained exactly. Let $S = Q = \mathbb{R}$, let q be the identity, and consider one operation with

$$T(x) = \lambda x, \qquad \widehat{T}(z) = \lambda z + \delta, \qquad x_0 = z_0 = 0,$$

where $\lambda, \delta \geq 0$. The local residual is exactly δ, and the reduced map has Lipschitz factor λ.

The detailed trajectory remains zero. The reduced trajectory satisfies

$$z_n = \delta + \lambda z_{n-1} = \delta \sum_{k=0}^{n-1} \lambda^k.$$

Since the values are nonnegative, the distance between the trajectories equals the displayed expression. The upper bound is therefore exact for this model.

With $\lambda = 2$, the error is $\delta(2^n - 1)$. A small constant local discrepancy can exceed any fixed tolerance if the horizon is sufficiently long. The example shows that a general inference from small one-step residual to uniform long-run accuracy needs additional assumptions.

The social interpretation remains limited. The scalar state is a mathematical counterexample to an approximation claim. It supplies no empirical assertion that a particular social process has the displayed sensitivity. A substantive application would need to justify the variables, update, and metric.

18.6 Threshold Decisions and Margins

An inquiry can use a numerical description to make a categorical decision. Let $g : Q \to \mathbb{R}$ satisfy

$$|g(u) - g(v)| \leq K_g d(u, v).$$

If $e_n \leq B_n$, then

$$|g(qx_n) - g(z_n)| \leq K_g B_n.$$

The metric bound therefore transfers to the readout.

Consider the classification $\mathbf{1}_{\{g \geq \theta\}}$. If

$$|g(z_n) - \theta| > K_g B_n, \tag{40}$$

the detailed and reduced classifications agree. When the predicted value exceeds $\theta + K_g B_n$, the detailed value remains strictly above the threshold. When it lies below $\theta - K_g B_n$, the detailed value remains strictly below it.

DRAFT

The margin condition is sufficient. Its failure leaves the classification unresolved by this bound. The actual classifications can still agree. Reporting agreement as guaranteed requires the appropriate margin or a stronger argument.

A small numerical discrepancy can matter near a threshold. If the classification enters a response rule, the two models can then select different subsequent operations. The same-word error theorem ceases to apply directly after that selection difference. A feedback approximation needs a further argument about policy stability or operation mismatch.

This observation connects approximation to social uptake. A descriptive error can remain small in its own metric while crossing a decision boundary that changes access, priority, or the next institutional step. The importance of the error depends on the use of the description.

18.7 Tolerance Relations and Transitive Closure

A common attempt to represent approximation identifies descriptions whenever $d(u, v) \leq \varepsilon$. The resulting relation is reflexive and symmetric, yet it can fail transitivity. Three real values $0, 0.6, 1.2$ with tolerance 0.7 give an elementary example.

Taking a transitive closure repairs transitivity at a further cost. On $\mathbb{R}$ with any $\varepsilon > 0$, the closure identifies every pair of points. For given x, y, choose a positive integer n with $|x - y|/n \leq \varepsilon$. The sequence

$$x, \quad x + \frac{y - x}{n}, \quad \ldots, \quad x + n\frac{y - x}{n} = y$$

joins them through ε-close pairs. Thus every pair belongs to the transitive closure.

A finite chain can exhibit the same problem at its own scale. Neighboring descriptions may each be within tolerance while the chain's endpoints are far apart. Closing the neighbor relation transitively merges the entire chain.

Consequently an equivalence constructed by closure can lose the original error guarantee. A partition into declared bins supplies another possible description, with its own boundary and diameter properties. The partition should be assessed through those properties, rather than through the tolerance relation it replaced.

This matters particularly for entity modeling. Approximate similarity of attributes can support a comparison among appearances. It leaves historical identity and continuity criteria to be supplied. An approximate state metric should not silently become an entity equivalence.

18.8 Evidence and the Scope of Approximate Adequacy

An approximate application should specify the distance, permitted discrepancy, residual bounds, update sensitivity, and horizon. It should also state which decisions depend on the description and whether those decisions have adequate margins.

Observation uncertainty and approximation residual are different inputs. A record may inaccurately measure the detailed state. A reduced update can also deviate from the detailed model even when that state is known. The general bound retains an initialization discrepancy, while a full measurement model may need uncertainty at several stages.

The theorem compares a fixed label sequence. Partial availability, adaptive choices, changing regimes, and stochastic transitions can require additional reasoning. These extensions should preserve the distinction between a mathematically derived bound and evidence that its assumptions hold in the application.

Approximation therefore broadens the architecture through quantified commitments. It permits a reduced description to be evaluated at a specified precision and horizon while retaining the exact construction as a reference point. The meaning and adequacy of that precision remain questions for the substantive inquiry.

DRAFT

19 Research Design and Revision Obligations

This section develops a proposed research design for evaluating the category architecture in a bounded social inquiry. It first specifies the unit of investigation and the competing representations. It then states evidence requirements for the six categories, explains how failures should be diagnosed, and identifies the conditions for extending or revising the model. The design remains prospective.

The conditional results establish relations among declared mathematical objects. Their use in social inquiry requires interpretations for those objects and evidence relevant to the resulting claims. A satisfactory study should make both levels visible. It should also retain discrepancies that reveal a poor representation, since those discrepancies can identify precisely which enrichment the inquiry needs.

19.1 A Bounded Arrangement and Its Comparison Questions

A first empirical study could follow one cooperative arrangement through formation, activation, and revision. The study would declare a temporal interval, a focal activity, and the organizations or other participants whose appearances enter the record. The cooperative example in Section 13 supplies a set of logical contrasts for designing such a study. Its binary states would be assessed and revised in light of the actual case.

The initial question should specify what the model is expected to recover. An inquiry into whether implementation occurred needs different evidence from an inquiry into the source of an authorization. An inquiry into the continuing identity of an organization needs a different comparison from one into the conditions enabling a particular action. These questions can share a case while retaining distinct success criteria.

A useful first comparison would involve three descriptions. A current-condition description would retain the variables initially proposed to determine the next operation. A history-enriched description would add the formation and occurrence information needed for selected historical questions. A feasibility-enriched description would add conditions that restrict execution. The comparison would assess each description against its declared task, including tasks for which its limitations are expected.

This design avoids rewarding a model simply for retaining more data. An expanded record gains value when the added information supports a stated question or repairs a demonstrated failure. It also carries costs: more demanding evidence, additional ambiguities, and a larger space of possible records. Those costs should be reported alongside gains in recoverability or consistency.

19.2 Evidence for Entity Continuity

Entity reidentification requires a declared relation among appearances and evidence relevant to that relation. The study would retain dated names or identifiers, membership records, succession claims, and the criteria used by the investigation. Participant assertions of continuity would receive their own record, allowing agreement and disagreement among sources to remain visible.

A discriminating case would compare unchanged membership after an interruption with changed membership under an uninterrupted institutional procedure. A membership-based criterion and a procedural-continuity criterion may give different answers. The inquiry should state which answer serves its focal question and what consequences follow from the alternative.

Fission and merger deserve explicit treatment. If one organization divides into two successors, a directed lineage record can preserve both successor relations. A single equivalence-based identity criterion must explain whether it selects one successor, regards both as new entities, or identifies a different continuing unit. The record should retain the lineage even when the focal identity criterion selects only part of it.

Research Obligation 19.1 (Identity criteria and evidential scope)**.** State the appearances being compared, the criterion under which they count as the same entity, and the evidence supporting each required continuity relation. Preserve alternative criteria when they alter a substantive inference.

DRAFT

The resulting obligation concerns the adequacy of a representation for a question. It permits several well-specified identity criteria within one study. It also permits a criterion to be rejected when its consequences conflict with the distinctions the study has committed to retain.

19.3 Evidence for Relations and Their Formation

A relation record should specify its participants, roles, scope, and formation information. For a cooperative arrangement, these might include which party can request performance, which party bears a stated obligation, and which recorded procedure established the arrangement. The coding would remain a proposed representation until checked against the relevant case evidence.

A particularly useful comparison involves two candidate histories leading to the same current-condition record. If the historical question gives different answers under those histories, the current record is insufficient for that question. Documentary evidence may narrow the compatible history set. Its effect should be reported as a reduction of uncertainty, with remaining alternatives identified.

Prospective effects require another comparison. The study must specify the continuation or intervention under which a relational difference is expected to matter. Two arrangements may have the same currently observed implementation status while differing in their response to a request, review, or withdrawal. The model should declare which aspects of the comparison are held fixed and which change.

Research Obligation 19.2 (Historical warrant and continuation comparisons)**.** Separate evidence that a relation was formed through a specified history from evidence that a selected continuation distinguishes its potential effects. State the comparison assumptions needed to attribute that difference to the relation.

This separation protects a central insight of the paper. A relation can remain relevant through unrealized continuations, while its actual formation remains a historical question. Evidence supporting one side can leave the other unresolved.

19.4 Evidence for Occurrences and Attempts

Occurrence records require a method for distinguishing individual events even when their transition descriptions coincide. The study would retain source identifiers, date or interval information, operation labels, and links among reports believed to concern the same occurrence. Conflicting reports would remain separate until their relation is assessed.

Repeated applications of an idempotent operation provide a decisive test of the chosen record. If two authorization attempts leave the represented condition unchanged after the first, a state-only record may merge them. A question about frequency, administrative burden, or procedural compliance requires the occurrence distinction.

Attempts and completions also need separate coding. A request can be submitted, rejected, withdrawn, or left unresolved. The relevant event boundary depends on the question. A record that counts only completed implementation can be adequate for an outcome query while being inadequate for an inquiry into barriers to implementation.

Temporal precision should match the inference. An ordered record can establish that one reported event precedes another without establishing the duration between them. Coarse dates may leave order unresolved. The study should retain those limits through partial temporal information or explicit uncertainty, rather than assign a convenient total order without support.

19.5 Evidence for Attributes and Measurement Choices

Attribute coding requires the subject, value domain, interpretation, and definedness conditions to be declared together. An investigator should be able to identify whether a missing value reflects unavailable evidence, an inapplicable predicate, a disputed classification, or a measurement that has yet to be performed.

DRAFT

When an attribute is used at a quotient level, the study should examine representatives within each proposed class. A value that changes among those representatives fails the descent criterion. The response can involve refining the quotient, changing the attribute question, or retaining the attribute at a more detailed level. The choice should reflect the inquiry's purpose.

Numerical attributes require particular care. A score can provide an ordered comparison without supporting arithmetic differences or averages. If a conclusion changes under a recoding permitted by the stated scale, the conclusion relies on more structure than the measurement convention supplies. A proposed aggregation should therefore state why the relevant operations on values have a substantive interpretation.

A coding rule can also have consequences when it is used by participants or an institution. The study should distinguish the classification recorded by the investigator from the classification that enters an actual decision rule. The feedback construction in Section 16 describes one way to represent uptake after its presence and form are established.

19.6 Evidence for State Sufficiency

A state description supports a declared future task when it retains the distinctions needed for the selected observations under the relevant operations. Empirical assessment therefore requires an operation repertoire, an observation scheme, and a comparison horizon.

The study should seek pairs of cases or modeled configurations with the same current record and different responses to a specified continuation. Such a pair can reveal hidden memory or an omitted condition. The interpretation depends on the evidence: the discrepancy could also reflect recording error, changed operation meaning, or an incorrect deterministic assumption.

Research Obligation 19.3 (Observation and operation design)**.** Specify which social question fixes the observation map, the operation repertoire, and the comparison horizon. Identify distinctions that these choices omit and test whether the omissions affect the intended use.

The continuation quotient gives an exact mathematical response once these inputs are fixed. A finite empirical sample typically supports a more restricted assessment. Successful agreement on observed continuations should be reported at that scope. The extension to unobserved continuations remains an assumption or a further test.

19.7 Evidence for Process Organization

A process record links occurrences through an organizing criterion. The study should state whether the process is bounded by a common objective, a procedural sequence, a continuing institutional activity, or another relation. The criterion determines which occurrences belong to the process and how interruptions are interpreted.

Intermediate conditions can be decisive. A final resource balance can conceal an unavailable intermediate step. A final implementation state can conceal failed attempts, temporary suspensions, or repeated reversals. A process account therefore needs the record required by its path-sensitive questions, even when its endpoint is well established.

Segmentation should also be justified. Grouping several operations into one phase can support explanation at a useful scale. A phase boundary can mark a change of authority, a resource threshold, or a shift in the relevant participants. Alternative segmentations should be compared when they alter the explanation of the process.

Duration introduces an additional evidence requirement. A word supplies an order of labels; durations require temporal data and a rule relating those data to the process. The idempotence counterexample shows why a composite effect alone generally cannot recover elapsed time or occurrence count.

DRAFT

19.8 Diagnosis of Discrepancies and Revision Order

A discrepancy between a model and a record should initiate diagnosis at the narrowest relevant level. The first task is to check that the observed record and the formal prediction refer to the same subject, time, operation meaning, and question. A mismatch of those references can produce an apparent contradiction.

The next task is to examine the representation's assumptions. An attribute may fail to descend, an identity criterion may collapse distinct participants, or a state may omit a formation variable. The mathematical counterexamples in the paper identify possible failure forms. Case evidence is needed to determine which form, if any, explains the discrepancy.

Revision should preserve a traceable account of what changes. Refining a state can alter its continuation classes and the records that depend on those classes. Revising entity identity can alter relation incidence and attributed properties. A coordinated model therefore needs to revisit dependent records after a material change.

The study should also record successful preservation results. A reduced description that retains the intended readouts under tested operations can justify a useful compression at that scope. Demonstrating such success makes the eventual limitations more informative: the inquiry can identify which new question or operation first requires additional structure.

19.9 Extension and Abandonment Conditions

The proposed architecture warrants further development when its distinctions organize evidence, reveal otherwise hidden assumptions, or produce comparisons that can discriminate among candidate models. A new enrichment should name the failure it repairs and the evidence supporting its added inputs.

Abandonment or substantial revision is appropriate when the proposed categories repeatedly obscure the case's central distinctions, when the required identity criteria cannot be defended for the focal question, or when the operation model suppresses the very changes the inquiry aims to explain. These are substantive limitations of an application, even when the conditional algebra remains correct.

The research program can therefore advance through both successful applications and informative failures. Its immediate task is to connect precise constructions to bounded questions while retaining uncertainty about the evidence, the interpretation, and the eventual theoretical reach of the framework.

20 Conclusion

This paper has developed a coordinated representation of six categories of social facts from an abstract action framework and explicitly declared enrichments. The construction assigns entity reidentification, historically formed dependence, event occurrence, attribute description, state comparison, and process history different tasks within a common inquiry. The conclusion draws together the formal results, their philosophical interpretation, and the research obligations that follow.

The central result is an architecture of representational commitments. A common dynamics can support several category-specific records, yet the data required by those records differ. A carrier and an action supply configurations and transformations. A preserved equivalence supports quotient dynamics. Occurrence indices, historical records, attribute interpretations, and identity criteria supply further information. Keeping their roles explicit permits an account to be evaluated at the level where its substantive commitments enter.

The entity construction begins from indexed appearances and a declared reidentification relation. Its quotient groups appearances according to that criterion. Forward reachability alone leaves the criterion underdetermined, and directed lineage retains information that an identity equivalence can obscure. The relational-unit example shows how a membership criterion can generate collective units from configurations while also showing how a change of operation repertoire can defeat a compressed description of those units.

The relation construction distinguishes participant incidence, historical formation, and prospective comparison. Incidence descends through a participant quotient only when it is invariant under the rel-

DRAFT

evant representative choices. Formation questions depend on the historical information retained by the record. Potential effects concern distinctions under declared continuations, including continuations that remain unrealized. A causal interpretation requires further comparison assumptions and evidence.

The event construction preserves occurrence identity separately from transition effects. Repeated idempotent operations can produce the same composite transformation while contributing different numbers of occurrences. Attempts, completions, and quotient-silent events therefore require records suited to the question. The event category supplies a location for those distinctions within the common dynamics.

The attribute construction specifies subjects, value domains, interpretations, and definedness. Its quotient criterion makes clear when a value is well-defined at a reduced descriptive level. Numerical interpretation adds measurement commitments beyond the existence of a value map. Classification can also enter subsequent dynamics through a declared response rule, creating a further distinction between description and social uptake.

The state construction asks which information supports selected current and future readouts. Equality of continuation observations gives a dynamically preserved equivalence under the declared operations. This established behavioral construction supplies a precise sufficiency criterion. Historical questions and entity identity can require distinctions that predictive sufficiency omits.

The process construction retains ordered occurrences and their intermediate states. Its reductions to products, transformations, and endpoints preserve different information. Segmentation, duration, interruption, and prefix feasibility require additional records when they form part of the inquiry. The usefulness of a composite effect is assessed together with the process questions it leaves unresolved.

The formal developments also repair several tempting shortcuts. The exact composition of collapse sets involves a preimage of the later collapse, which prevents an unjustified additive count. Positive-future equivalence differs from a comparison that includes the present observation. A family of internally consistent descriptive regimes can fail to preserve distinctions across a regime switch. A probabilistic quotient requires equal transition masses into each block, extending the deterministic preservation condition through an established finite-state result.

The cooperative-agreement illustration connects the categories in a complete finite action. Its twelve nonempty-word transformations are derived through their normal forms. The example distinguishes order effects, jointly enabling operations, historical alternatives, and several choices of observation. The graph illustration adds a different test: a component-level description supports edge additions while edge deletions can expose distinctions it omits. Together the examples show how a representation's adequacy depends on the operations and questions attached to it.

The philosophical position remains one of ontological suspension. The six categories are developed through the analytical work they perform and the commitments required to sustain that work. This position permits substantive criticism of a model's identity criteria, historical omissions, classification choices, and explanatory reach. It keeps the broader ontological question available for separate investigation.

A bounded application is the next evidential task. Such an application should declare its focal arrangement, category records, operation meanings, observations, and comparison questions. It should examine competing representations and preserve the discrepancies that force revision. The conditional results provide a framework for that assessment; the evidence determines which proposed interpretations survive.

Chapter 1

Historical Conditions of the Contemporary Economy

This chapter establishes the historical ground from which Generative Relational Economics (GRE) becomes intelligible as a contemporary economic research programme. Its role within Part I is preparatory and diagnostic. Before the book reconstructs the intellectual lineages of GRE in Chapter 2 or states its disciplinary constitution in Chapter 3, the present chapter asks what historical transformations make a relational and generative reconsideration of economic life increasingly salient. The objective is therefore to locate GRE within a changing material, institutional, epistemic, and technical environment. The chapter treats economic categories, economic subjects, and economic objects as historically stabilized formations whose analytical usefulness depends on the conditions under which they are produced, recognized, and governed.

The discussion follows a historical-material orientation without reducing economic thought to a mechanical reflection of productive conditions. Economic concepts emerge within relations among productive forces, institutions, law, administrative practice, scientific techniques, political norms, and historically specific problems of coordination and allocation. Categories such as labor, capital, property, firm, household, scarcity, and allocation acquired particular analytical force because modern economic orders made corresponding subjects, resources, and transactions increasingly legible and actionable. Entity-centered and allocation-centered approaches therefore appear in this chapter as historically successful abstractions with identifiable scope conditions. Their historical success forms part of the explanation for GRE's emergence, because a new framework has to account for the achievements of inherited abstractions as well as the situations in which those abstractions become strained.

The chapter develops its argument through three connected movements. Sections 1–7 reconstruct the historical formation of economic categories, economic problematics, modern institutional entities, allocation mechanisms, and differentiated sources of economic power. Sections 8–18 then follow the expansion of relational production through organizational interdependence, transnational networks, digital mediation, artificial intelligence, changing forms of scarcity, capability asymmetry, symbolic abundance, and the destabilization of inherited economic subject positions. This middle movement gradually shifts the analytical focus from

entities considered in relative isolation toward relations that constitute subjects, distribute capacities, and alter future possibilities. Sections 19–27 examine the scientific, computational, evidential, political, legal, and institutional conditions that make richer relational and generative analysis increasingly feasible, while also identifying the epistemic and governance limits that accompany this expansion of analytical capacity. Sections 28–29 synthesize these developments into an account of the historical opening, possibilities, and limits of GRE.

A central distinction throughout the chapter concerns the difference between relational importance and generative importance. Economic life has always depended on relations. The contemporary issue is that more of what matters economically is becoming difficult to understand through recipient-level states, isolated transactions, or stable entity boundaries alone. Relations can organize access, recognition, dependence, knowledge, authority, and productive coordination; they can also transform the capacities of the participants and the conditions under which later relations become possible. Generative analysis begins when the object of inquiry includes these downstream transformations: the production of new subjects, capabilities, constraints, institutional forms, option spaces, and transformation rules. GRE therefore enters the chapter gradually, after the historical and institutional conditions that motivate this extension have been reconstructed.

The same historical transformations that enlarge the relevance of relational and generative analysis also enlarge the risks of overclaiming. Digital infrastructures increase observability while creating new possibilities for surveillance and classification. Computational capacity enables larger and more heterogeneous models while increasing dependence on representation, parameterization, and model selection. Artificial intelligence expands productive and analytical capacity while intensifying questions concerning concentration, epistemic dependence, subjecthood, and the conversion of capability asymmetry into economic power. Political participation, human-rights recognition, capability-oriented development, commons institutions, and environmental or intergenerational concerns broaden the range of economically relevant relations and values, while preserving normative plurality. The chapter therefore treats technical possibility, evidential possibility, institutional possibility, and normative justification as distinct dimensions.

The resulting historical claim is modest in form and substantial in consequence. GRE is situated within a period in which relational and generative processes have become increasingly consequential for production, allocation, subject formation, value creation, knowledge, and power, while contemporary analytical infrastructures make those processes more accessible to systematic inquiry. This conjunction supplies neither a proof of GRE nor a prediction that economics must converge toward it. It establishes a problem-space in which GRE can be developed, compared with existing theories, tested against evidence, and revised through later inquiry. The next chapter turns from these historical conditions to the intellectual lineages and theoretical resources through which such a programme becomes conceptually possible.

1.1 Material Conditions of Economic Thought

This section establishes the historical-material premise of the chapter. Its role is to explain how economic categories, analytical objects, and preferred abstractions acquire their scope within historically specific social orders. The objective is narrower than a general philosophy of economic knowledge: the discussion identifies material, institutional, and epistemic conditions that make particular forms of economic reasoning possible, useful, and credible at particular moments. The argument proceeds in five stages. It first treats economic categories as historical formations; it then considers how productive capacities alter the practical and epistemic environment of inquiry, how relations of production become stabilized through institutions, how abstraction depends on historically available techniques of representation, and how the objects recognized by economics can change with these conditions. The method is historical and interpretive. Several established traditions are used as partial resources for specifying the problem, while the chapter keeps their stronger ontological and teleological commitments open for later examination.

The guiding position is that economic thought develops within the same world it seeks to describe. Changes in production, administration, law, measurement, communication, and institutional organization therefore have a double relevance: they alter economic life, and they alter the evidence, categories, and representations through which economic life becomes intelligible. Marx's materialist formulation is important for the first dimension because it connects productive forces, relations of production, and forms of social consciousness while locating legal and political forms within a wider material configuration (Marx 1859). Historical studies of quantification and statistics are important for the second dimension because they show that objectivity, classification, and measurement acquire authority through specific institutional settings and practical demands (Porter 1995; Desrosières 1998). GRE takes these contributions as reasons to historicize its own concepts. A theory that treats institutions, subjects, and values as generated within relations should also expect its categories to bear traces of the historical conditions under which they became thinkable.

1.1.1 Economic Categories as Historical Formations

The first analytical task is to distinguish the recurrence of an economic phenomenon from the historical stability of the category used to describe it. Exchange, provisioning, obligation, accumulation, scarcity, and coordination occur across very different social formations. Their recurrence leaves open whether the same analytical category has the same extension, institutional support, or causal role in each setting. A category such as labor, property, market, capital, household, or economy becomes analytically determinate through a historically specific configuration of practices, institutions, legal forms, measurement procedures, and relations among participants. Historical ontology provides a useful philosophical vocabulary for this point because concepts and objects can emerge together with new styles of reasoning and new practices of classification (Hacking 2002). The implication for GRE is methodological: historical inquiry concerns the formation and stabilization of an economic object together with the vocabulary and practices through which that object becomes describable.

Marx's critique of political economy offers an early and influential formulation of this historical specificity. In the 1859 Preface, relations of production are linked to a definite stage in the development of material productive forces, and legal and political forms are treated as historically connected with that economic structure (Marx 1859). The relevance here lies in the mode of inquiry. Stage claims and teleological implications associated with later readings of historical materialism remain separate questions. Economic categories acquire their content within determinate social relations. Capital, for example, is analytically different from a generic stock of useful objects because the category refers to a structured relation among property, production, labor, exchange, and accumulation. The same discipline applies to categories that appear more neutral. A household, a firm, a worker, or a market becomes an analytical unit through institutional and representational practices that determine which relations are treated as internal, external, relevant, or invisible.

Polanyi's historical account strengthens this point from a different direction. His analysis of nineteenth-century market society treats the expansion of market relations as part of a historically specific reorganization of economic and social relations (Polanyi 1944). This perspective matters for GRE because it shifts attention from the mere presence of exchange to the organization of exchange within a wider relational order. A market category may be analytically adequate in one domain and much less adequate when generalized across activities organized by reciprocity, household provision, public obligation, care, or other institutional forms. Historical specificity therefore constrains both the object under analysis and the permissible range of abstraction.

The historical character of categories also applies to the category of "the economy" itself. Mitchell reconstructs the modern understanding of the economy as a bounded totality of production, distribution, and consumption as a product of a mid-twentieth-century transformation in economic representation (Mitchell 1998). This example is important because changes in economic theory can accompany changes in the scale and boundary of the object itself. Once a national economy is represented as an integrated totality, questions about aggregate output, demand, employment, growth, and management become newly central, while many relations remain outside the principal frame. The formation of an economic category can therefore be an epistemic gain and a selective construction of visibility at the same time.

GRE adopts this historical stance while preserving standards of analytical adequacy. Categories can be more or less adequate to the relations they are used to analyze, and historically formed categories can still identify durable mechanisms or recurrent structures. The relevant discipline is to separate analytical usefulness from presumed timelessness. A category earns its place through the work it performs in a specified relational and historical domain, and its continued use remains open to revision when the domain, evidence, or relations change.

1.1.2 Productive Forces and Forms of Economic Knowledge

The second analytical task is to identify how transformations in productive capacity alter the environment in which economic knowledge is produced. Productive forces are used here in a broad historical sense that includes material techniques,

energy systems, transport, communication, computational capacity, organizational techniques, and the skills through which production can be coordinated. Their development changes the practical problems that demand explanation and the epistemic possibilities available for explaining them. GRE treats the relation between productive capacity and theory as historically mediated and contingent. Marx's formulation remains useful because it directs attention to the relation between changing productive capacities and changing relations of production while leaving room for more specific mechanisms through which knowledge responds (Marx 1859).

Changes in productive capacity can affect economic knowledge through several channels. New forms of production can generate new contractual relations, organizational units, and coordination problems. Changes in transport and communication can enlarge the spatial scale at which economic activity is coordinated. Changes in recording and computation can alter temporal resolution, making processes observable continuously or at shorter intervals. Productive development can also create new evidential infrastructures. Accounting systems, censuses, surveys, standardized classifications, and computational records participate in determining which economic differences can be aggregated, compared, and acted upon.

The history of quantification makes this point especially clear. Porter argues that the authority of quantitative objectivity developed partly in response to institutional demands for impersonal and standardized judgment across settings such as government, business, engineering, and social inquiry (Porter 1995). Desrosières reconstructs statistical reasoning through the history of classification, coding, aggregation, correlation, and modeling, emphasizing the conventions through which heterogeneous cases become comparable (Desrosières 1998). These histories place measurement inside the institutional history of economic knowledge. Measurement practices can become part of economic reality because decisions, eligibility, budgets, targets, and expectations are organized around the quantities they produce.

This observation is central to the historical possibility of GRE. Earlier economic thought analyzed relations with the conceptual and technical resources then available. Contemporary computation changes the tractability of relational questions by making large networks, longitudinal records, higher-order interactions, and multiscale simulations technically accessible. A relation-centered or generative analysis therefore has a historical condition of possibility in the development of computational and evidential infrastructures, while its concepts retain analytical content beyond the infrastructures that support their investigation. Contemporary productive forces enlarge the possibility of GRE by making certain relational and generative questions more systematically researchable than under earlier technical conditions.

The same development creates new epistemic risks. Expanding measurement can encourage the identification of an object with its measurable manifestation. A productive system may become legible through variables that are administratively stable while remaining partial descriptions of its relational structure. Large computational representations can intensify this tendency by creating an appearance of completeness through scale. GRE therefore treats technical capacity as an expansion of possible inquiry accompanied by a stronger requirement to distinguish relational reality, manifestation, and representation. Productive forces transform both the reach of economic knowledge and the forms of error that economic knowledge can institu-

tionalize.

1.1.3 Relations of Production and Institutional Form

The third analytical task is to connect economic relations with the institutional forms that stabilize them. Relations of production concern organized positions in production, access to resources, authority over decisions, claims on output, and the conditions under which participants enter, remain within, or leave a productive arrangement. These relations become durable through legal, organizational, administrative, cultural, and infrastructural forms. Institutional form therefore participates in constituting the economic relation and the terms under which that relation can be recognized.

The materialist tradition provides one route into this problem by linking property relations and relations of production with stages of productive development (Marx 1859). Polanyi provides another by showing that market society depended on institutional transformations that reorganized the relation between economic exchange and wider social life (Polanyi 1944). Read together while preserving their differences, these approaches support a modest claim useful to GRE: productive activity is mediated by historically specific institutional arrangements, and changes in those arrangements can transform the economic meaning of otherwise similar acts. The transfer of an object, the performance of labor, or the provision of care can occupy different economic positions depending on property rules, contractual status, household organization, public provision, professional classification, and institutional recognition.

Institutional form also affects the scale at which economic entities appear coherent. A corporation can be treated as a unit in accounting, law, taxation, and contract because multiple internal relations are condensed into a recognized organizational person. A household can appear as a consumption unit, a care relation, a property-sharing arrangement, or an internally differentiated organization depending on the institutional and analytical frame. The same nominal entity can therefore support multiple relational descriptions. GRE later develops this point as a problem of economic architecture; its historical implication belongs here because the apparent stability of entities is partly an achievement of institutional form.

The relation between institution and economic knowledge is recursive. Institutions stabilize categories, and categories feed back into institutions. Once an administrative system recognizes a class of worker, firm, asset, household, industry, or transaction, the category can organize reporting, eligibility, taxation, regulation, contracting, and comparison. Desrosières' history of statistical classification is relevant because classification and encoding are practical operations that help create standardized populations for analysis (Desrosières 1998). Hacking's historical ontology supplies a broader philosophical formulation: classifications and styles of reasoning can participate in the historical emergence of the objects to which they refer (Hacking 2002). In economic life, institutional categories can therefore become causally effective while remaining partial representations of the relational realities they organize.

GRE approaches institutional form through two linked concerns. Stabilization concerns the rules, classifications, infrastructures, and expectations that make a relation durable enough to function as an economic object. Transformation concerns changes

in those supports that alter the relation itself. This dual focus treats institutions as historically generated relational arrangements that condition later economic action while remaining open to reproduction, contestation, and change.

1.1.4 Economic Abstraction under Historical Constraints

The fourth analytical task concerns abstraction. Abstraction is constitutive of economic inquiry because comparison, aggregation, and explanation require some differences to be suppressed. The historical question concerns which abstractions become credible, operational, and institutionally consequential under particular conditions, together with the relations that disappear when those abstractions are generalized beyond their domain of adequacy.

Quantification provides a clear example. A numerical category can coordinate judgment across distance by replacing local variation with standardized comparison. Porter emphasizes that quantitative objectivity gained authority partly because it could support impersonal forms of decision under institutional conditions in which reliance on individual discretion was difficult or contested (Porter 1995). Desrosières shows that statistical reasoning depends on conventions of equivalence through which heterogeneous cases are classified and made comparable (Desrosières 1998). These accounts reveal abstraction as an institutional achievement. A statistical aggregate becomes useful because differences judged irrelevant to a task have been suppressed in a repeatable way.

Economic abstraction is constrained by the historical availability of such operations. A national aggregate presupposes classifications, territorial boundaries, reporting systems, institutional capacities, and conventions through which dispersed activities can be treated as commensurable. Mitchell's account of the emergence of "the economy" demonstrates how representation helped establish a national economic totality as an object of expertise and intervention (Mitchell 1998). The abstraction made aggregate economic management thinkable, and the gain depended on a selective boundary around the relations represented. Every successful abstraction therefore establishes an analytical field together with a remainder.

For GRE, the remainder has methodological importance. Entity-centered accounting can be highly effective for questions concerning ownership, liability, taxation, or the direct recipient of a transfer. The same abstraction can be insufficient when the research question concerns how a transfer changes trust, dependence, coordination, knowledge, or future relational capacity. A graph representation may reveal connectivity while suppressing legal meaning; an ethnographic reconstruction may recover meaning while offering weak estimates of prevalence; a macroeconomic aggregate may represent total activity while hiding the distribution of relational conditions that generated it. The appropriate response is explicit specification of the abstraction's object, excluded differences, and historical conditions of usability.

This perspective also changes the interpretation of theoretical disagreement. Two economic theories can appear to conflict because they abstract at different scales, stabilize different objects, or preserve different relations. A theory centered on individual choice and a theory centered on institutions may produce incompatible descriptions when each is treated as complete, while still identifying real structures at

different levels. GRE later develops translation among theories as a distinct research programme. The material point established here is prior: abstraction is historically conditioned, and theoretical categories should be evaluated partly by the relations they preserve and the relations they suppress.

1.1.5 Transformation of Economic Objects across Historical Periods

The final analytical task draws the preceding arguments together into a historical view of changing economic objects. Economic history includes changes in quantities and institutions, and it also includes changes in what can appear as an economic object in the first place. New forms of production, administration, measurement, and political organization can stabilize entities and aggregates absent from earlier analytical languages or differently organized within them. Hacking's account of historically emergent concepts and objects provides a general philosophical frame for this possibility (Hacking 2002). Mitchell's reconstruction of the twentieth-century emergence of "the economy" provides a specifically economic example in which a new bounded object of macroeconomic representation became available to expertise and intervention (Mitchell 1998).

This transformation concerns relational visibility and institutional coordination. Activities later assembled into a national economy existed before the aggregate became a dominant object of analysis. The historical change lay in the representational and institutional configuration through which those activities could be organized as one object, measured through common categories, and treated as a target of coordinated intervention. A similar caution applies to newer objects. Data, attention, platform intermediation, algorithmic labor, knowledge infrastructures, and artificial productive capacity can become increasingly salient to economics because productive relations and measurement systems make their economic effects more visible and more consequential. Their appearance as economic objects therefore reflects both underlying changes in relations and changes in the apparatus through which those relations are represented.

The historical transformation of objects has two consequences for GRE. First, the field should expect its own object list to remain open. Relations, capacities, constraints, value forms, and generative possibilities that are analytically peripheral today may become central under different productive and institutional conditions. Second, economic theory should preserve the historical provenance of its categories. A concept developed for industrial wage labor, territorially organized markets, or nationally bounded accounting may continue to be useful under digital and transnational conditions, yet its range of adequacy requires renewed examination when the relations denoted by the term change. Historical continuity of terminology can conceal transformation in the underlying relational structure.

The historical-material argument developed in this section therefore establishes a limited premise: economic categories and objects are historically conditioned, and transformations in productive forces, institutional relations, and representational capacities can change both the economy and the forms of knowledge through which it becomes intelligible. The subsequent sections examine how modern entity-centered economic structures were historically stabilized, how digitalization and artificial in-

telligence strain some inherited abstractions, and why contemporary scientific and computational conditions create a specific opening for relational and generative economic analysis.

1.2 Genealogy of Economic Problematics

This section reconstructs a selective genealogy of the problems that have organized modern economic inquiry. Its role is to show how the center of economic analysis has shifted as productive arrangements, institutions, and techniques of representation changed. The objective is analytical rather than encyclopedic: the discussion follows five recurring problem-fields—wealth and exchange, production and division of labor, labor and capital, allocation and welfare, and information and institutions—and examines how each made particular economic relations visible while placing others in the background. The method is genealogical and comparative. Canonical works are used as indicators of changing problem-spaces, without treating the history of economics as a linear succession in which one problematic simply replaces another. Earlier questions persist, are reformulated, and often return inside later frameworks with altered meanings.

A genealogy of problematics differs from a chronology of doctrines. Chronology asks which theory came first and which school followed. Genealogy asks what had to become practically consequential and analytically representable for a particular question to acquire disciplinary centrality. The relevant movement is therefore one of changing emphasis. Wealth remains relevant after production becomes central; production remains relevant after allocation is formalized; allocation remains relevant when information and institutions enter the analysis. What changes is the configuration of problems through which economic reality is rendered intelligible. This section prepares the later historical argument by showing that modern economics was repeatedly reorganized around newly salient relations rather than by a single permanent definition of its subject matter.

1.2.1 Wealth and Exchange

The first problematic considered here concerns the production, circulation, and composition of wealth. In early modern political economy, wealth was inseparable from questions of trade, money, revenue, taxation, and the conditions under which national production could expand. Adam Smith's *An Inquiry into the Nature and Causes of the Wealth of Nations* makes the scale of this problematic explicit in its title and organization. The opening books move from the productive powers of labor through division of labor, money, prices, wages, profits, and rent before extending the analysis to accumulation, trade, public revenue, and state expenditure (Smith 1776). The object called wealth was therefore already relationally distributed across production, exchange, class incomes, public institutions, and international commerce.

Exchange acquired analytical importance because it offered a visible interface among otherwise heterogeneous activities. Money prices, market transactions, and trade flows provided forms in which dispersed production could be compared and coordinated. Smith's analysis of money and market exchange did not reduce social

wealth to circulation alone, yet exchange supplied a tractable surface on which value, price, and distribution could be investigated. The practical importance of expanding markets reinforced this analytical role. Exchange connected local productive activity to wider systems of demand, specialization, taxation, and accumulation, making the relation between individual transactions and national prosperity a durable economic question.

Ricardo's *On the Principles of Political Economy and Taxation* sharpened this problematic by organizing analysis around value, rent, wages, profits, foreign trade, taxation, machinery, and the distribution of the social product (Ricardo 1817). The book's structure reveals a significant shift in emphasis. Wealth and exchange remain central, yet their analysis increasingly depends on the distributional relations among classes and on the conditions of production that determine rents, wages, and profits. A transaction can no longer be understood solely as an exchange between two owners; it participates in a wider distributional structure whose effects become visible only when production and class positions are included.

For GRE, the significance of this early problematic lies in the relation between visibility and abstraction. Exchange produces highly legible manifestations: prices, quantities, payments, debts, and transfers. These manifestations can be recorded, compared, and aggregated. They therefore provide a powerful analytical interface with economic reality. The same visibility can privilege relations that culminate in exchange over relations whose effects are indirect, delayed, or institutionally unpriced. Care, trust, knowledge formation, environmental reproduction, and the maintenance of social capacities may condition exchange while appearing only weakly within the transaction itself. The genealogy of wealth and exchange thus supplies an early example of a recurring theme in this book: analytically successful manifestations can organize a field of inquiry while leaving part of the generative structure outside the dominant representation.

1.2.2 Production and Division of Labor

The production problematic shifts attention from the circulation of finished goods toward the organization of productive activity. Smith's treatment of the division of labor is a canonical expression of this move. He attributes major improvements in the productive powers of labor to specialization and links the extent of specialization to the extent of the market (Smith 1776). Productivity, on this account, is already relational in a straightforward sense: the output of an individual worker depends on an organized division of tasks, the circulation of intermediate outputs, accumulated skills, tools, and a market large enough to sustain specialization.

The analytical importance of division of labor extends beyond the familiar claim that specialization raises productivity. It changes the unit through which productive capacity is understood. A worker's output cannot be read only from individual effort or skill because productivity is partly constituted by the position occupied within a differentiated productive arrangement. The pin factory is analytically important precisely because the productive effect appears at the level of coordination among tasks. Individual capacities matter, yet their economic effect depends on sequencing, complementarity, repetition, tools, supervision, and the relation between the workshop

and its market.

This transformation also introduces dependence as an economic fact. Greater specialization increases productive power while making participants more reliant on activities performed elsewhere in the system. The same relation that raises output can narrow self-sufficiency. A productive order therefore generates capacities and dependencies together. Classical political economy did not need the later language of networks or relational fields to identify this structure; division of labor made interdependence visible through the organization of production itself.

The problem of coordination follows immediately. Once production is divided, economic analysis must explain how differentiated activities become mutually compatible. Market exchange supplies one answer, managerial organization another, custom and institution others. The division of labor therefore sits at an intersection between production and coordination. It makes clear that an economy cannot be represented only as a collection of independent producers because the productivity of each participant depends on relations that organize the activity of others.

GRE later develops this point in stronger form by asking which relations generate capacities that cannot be assigned to any isolated participant. The present historical section makes a more limited claim. The rise of the production problematic already shifted economic inquiry toward arrangements in which outcomes are properties of organized relations. This prepared the ground for later theories of the firm, industrial organization, networks, institutions, and collective productive capacity.

1.2.3 Labor, Capital, and Industrial Production

Industrialization deepened the production problematic by stabilizing labor and capital as central analytical categories. Ricardo's analysis of wages, profits, and rent placed distribution among classes close to the center of political economy (Ricardo 1817). Marx's *Capital* subsequently reorganized the field around the production process of capital, including the purchase of labor-power, the labor process, surplus value, cooperation, manufacture, machinery, and modern industry (Marx 1867). The economic object under investigation became increasingly processual: capital was analyzed through accumulation and reproduction, while labor appeared both as human activity and as a socially organized relation within production.

The shift matters because industrial production makes the economic effect of institutional position difficult to ignore. The worker and the owner enter production with different claims over productive assets, different forms of dependence, and different capacities to appropriate the resulting output. These positions are sustained by property, contract, labor markets, organizational authority, and the material concentration of productive means. Industrial economic analysis therefore cannot remain at the level of exchange among formally equivalent owners. The exchange of a wage for labor-power is embedded within a productive structure that determines what each party can contribute, control, and claim.

Marx's analysis is especially important for the genealogy pursued here because it treats production relations as constitutive of the economic process rather than as external conditions surrounding exchange. Cooperation and machinery do more than raise a given worker's productivity. They reorganize the labor process, concentrate

control, alter skill requirements, and transform the relation between workers and the means of production (Marx 1867). Industrial production consequently generates new economic capacities together with new asymmetries. The productive effect of machinery belongs to a configuration involving capital investment, technical knowledge, labor organization, ownership, and markets; its distributional effects depend on the relations through which that configuration is governed.

This industrial problematic also strengthens the importance of reproduction through time. Capital must be maintained and accumulated; labor capacity must be reproduced; firms and institutions must persist; technical systems require replacement, learning, and coordination. Economic analysis therefore acquires an increasingly temporal object. Current output depends on inherited productive structures, and current investment changes the conditions under which later production occurs. The distinction between a present allocation and a future productive capacity begins to matter even before generativity is made explicit as a theoretical category.

GRE does not inherit any single classical or Marxian theory of value, class, or historical development as a complete account. The genealogical lesson is narrower and more durable. Industrial political economy made visible that economic outcomes arise within structured relations among labor, capital, technology, ownership, and organization. Those relations generate capacities and asymmetries that persist beyond the individual transaction. Later sections of this chapter examine how modern institutions stabilized these relations into recognizable economic subjects such as worker, owner, household, firm, and corporation.

1.2.4 Allocation, Distribution, and Welfare

The allocation problematic reorganizes economic inquiry around choice among alternative uses of scarce means, the distribution of resulting goods and incomes, and the evaluation of economic arrangements. Marshall's *Principles of Economics* retains the older language of production, distribution, exchange, and consumption while developing a more unified analysis around demand, supply, value, and marginal adjustment (Marshall 1890). His treatment illustrates a transition in which economic reasoning increasingly abstracts from the full historical structure of production in order to analyze choice and adjustment within a specified field of alternatives.

Robbins later gave the scarcity formulation a particularly influential methodological expression by defining the economic aspect of conduct in terms of ends and scarce means with alternative uses (Robbins 1932). The significance of this formulation for the present genealogy lies in its portability. Once the economic problem is specified through scarcity and alternative use, the same analytical grammar can travel across households, firms, public budgets, time allocation, and other domains. The gain is considerable: heterogeneous substantive problems can be represented through a common structure of constrained choice. The corresponding methodological question concerns what must already be specified before the allocation problem can be solved—the relevant ends, available means, feasible alternatives, boundaries of the decision, and the units whose welfare or claims enter the analysis.

Welfare economics made these evaluative conditions more explicit. Pigou's *The Economics of Welfare* links economic welfare to the national dividend and examines

situations in which private and social net products diverge, thereby making the relation between decentralized economic activity and social evaluation a central problem (Pigou 1920). Allocation consequently becomes more than the placement of scarce resources. It becomes a question about the criteria under which one arrangement is judged preferable to another and about the institutional conditions under which private decisions produce socially consequential effects.

This movement supplied economics with powerful tools for policy analysis because it made trade-offs expressible within comparatively standardized frameworks. Budgets could be allocated, marginal changes compared, and welfare effects discussed with greater analytical discipline. The abstraction also encouraged a recipient-centered representation of policy: resources are assigned to persons, households, firms, sectors, or jurisdictions, and evaluation asks how outcomes change for those units. Under many administrative conditions this is both necessary and effective. Legal responsibility, taxation, eligibility, accounting, and payment systems all require identifiable recipients.

The GRE problem begins where the consequences of allocation exceed the recipient representation. A transfer to a person can change household dependence, trust, mobility, bargaining power, or participation. Funding to an organization can alter internal authority, external alliances, knowledge flows, and future access to institutions. Infrastructure expenditure can generate option spaces for actors who were not direct recipients. These effects do not invalidate allocation analysis; they reveal an additional layer in which allocation acts through relational structure. The historical importance of the allocation problematic is therefore twofold. It created a highly general language for disciplined choice under scarcity, and it made increasingly visible the need to specify which consequences and relations enter the evaluative frame.

1.2.5 Information, Institutions, and Coordination

Twentieth-century economic inquiry increasingly treated information, organization, and institutions as central to coordination. Hayek's analysis of dispersed knowledge reformulated the coordination problem by emphasizing that the information required for economic adjustment is distributed across participants and is never available in fully concentrated form to a single decision-maker (Hayek 1945). The economic problem thereby acquires an epistemic dimension: coordination depends on how locally held and frequently changing knowledge enters practical adjustment.

Coase's theory of the firm introduced a complementary organizational question. If market exchange coordinates activity through prices, the existence of firms requires an account of why some transactions are organized through authority and internal direction. Coase's answer directs attention to the costs of using the price mechanism and to the boundary between market and organization (Coase 1937). The firm becomes more than a production function or legal owner of assets; it becomes an institutional arrangement that coordinates relations differently from a sequence of market contracts.

Institutional economics extends this shift by treating rules, norms, enforcement, and organizational arrangements as constitutive of economic performance. North characterizes institutions as humanly devised constraints that structure interaction

and argues that institutional change shapes economic performance through time (North 1990). This moves the coordination problematic beyond the instantaneous matching of decentralized choices. Economic action occurs within rule systems that shape incentives, transaction costs, expectations, learning, and the feasible forms of organization. History enters because institutional arrangements persist, change incrementally, and condition later choices.

The convergence of information and institutional problems expands the range of relations that economics must represent. Coordination depends on prices, yet also on authority, rules, conventions, trust, expertise, legal recognition, and infrastructures through which information can move. Different arrangements solve different coordination problems and distribute knowledge, discretion, and power differently. A price system can aggregate some dispersed information while leaving organizational knowledge local; a firm can coordinate complex tasks while concentrating authority; an institution can reduce uncertainty while stabilizing rules that later become costly to change.

This expanded problematic provides an important bridge toward GRE. The genealogy traced across this section shows successive enlargements of the economic field: from wealth and exchange, to organized production, to industrial relations among labor and capital, to allocation and welfare, and then to information, institutions, and coordination. The sequence is cumulative rather than substitutive. Contemporary economic life contains all of these problematics simultaneously, and each preserves analytical strengths developed under different historical conditions.

The implication for GRE is methodological and historical. A generative relational approach should enter this accumulated field as another language of inquiry rather than as a declaration that earlier economics studied the wrong objects. Its distinctive question concerns what becomes visible when relations are examined for the capacities, constraints, subjects, values, and future possibilities they generate. That question arises from the tensions internal to the inherited problematics themselves: exchange depends on production; production depends on coordination; allocation changes relations; institutions shape feasible action; and information is distributed through structures that themselves evolve. The remaining sections of Chapter 1 reconstruct the historical order in which these relations became increasingly consequential and increasingly difficult to treat as fixed background conditions.

1.3 Industrial Modernity and the Modern Economic Order

This section reconstructs the institutional architecture that made the modern economic order simultaneously productive, administratively legible, and analytically tractable. Its role in the chapter is to connect the genealogy of economic problematics developed in Section 1.2 with the later construction of recognizable economic subjects and entities. The objective is to identify the historical configuration in which industrial production, wage labor, property, firms, markets, and states became mutually reinforcing components of economic organization. The discussion proceeds through five dimensions: material production and scarcity, wage labor and social reproduction, property and productive assets, firms and administrative organization,

and the coordination of market and state. The method is historical and institutional. The section does not treat industrial modernity as a single globally uniform stage; it uses the term for a family of arrangements whose concrete forms varied across jurisdictions and periods while sharing several recurrent organizational features.

The central analytical point is that the modern economic order stabilized relations that could increasingly be represented through identifiable entities, contracts, accounts, incomes, assets, and administrative categories. Industrial production concentrated productive means and coordinated differentiated labor. Wage relations connected participation in production to monetary income. Property regimes stabilized claims over productive assets. Firms organized activities internally through authority and administration. States supplied legal, fiscal, infrastructural, and statistical conditions within which markets could operate at expanding scales. These arrangements did more than support production. They helped determine which economic subjects became visible, which claims could be administered, and which flows could be represented as movement among recognized units. The later entity-centered architecture of allocation emerged from this institutional history rather than from a purely methodological preference.

1.3.1 Industrial Production and Material Scarcity

Industrial production altered the relation between productive capacity and material organization by concentrating machinery, energy, fixed capital, labor, and technical knowledge within increasingly coordinated processes. Marx's analysis of machinery and modern industry treats mechanized production as a reorganization of the labor process rather than as a simple addition of more productive tools (Marx 1867). The relevant historical development for GRE is the growing dependence of output on combinations of assets and relations whose productive effect could not be assigned to isolated participants. Machinery required capital investment, maintenance, energy, technical knowledge, supplies, coordinated labor, and access to markets. Industrial capacity therefore existed in organized configurations before it appeared in the output attributed to a firm, sector, or worker.

Material scarcity remained a central organizing condition within this order. Productive assets, energy, land, raw materials, transport capacity, working time, and financial means could not be expanded without cost or delay. Industrial organization responded by concentrating resources, improving throughput, extending specialization, and creating institutions capable of coordinating larger stocks and flows. The economic importance of scarcity consequently attached not only to final consumption goods but also to access to the productive conditions through which future goods could be generated. A machine, factory site, transport connection, patent, or stock of working capital mattered because it conditioned later production. The industrial order therefore strengthened the distinction between current possession and productive capacity.

Scarcity also became increasingly mediated by infrastructure. Railways, ports, warehouses, energy systems, urban utilities, and communication networks changed the effective availability of resources by altering distance, timing, reliability, and scale. A material resource could be physically present while remaining economically

inaccessible because transport, finance, legal permission, or organizational coordination was absent. Conversely, infrastructure could transform distant resources into practically available inputs. The economic meaning of scarcity was therefore relational even where the scarce object was material: availability depended on the configuration connecting the resource to those capable of using it.

This configuration helps explain why industrial economics could profitably abstract toward measurable inputs and outputs. Factories, inventories, wages, investment, prices, and physical production created comparatively legible interfaces with economic activity. Accounting and administrative practices could attach costs and claims to recognizable organizational units. The resulting abstractions were historically powerful because they corresponded to material arrangements in which production was increasingly concentrated, standardized, and measured. Their usefulness did not require every generative relation to be visible. It required enough stability that productive resources, organizations, and recipients could be treated as identifiable over the horizon relevant to management and policy.

The GRE significance of industrial materiality lies in this combination of concentration and relational dependence. Industrial production made entities such as factories and firms appear increasingly substantial while simultaneously deepening the relations on which their productive capacities depended. The entity and the relational configuration developed together. Later economic analysis inherited the entity because it was legally and administratively useful; GRE returns to the surrounding configuration because the capacity attributed to the entity was generated through it.

1.3.2 Wage Labor and Social Reproduction

Wage labor supplied one of the principal institutional links between productive participation and access to livelihood in industrial economies. Marx's treatment of labor-power makes this relation explicit by distinguishing the worker's capacity to labor from the labor performed within production and by connecting the reproduction of labor-power to the means of subsistence required for its continued availability (Marx 1867). The analytical importance of the wage relation extends beyond the wage as a price. It connects production, income, household provisioning, time discipline, mobility, bargaining position, and future participation in the labor process.

Polanyi's account of market society provides a complementary historical perspective by emphasizing the institutional transformation involved when labor, land, and money are organized through market mechanisms (Polanyi 1944). Labor is especially revealing because the object transacted in a labor market remains inseparable from the person whose activity is organized. The labor relation therefore couples a market contract to domains that exceed the transaction itself: health, family life, residence, education, social membership, and the reproduction of the capacity to work. The wage can be recorded as a payment to an individual worker, while the conditions that make labor possible are distributed across households, communities, public institutions, and infrastructures.

This distributed structure gives social reproduction a direct economic relevance. Industrial production requires renewed labor capacity across days and generations. Food, housing, care, education, health, socialization, and periods outside paid em-

ployment contribute to that reproduction through arrangements whose institutional forms vary historically. Some are purchased in markets, some are provided within households, some are organized publicly, and some are sustained through community relations. The wage relation becomes especially consequential when access to these conditions depends heavily on employment income. Employment then mediates more than contribution to production; it mediates access to a wider field of material and institutional resources.

The resulting architecture stabilizes the worker as an economic subject. Payroll systems, labor contracts, taxation, social insurance, workplace rules, and household budgets can all identify the worker as a recipient of income and bearer of obligations. This administrative clarity is historically significant. It permits production costs to be assigned, income to be taxed, entitlements to be calculated, and labor supply to be represented in aggregate. The same clarity places part of the reproductive structure outside the immediate representation. A wage record identifies the payment while saying relatively little about the household relations, care arrangements, commuting infrastructure, education, health, or social supports through which the worker remains capable of participation.

For GRE, the wage relation is therefore an early example of a relation whose economic effects propagate beyond the nominal parties to a contract. Changes in wages, employment security, working time, or workplace authority can alter household dependence, geographic mobility, care burdens, learning opportunities, and future bargaining power. The historical prominence of wage labor helped make the individual worker a practical unit of economic administration, yet the capacity represented by that worker was reproduced through a wider relational system. The distinction between recipient and generative conditions later becomes central to GRE's treatment of allocation and value.

1.3.3 Property and Productive Assets

Property regimes stabilized claims over productive assets and thereby shaped who could decide how resources were used, who could exclude others, who could transfer claims, and who could receive returns generated through production. North's institutional analysis treats property rights and other formal rules as part of the institutional structure that shapes incentives and economic performance through time (North 1990). For the present argument, the important point is that a productive asset becomes economically consequential through a relation among material control, legal recognition, organizational use, and expectations concerning future returns.

Industrial production increased the importance of this stabilization because productive means became increasingly durable, specialized, and costly. Ownership of land, machinery, buildings, inventories, and financial claims could organize access to productive opportunities over horizons much longer than a single transaction. Property therefore linked present legal claims to future streams of decision-making and income. A productive asset was valuable partly because it could be inserted into an institutional environment in which exclusion, transfer, contracting, financing, and enforcement were sufficiently reliable for long-horizon organization.

The relation between property and productive capacity also clarifies why owner-

ship and control deserve analytical separation. A legal owner may delegate operational control to managers; creditors may constrain decisions without owning the asset; regulators may determine permissible uses; workers may possess indispensable knowledge; suppliers and platforms may control access to complementary infrastructure. Industrial organization consequently produces layered claims around the same productive object. Ownership remains economically important, yet its practical effect is mediated through a configuration of rights, contracts, dependencies, and institutional authorities.

Property also contributes to the stabilization of economic boundaries. Assets can be assigned to persons, firms, households, public bodies, or other recognized entities. Accounting systems can record acquisition, depreciation, liabilities, and returns relative to those boundaries. Contracts can specify transfers across them. This improves administrative legibility and supports the representation of economic activity as flows among units with identifiable holdings. The boundary is institutionally real because claims and obligations are enforced through it, even when the productive process itself crosses that boundary through labor relations, supply chains, shared infrastructure, finance, and knowledge flows.

GRE later develops a relational account of ownership, control, access, and allocation in greater detail. At this historical stage, the relevant result is that property helped make productive resources administratively attachable to entities while organizing the relations through which those resources could generate future value. The institutional success of entity-centered representation therefore rested on relational arrangements that stabilized entities sufficiently for ownership, contracting, and accounting to operate.

1.3.4 Firms and Administrative Organizations

The industrial firm gave durable organizational form to coordination that could not be represented adequately as a sequence of isolated exchanges. Coase's analysis begins from precisely this problem: market exchange coordinates through the price mechanism, while the firm coordinates some activities through internal direction because using markets also entails costs (Coase 1937). The firm therefore marks an institutional boundary across which the dominant mode of coordination changes. Prices remain important outside and within the organization, yet authority, routines, roles, schedules, budgets, technical standards, and managerial judgment coordinate many productive relations internally.

This organizational form expanded the range of activities that could be planned across time. Capital investment, hiring, training, procurement, production sequencing, inventory, quality control, sales, and finance could be coordinated through administrative structures that persisted beyond individual contracts. The firm became an economic subject because law, accounting, taxation, and organizational practice treated it as a continuing unit capable of owning assets, entering contracts, receiving revenue, bearing liabilities, and employing workers. Its continuity depended on relations among participants, yet the organization could be represented as an entity for many practical purposes.

Administrative organization also transformed information. A large productive pro-

cess requires knowledge to be distributed among specialized roles while remaining coordinated sufficiently for collective action. Records, reports, budgets, plans, technical specifications, and chains of authority create channels through which local knowledge is translated into organizational decisions. Some knowledge remains tacit or local, and some is formalized into procedures and indicators. The organization therefore does not merely collect information; it structures which information can travel, who is authorized to interpret it, and which representations acquire decision-making force.

This point links the firm to the broader genealogy of coordination developed in Section 1.2. Hayek's account of dispersed knowledge emphasizes the difficulty of concentrating the information relevant to economic adjustment (Hayek 1945). The firm does not eliminate that difficulty. It creates another coordination regime in which some decisions are internalized, some knowledge is formalized, and some authority is concentrated. Market and organization consequently represent different relational arrangements for coordinating heterogeneous knowledge and activity rather than mutually exclusive forms of economic order.

The GRE relevance of the firm lies in the contrast between entity manifestation and relational constitution. The firm is sufficiently stable to sign a contract, own an asset, receive funding, report profit, and appear as a node in administrative data. At the same time, its capacities depend on internal authority, cooperation, knowledge flows, routines, worker relations, supplier relations, finance, law, and infrastructure. Treating the firm as an entity is therefore often operationally indispensable. Treating the entity as analytically self-sufficient obscures the relations that generate its capacities and determine how an intervention directed at the firm propagates through the surrounding system.

1.3.5 State, Market, and Economic Coordination

Industrial modernity joined market coordination to a dense institutional architecture of law, public authority, infrastructure, taxation, monetary organization, administration, and social provision. Polanyi's historical account is especially useful here because it treats market society as institutionally produced and politically sustained rather than as the spontaneous expansion of exchange alone (Polanyi 1944). North similarly places economic performance within rule systems that structure incentives and reduce or redistribute uncertainty (North 1990). The modern market therefore operates through institutional conditions that define property, contract, legal personality, money, enforcement, and permissible forms of organization.

The state participates in this order through several analytically distinct roles. It recognizes and enforces legal claims; raises and spends revenue; builds and regulates infrastructure; produces statistics and administrative classifications; supplies or finances services; defines corporate, labor, and property forms; and intervenes in crises. These activities vary widely across historical periods and political systems. Their common relevance lies in the production of conditions under which dispersed economic actors can coordinate over scales that exceed local relations. State capacity can enlarge markets by standardizing rules, currencies, transport, information, and enforcement even when many transactions remain privately organized.

Market coordination addresses a different dimension of the same problem. Hayek's account of the price system emphasizes its capacity to communicate information relevant to adjustment when knowledge is dispersed among many participants (Hayek 1945). Prices can coordinate decentralized decisions without requiring a central actor to possess all local knowledge. Their informational economy is powerful precisely because the system does not attempt to reproduce every relation or circumstance in a complete representation. A price condenses some conditions into a signal useful for action while leaving many causal and normative dimensions outside the signal.

The institutional and market dimensions of coordination therefore operate through different forms of selective representation. Law translates heterogeneous social relations into rights, duties, persons, and claims. Administration translates them into categories, records, eligibility conditions, and budgets. Markets translate some dispersed conditions into prices and contracts. Firms translate productive complexity into organizational roles, accounts, and plans. Each representation supports coordination by reducing complexity, and each leaves a remainder that can become economically consequential when conditions change.

This selective structure is the historical bridge to the next sections of the chapter. Industrial modernity did not merely produce more goods or larger organizations. It stabilized a recognizable architecture of workers, owners, households, firms, assets, contracts, markets, and states. These units became economically real through persistent relations and institutionally powerful manifestations. They could be taxed, regulated, funded, counted, contracted with, and made responsible. The resulting order made entity-centered economic analysis unusually effective because economic administration itself increasingly operated through entities.

The same historical achievement establishes the limit that GRE later addresses. Coordination through entity boundaries and compressed representations works best when the relevant entities remain sufficiently stable and when the consequences of action can be assigned within the chosen boundary and horizon. As production becomes more networked, knowledge-intensive, transnational, platform-mediated, and dependent on distributed infrastructures, those conditions become less secure. The next sections therefore examine how modern economic subject positions and institutional entities were constructed before turning to the contemporary transformations that place increasing pressure on the architecture industrial modernity stabilized.

1.4 Historical Formation of the Economic Subject

This section reconstructs the historical formation of the principal subject positions through which modern economic life became administratively and analytically intelligible. Its role in the chapter is to move from the institutional architecture of industrial modernity to the actors that this architecture made recognizable as bearers of labor, property, consumption, responsibility, and organizational capacity. The objective is to show that the worker, owner, consumer, household, firm, and corporation acquired economic salience through historically specific relations and institutions rather than entering economic analysis as timeless units. The discussion proceeds

through five subject positions and uses a historical-institutional method: each position is examined through the relations that stabilize it, the capacities and claims attached to it, and the forms of representation through which economic analysis and administration can act upon it.

The term *economic subject* is used here in a deliberately limited sense. It designates a configuration that can occupy an economically consequential position, enter recognized relations, receive or control resources, bear claims or obligations, and become a unit of observation or intervention. The term therefore concerns economic standing rather than a complete theory of personhood or agency. A biological person may occupy several economic subject positions at once; an organization may acquire a durable economic position despite lacking the experiential properties associated with a human subject. This distinction permits the historical analysis to remain compatible with the ontological restraint developed later in the book.

Industrial modernity strengthened the stability of several such positions simultaneously. Wage labor made the worker legible through employment and remuneration. Property institutions stabilized the owner as a bearer of enforceable claims. Expanding markets and demand analysis strengthened the consumer as a distinct economic role. Household organization linked income, care, consumption, and reproduction. Firms and corporations condensed collective productive relations into continuing organizational subjects. These positions overlap in practice, yet their differentiation made modern economic administration unusually capable of assigning income, liability, entitlement, taxation, and policy effects to recognizable units.

1.4.1 Worker as Economic Subject

The worker became a particularly consequential economic subject through the institutional expansion of wage labor. Industrial production required large numbers of people to enter continuing relations in which labor capacity could be contracted, scheduled, supervised, remunerated, and coordinated with machinery and organizational routines. Marx's analysis of labor-power and the industrial labor process treats this relation as constitutive of capitalist production: productive activity is organized through a relation between those who control productive assets and those who sell labor-power within the production process (Marx 1867). Polanyi later emphasized the historical specificity of treating labor as if it were a commodity available to market coordination, while insisting that labor remains inseparable from the lives of the persons who supply it (Polanyi 1944).

The economic importance of the worker position lies partly in the forms of legibility that wage labor makes possible. Employment attaches income to a recognizable relation between worker and employer. Hours, wages, occupations, contracts, payrolls, and employment status create administrative traces through which labor can be taxed, regulated, insured, compared, and statistically represented. The worker can therefore appear as a unit of production and as a recipient of income at the same time. This dual standing helped make employment one of the principal institutional bridges between productive contribution and access to material resources in modern economies.

The worker position also illustrates the difference between an economic subject

and the whole person occupying that position. A person who appears in an employment relation as a worker may simultaneously be a household member, caregiver, consumer, owner of some assets, citizen, borrower, learner, or participant in a professional community. Economic administration frequently selects one of these relations because a particular institution requires a determinate role. Payroll systems need an employee; labor law needs parties to an employment relation; national accounts need categories of compensation and production. The resulting representation is operationally powerful precisely because it suppresses dimensions that are irrelevant to the immediate administrative task.

The relational constitution of the worker remains visible even within this compressed representation. Productive capacity depends on education, health, transport, care, technical infrastructure, organizational knowledge, legal protection, bargaining arrangements, and access to employment. The wage received by one worker may support several household members; a change in scheduling may alter care relations; a change in technology may reallocate authority and skill inside the workplace. The worker is therefore economically real as a stabilized subject position, while the capacities attached to that position remain generated and sustained through a wider relational field.

This historical construction becomes especially important later in the chapter when artificial intelligence and automation place pressure on employment as a mechanism of economic recognition and allocation. The relevant historical point at this stage is narrower. Modern institutions made the worker sufficiently stable and legible to serve simultaneously as a productive subject, an income recipient, a bearer of labor rights, and an object of economic measurement. That stabilization was an institutional achievement with a history, and its future transformation is therefore also historically possible.

1.4.2 Owner as Economic Subject

The owner position formed around enforceable claims to assets, resources, and the income streams associated with them. Property institutions identify a subject that may exclude others from specified uses, transfer claims, pledge assets, authorize access, and receive returns. The economic owner is therefore constituted through a relation among the claimant, the asset, other potential users, and the institutions that recognize and enforce the claim. North's institutional analysis is relevant because property and contracting arrangements operate within rule systems that structure incentives, expectations, and the security of exchange over time (North 1990).

Industrial development increased the importance of ownership by expanding the scale and durability of productive assets. Land, machinery, factories, inventories, financial claims, intellectual resources, and later corporate securities could be assigned to recognized owners and represented through accounts, registries, contracts, and balance sheets. Ownership thereby became a major interface between present control and future income. The owner could appear in economic analysis as a recipient of profit, rent, interest, or capital gain even when the productive process generating those returns depended on many relations extending beyond the owner's direct activity.

The position is internally differentiated. Ownership may coexist with delegated management, creditor claims, regulatory constraints, contractual commitments, shared ownership, or limited rights of use. An owner may hold legal title while another actor exercises operational control; several owners may share claims to the same organization; a lender may constrain asset use without becoming owner. These arrangements show that ownership is a structured bundle of recognized relations rather than a simple physical connection between a person and a thing. The stability of the subject position comes from institutional recognition of those relations and from the capacity to reproduce them through transfer, enforcement, and accounting.

Ownership also shapes the distribution of economic possibility. A productive asset can support future borrowing, investment, bargaining, mobility, inheritance, and access to organizational opportunities. The economic consequence of ownership therefore exceeds the current income attached to the asset. It can alter the owner's future action space while simultaneously affecting the access of others. This temporal dimension becomes central later in GRE's analysis of generative value, capability, and option-space transformation.

The owner position consequently provides an early example of a subject whose economic significance is relational and generative even when conventional representation is entity-centered. Administrative systems may record that an asset belongs to a named owner, and this representation is often indispensable. The effects of that ownership emerge through relations of exclusion, access, finance, production, inheritance, and institutional recognition. Section 1.5 develops the legal and administrative construction that makes these ownership relations increasingly durable and governable.

1.4.3 Consumer as Economic Subject

The consumer became a distinct economic subject as demand, choice, and the allocation of expenditure acquired greater analytical and practical importance. Marshall's synthesis of demand, supply, wants, value, and marginal adjustment gives consumption a systematic place within a unified account of economic coordination (Marshall 1890). The consumer in this framework appears as a chooser whose demands help organize production through market exchange. Later scarcity-centered formulations extended the same analytical grammar by representing economic conduct through the allocation of scarce means among alternative ends (Robbins 1932).

The rise of the consumer position depended on more than an intellectual shift in economic theory. Expanding markets, standardized goods, monetary income, retail infrastructures, advertising, credit, transport, and mass production increased the practical importance of household expenditure and individualized purchasing decisions. Prices and product categories made heterogeneous goods comparable within budgets, while market institutions provided repeated occasions on which persons could be addressed primarily through their role as buyers. The consumer therefore became both an analytical unit and an institutional target for pricing, marketing, credit, taxation, regulation, and later consumer protection.

This subject position has a characteristic abstraction. The consumer is represented through preferences, purchasing power, observed choices, or welfare effects, while

the relations that formed those preferences and capacities may remain outside the immediate model. Income depends on labor, ownership, transfers, or household relations; access depends on infrastructure and geography; preferences may be shaped by culture, information, social position, and commercial representation; credit can move purchasing power across time. A demand curve or expenditure record captures an economically meaningful manifestation while leaving many of its generative conditions unresolved.

The distinction becomes more important when consumption itself generates relations. Repeated purchases can sustain platforms and distribution networks; credit creates durable obligations; subscription models establish continuing dependence; digital consumption produces data that can be converted into commercial knowledge; consumption inside households redistributes access among members. These effects do not eliminate the analytical usefulness of the consumer. They reveal that the consumer is one stabilized position within a larger relational process.

The historical formation of the consumer therefore complements the formation of the worker and owner. Industrial modernity increasingly organized persons through several differentiated roles: contribution could be represented through work, command over assets through ownership, and access to goods through consumption. Economic policy could then act upon each role through different instruments. The later GRE problem is to understand how these roles interact, how they generate one another's capacities, and how contemporary digital systems increasingly blur their boundaries.

1.4.4 Household as Economic Subject

The household occupies a distinctive position because it joins economic subjecthood to a relational configuration that is visibly composite. Modern economic analysis and administration frequently treat the household as a unit of income, expenditure, taxation, welfare, housing, saving, and consumption. At the same time, the household contains relations of care, dependence, authority, contribution, inheritance, and intergenerational support that cannot be inferred from aggregate household resources alone. The household therefore makes especially clear how an entity-level representation can be administratively necessary while remaining analytically incomplete.

Industrial wage labor strengthened the household's role as a bridge between production and social reproduction. Wages and other incomes enter the household through members occupying positions in labor, ownership, or public transfer systems. Food, shelter, care, education, health, and time are then organized through internal relations that reproduce capacities required for future participation in economic and social life. Polanyi's account of market society is useful for locating this process historically because the expansion of labor markets placed livelihoods under market dependence while social institutions continued to mediate the reproduction of persons and communities (Polanyi 1944).

The household also became a practical allocation unit. Taxes, benefits, housing policy, social insurance, surveys, and consumption statistics frequently require a boundary within which income and need can be aggregated. Such aggregation enables public administration to compare households and distribute resources at scale.

The boundary acquires causal force because eligibility rules, tax liabilities, benefits, and legal responsibilities may depend on who counts as a member. Economic subjecthood is therefore partly generated by the institutional act of recognizing a household and assigning consequences to its boundary.

Aggregation can also conceal internal asymmetry. Two households with the same measured income may distribute time, care, consumption, control, and risk very differently. A transfer formally received by one member may alter bargaining relations among several members. Unpaid care can sustain labor-market participation without appearing as wage income. Intergenerational transfers can expand the future options of some members while limiting those of others. These possibilities show why the household is an important bridge from entity-centered economics toward relational analysis: the entity is empirically real and administratively consequential, yet the distribution of capacities within it depends on internal relations.

GRE therefore has reason to retain the household as an economic subject while refusing to treat its boundary as self-explanatory. Later chapters can ask how resources entering a household propagate through internal relations, how care and dependence generate capabilities, and how household membership affects access to institutions. The historical point developed here is that modern economic order increasingly stabilized the household as a recognizable recipient and decision unit, creating a powerful administrative representation whose relational interior remains economically consequential.

1.4.5 Firm and Corporation as Collective Economic Subjects

The firm and corporation extend economic subjecthood beyond the individual and household by stabilizing a collective organization as a continuing participant in economic relations. Coase's analysis of the firm identifies an organizational domain in which coordination occurs through internal direction rather than through a sequence of market exchanges, thereby making the boundary of the firm an economic problem in its own right (Coase 1937). The corporation adds greater durability through institutional forms that allow assets, contracts, liabilities, roles, and organizational purposes to persist across changes in particular participants.

Collective economic subjecthood depends on the capacity to act through organized relations. A firm can hire workers, purchase inputs, own or control assets, borrow, sell outputs, enter contracts, maintain accounts, and make investment decisions because internal authority and procedures translate distributed activity into organizational action. No single participant needs to perform every function. The organization acquires practical continuity through roles, routines, records, governance structures, and external recognition. Its economic agency is therefore generated through coordination among relations that are distributed across many persons and institutional interfaces.

The collective subject also produces a distinctive form of representation. Revenue, cost, profit, debt, assets, employment, and output can be assigned to the organizational boundary even though the processes generating these quantities extend through workers, suppliers, creditors, customers, regulators, infrastructures, and knowledge networks. Accounting and legal systems make the organization suffi-

ciently coherent to appear as one unit in contracts, taxation, statistics, investment, and policy. The unit is therefore neither fictitious in the ordinary sense nor analytically exhaustive. It is a stabilized manifestation of a more complex relational configuration.

This distinction matters for economic intervention. A subsidy paid to a firm may alter wages, investment, bargaining power, supplier dependence, market position, knowledge accumulation, or shareholder returns. A liability imposed on a corporation may be redistributed internally through prices, employment, contracting, or investment decisions. Entity-level policy therefore operates through collective subjects whose responses are generated by internal and external relations. The organization can remain the correct administrative recipient while relational analysis is required to understand the consequences of intervention.

The historical formation of the firm and corporation closes the section because it reveals the general pattern most clearly. Modern economic subject positions became powerful through institutional stabilization, selective representation, and repeated practical use. Worker, owner, consumer, household, firm, and corporation are heterogeneous kinds of subject, yet all can become economically real through durable participation in recognized relations. Section 1.5 turns from these subject positions to the legal, contractual, accounting, statistical, and administrative mechanisms that construct the entities through which modern economic systems allocate rights, resources, obligations, and responsibility.

1.5 Institutional Construction of Economic Entities

This section examines the institutional processes through which heterogeneous persons, organizations, assets, activities, and relations become recognizable as bounded economic entities. Its role in the chapter is to connect the historically formed economic subjects of Section 1.4 to the administrative architecture that permits modern economies to assign ownership, liability, income, taxation, reporting, eligibility, and responsibility to identifiable units. The objective is to show how legal personality, property, contract, accounting, statistics, and institutional membership jointly stabilize economic boundaries without requiring those boundaries to coincide with every relation that generates the entity's capacities. The discussion proceeds through five institutional mechanisms and uses a historical-institutional method: each mechanism is treated as a practical technology of recognition that makes an economic unit durable enough to enter law, administration, measurement, and allocation.

The term *economic entity* refers here to a recognized unit to which economically consequential attributes can be attached. Such attributes include assets, liabilities, income, expenses, rights, obligations, tax status, employment, eligibility, and reporting responsibility. This use remains compatible with the ontological restraint of GRE. Institutional recognition can make an entity relationally and causally consequential without settling the ultimate ontology of the person, organization, or collective concerned. The relevant historical achievement is the stabilization of boundaries that permit repeated action upon a unit across time.

Modern economic coordination depends heavily on this achievement. Credit re-

quires a debtor whose obligations can be identified. Property requires a bearer of enforceable claims. Contracts require parties. Accounting requires a reporting boundary. Statistics require units that can be classified and aggregated. Public administration requires membership criteria that determine who enters a category, receives a transfer, pays a tax, or bears a duty. These mechanisms operate differently, yet together they transform fluid relational configurations into operationally persistent entities. The resulting compression makes large-scale economic coordination possible while creating a recurrent analytical tension between the recognized unit and the wider relations on which its capacities depend.

1.5.1 Legal Personality

Legal personality supplies one of the strongest mechanisms for stabilizing an economic entity through time. Organizational law provides standardized legal forms through which an enterprise can hold assets, enter agreements, incur liabilities, and persist across changes in the individuals who participate in it. Hansmann and Kraakman's analysis of organizational law emphasizes asset partitioning: organizational law can separate a pool of entity assets from the personal assets and creditors of owners or managers, thereby creating a durable structure of claims around the organization (Hansmann and Kraakman 2000). This separation supports the practical treatment of the organization as a continuing economic unit.

The significance of legal personality for GRE lies in its capacity to stabilize relations into a recognizable locus of responsibility. A corporation, association, trust, or other recognized organization may contain many internal relations and participate in many external ones, yet legal form gives selected relations a persistent boundary. Contracts can be entered in the entity's name. Assets can remain attached to the organization when shareholders, managers, or employees change. Creditors can direct claims toward specified pools of assets. Courts and regulators can address the organization as a continuing bearer of rights and duties. Legal personality therefore creates temporal continuity that exceeds the continuity of any individual participant.

This institutional continuity should be distinguished from the complete economic reality of the organization. The legal entity identifies a powerful boundary, yet productive capacity may depend on workers, suppliers, public infrastructure, household reproduction, financing networks, tacit knowledge, and social trust that extend beyond that boundary. The legal unit nonetheless remains economically consequential because claims, liabilities, and decision authority are routed through it. Entity-centered analysis gains much of its practical force from this institutionally produced concentration of responsibility.

The relation between legal and economic entityhood becomes especially clear in systems of national accounting. The System of National Accounts treats institutional units as fundamental economic units capable of owning assets, incurring liabilities, engaging in transactions, and taking economic decisions on their own behalf (European Commission et al. 2009). Legal responsibility and accounting capacity are therefore closely connected to the statistical constitution of the economy. The institutional unit is useful because economic flows can be attributed to a recognizable bearer across repeated transactions and accounting periods.

Legal personality also demonstrates that economic entities can be generated through institutional recognition. The organization does not become economically significant merely because a legal label is attached to it; the label works because it reorganizes relations of ownership, liability, contracting, and enforcement. The legal form is therefore performative in an economically specific sense: recognition creates durable channels through which resources, obligations, and claims can circulate. Later GRE chapters return to this point when examining how institutional recognition can generate capacities and constraints beyond the immediate legal relation.

1.5.2 Property and Contract

Property and contract deepen entity stabilization by attaching resources and obligations to recognized parties. Property identifies who may hold, transfer, exclude, pledge, or authorize uses of an asset within a given institutional order. Contract identifies parties whose commitments can be interpreted, enforced, and carried forward through time. Together they create a relational grammar in which economically consequential claims can be assigned to named units and transferred among them.

North's account of institutions is relevant because property and contracting operate through rule systems that structure incentives, reduce some forms of uncertainty, and make repeated exchange more predictable (North 1990). Coase's analysis of the firm similarly shows that contracting and market exchange have costs and that organizations emerge partly through alternative arrangements for coordinating transactions (Coase 1937). These traditions differ in focus, yet both demonstrate that exchange depends on institutional structures that define who can commit, what can be transferred, and how agreements are sustained.

Property contributes to entity formation by linking a recognized subject to a durable set of claims over resources. Organizational law can intensify this effect through asset partitioning. Hansmann and Kraakman show that the ability to shield entity assets from the personal creditors of owners or managers supports the construction of large-scale organizations whose assets can remain committed to organizational purposes (Hansmann and Kraakman 2000). The entity thereby acquires a resource base whose continuity is institutionally protected.

Contract contributes a complementary temporal structure. An agreement links present recognition to future performance. Parties can coordinate production, finance, labor, supply, insurance, and exchange across time because obligations have a recognized bearer and an enforceable form. Contractual relations therefore extend the temporal horizon of economic organization. They also connect entity boundaries: one firm's obligation becomes another firm's claim, one household's debt becomes another unit's asset, and one employment contract links a worker position to an organizational position.

The resulting architecture makes economic activity legible as relations among entities with identifiable holdings and commitments. This architecture is analytically powerful because many economically important questions genuinely concern the distribution and transfer of recognized claims. The same architecture also compresses relational complexity. A contract records selected obligations, while leaving many

background relations unstated. Property identifies a recognized claimant, while the asset's productive use may depend on wider infrastructures and collective conditions. GRE therefore treats property and contract as real institutional structures whose analytical boundaries remain narrower than the total field of relations sustaining economic activity.

1.5.3 Accounting and Organizational Boundaries

Accounting converts organizational continuity into a recurring representational boundary. Assets, liabilities, equity, income, and expenses are recorded relative to a reporting entity, allowing economic activity to be summarized across a period and compared across periods. The reporting boundary makes a heterogeneous organizational process appear as a unit with a balance sheet, flows, and a calculable financial position. This representation supports investment, lending, taxation, governance, and organizational decision-making.

The IFRS Conceptual Framework makes the constructed character of this boundary explicit. A reporting entity can be a single legal entity, a portion of an entity, or a group of entities, and the reporting boundary therefore need not coincide exactly with legal personality (IFRS Foundation 2018). Consolidated accounts may represent a parent and its subsidiaries as one reporting entity even though several legal entities remain in existence. Combined accounts can likewise gather economic activities across organizational units when the reporting purpose requires a wider boundary.

This flexibility reveals an important methodological point for GRE. Economic entityhood is partly representation-dependent because different institutional practices may draw different boundaries around the same relational field. Legal personality, managerial control, accounting consolidation, statistical sectoring, and productive coordination can produce overlapping rather than identical entities. A corporate group may be many legal persons, one consolidated reporting entity, several operational divisions, and part of a wider supply network at the same time. Each boundary serves a different analytical and institutional function.

Accounting nonetheless gives these boundaries substantial causal force. Budgets, performance measures, debt covenants, taxation, capital allocation, and managerial evaluation are frequently organized around reported units. Once a reporting boundary is stabilized, internal and external flows are classified differently depending on which side of the boundary they occur. A transfer between subsidiaries may disappear in consolidated reporting while remaining visible in the accounts of each subsidiary. The representational boundary therefore changes which economic relations appear as internal coordination and which appear as transactions between entities.

This point provides a direct bridge from institutional construction to later GRE analysis. The entity represented in accounts is neither arbitrary nor exhaustive. It is selected for an institutional purpose, sustained through conventions and control relations, and capable of shaping decisions once established. Accounting therefore participates in the economic reality it represents: it defines operational units, channels attention, and conditions how resources are compared and allocated. The relational question is consequently not only whether the accounts are accurate, but also which relations become internal, external, visible, or invisible under the chosen boundary.

1.5.4 Statistics and Administrative Legibility

Statistical systems extend entity construction from organizations to entire economies. Large-scale administration requires units that can be counted, classified, compared, and aggregated. Households, corporations, government units, workers, industries, sectors, residents, and non-residents become statistical categories through definitions that specify membership and delimit the observations that belong together. Desrosières' history of statistical reasoning shows that classification and quantification depend on conventions that make heterogeneous cases comparable, while Porter emphasizes the institutional role of standardized quantitative procedures in producing impersonal forms of judgment (Desrosières 1998; Porter 1995).

The System of National Accounts provides a particularly clear example. It organizes macroeconomic accounting around institutional units and sectors, treating units capable of owning assets, incurring liabilities, entering transactions, and making economic decisions as the building blocks of the statistical economy (European Commission et al. 2009). Corporations, government units, nonprofit institutions, and households are then grouped according to functions and institutional characteristics. This statistical architecture permits production, income, saving, investment, assets, and liabilities to be aggregated into coherent macroeconomic accounts.

Administrative legibility emerges through similar operations. Tax systems define taxable persons and entities. Social insurance systems define contributors and beneficiaries. Business registries identify organizations. Labor statistics classify employment status and occupation. Regulatory systems distinguish sectors, ownership forms, and reporting obligations. Each system draws a boundary around the unit relevant to its task and attaches standardized attributes to that unit. The economy becomes governable partly because actors and activities can be entered into interoperable categories.

These classifications have practical consequences. Eligibility, tax liability, regulatory burden, access to programs, statistical visibility, and policy targeting can depend on categorical membership. The category therefore becomes more than a passive description. Hacking's historical work on classification is useful for understanding how classificatory practices can participate in the formation of the objects and kinds they describe (Hacking 2002). In economic administration, classification can alter incentives, organizational forms, reporting behavior, and the distribution of resources.

GRE inherits both the analytical power and the caution implied by this history. Statistical units are indispensable for large-scale comparison and coordination. Their usefulness depends on abstraction: a household or corporation must be treated as sufficiently coherent for aggregation to work. The same abstraction can conceal internal relations, boundary disputes, informal activity, cross-border structures, and dependencies that do not fit the chosen classification. Administrative legibility therefore increases the capacity to act on an economy while narrowing the dimensions that remain visible within the administrative representation.

1.5.5 Economic Recognition and Institutional Membership

Economic recognition completes the institutional construction of entities by determining which units count as members of particular economic categories and which rights, duties, resources, and observations follow from that membership. Recognition occurs through law, registration, accounting, statistics, employment, taxation, licensing, residence, organizational affiliation, and many other institutional practices. The resulting membership conditions establish who is visible to a system and in what capacity.

Institutional membership is rarely singular. A person may simultaneously be recognized as worker, taxpayer, household member, shareholder, resident, borrower, student, beneficiary, and citizen. An organization may be recognized as employer, corporation, taxpayer, regulated firm, statistical unit, contractor, or recipient of public support. Each membership relation attaches a different set of capacities and obligations. Economic subjecthood therefore becomes layered through multiple institutional recognitions rather than exhausted by one universal status.

The SNA illustrates this layering at the macroeconomic level. Institutional units are assigned to sectors and to residence categories so that transactions and balances can be organized consistently (European Commission et al. 2009). The classification is analytically productive because it creates stable membership rules for statistical aggregation. Similar logics operate in administrative systems: participation in a program or regulatory regime depends on satisfying criteria that determine whether an actor belongs inside or outside the relevant category.

Recognition can also generate economic capacity. Registration may permit an organization to open accounts, contract, receive funds, employ workers, or incur debt. Employment status may provide access to wages, insurance, pensions, or legal protections. Residence may determine access to public services or tax obligations. Institutional membership thus changes the action space available to an actor. North's treatment of institutions as constraints structuring interaction helps clarify why recognized status can alter incentives and feasible conduct (North 1990).

The generative consequence is important for the chapters that follow. An entity becomes economically durable when several systems converge in recognizing it: law attaches rights and duties, accounting draws a reporting boundary, statistics assign a category, administration records membership, and counterparties organize expectations around the resulting unit. These recognitions reinforce one another and make the entity increasingly actionable. Once stabilized, the entity can receive resources, bear obligations, appear in models, and become the target of intervention.

This institutional success explains much of the historical power of entity-centered economics. Modern economies created entities that were genuinely useful for administration because institutional systems repeatedly acted through them. The limit appears when economic effects propagate through relations that cross the recognized boundary or when important participants remain weakly recognized by the institutions that allocate resources and visibility. Section 1.6 therefore turns from the construction of entities to the historical logic of allocating scarce resources through administratively identifiable recipients.

1.6 Entity-Centered Allocation in Historical Context

The institutional construction of economic entities described in Section 1.5 made a particular form of allocation historically practical: resources could be assigned to recipients represented as persons, households, firms, corporations, public bodies, or other administratively identifiable units. This section examines the historical conditions under which recipient-centered allocation became a powerful economic abstraction. Its objective is explanatory rather than dismissive. The analysis proceeds through five steps: the formation of administrative recipients, the relation between material scarcity and allocation, the role of employment in connecting productive participation to livelihood, the relation between competitive capability and resource claims, and the limits that appear when evaluation stops at the recipient boundary. The method is historical and institutional. Entity-centered allocation is treated as an achievement of modern economic organization whose usefulness depends on the social and administrative conditions that made recipients sufficiently stable, comparable, and actionable.

1.6.1 Administrative Recipients

Allocation requires a recipient that an institution can identify before resources can be transferred, taxed, credited, insured, subsidized, or otherwise assigned. Modern economic administration therefore depends on categories that answer a practical question of membership: which unit is entitled, liable, responsible, or eligible within a given scheme. The institutional units of national accounting provide one explicit example. The System of National Accounts organizes production, income, saving, assets, and liabilities around units capable of owning assets, incurring liabilities, making economic decisions, and entering transactions (European Commission et al. 2009). Similar recipient structures appear in taxation, social insurance, business registration, corporate finance, public procurement, and household-based benefit systems.

The administrative recipient is consequently a historically stabilized interface between a relational economy and an allocative act. A transfer rarely reaches an abstract individual in isolation. It reaches a legally or administratively recognized unit whose identity has already been produced through registration, residence, employment, ownership, household membership, organizational status, or another institutional relation. The recipient category compresses these relations into a unit upon which an administrative system can act.

This compression yields substantial practical advantages. A public authority can assign a benefit to a registered household without reconstructing every relation within the household. A bank can lend to a corporation whose legal and accounting boundaries are sufficiently stabilized for liability and repayment to be represented. A firm can pay wages to an employee whose contractual status identifies both the payer and the recipient. Large-scale allocation becomes feasible because institutional systems can repeatedly address the same kinds of units without reproducing the whole relational history that makes those units possible.

Recipient construction also standardizes accountability. An allocation can be recorded as having been made to a defined unit; the unit can be asked to report,

repay, comply, or demonstrate eligibility. The reporting-entity logic discussed in the preceding section illustrates how flexible such units can be: accounting may construct a reporting boundary around one legal entity, part of an entity, or several entities when the institutional purpose requires it (IFRS Foundation 2018). Administrative allocation operates through the same general principle. The actionable unit is selected according to the function of the allocative regime.

The success of this architecture explains why recipient-centered analysis became deeply embedded in economic reasoning. Once recipients are legally, statistically, and administratively stabilized, flows among them can be represented with exceptional clarity. Income is received by households, investment is made by firms, taxes are collected from persons and organizations, transfers are paid to beneficiaries, and assets are assigned to owners. The representation is institutionally grounded rather than merely convenient. Modern economies developed extensive infrastructures that made entity-level flows real objects of administration.

1.6.2 Scarce Resources and Allocation

The allocative significance of stable recipients increased under conditions in which material resources, income, productive assets, public budgets, and institutional opportunities were treated as scarce relative to competing claims. Robbins' influential formulation of economics around scarce means with alternative uses made this structure explicit at the disciplinary level (Robbins 1932). Scarcity does not by itself determine who should receive a resource, yet it creates the recurrent requirement to choose among possible uses and recipients.

Entity-centered allocation offered a tractable response to that requirement. Once a scarce resource could be represented as a quantity and potential recipients could be represented as discrete units, allocation could be organized through prices, wages, contracts, budgets, eligibility rules, credit decisions, taxation, transfers, or administrative assignment. The institutional problem acquired a common form even when the mechanisms differed: a bounded quantity was distributed among recognized claimants.

This form was especially compatible with the accounting and statistical infrastructures of industrial modernity. Monetary valuation allowed heterogeneous resources to enter common ledgers; property rules identified control; organizational accounts located assets and liabilities; state statistics aggregated households and firms; and administrative records linked claims to recognized recipients. Allocation could therefore be represented through flows that entered and left defined units. The entity-centered picture matched the operational needs of institutions that had to decide, record, compare, and audit distributions at scale.

Welfare economics extended the allocative problem from private choice to the evaluation of social arrangements. Pigou's analysis of economic welfare connected economic assessment to the national dividend and to divergences between private and social net product (Pigou 1920). Whatever normative criterion is adopted, such analysis presupposes some representation of who receives benefits and bears costs. Recipient categories thereby enter both administrative action and evaluative reasoning.

The historical importance of this architecture should be separated from a claim

of timeless necessity. Material scarcity remains economically consequential, and recipient-level distribution remains indispensable in many domains. A household requires income, a firm requires financing, and a public program requires rules for eligibility. The historical question concerns the scope of the abstraction. Recipient-centered allocation became powerful because the major resources and institutions of modern economic organization could often be represented through identifiable owners, workers, firms, taxpayers, and beneficiaries. The same abstraction becomes less complete when the economic consequence of an allocation depends heavily on relations that extend beyond the recipient unit.

1.6.3 Employment and Access to Livelihood

Employment became one of the central institutional relations connecting productive participation to command over resources. Under wage labor, the employment relation links the contribution of labor to a monetary claim that can be exercised elsewhere in the economy. Marx's analysis of labor-power and the wage relation places this institutional form within the production process of capital, while Polanyi's historical account emphasizes the broader social transformation involved in organizing labor through markets (Marx 1867; Polanyi 1944). The importance of employment for allocation follows from its position between production and livelihood.

For the worker, wage income supplies purchasing power. For the firm, employment identifies a recognized contributor within an organizational structure and a recurrent claim on organizational resources. For public administration, employment status can become an observable category used in taxation, insurance, pensions, labor regulation, and statistical classification. The employment relation therefore coordinates several institutional systems at once. Productive participation, monetary income, legal status, organizational membership, and administrative recognition become partially coupled through one relation.

This coupling makes employment more than a production arrangement. In societies where access to many goods and services is mediated by monetary income, labor-market position influences the practical ability to secure housing, food, mobility, education, care, and other conditions of life. The strength of the connection varies across welfare regimes, households, property structures, and public institutions, yet the general architecture remains significant: employment often provides a major route through which productive participation is converted into an individual or household resource claim.

The recipient-centered form is visible in the way the wage appears. A complex production process involving technologies, infrastructures, organizations, legal protections, accumulated knowledge, suppliers, customers, and public institutions results in a payment assigned to an identifiable worker. The wage is real and materially consequential, while the recipient unit abstracts from the wider relations that made the productive process possible. The same structure appears on the employer side, where revenues and profits are attributed to legally and organizationally bounded entities even when production depends on extended relational networks.

Employment therefore helped stabilize a broader social expectation: participation in production could function as a legitimate basis for access to income. This expec-

tation never exhausted the sources of livelihood, since property income, household transfers, public provision, informal production, inheritance, and many other mechanisms also mattered. Its analytical significance lies in how effectively it connected three institutional domains that might otherwise remain separate: production, recognition, and allocation. Later sections will examine why artificial intelligence and changing productive capabilities place pressure on this historically powerful connection.

1.6.4 Competitive Capability and Resource Claims

Market allocation frequently connects resource claims to capabilities that can be exercised within recognized exchange and production relations. Labor earns income when a worker's capacities can be supplied under an employment relation; property generates claims when an owner controls an asset that can be leased, sold, financed, or used productively; firms obtain revenue when organizational capacities produce goods or services that counterparties purchase. Competitive capability therefore matters because institutions convert certain capacities into claims over resources.

The conversion is mediated rather than automatic. A capability has economic consequence only within a structure that recognizes, prices, contracts, or otherwise enables its exercise. The same skill may command a high wage in one labor market and little income in another. An asset may generate revenue under one property regime and remain economically inactive under another. Organizational knowledge may become valuable when complemented by finance, infrastructure, legal permission, and market access. Resource claims consequently depend on the relation among capability, institution, and opportunity rather than on capability considered in isolation.

Sen's entitlement analysis offers a particularly clear formulation of the distinction between aggregate availability and a person's command over resources. His analysis of famine shifts attention from total food supply toward the legally available means through which persons can command food, including production possibilities, trade opportunities, and state entitlements (Sen 1981). The argument is narrower than a general theory of allocation, yet its structural lesson is important here: the existence of a resource in an economy does not establish an actor's effective claim upon it. Claims are mediated by ownership, exchange, production, public provision, and other institutional relations.

This perspective clarifies the historical connection between competitive capability and allocation. Markets can translate productive or exchange capabilities into monetary claims when institutions recognize the relevant relations. The resulting claims can then be exercised against other resources. A worker's labor capacity, a firm's organizational capacity, an owner's asset, or a creditor's contractual right enters an allocative system through a different institutional channel, yet each channel links a recognized position to a claim.

The architecture also generates asymmetry. Differences in productive capability, asset ownership, bargaining position, institutional recognition, and access to markets can become differences in resource command. Once resource command changes, it can alter future capabilities by affecting education, health, mobility, technology, finance, networks, and institutional access. Recipient-centered allocation therefore

contains a dynamic dimension even when the immediate transaction is represented as a transfer between fixed entities. Present claims influence the conditions from which future claims can be made.

The historical relevance of this mechanism becomes especially important when capabilities change rapidly. If productive capacity is increasingly concentrated in artificial systems, platforms, capital-intensive infrastructures, or organizations that control them, the inherited connection between individual productive contribution and resource claims may weaken. Chapter 1 develops this problem later. The present point is preparatory: modern allocation systems often rely on institutional pathways that translate recognized capabilities and positions into claims, and those pathways have histories rather than universal form.

1.6.5 Historical Limits of Recipient-Centered Evaluation

Recipient-centered evaluation is strongest when the principal question concerns the immediate distribution of a resource among identifiable units. It can show who received income, credit, property, benefits, or public expenditure; it can compare quantities across households or firms; and it can support accountability for decisions made under scarcity. These capacities remain indispensable. The limitation emerges when the evaluative object extends from receipt to the relational and generative consequences of receipt.

The first limit concerns internal structure. Two households receiving the same transfer may contain different dependency relations, care obligations, decision structures, and access conditions. Two firms receiving the same investment may organize labor, knowledge, ownership, and external suppliers differently. A recipient-level measure records the transfer accurately while leaving the internal relational configuration unresolved. The resulting abstraction is often appropriate for administration, although it cannot by itself establish how the resource changes relations within the recipient unit.

The second limit concerns external structure. A resource assigned to one entity may alter other actors through prices, employment, bargaining, supply relations, debt, care obligations, network access, or institutional precedent. These effects cross the administrative boundary used to record the allocation. The same nominal transfer can therefore generate different economic consequences depending on the recipient's position within wider relational configurations.

The third limit concerns effective command. Sen's entitlement analysis demonstrates, in an especially stark domain, that aggregate resource availability does not determine who can command the resource (Sen 1981). Recipient-centered evaluation can likewise become incomplete when formal receipt and effective access diverge. A formally allocated resource may be unusable without complementary infrastructure, knowledge, legal status, time, mobility, or relational support. The allocative event and the realized capability can therefore differ substantially.

The fourth limit concerns temporal extension. Immediate receipt is an event; its consequences may unfold through a trajectory. An educational grant can alter later capabilities and networks. Credit can enable production while also creating dependence. Infrastructure can change future market access. A transfer to an organization

can reshape internal authority or external bargaining power. Evaluating only the first recipient and the first period captures a real part of the process while omitting the later relations generated by the allocation.

These limits establish the historical transition that motivates GRE without retroactively invalidating entity-centered economics. Modern law, accounting, statistics, markets, and public administration created stable recipients because large-scale allocation required them. Economic theory developed abstractions that corresponded closely to this institutional architecture. The contemporary challenge arises as increasingly important economic effects depend on networks, platforms, knowledge infrastructures, institutional access, heterogeneous capabilities, and long-horizon transformations that cross recipient boundaries.

Recipient-centered allocation therefore remains a valid analytical layer within a wider relational account. GRE's later allocation theory will retain the administrative recipient while asking additional questions about the relations through which resources become usable, the configurations altered by transfer, and the future capacities and constraints generated afterward. Before that theory can be developed, Chapter 1 must first reconstruct how capital, labor, and knowledge became historically differentiated sources of economic power. Section 1.7 takes up that task.

1.7 Capital, Labor, Knowledge, and Economic Power

The preceding sections reconstructed the institutional conditions that made economic subjects legible and recipient-centered allocation administratively tractable. This section turns to the historically differentiated capacities through which economic subjects could command resources, participate in production, and influence the conditions of later action. Its objective is to clarify how capital, labor, and knowledge became distinct yet convertible sources of economic advantage and how their institutional conversion contributed to economic power. The discussion proceeds through five steps: capital as productive control, labor as the material basis of social reproduction, knowledge as a productive resource whose scarcity differs from that of material goods, expertise as an institutionally organized hierarchy of epistemic capability, and the conversion among capability, resources, and power. The method is historical and relational. Each source of advantage is treated through the relations that make it effective rather than as an isolated substance possessed independently of institutions, organizations, and other economic subjects.

1.7.1 Capital and Productive Control

Capital acquired historical significance through more than the accumulation of valuable objects. Productive assets become economically consequential when ownership, finance, organization, and law permit their holders to determine how production is initiated, combined, expanded, or withheld. The distinction matters because the same physical object can occupy very different economic positions according to who controls it, what claims are attached to it, and which organizational relations it enables. A machine incorporated into a firm, a parcel of land pledged as collateral, and

a financial claim that can be mobilized for investment all participate in productive control through different institutional arrangements.

Marx's analysis of capital emphasized this relational dimension by locating capital within a production process in which money, means of production, and purchased labor-power are organized toward the production of surplus value (Marx 1867). Whatever theoretical commitments are adopted regarding value, the historical insight is broader: control over productive assets can organize the labor of others, determine access to productive opportunities, and shape the technical form of production. Capital therefore carries a capacity to structure relations in addition to representing stored wealth.

Modern organizational law strengthened this capacity by creating durable arrangements through which assets could be partitioned, committed to organizational purposes, and insulated from some claims against owners or managers (Hansmann and Kraakman 2000). Productive control could thereby persist beyond the lifespan or immediate decisions of particular individuals. Corporations, banks, partnerships, and other organizational forms stabilized pools of assets and claims that could hire labor, purchase technology, enter contracts, and accumulate further resources. Capital increasingly operated through organizations rather than through isolated proprietors alone.

Financial institutions added another layer. Access to credit allows claims on future income to be converted into present productive capacity, while collateral and creditworthiness determine which subjects can perform that conversion on favorable terms. Productive control can consequently expand without prior possession of the full material resources required for production. The institutional ability to mobilize claims, pledge assets, and coordinate investment becomes part of the effective content of capital.

This historical structure created a recursive advantage. Control over productive assets can generate income; income can be retained or invested; investment can expand productive capacity; expanded capacity can strengthen bargaining position and access to finance. The recursion is neither automatic nor uniform, because markets, crises, regulation, competition, technological change, and collective organization can interrupt it. The important point for the present chapter is structural: capital can reproduce its economic effectiveness through institutional channels that connect present control to future control.

Economic power begins to appear within this recursion. At this stage, the term refers provisionally to an actor's capacity to influence access to productive conditions, the organization of production, or the feasible economic actions of other participants. A firm controlling essential infrastructure, a lender controlling access to finance, or an owner controlling a productive asset can affect choices available to subjects who depend on those conditions. Later chapters develop a fuller theory of power. The historical task here is to identify the material and institutional channels through which productive control became one of its recurrent economic sources.

1.7.2 Labor and Material Reproduction

Labor occupies a different position because productive activity is inseparable from the reproduction of the persons and households that perform it. Wage labor links these domains by converting participation in production into income through which food, shelter, care, mobility, education, and other conditions of continued life are acquired. The employment relation therefore connects the organization of production to the material reproduction of economic subjects.

Marx's treatment of labor-power made this connection explicit by distinguishing labor from the capacity to labor and by locating the reproduction of labor-power within the material conditions required for its continued availability (Marx 1867). Polanyi's historical account likewise emphasized the social transformation involved in subjecting labor to market organization, since labor is inseparable from the human beings whose lives are affected by the conditions under which it is bought and sold (Polanyi 1944). These traditions differ in theory and purpose, yet both illuminate the historical dependence of wage labor on arrangements extending beyond the immediate labor contract.

The worker's productive capacity depends on relations that precede the employment encounter. Health, education, care, household support, transportation, legal status, social networks, and public infrastructure all condition whether labor can be offered and under what terms. The wage relation makes only part of this supporting structure visible in monetary form. A firm pays for labor according to institutional and market conventions, while many conditions that reproduce labor are provided by households, communities, public institutions, or earlier investments whose contribution is not represented in the wage itself.

Labor also generates capacities that can outlast particular employment relations. Skills are learned through practice; workers acquire knowledge of technologies, organizations, clients, procedures, and collective routines; occupational communities transmit standards and techniques. Employment can therefore reproduce and transform productive capability at the same time that it uses it. The distribution of learning opportunities becomes economically important because work positions differ in the degree to which they expand future capability.

The relation between labor and power follows from this dual character. A worker may depend on employment for livelihood while an organization depends on workers for productive continuity. The relative strength of these dependencies varies with labor-market conditions, legal protections, skill scarcity, collective organization, ownership structure, mobility, and the availability of alternatives. Labor power in the ordinary political-economic sense and productive capability in the present historical reconstruction meet at this point: the capacity to work becomes economically consequential through institutions that determine who can withhold, replace, coordinate, or reorganize that capacity.

This perspective also clarifies why labor cannot be reduced to a quantity of effort. Labor is situated within a relational infrastructure of reproduction and learning. Its economic effect depends on technical systems, organizational coordination, access to tools and information, household conditions, and institutional recognition. The material reproduction of labor and the productive use of labor are therefore connected

moments of one economic architecture. That architecture becomes especially important once knowledge and expertise begin to account for a larger share of differentiated productive capability.

1.7.3 Knowledge as a Scarce Productive Resource

Knowledge entered modern economic analysis through several routes that gradually made its productive importance more explicit. Industrial production had long depended on skill, scientific knowledge, technical design, and accumulated experience. During the twentieth century, economic theory increasingly represented education, training, information, and innovation as objects of investment and coordination in their own right. This development expanded the concept of productive resources beyond physical assets while also revealing that knowledge obeys a different scarcity structure from many material goods.

Human-capital analysis provided one influential formulation. Becker treated education and on-the-job training as investments that affect earnings, employment, and productivity, thereby representing acquired knowledge and skill as economically consequential capacities rather than as external cultural attributes (Becker 1964). This framework made differences in training and education analytically comparable with other forms of investment, while leaving open broader questions about the institutions through which learning is provided and recognized.

Hayek approached knowledge from the problem of coordination. His argument centered on the dispersion of incomplete and frequently local knowledge across separate individuals, emphasizing that economically relevant information is rarely concentrated in one mind or institution (Hayek 1945). Knowledge scarcity in this sense concerns location and access as much as aggregate quantity. A system may contain the relevant knowledge while no participant possesses a complete representation of it.

Arrow's analysis of invention introduced another important distinction. Information generated through inventive activity has economic properties that complicate ordinary commodity treatment, including uncertainty about its production and difficulties surrounding appropriation once information becomes available (Arrow 1962). The result is a productive resource whose cost of creation, cost of transmission, and cost of repeated use can differ sharply. A technical insight may require substantial investment to produce while becoming inexpensive to reproduce after codification. Knowledge can therefore be scarce at one stage and abundant at another.

These observations support a more differentiated historical account of knowledge scarcity. Scarcity may arise in discovery, acquisition, verification, interpretation, certification, access, or the ability to apply knowledge effectively. Codified information can circulate widely while the capacity to understand or operationalize it remains concentrated. Scientific knowledge can be publicly available while access to laboratories, data, compute, professional networks, or institutional authority remains restricted. The economically relevant unit is consequently broader than a stock of information.

Knowledge also has cumulative properties. Earlier discoveries provide inputs to later discoveries; education increases the ability to acquire further knowledge; or-

ganizations develop routines that preserve experience; scientific communities build infrastructures through which findings can be criticized and extended. These cumulative relations can generate increasing advantages for subjects already positioned within rich knowledge environments. The historical scarcity of knowledge therefore concerns both the content known and the relations through which further knowing becomes possible.

This distinction prepares an important transition in Chapter 1. Industrial modernity treated many forms of expertise as scarce because advanced knowledge required long training, specialized institutions, and limited access to technical infrastructures. Contemporary artificial intelligence alters parts of this scarcity structure by reducing the cost of producing certain symbolic and cognitive outputs. Section 1.11 develops that transformation. The present section first establishes the earlier architecture in which knowledge scarcity supported differentiated expertise and economic hierarchy.

1.7.4 Expertise and Epistemic Hierarchy

Expertise is knowledge placed within an institutional relation of recognized competence. An individual may know something without occupying an expert position, while an expert position usually depends on certification, organizational role, professional reputation, demonstrated performance, or another mechanism through which others are authorized to rely on that knowledge. Epistemic hierarchy arises when these recognition structures distribute unequal authority to interpret information, define problems, evaluate evidence, or make decisions whose consequences extend to other participants.

The economic significance of expertise follows from its connection to scarce productive and coordinative tasks. When training is costly and specialist knowledge is unevenly distributed, expertise can affect wages, occupational access, organizational authority, and bargaining position. Human-capital analysis captures part of this structure by linking education and training to productivity and earnings (Becker 1964). The wider institutional structure includes professional licensing, educational credentials, technical standards, internal promotion systems, and reputational mechanisms that determine which capabilities receive economic recognition.

Expertise also creates organizational dependence. Complex production requires decisions about design, maintenance, finance, medicine, law, logistics, software, research, and many other specialized domains. Organizations therefore allocate decision rights partly according to recognized competence. The resulting hierarchy can be productive because it concentrates responsibility where relevant knowledge is expected to be available. At the same time, dependence on specialized judgment creates asymmetry between those who possess or are recognized as possessing relevant knowledge and those who must act on their conclusions.

Hayek's account of dispersed knowledge places an important limit on epistemic hierarchy. Local participants often possess situational knowledge unavailable to centralized experts, and coordination problems arise when institutions fail to transmit or respond to such distributed information (Hayek 1945). The tension is structural. Specialized expertise may be indispensable for tasks requiring deep technical knowl-

edge, while economic systems also depend on dispersed, contextual, and practical knowledge that cannot be fully centralized.

The hierarchy of expertise is consequently shaped by both knowledge and recognition. Credentials can signal capability, yet they also determine access to occupations and decision arenas. Organizational roles can place experts close to resources and strategic information, which in turn expands their opportunities for further learning. Research institutions can accumulate instruments, data, and networks that make future knowledge production easier. Epistemic advantage can therefore become institutionally self-reinforcing even when the underlying knowledge remains contestable or distributed.

This structure matters for GRE because economic power can arise through control over interpretation as well as control over material resources. Subjects able to classify risk, certify quality, authorize technical claims, design information systems, or define admissible evidence can shape which actions appear feasible to others. Later chapters examine epistemic power more directly. The historical point here is that modern economies increasingly organized productive differentiation around recognized knowledge, thereby adding an epistemic dimension to the older relations of capital and labor.

1.7.5 Conversion among Capability, Resources, and Power

Capital, labor, and knowledge become most consequential when their economic effects are examined through conversion. Productive capability can generate income; income can purchase education, tools, mobility, or access; knowledge can attract finance; ownership can purchase expertise; organizational position can provide information; and institutional recognition can convert a capability into an authorized claim on resources. Economic advantage therefore develops through pathways that translate one form of capacity or resource into another.

The conversion from capability to resources is institutionally mediated. Becker's human-capital framework links acquired education and training to earnings and productivity, yet the strength of that link depends on labor markets, credentials, organizational demand, discrimination, bargaining arrangements, and other institutions (Becker 1964). A capability that lacks recognition, market demand, legal permission, or access to complementary resources may generate little income. Productive capacity and resource command therefore remain analytically distinct.

The reverse conversion is equally important. Income and wealth can finance training, relocation, health, experimentation, equipment, and time for learning. Capital can purchase access to expertise and technical infrastructure. Organizational resources can support research whose results create further capability. Resource inequality can consequently become capability inequality through cumulative investment, while capability inequality can become resource inequality through differentiated returns. These conversions create feedback across time.

Sen's entitlement analysis provides a related insight from a different problem-space: aggregate availability of resources does not determine what particular persons can command, because access depends on the entitlement relations through which resources are obtained (Sen 1981). The same principle applies more broadly

to capability conversion. Possessing a useful skill does not by itself establish access to the assets, institutions, markets, or rights required to exercise it. Resources become effective through relations, and capabilities become economically consequential through conversion structures.

Power enters when these conversions affect the feasible actions of others or the rules governing access. Control over capital can determine who receives finance; recognized expertise can determine which claims are accepted; organizational authority can allocate productive opportunities; ownership can restrict access to infrastructure; labor scarcity can strengthen the capacity to bargain or withhold participation. Economic power therefore often emerges through control of conversion points rather than through possession of a single resource considered in isolation.

The conversion structure also helps explain persistence. An actor with capital may purchase knowledge, hire labor, and expand organizational capacity. An actor with recognized expertise may gain income and authority, then use those resources to acquire further credentials, networks, or productive assets. A worker in a position rich in learning opportunities may accumulate capabilities that widen future options. Conversely, subjects lacking access to key conversion interfaces may experience cumulative disadvantage even when they possess valuable capacities. Historical inequality can therefore reproduce itself through unequal conversion conditions.

This synthesis provides the bridge to the next stage of Chapter 1. Capital, labor, and knowledge are distinct sources of productive capacity, yet their economic effects depend on relations that connect subjects across organizations, infrastructures, institutions, and markets. As production becomes more interdependent, the relevant unit of analysis increasingly extends beyond the isolated owner, worker, or expert. Section 1.8 develops this expansion by examining relational production through division of labor, organizations, production networks, knowledge infrastructures, and transnational economic relations.

1.8 Expansion of Relational Production

The preceding sections reconstructed the modern economic subject and the institutional mechanisms through which capital, labor, and knowledge became recognizable sources of productive capability and economic power. This section changes the scale of analysis. Its role is to show how production increasingly depended on relational configurations that extended beyond any single worker, owner, firm, or administrative recipient. The objective is to identify the historical forms through which productive activity became distributed across interdependent tasks, organizations, supply relations, knowledge infrastructures, and multiple territorial scales. The discussion proceeds from division of labor to organizations, production networks, scientific and knowledge infrastructures, and transnational relations. The method is historical and relational: each form of production is examined through the dependencies, coordination mechanisms, and infrastructures that make distributed activity productive as a configuration.

1.8.1 Division of Labor and Interdependence

The division of labor offers one of the clearest historical routes from entity-centered description toward relational production. Smith treated specialization as a source of increased productive power because repeated tasks permit greater dexterity, reduce time lost in switching activities, and encourage the development of specialized machinery (Smith 1776). The resulting productivity, however, belongs to a configuration of differentiated activities rather than to any isolated worker. Specialization increases output by making each participant more dependent on the complementary work of others.

This dependence changes the economic meaning of productive capability. A highly specialized worker may possess a narrow and valuable skill while being unable to produce a finished good independently. A specialized machine may be extremely productive within one production sequence while having little use outside it. A firm may excel at one stage of production while relying on logistics, suppliers, finance, standards, infrastructure, and downstream distribution. Productive capability therefore becomes increasingly positional: its value depends on how a capacity is connected to other capacities within an organized sequence.

The relation between specialization and interdependence is historically important because it expands the coordination problem at the same time that it expands productive capacity. Tasks must be sequenced, inputs must arrive at appropriate times, specifications must be compatible, and failures in one component can propagate to others. Market prices can coordinate some of these relations, while organizations, contracts, standards, routines, and long-term exchange relationships coordinate others. Hayek's account of dispersed knowledge captures one dimension of this problem by emphasizing that economically relevant knowledge is distributed across participants and cannot be fully concentrated in a single mind or office (Hayek 1945).

Interdependence also makes attribution more difficult. An observed output can often be assigned legally or administratively to a firm, yet the productive conditions of that output may include workers trained elsewhere, infrastructure financed publicly, suppliers operating under long-standing technical standards, scientific knowledge produced in universities, and demand coordinated through institutions beyond the firm. The administrative unit remains useful for accounting and responsibility, while the productive process exceeds it.

Granovetter's analysis of embeddedness sharpened this point by arguing that economic action is situated within ongoing structures of social relations rather than adequately represented by atomized actors alone (Granovetter 1985). For the historical argument developed here, the significance lies in the unit of explanation. Productive outcomes increasingly depend on the pattern of relations among specialized actors, and the stability, trust, information, and expectations carried by those relations can affect what the participants are able to accomplish.

Relational production therefore begins with a simple historical observation: specialization makes productive capacity increasingly distributed. The more extensive the division of labor, the less adequate it becomes to identify production solely with the attributes of a nominal producer. The relevant productive object begins to include the configuration through which differentiated capacities are connected.

1.8.2 Organizations as Relational Structures

Organizations provide one institutional response to the coordination demands generated by specialization. Section 1.5 examined the legal and accounting mechanisms that stabilize organizations as recognizable entities. The present subsection examines their internal productive structure. An organization can act as an economic unit because relations among roles, authority, information, assets, routines, and responsibilities are sufficiently stabilized to sustain coordinated action over time.

Coase's analysis of the firm framed the organizational question through the costs of using the price mechanism and the circumstances under which coordination is brought inside the firm (Coase 1937). That formulation remains important because it makes organizational boundaries economically consequential. Yet the boundary does not eliminate relational complexity. It reorganizes it. Activities that might otherwise be coordinated through repeated market transactions become connected through employment, managerial authority, internal procedures, budgeting, technical standards, and shared infrastructure.

The internal productive capability of a firm is consequently distributed across relations among positions. A design team depends on manufacturing knowledge; manufacturing depends on procurement and maintenance; sales depends on production and logistics; finance depends on information generated throughout the organization. The formal organization chart captures part of this architecture, while informal relations, professional communities, accumulated routines, trust, and tacit knowledge often carry coordination that the formal chart does not specify.

Network forms of organization make the relational character of production even more visible. Powell describes network forms as organized through reciprocal patterns of communication and exchange that differ from both discrete market transactions and hierarchical command (Powell 1990). Such arrangements can support collaboration where participants remain organizationally distinct yet require continuing coordination, mutual adjustment, and information exchange. Productive organization therefore admits more than a binary choice between market and hierarchy.

This plurality matters for economic analysis because the same nominal set of assets and workers can perform differently under different relational arrangements. A tightly centralized organization, a federated organization, a long-term alliance, and a project network distribute authority, information, learning, and risk differently. Productive capability is consequently partly a property of organizational architecture. Reorganization can alter output without changing the physical assets or formal skills initially available, because the relations through which those resources are combined have changed.

Organizations also accumulate relational memory. Routines preserve solutions to recurrent problems; reputations shape expectations; shared standards reduce coordination costs; informal communication channels accelerate problem solving; and prior collaboration changes the ease with which new collaboration can occur. These features make organizational history productive. Present capability depends partly on relations generated through earlier activity.

The firm remains a legitimate unit of economic analysis, especially where legal responsibility, financial reporting, and contractual control are concerned. Relational

analysis adds a second description: the firm is also a stabilized configuration of internal and external relations whose productive capacity depends on how those relations are maintained and transformed. This dual description becomes increasingly necessary once production extends across organizational boundaries.

1.8.3 Production Networks and Supply Chains

Production networks extend relational production beyond the boundaries of a single organization. Modern goods and services are frequently produced through sequences in which design, components, assembly, logistics, finance, certification, distribution, and after-sales support are distributed among legally distinct organizations. The resulting system cannot be understood only by adding the attributes of participating firms, because the pattern of dependence among them affects coordination, bargaining, learning, vulnerability, and the distribution of returns.

Supply relations differ in depth. Some transactions are relatively standardized and can be shifted among suppliers with limited reorganization. Others require dedicated equipment, jointly developed specifications, long-term learning, quality assurance, shared information systems, or repeated adaptation. The economic relation between buyer and supplier therefore ranges from relatively impersonal exchange to durable interdependence. These differences affect how productive knowledge moves and how risks are distributed across the network.

The global value-chain literature provides a developed account of such variation. Gereffi, Humphrey, and Sturgeon identify governance patterns ranging from market relations to modular, relational, captive, and hierarchical forms, with differences shaped by transaction complexity, codifiability, and supplier capabilities (Gereffi et al. 2005). Their typology is valuable here because it shows that formally separate firms can stand in relations with very different degrees of coordination and power asymmetry. A contractual boundary therefore provides limited information about the substantive structure of production.

Network position can also affect access to opportunity. A firm connected to technically demanding customers may receive information, standards, and incentives that support learning, while a supplier confined to narrowly specified tasks may have fewer opportunities to develop independent capabilities. The productive consequences of a relation can therefore extend beyond the immediate exchange. Repeated transactions may generate new competencies, lock in specialized investments, deepen dependence, or alter the set of future partners available to each participant.

This perspective clarifies why disruptions propagate. A production network can appear decentralized because ownership is distributed among many firms, while remaining operationally concentrated around a small number of critical nodes, standards, logistics routes, or technological interfaces. Failure at one point can interrupt production elsewhere even when downstream firms remain financially solvent and legally intact. The vulnerability belongs to the relational configuration through which production is organized.

Relational production also complicates the attribution of value creation. Final prices and accounting systems assign revenues to identifiable organizations, but

productive contribution may be dispersed across suppliers, infrastructure providers, workers, knowledge institutions, and complementary technologies. The question of how value generated through a network is recognized, converted, and distributed will become central in later GRE chapters. At this historical stage, the important development is the expansion of production beyond the boundaries used to identify economic recipients and owners.

Supply chains therefore provide a concrete transition from entity-centered production to relational architecture. Firms remain real and consequential economic subjects, yet their productive capacities are conditioned by positions within networks of dependence, learning, standards, and exchange. The unit of production increasingly spans relations among organizations.

1.8.4 Scientific and Knowledge Infrastructures

Knowledge-intensive production makes the relational basis of productive capacity especially visible because usable knowledge depends on infrastructures that no single organization normally creates by itself. Universities, laboratories, professional associations, journals, standards bodies, databases, patent institutions, training systems, public research agencies, and technical communities contribute to the production, verification, transmission, and preservation of knowledge. Firms and workers draw on these infrastructures even when the resulting commercial output is attributed to a particular organization.

Arrow's analysis of invention emphasized uncertainty and the distinctive appropriation problems surrounding information production (Arrow 1962). These features help explain why knowledge production has repeatedly relied on institutional forms that differ from ordinary commodity exchange. Public funding, professional norms, publication systems, intellectual-property regimes, collaborative research, and organizational secrecy create different arrangements for balancing dissemination, appropriation, and continued investment.

The productive importance of knowledge infrastructures extends beyond the stock of published information. Scientific and technical work depends on instruments, methods, repositories, standards, peer communities, credibility systems, and trained personnel able to interpret results. A published finding may be widely accessible while the capability to reproduce, evaluate, or apply it remains concentrated in institutions possessing complementary infrastructure. Knowledge abundance at the level of symbols can therefore coexist with scarcity at the level of effective participation.

Interorganizational collaboration provides one mechanism through which such capabilities are distributed. Powell, Koput, and Smith-Doerr's study of biotechnology located important innovation processes within networks of learning that crossed organizational boundaries (Powell et al. 1996). The broader lesson is not specific to biotechnology. Where relevant knowledge is dispersed and rapidly developing, productive capability can depend on access to relations through which organizations learn from one another, recruit expertise, interpret developments, and combine complementary resources.

Knowledge infrastructures are also cumulative. Training institutions reproduce specialist communities; standards allow artifacts produced in different places to in-

teroperate; archives and databases preserve earlier results; professional criticism filters claims; and shared technical vocabularies reduce the cost of future coordination. These infrastructures are products of earlier relations and conditions for later production. Their economic contribution is therefore temporally extended and difficult to assign to a single transaction.

This structure matters for the historical emergence of GRE because it weakens the correspondence between ownership of an output and generation of the conditions that made the output possible. A firm may own a patent or sell a product while depending on publicly financed science, professional standards, prior open knowledge, supplier learning, and collective technical infrastructures. The administrative attribution of revenue can remain precise even when the generative history of capability is distributed.

Knowledge-intensive production thus expands the economic object from information possessed by an actor to an infrastructure of relations through which knowing becomes possible, credible, applicable, and renewable. Later chapters will examine the implications for knowledge capital, epistemic economy, and generative return. The present section establishes the historical condition: productive knowledge increasingly operates through relational infrastructures whose boundaries exceed the firms that commercialize their outputs.

1.8.5 Transnational and Multiscalar Economic Relations

The expansion of relational production eventually exceeds both organizational and territorial boundaries. Production can be coordinated through relations among workers, firms, financial institutions, public authorities, standards bodies, logistics systems, and knowledge institutions located in different jurisdictions. The resulting architecture is multiscalar: local workplaces operate within organizations; organizations operate within production networks; networks depend on national institutions and transnational infrastructures; and changes at one scale can alter feasible actions at another.

This multiscalar structure changes the meaning of economic location. A plant is physically situated in one place while depending on financing, intellectual property, technical standards, intermediate inputs, software, demand, and managerial decisions distributed across other places. A worker's employment conditions can be affected by procurement decisions made elsewhere. A supplier's upgrading opportunities can depend on standards imposed by lead firms or regulatory regimes outside its jurisdiction. Territorial location therefore remains important while becoming only one coordinate of economic position.

Global value-chain analysis again illustrates the point. Governance patterns within transnational production can distribute coordination and power asymmetrically even where production is legally fragmented across independent firms (Gereffi et al. 2005). The economic significance of a firm consequently depends partly on its relation to lead firms, standards, technologies, logistics channels, and markets that operate at larger scales.

Multiscalar production also connects different institutional tempos. Employment law, industrial capacity, infrastructure, financial conditions, and technical standards

change at different rates. A rapid shift in procurement or finance can therefore encounter much slower changes in worker skills, transport systems, regulatory institutions, or regional productive structures. The historical consequences of production cannot always be understood on the timescale of the transaction that initiated them. This observation prepares the later GRE treatment of generative spacetime and fast–slow economic dynamics.

The expansion across scales also changes the distribution of responsibility. Economic benefits and harms may be generated through chains of relations in which no single participant controls the whole configuration. Lead firms may influence specifications without directly employing workers who implement them; investors may alter financing conditions without managing production; states may regulate entities within their jurisdiction while key dependencies lie elsewhere. Legal and administrative responsibility remains essential, yet causal and generative responsibility can extend across a wider relational field.

Section 1.9 develops globalization as a distinct historical transformation of these relations, including transnational production, capital flows, distributed labor, institutional interdependence, and economic relations beyond territorial boundaries. The present section establishes the prior analytical shift. Once productive activity is distributed across interdependent tasks, organizations, networks, knowledge infrastructures, and scales, the economy becomes increasingly difficult to represent as a collection of independently productive entities connected only by exchange. Relational production becomes part of the historical architecture of economic life.

1.9 Globalization and the Extension of Economic Relations

The preceding section showed how productive activity expanded from specialized tasks and organizations into interorganizational networks and knowledge infrastructures. This section extends the historical scale once more. Its role is to reconstruct globalization as an enlargement and densification of economic relations across territorial, organizational, and jurisdictional boundaries. The objective is to identify how production, capital, labor, institutions, and claims upon value became increasingly transnational while remaining embedded in unequal capacities, legal regimes, and historically specific forms of coordination. The discussion proceeds through transnational production, global capital flows, distributed labor and unequal exchange, global institutional interdependence, and economic relations whose operative structure exceeds a single territorial container. The method is historical and relational: globalization is treated as a reorganization of connections among economic actors and institutions rather than as a simple increase in the volume of international transactions.

1.9.1 Transnational Production

Transnational production extends the relational structure of production across territorial jurisdictions. A finished good, service, or technological system may combine design in one location, components from several others, assembly elsewhere, financing through another jurisdiction, and distribution through globally coordinated logis-

tics. The productive object presented to a final buyer can therefore be the terminal manifestation of a geographically dispersed system of relations among firms, workers, infrastructures, standards, and institutions.

Global value-chain analysis made this architecture analytically visible by distinguishing different governance forms through which lead firms and suppliers coordinate complex transactions. Gereffi, Humphrey, and Sturgeon show that transaction complexity, the codifiability of information, and supplier capabilities help shape governance arrangements ranging from relatively market-like relations to more captive and hierarchical forms (Gereffi et al. 2005). Their framework is useful here because it shows that geographic dispersion does not imply organizational dispersion in the same degree. Production can be territorially distributed while coordination, specification, intellectual property, market access, or strategic decision-making remains highly concentrated.

This distinction changes the meaning of location. A factory is located in a territory, yet its productive role may be defined by relationships extending far beyond that territory. Its output may depend on imported components, standards specified by a distant lead firm, credit provided through international financial networks, software maintained elsewhere, and demand originating in multiple markets. The economic significance of the local unit therefore cannot be inferred from territorial location alone. Position within a transnational production structure affects bargaining power, learning opportunities, vulnerability to substitution, and the share of downstream value that can be retained.

Transnational production also separates several forms of economic control that industrial organization had often joined within the same firm or national economy. Ownership may be located in one jurisdiction, production in another, technical authority in a third organizational center, and consumption across many territories. Contractual relations can coordinate these distributed elements without bringing them under a single legal person. The resulting architecture combines entity-level responsibility with relational dependence across entities.

The historical importance of this arrangement lies in the enlargement of the relevant economic system. A national economy remains a meaningful institutional and statistical object, yet many productive processes acquire conditions of reproduction that extend beyond national boundaries. Input availability, logistics, exchange rates, standards, foreign demand, and decisions by transnational firms can alter domestic production without originating within the domestic institutional field. Globalization therefore expands the set of relations that must be considered when explaining how a nominally local economic capability is generated and sustained.

This expansion does not erase territory. Infrastructure, labor law, taxation, education, energy systems, political authority, and physical logistics continue to be territorially organized to substantial degrees. Transnational production instead layers cross-border coordination upon territorial institutions. The result is a multiscalar productive architecture in which local, national, regional, and global relations jointly condition what any single economic actor can do.

1.9.2 Global Capital Flows

Global capital flows extend economic relations through claims on assets, liabilities, income streams, and future payments. Cross-border finance allows savings generated in one jurisdiction to support investment in another, firms to raise funds from foreign investors, states to issue debt internationally, and households or institutions to hold claims on assets located elsewhere. The relevant relation is therefore partly financial and partly temporal: present resources are connected to expectations about future returns across institutional and territorial boundaries.

The expansion of gross external positions illustrates how strongly these relations can exceed the scale suggested by net flows alone. Lane and Milesi-Ferretti constructed estimates of foreign assets and liabilities for a large set of countries and documented the growing scale and changing composition of international financial positions during the late twentieth century (Lane and Milesi-Ferretti 2006). For relational analysis, the importance of such data lies less in a single aggregate measure than in the multiplication of cross-border creditor, debtor, equity, reserve, and direct-investment relations that bind economic actors to developments outside their immediate jurisdiction.

Financial integration can redistribute both opportunity and exposure. Access to external capital may relax domestic financing constraints, support investment, and diversify risk. The same relational extension can transmit shocks through balance sheets, refinancing conditions, exchange-rate movements, and changing investor expectations. A financial relation that appears as an asset to one actor is simultaneously a liability or obligation within another balance sheet. Changes in one part of the system can therefore alter the conditions faced by actors connected through portfolios, credit lines, collateral structures, or payment systems.

Capital mobility also changes the relation between economic activity and institutional jurisdiction. Productive facilities remain materially situated, while claims on their earnings can circulate through financial centers and legal vehicles far from the site of production. Ownership, control, risk bearing, and income receipt can thus become geographically separated. These separations complicate any analysis that equates the location of productive activity with the location of economic benefit or decision power.

The same architecture creates asymmetry among participants. Actors with access to deep financial markets, reserve currencies, diversified portfolios, sophisticated intermediaries, or favorable legal jurisdictions can often manage cross-border exposure differently from actors dependent on a narrow set of external creditors or volatile financing channels. Global capital flows consequently create a relational field in which mobility itself becomes unequally distributed capability. The ability to enter, exit, hedge, refinance, or relocate a claim may matter as much as the nominal size of the resource being moved.

For GRE, the historical lesson is preparatory. Capital becomes increasingly intelligible as a set of mobile claims embedded in institutional relations, rather than only as a stock attached to a territorial owner. The later analysis of power, value circulation, and conversion will require this distinction because financial mobility can transform resources, obligations, and bargaining positions across scales without any

corresponding movement of the underlying productive activity.

1.9.3 Distributed Labor and Unequal Exchange

The globalization of production distributes labor across economies characterized by different wage structures, productivity levels, bargaining institutions, currencies, social protections, and positions within international production networks. This distribution generates a long-standing problem in political economy: similar productive interdependence can coexist with markedly unequal compensation, bargaining power, and capacity to appropriate the gains associated with international exchange.

The structuralist tradition formulated an early version of this problem through the center–periphery distinction. Prebisch's analysis of Latin American development emphasized asymmetries in productivity, industrial structure, and terms of trade between industrial centers and primary-exporting peripheral economies (Prebisch 1950). The analytical significance of this tradition lies in its insistence that participation in international exchange occurs from historically differentiated productive positions. Exchange connects economies whose capacities to innovate, set prices, absorb shocks, and alter the composition of production may differ substantially.

Theories of unequal exchange developed the argument in a more explicitly distributive direction. Emmanuel linked international exchange to persistent differences in wages and to the international organization of production, arguing that trade can reproduce transfers of value between differently positioned economies (Emmanuel 1972). This is a contested theoretical tradition, and the present chapter does not adopt its full value-theoretic apparatus. Its relevance to the historical argument is narrower: globalization made it increasingly necessary to ask how the distribution of labor across jurisdictions interacts with price formation, wage differentials, ownership, and the allocation of returns across the production process.

Global production networks sharpen the question because the physical contribution of labor and the capacity to command downstream returns can be institutionally separated. Workers and suppliers may perform indispensable stages of production while lead firms control design, standards, branding, finance, intellectual property, market access, or final distribution. The governance patterns identified in global value-chain research provide one way to describe these asymmetries without presupposing a single theory of value (Gereffi et al. 2005). Different positions in the chain carry different opportunities for learning, upgrading, substitution, and bargaining.

The term *unequal exchange* therefore names more than one possible mechanism and should be used carefully. Terms-of-trade dynamics, wage differentials, ownership structures, market concentration, technological dependence, currency hierarchy, and contractual governance can each contribute to unequal distributions of gains. Their relative importance is an empirical and theoretical question. A relational framework gains little by compressing them prematurely into one explanation.

The more durable insight is that labor mobility, capital mobility, and value appropriation need not move together. Capital and contractual authority can cross borders with relative ease in some settings, while workers remain subject to migration law, local labor institutions, family obligations, language, and other forms of territorial

embeddedness. The resulting asymmetry can alter bargaining positions across the global production system. Globalization therefore expands productive interdependence while also creating new sites at which differences in mobility, institutional protection, and control shape distribution.

This historical problem prepares a later GRE question concerning heterogeneous value and conversion. Labor performed in different institutional settings becomes comparable through prices, contracts, accounting systems, and exchange rates, yet those mechanisms of commensuration may also conceal relations that produced the observed distribution. Section 1.9 remains at the historical level; later chapters will return to the normative and power-theoretic consequences of such conversion structures.

1.9.4 Global Institutional Interdependence

Globalization depends on institutions that make cross-border relations sufficiently stable to support repeated economic activity. Trade agreements, customs rules, financial regulation, payment systems, accounting standards, investment regimes, central-bank arrangements, dispute procedures, technical standards, and private certification systems all contribute to the conditions under which transnational exchange can occur. Economic integration is therefore institutionally produced as well as commercially enacted.

Institutional interdependence creates a layered structure of authority. A firm operating transnationally may face domestic corporate law, foreign labor and environmental regulation, international trade rules, sectoral standards, contractual obligations, financial-market requirements, and private platform or certification rules at the same time. These rule systems differ in source and enforceability, yet jointly shape the feasible actions of the firm. The economic relation is consequently embedded in overlapping jurisdictions rather than contained by one institutional order.

This layering also reveals a persistent tension between economic reach and political jurisdiction. Rodrik emphasizes that deep international economic integration encounters constraints created by national jurisdiction and political organization (Rodrik 2000). The point is especially useful for relational analysis because the relevant boundaries do not coincide: production networks, capital claims, information flows, and market relations may extend globally while taxation, social protection, electoral accountability, and many regulatory capacities remain organized primarily through territorial states.

Institutional interdependence therefore changes the consequences of domestic decisions. A regulatory change in one major market can alter production standards elsewhere; a monetary or financial decision can affect external borrowers; a change in customs treatment can reorganize sourcing relations; a shift in certification requirements can redistribute access to markets. The causal chain often crosses several jurisdictions and organizations before reaching the affected actor.

The resulting structure can also redistribute institutional power. Actors capable of setting standards, providing settlement infrastructure, controlling market access, or defining widely adopted contractual forms can shape behavior beyond their formal territorial authority. Smaller jurisdictions and firms may retain legal autonomy while

adapting to rules generated elsewhere because access to a larger network depends on compliance. Such influence operates through relational position and dependence rather than through direct command alone.

Global institutional interdependence thus extends the economic field beyond trade volumes. It includes the rule-producing and rule-transmitting relations that allow transnational production and finance to remain coordinated. These institutional layers will become important later when GRE distinguishes resource ownership from access, capability from effective control, and formal sovereignty from relational dependence.

1.9.5 Economic Relations beyond Territorial Boundaries

The combined development of transnational production, global finance, distributed labor, and institutional interdependence produces economic relations whose operative boundaries differ from territorial boundaries. A production network may span several states; a financial position may connect balance sheets located on different continents; a technical standard may organize firms across many jurisdictions; and an ownership structure may separate the place of production from the place in which claims on its income are legally held.

Territory remains economically consequential because infrastructure, coercive authority, taxation, public services, labor regulation, and political membership are still extensively territorialized. Globalization adds relational structures that cut across these territorial containers. The same actor can therefore occupy several economic spaces simultaneously: a local labor market, a national legal order, a transnational supply chain, an international financial network, and a global market for knowledge or standards.

This multiplicity creates analytical problems for any unit of analysis treated as self-contained. National accounts can describe production and income according to carefully defined territorial and residence conventions, firms can report consolidated entities, and trade statistics can record cross-border transactions. These representations remain indispensable. Their boundaries, however, answer specific administrative and analytical purposes. They do not exhaust the relations through which productive capability, vulnerability, knowledge, risk, and bargaining power are generated.

A relational description therefore supplements territorial accounting with attention to connection, position, dependence, and cross-scale transmission. The relevant questions concern which actors are connected, which infrastructures mediate those connections, which institutions govern them, how easily relations can be substituted, and how effects propagate when one node or jurisdiction changes. Such questions become increasingly important as the same production process is divided among actors whose legal, financial, and political environments differ.

Globalization also changes the meaning of economic distance. Geographic separation can coexist with tightly synchronized production, while neighboring actors can remain weakly connected economically. Contractual standards, transport infrastructure, communication systems, legal compatibility, financial access, and organizational integration can reduce some forms of distance while preserving or enlarging

others. Economic proximity becomes partly relational rather than purely spatial.

The historical transition examined in this section therefore prepares the move to digital modernity. Once economic coordination already extends beyond territorial and organizational boundaries, digital infrastructures can intensify mediation, observation, matching, and algorithmic coordination across those relations. Section 1.10 develops that next stage. The globalization considered here establishes the preceding transformation: economic activity becomes increasingly organized through multiscalar relations whose effective boundaries exceed the entities and territories through which they are administratively represented.

1.10 Digital Modernity and Relational Intermediation

This section locates digital modernity within the historical expansion of relational production developed in Sections 1.8 and 1.9. Its role is to identify how digital infrastructures alter the conditions under which economic relations are formed, observed, coordinated, and concentrated. The objective is to show that digitalization changes more than the speed or scale of existing transactions: it creates new infrastructures of information, inserts platforms between previously more direct relations, increases the frequency and granularity of observation, delegates parts of coordination to algorithmic systems, and changes the returns associated with network position. The discussion proceeds through information as productive infrastructure, platforms as mediators, data-intensive observation, algorithmic coordination, and the concentration dynamics associated with network effects. The method is historical and relational. Digital technologies are treated as institutional and technical arrangements that reorganize connections among economic actors rather than as a separate economy detached from earlier productive structures.

1.10.1 Information as Productive Infrastructure

Digitalization changes the economic role of information by making its storage, processing, replication, transmission, and recombination available at scales and speeds that earlier organizational forms could not sustain. Information has always mattered to production, exchange, administration, and coordination. Digital infrastructures deepen that dependence by embedding information-processing capacities directly into productive systems, logistics, finance, communication, and organizational decision-making.

Goldfarb and Tucker characterize digital economics through reductions in several costs associated with digital activity, including search, replication, transportation of information, tracking, and verification (Goldfarb and Tucker 2019). This formulation is useful for the present historical argument because each cost reduction modifies a relation. Lower search costs alter how buyers, sellers, workers, firms, and information sources find one another. Lower replication and transmission costs change the circulation of symbolic and informational goods. Lower tracking costs expand the observability of interactions. Lower verification costs can reorganize the institutional arrangements through which claims are authenticated.

Information therefore becomes infrastructural in a stronger sense than simply being an input possessed by an organization. Digital production depends on shared protocols, databases, cloud services, communication networks, identifiers, software standards, application interfaces, payment rails, and security systems. These infrastructures establish conditions under which geographically distributed actors can coordinate actions that remain intelligible to one another. A transaction recorded in one system can trigger inventory updates, logistics instructions, payment processes, compliance checks, and subsequent recommendations across several organizational boundaries.

The productive significance of such infrastructure often appears indirectly. A database or protocol may generate little value as an isolated object while enabling a large number of downstream relations. Its economic importance can therefore reside in the range of interactions it makes possible, the compatibility it establishes, and the future actions it renders easier or harder. This is an early instance of a distinction developed later in GRE between possession of a resource and the generative conditions supported by that resource.

Digital infrastructure also changes the temporal structure of coordination. Information that previously arrived through periodic reports can be transmitted at much shorter intervals. Inventory, demand, prices, locations, payments, and user interactions may be updated in near real time. Decisions can consequently respond to changing conditions before slower administrative routines would have registered them. The historical consequence is a tighter coupling between observation and action, a theme that becomes central in the later discussion of data and algorithmic coordination.

The expansion of information infrastructure does not remove the material basis of economic activity. Data centers require energy and equipment; communication networks require physical infrastructure; software systems depend on organizations and trained labor; digital records rely on institutional conventions that make identifiers, permissions, and categories operational. Digital modernity therefore adds a dense informational layer to material production while also making many productive relations increasingly dependent on that layer.

1.10.2 Platforms and Mediated Relations

Platforms reorganize economic relations by becoming durable intermediaries between groups whose interactions were previously arranged through more fragmented markets, organizations, or bilateral channels. Search platforms connect users and information providers; marketplaces connect buyers and sellers; payment systems connect merchants, consumers, and financial institutions; labor platforms connect clients and workers; application ecosystems connect developers, device owners, advertisers, and infrastructure providers. The platform's economic object is therefore frequently a configuration of relations among several participant groups.

The economics of two-sided markets provides an established account of this structure. Rochet and Tirole analyze platforms whose viability depends on bringing multiple sides of a market into participation and on choosing a price structure that reflects interactions across those sides (Rochet and Tirole 2003). Their formulation shows

that the platform cannot be understood adequately by examining a single bilateral transaction in isolation. Participation on one side changes the attractiveness and economic possibilities available on another.

Relational mediation gives the platform several forms of influence. It can determine conditions of entry, specify contractual terms, rank or recommend participants, standardize interfaces, collect fees, define permitted forms of interaction, and alter which information is visible to whom. These functions need not be exercised uniformly, and their institutional significance varies across platform types. The common feature is positional: the platform occupies an interface through which other actors reach one another.

This interface position can reorganize the distinction between internal and external economic relations. A seller may remain legally independent while depending on a platform for discovery, payment, reputation, and access to demand. A worker may formally contract as an independent provider while task allocation, evaluation, and visibility are mediated by platform rules. A developer may own an application while access to users depends on an operating system, store, or technical interface controlled elsewhere. Legal independence can therefore coexist with substantial relational dependence.

Platforms also transform market boundaries. The relevant market may become partially constituted by technical standards, ranking systems, identity protocols, and participation rules maintained by the intermediary. Changing an interface or recommendation policy can alter demand allocation without changing the underlying legal status of participants. Economic coordination increasingly occurs through modifications to the architecture of mediation itself.

For GRE, the historically significant development is the emergence of intermediaries whose productive role consists partly in organizing relations among others. This does not make the platform external to the economy it mediates. The platform becomes one participant within the relational configuration, while its position gives it unusual capacity to alter the conditions under which other relations form and persist.

1.10.3 Data and Continuous Observation

Digital mediation produces data as a recurrent by-product of economic interaction. Searches, purchases, clicks, payments, movements, communications, ratings, inventories, delivery events, and work activities can generate machine-readable traces as they occur. Economic observation consequently shifts from periodic description toward increasingly granular and high-frequency recording in domains where digital infrastructures are present.

Einav and Levin describe the growing use of large-scale administrative and private-sector data in economics and emphasize that such data can provide granular and increasingly timely views of economic activity (Einav and Levin 2014). Their discussion concerns economic research, yet the same historical transformation extends beyond research. Firms, platforms, governments, and other organizations can use transaction-level or interaction-level data as operational inputs to pricing, logistics, risk assessment, advertising, fraud detection, performance evaluation, and service

design.

The reduction of tracking costs identified by Goldfarb and Tucker is especially consequential here (Goldfarb and Tucker 2019). Observation becomes woven into the transaction itself. A purchase records demand; a delivery records location and timing; a recommendation records exposure and response; a digital workflow can record sequence, duration, completion, and evaluation. The distinction between conducting an activity and producing a record of that activity narrows in systems designed around continuous data capture.

This increased observability changes economic power because visibility is distributed unevenly. A platform may observe interactions among many participants while each participant sees only a narrow local portion of the system. A firm operating a digital marketplace can possess information about aggregate demand, search behavior, conversion rates, and seller performance that individual sellers cannot reconstruct independently. Data concentration can therefore produce epistemic asymmetry even where the underlying transactions involve formally independent parties.

Data also depend on categories. A recorded event becomes usable only after a system defines what counts as a user, transaction, impression, conversion, task, defect, risk, or successful outcome. Continuous observation therefore increases the importance of classification rather than eliminating it. What can be optimized depends on what has been rendered observable, and what is observable depends on technical and institutional decisions embedded in the data infrastructure.

The resulting expansion of evidence has an ambivalent historical character. Granular observation can reveal heterogeneity, improve coordination, detect failures, and make previously opaque processes available for analysis. The same infrastructure can intensify surveillance, concentrate informational advantage, and encourage action toward what is easiest to record. Later chapters examine these epistemic and normative consequences directly. At this stage, the central transformation is that economic relations increasingly generate traces that can feed back into the organization of those relations at short temporal intervals.

1.10.4 Algorithmic Coordination

The accumulation of machine-readable data creates conditions for algorithmic coordination. Rules encoded in software can match participants, rank alternatives, set prices, route deliveries, detect anomalies, recommend actions, schedule labor, allocate attention, and update decisions in response to incoming information. Economic coordination thereby acquires a computational layer operating between observation and action.

Algorithmic coordination differs from simple automation of a fixed task when the system continually mediates relations among multiple actors. A recommendation system affects which producers become visible to which users. A dispatch system allocates work across drivers and locations. A pricing system changes incentives and demand across a marketplace. A ranking system redistributes attention among competing participants. In each case, the algorithm operates upon a relational configuration and can alter that configuration through repeated decisions.

Organizational research has documented this development in the workplace. Kellogg, Valentine, and Christin synthesize research on algorithmic control and identify mechanisms through which employers can use algorithms to direct, evaluate, and discipline work (Kellogg et al. 2020). Their account is relevant beyond labor control because it demonstrates a broader institutional change: observation, classification, recommendation, evaluation, and sanction can be integrated into computational systems that operate repeatedly and at scale.

The economic significance of algorithmic coordination depends on both the rule and the information available to it. A technically sophisticated allocation rule produces little if the relevant state of the system is poorly observed. Conversely, extensive data can have limited operational effect until a decision process translates them into rankings, predictions, or actions. Digital infrastructures therefore join observation and coordination through feedback: records generated by interaction become inputs to later decisions, and later decisions generate new records.

Such feedback can make coordination highly adaptive while also producing path dependence. Ranking based on prior activity can direct attention toward already visible participants; recommendation based on accumulated behavior can reinforce established patterns; performance metrics can induce workers or firms to adapt toward measured criteria. The resulting economic order is partly generated through repeated interaction between participants and the computational procedures that mediate them.

Algorithmic coordination remains institutionally situated. Objectives, permissible actions, data access, error tolerances, review procedures, and accountability structures are supplied by organizations and legal systems. The algorithm is therefore neither an autonomous economic subject by default nor a neutral technical layer. It is part of an institutional relation through which some actors obtain the capacity to coordinate the actions of others at increased scale and frequency. The later treatment of artificial intelligence will examine what changes when computational systems acquire substantially greater productive and epistemic capabilities.

1.10.5 Network Effects and Digital Concentration

Digital intermediation can generate concentration through the interaction of network effects, accumulated participation, data, standards, and control of interfaces. The mechanism begins from a relational property: the usefulness of some systems depends partly on how many other participants, complementary products, or compatible services are connected to them.

Katz and Shapiro analyze systems markets in which compatibility and network effects make popular products more valuable and influence adoption dynamics, competition, and standardization (Katz and Shapiro 1994). Platform markets add cross-group effects: participation by one side can increase the value of the platform to another side, creating feedback across participant populations (Rochet and Tirole 2003). These mechanisms do not guarantee monopoly, yet they can make installed participation and interface control economically consequential assets.

Concentration can arise through several mutually reinforcing channels. A larger participant base may attract more complementary suppliers; greater activity may

generate more data; more data may improve matching or prediction; improved coordination may attract further participation; and wider adoption may increase incentives for complementary products to conform to the platform's standards. The result is a feedback structure in which relational position contributes to future capacity.

This process changes the meaning of capital and competitive advantage. Productive assets remain important, yet control of a widely used interface, identity system, communication network, data repository, technical standard, or application ecosystem can become a durable source of economic power. The value of such an asset may depend less on its isolated technical properties than on the relations already organized through it and the costs participants face when moving elsewhere.

Digital concentration also creates asymmetry between scale and jurisdiction. A platform can mediate relations across many territories while regulation, labor law, taxation, consumer protection, and public accountability remain divided among jurisdictions. The multiscalar tension developed in Section 1.9 therefore persists within digital modernity, now combined with technical mediation and high-frequency observation. Concentrated intermediaries can coordinate relations at a scale larger than many institutions responsible for governing their effects.

The historical importance of digital concentration lies in the coupling of relational centrality with productive and epistemic capability. A central intermediary can influence access, visibility, standards, data collection, and coordination simultaneously. Economic power consequently becomes increasingly difficult to infer from ownership of conventional productive assets alone. Position within a digital relational architecture can itself generate capabilities that reinforce that position.

Digital modernity thus intensifies several tendencies developed across this chapter: production becomes more relational, observation becomes more continuous, coordination becomes more mediated, and economic power becomes increasingly connected to control over interfaces and infrastructures. Section 1.11 turns to artificial intelligence, where these digital conditions support a further transformation in cognitive production, symbolic generation, knowledge production, and comparative productive capability.

1.11 Artificial Intelligence and Productive Transformation

This section identifies the transformation that artificial intelligence introduces into the productive conditions established by digital modernity. Its role is to distinguish the economic significance of contemporary AI from the preceding expansion of information infrastructure and algorithmic coordination. The objective is to show how artificial systems increasingly participate in tasks historically performed through human cognitive labor, generate symbolic outputs at very low marginal cost, enter organized processes of knowledge production, alter comparative productive capability across workers and organizations, and concentrate important forms of productive capacity in the infrastructures that make advanced models possible. The discussion proceeds from cognitive-task automation to symbolic generation, machine-mediated knowledge production, comparative capability, and concentration. The method is

historical and economic. Artificial intelligence is treated here through the productive relations it changes rather than through a claim about machine consciousness, intelligence in the philosophical sense, or the ontological status of artificial systems. Those questions remain open and are addressed only where their economic consequences require them.

1.11.1 Automation of Cognitive Production

Earlier waves of mechanization transferred portions of physical production from human labor to machines. Contemporary artificial intelligence extends automation into tasks whose outputs were historically associated with human cognitive labor: drafting, classification, prediction, translation, coding, summarization, pattern recognition, search, recommendation, and parts of analytical work. The economic novelty does not lie in the appearance of automation itself. It lies in the widening range of tasks for which computational systems can produce outputs that enter ordinary organizational workflows.

A task-based perspective provides a useful starting point. Acemoglu and Restrepo distinguish automation from productivity improvement in already assigned tasks by emphasizing changes in the allocation of tasks between labor and capital (Acemoglu and Restrepo 2019). In their framework, automation creates a displacement effect when capital substitutes for labor in tasks previously performed by workers, while the creation of new tasks can generate a reinstatement effect that expands domains in which labor retains comparative advantage. The framework is deliberately more precise than a binary contrast between "jobs lost" and "jobs created." Production is decomposed into tasks, and technological change alters who or what can perform them.

Generative AI extends this task reallocation into forms of work whose intermediate products are symbolic. A worker drafting a memorandum, preparing a customer response, writing code, summarizing a document, or producing a first-pass analysis can now combine human judgment with machine-generated candidate outputs. This arrangement does not imply complete substitution. It alters the sequence of production. Human effort can move away from some acts of initial generation toward specification, selection, correction, verification, integration, and responsibility for the final result.

Experimental evidence already demonstrates that this reorganization can be economically consequential in bounded tasks. Noy and Zhang randomly assigned college-educated professionals to complete occupation-specific writing tasks with or without access to ChatGPT and found substantial reductions in completion time together with improvements in evaluated output quality (Noy and Zhang 2023). Brynjolfsson, Li, and Raymond study the staggered introduction of a generative-AI assistant among customer-support workers and report an average productivity increase, with especially large gains among less experienced and lower-skilled workers (Brynjolfsson et al. 2025). The studies concern particular tasks and organizational settings, yet they establish a point needed for the historical argument: systems generating language can already change the productive performance of human workers rather than merely serving as experimental demonstrations outside production.

The resulting transformation is therefore relational. Productive capability no longer resides only in the worker or only in the model. It can arise from a configuration involving the worker, the model, the interface through which prompts and outputs are exchanged, the organization's proprietary information, evaluation procedures, and the institutional rules determining which outputs may be used. A model that performs impressively in isolation may contribute little where data access, workflow integration, or verification is absent. Conversely, a modest model embedded in a well-designed process may alter productivity substantially. The productive object is increasingly the human–machine arrangement rather than either component taken alone.

This reorganization also changes the meaning of skill. Some skills remain directly productive because the worker performs the task. Others become supervisory or evaluative because the worker judges machine-generated candidates. Still others become more valuable because AI lowers the cost of complementary activities. The historical transition is therefore better understood as a redistribution of productive functions than as the simple removal of human cognition from production. Section 1.13 later examines the allocation consequences when such redistribution creates persistent asymmetries in comparative capability.

1.11.2 Machine-Generated Symbols

Generative models also alter the material conditions of symbolic production. Text, software code, images, audio, structured summaries, translations, synthetic examples, and other representational outputs can be produced at scales and speeds that differ sharply from earlier human-only processes. Digitalization had already lowered the cost of storing, copying, transmitting, and searching symbols. Generative AI lowers the cost of producing new symbolic arrangements in response to instructions and context.

This distinction matters because symbolic production had historically remained constrained by human time even after reproduction became cheap. A digital document can be copied almost without limit, yet drafting the first document still required someone to produce it. Generative systems weaken that bottleneck. Once a model is available, additional candidate texts, images, code fragments, classifications, or reformulations can be generated at low marginal cost relative to the human labor that would have been required to produce each candidate independently.

The resulting abundance should be interpreted carefully. Symbolic output is not identical with meaning, truth, or knowledge. Bender, Gebru, McMillan-Major, and Mitchell emphasize that large language models operate over linguistic form and warn against attributing understanding merely from the fluency of generated text (Bender et al. 2021). Their argument is particularly useful for GRE because it separates an economic fact from an epistemic conclusion. The economic fact is that systems can generate symbols that are usable within many production processes. The epistemic standing of those symbols depends on their relation to evidence, context, interpretation, verification, and subsequent use.

Machine-generated symbols therefore create a new selection problem. When candidate production becomes cheap, the scarce activity can migrate toward speci-

fication, evaluation, authentication, and attention. A writer facing one blank page confronts a production problem. A writer facing hundreds of plausible machine-generated drafts confronts a different problem: selecting, interpreting, checking, and integrating among abundant candidates. The productive constraint shifts from generation alone toward orientation and judgment.

The same shift occurs in organizations. Marketing teams can generate many variations of copy; software teams can generate multiple code suggestions; researchers can generate candidate summaries or hypotheses; administrative systems can generate draft classifications and reports. In each case, the volume of symbolic material can expand more quickly than the institutional capacity to evaluate its accuracy, relevance, provenance, or consequences. Symbolic abundance can therefore increase the demand for trustworthy filters even while reducing the direct cost of producing symbols.

This transformation provides the immediate historical background for the representational crisis examined in Section 1.14. Economic institutions depend on symbols: prices, reports, contracts, classifications, credentials, ratings, applications, records, and claims about states of the world. When symbol generation becomes abundant, the old inference from costly production to evidential significance becomes less reliable. The problem moves from whether a representation can be produced toward how its relation to a referent is established and maintained.

1.11.3 Machine-Mediated Knowledge Production

Artificial intelligence enters knowledge production through a more demanding pathway than symbolic generation. Knowledge is an institutional and epistemic achievement: claims must be related to evidence, methods, prior work, standards of justification, and communities capable of criticism and revision. A fluent output becomes economically useful knowledge only when it is incorporated into relations that establish why it should be relied upon.

AI can nevertheless alter those relations materially. Systems can search large information spaces, retrieve and reorganize documents, generate code for analysis, propose candidate explanations, identify patterns, produce simulations, and translate material across technical or linguistic boundaries. These functions can shorten the path between a question and a set of candidate answers. They can also make forms of expertise available to workers who would previously have required longer training, specialized assistance, or access to a more experienced colleague.

The productivity evidence from generative AI illustrates this knowledge-transfer function without establishing that the model itself possesses knowledge in the same sense as a person or institution. Brynjolfsson, Li, and Raymond find especially large gains among less experienced customer-support workers and present evidence consistent with the system disseminating practices associated with stronger workers (Brynjolfsson et al. 2025). The economically important mechanism is relational: information distilled from prior interactions becomes available through the model to workers who did not personally accumulate the same experience.

This possibility changes the historical scarcity of expertise. Expertise traditionally combined knowledge with the time required to learn, practice, encounter rare cases,

and gain entry to communities and institutions where such learning occurs. AI can reduce some of these access costs by placing codified or statistically reconstructed regularities into an interface available during performance. The result may narrow capability differences in some tasks, as the heterogeneous productivity effects in experimental and workplace studies suggest (Noy and Zhang 2023; Brynjolfsson et al. 2025).

The transformation remains partial. Tacit knowledge, situated judgment, responsibility, domain-specific interpretation, and the recognition of novel or misleading circumstances may remain difficult to externalize. AI outputs can also be incorrect, weakly grounded, or inappropriate to the local context. The epistemic problem therefore changes rather than disappears. A worker may gain access to a larger candidate knowledge space while simultaneously acquiring a new burden of verification.

Knowledge production also becomes more recursive. Human-generated records train or condition models; models generate outputs that enter human workflows; those workflows produce new records; and later systems may be trained, evaluated, or adapted using traces of the resulting activity. The boundary between knowledge infrastructure and productive activity therefore becomes increasingly porous. What an organization knows can be partly embodied in databases, models, prompts, retrieval systems, evaluation procedures, and the accumulated interaction between artificial systems and human participants.

For GRE, the important historical consequence is that knowledge can become both more abundant and more infrastructurally concentrated at the same time. Access to a general-purpose model can diffuse capabilities widely, while the production, training, adaptation, and control of the most capable systems may remain concentrated. Section 1.12 examines the corresponding transformation of scarcity, while Section 1.17 later returns to the economic organization of knowledge and epistemic capacity.

1.11.4 Transformation of Comparative Productive Capability

The economic significance of AI becomes sharper when productive capability is treated comparatively rather than absolutely. A worker can become more productive after adopting AI and simultaneously lose relative scarcity if similar or greater capability becomes available to many others at low cost. Conversely, a worker whose domain expertise complements AI effectively may become more productive and more valuable even though the technology performs parts of the underlying task. The relevant transformation concerns the distribution of comparative capability across participants.

Task-based automation already provides the structure for this analysis. When technology performs tasks previously assigned to labor, the task content of production shifts. New tasks, complementary skills, or organizational roles can partly counterbalance displacement (Acemoglu and Restrepo 2019). Generative AI makes this reallocation unusually visible in cognitive and symbolic tasks because the same system can assist drafting, coding, classification, summarization, translation, and other activities across occupations rather than being confined to one narrowly engineered physical process.

Evidence from current deployments suggests that the effect can be heterogeneous

across prior capability levels. Noy and Zhang report larger gains among initially weaker performers in professional writing tasks (Noy and Zhang 2023). Brynjolfsson, Li, and Raymond similarly find larger improvements among less experienced and lower-skilled customer-support workers, while effects for the most experienced workers are smaller (Brynjolfsson et al. 2025). These findings do not establish a universal equalizing effect. They demonstrate that AI can change the shape of a productivity distribution rather than simply shifting every participant upward by the same amount.

This transformation can alter the economic value of accumulated experience. Some experience is encoded in routines that a model can reproduce or make available to newcomers. Other experience becomes more valuable because it supports verification, problem framing, exception handling, or judgment in cases where machine output is unreliable. Comparative advantage therefore moves within the task structure. A capability that once differentiated an expert may become common, while a previously secondary capability becomes the new bottleneck.

The same logic applies at the organizational level. Firms differ in proprietary data, complementary software, workflow design, managerial capacity, domain expertise, computing infrastructure, and the ability to redesign production around new tools. Access to the same general-purpose model can therefore yield different productive effects. AI capability is not a scalar resource added uniformly to every organization; it enters a pre-existing relational architecture and combines with other capacities.

Comparative productive capability also has distributive consequences because modern institutions connect productive contribution to wages, profit, bargaining position, investment, access, and organizational authority. A technology that changes comparative capability can therefore alter resource claims even before aggregate output changes dramatically. The later sections on scarcity, allocation, and subjecthood examine the resulting tension: an economic order historically organized around comparative productive necessity encounters artificial systems capable of performing an expanding range of tasks at potentially much lower replication cost.

1.11.5 Concentration of Artificial Productive Capacity

The diffusion of AI-generated outputs coexists with concentration in the infrastructure that produces frontier artificial capability. This combination is historically important. A service can be accessible to millions of users while the training, deployment, and strategic control of the underlying systems remain located in a relatively small number of organizations and technical infrastructures.

The Stanford AI Index documents this concentration at the frontier. Its 2026 report states that industry produced more than 90 percent of notable AI models in 2025 and records rapid growth in global AI compute capacity together with substantial concentration in advanced hardware and hyperscale infrastructure (Stanford Institute for Human-Centered Artificial Intelligence 2026). These observations do not imply that useful AI is available only from a few firms. Open-weight models, smaller systems, local adaptation, and falling inference costs can diffuse access widely. The relevant distinction is between diffusion of use and control over the resources required to create or operate the most capable systems.

Artificial productive capacity depends on several complementary layers: specialized chips, data centers, energy, network infrastructure, model architectures, training data, engineering talent, capital, and organizational experience in large-scale deployment. Bottlenecks at any layer can shape who can develop frontier systems. The productive asset is therefore not the model file alone. It is a relation among computational, financial, informational, organizational, and infrastructural capacities.

Concentration at these interfaces can create economic leverage beyond conventional ownership of a single productive asset. An organization controlling model access can influence prices, usage conditions, permissible applications, data retention, technical compatibility, and the pace at which downstream users receive new capabilities. Cloud providers and hardware suppliers can shape the cost and feasibility of model development. Organizations possessing proprietary data or distribution networks can combine those assets with models in ways that new entrants cannot easily reproduce.

The structure is therefore double-sided. AI can decentralize capability by allowing a small organization or individual worker to perform tasks that previously required a larger team or specialized expert. The same technological system can centralize upstream productive power by increasing dependence on compute, model providers, data infrastructure, and technical standards. Decentralized use and centralized capacity are compatible because they occur at different layers of the productive architecture.

This layered concentration complicates conventional measures of economic power. Ownership of factories, machinery, or financial assets remains relevant, yet control of artificial productive capacity may depend on infrastructure positions that organize access for many downstream actors. A user can possess no share of the model provider while becoming deeply dependent on the provider's interface. A firm can own its data while lacking the compute or model capability needed to extract comparable productive value from them. Relational position becomes increasingly important to effective command.

Artificial intelligence therefore intensifies the historical tendencies developed in Sections 1.7 through 1.10: knowledge becomes a productive resource, production becomes distributed across networks, digital interfaces mediate access, and informational advantage can become economic power. AI adds the capacity to generate cognitive and symbolic outputs at scale and to reorganize comparative capability. The next section turns to the resulting transformation of scarcity: abundance in some forms of production can coexist with new scarcities in attention, trust, institutional access, infrastructure, and meaningful opportunities to participate in generative economic relations.

1.12 Transformation of Economic Scarcity

This section consolidates the productive changes described in Sections 1.10 and 1.11 into a historical account of changing scarcity. Its role is to clarify that technical abundance in one domain can redistribute scarcity across the wider economic system. The objective is to distinguish continuing material scarcity from the rapid expansion of

symbolic and codified informational output, then identify the growing importance of attention, trust, institutional access, and opportunities for consequential participation. The discussion proceeds from material constraints to symbolic abundance, qualified knowledge abundance, emergent relational scarcities, and generative opportunities. The method is historical and economic. Scarcity is treated as a relation between available means, institutional arrangements, technological capacities, and the uses through which those means become consequential; no claim is made that contemporary economies have entered a general condition of abundance.

1.12.1 Material Scarcity

Material scarcity remains a constitutive condition of economic organization. The digitalization of information and the automation of cognitive tasks alter the cost structure of production, yet they continue to depend on energy, land, physical infrastructure, computing equipment, logistics, human time, and access to productive assets. The historical transformation therefore concerns the composition and location of scarcity as much as its aggregate level. A task can become cheap in one dimension while becoming more dependent on scarce complementary resources in another.

The classical economic language of scarce means retains its relevance here. Robbins's influential formulation treated economics as concerned with human behavior under conditions in which means are scarce relative to alternative uses (Robbins 1932). Contemporary digital production changes which means are scarce and which alternatives compete for them. Storage and replication costs can fall sharply while advanced computation, energy, specialized hardware, skilled maintenance, and infrastructure access become more economically consequential. The relevant scarcity therefore shifts across the production system rather than simply receding.

Artificial intelligence makes this redistribution especially visible. Frontier systems can generate symbolic outputs at very low marginal cost once a model has been trained and deployed, yet the capacity to build and operate such systems remains materially intensive. The 2026 AI Index documents continued growth in the scale and concentration of advanced AI compute and infrastructure, alongside broader diffusion of downstream use (Stanford Institute for Human-Centered Artificial Intelligence 2026). The coexistence of cheap generated output and concentrated upstream capacity illustrates the central point: abundance at the output interface can rest on scarcity and concentration in the infrastructure that makes the output possible.

Material scarcity also persists through bottlenecks that lie outside the immediate production process. A digitally abundant service may still depend on limited transmission capacity, electricity supply, physical distribution, regulatory permission, or geographic access. Similarly, an organization may possess abundant information while lacking the personnel, time, or institutional authority required to act upon it. The economic significance of scarcity therefore depends on the relations linking resources to use. A resource can be physically present and economically unavailable when the institutional or relational conditions of access are absent.

This historical persistence of material constraint prevents a simple narrative in which digital technology replaces scarcity with abundance. The more precise development is a differentiation of scarcity. Some forms of production become increas-

ingly reproducible and automatable, while other inputs become relatively more decisive because they remain difficult to reproduce, difficult to access, or concentrated in a small number of institutional locations. This differentiation prepares the analysis of symbolic abundance, where the cost of producing representations falls much faster than the cost of interpreting, validating, and acting upon them.

1.12.2 Symbolic Abundance

Symbolic production has undergone one of the sharpest scarcity transformations in the contemporary economy. Digital technologies reduced the costs of copying, transmitting, searching, and storing information, while generative AI extends the cost reduction to the production of new symbolic arrangements. Goldfarb and Tucker characterize digital technologies through reductions in several economic costs associated with search, replication, transportation, tracking, and verification (Goldfarb and Tucker 2019). Generative systems add another layer by lowering the cost of producing candidate texts, images, software code, classifications, and other representations.

The economic consequence is a rapid expansion in the supply of symbols relative to the human time required to inspect them. Section 1.11 distinguished this expansion from knowledge production in the stronger epistemic sense. That distinction remains essential. Bender and colleagues caution against inferring understanding from fluent language output and thereby provide a useful boundary between symbolic competence and epistemic warrant (Bender et al. 2021). Symbolic abundance therefore describes an observable productive condition: representations can be generated at scales that no longer require proportional human authorship. It does not establish that truth, justification, or understanding have become correspondingly abundant.

This shift alters the location of economic effort. When symbolic generation is expensive, production itself absorbs time and skill. When candidate production becomes cheap, selection, comparison, verification, interpretation, provenance assessment, and integration become relatively more important. The scarcity problem moves downstream. An organization may be able to generate hundreds of reports, designs, or strategic options while lacking the attention required to evaluate them. A researcher may generate many plausible hypotheses while still facing the harder task of determining which ones merit sustained inquiry. A consumer may face abundant recommendations while remaining uncertain which sources deserve trust.

Symbolic abundance also changes the strategic value of visibility. When publication or generation costs fall, the ability to enter an informational environment no longer guarantees that an output will be noticed. Search ranking, platform position, reputational signals, institutional endorsement, and network location become increasingly important in determining which symbols reach consequential audiences. The problem of scarcity therefore reappears through channels of selection and recognition.

The expansion of machine-generated symbols further increases the importance of provenance. When many outputs can be produced rapidly and with similar stylistic plausibility, the economic value of knowing where a representation came from, which process produced it, and what evidential relations support it can rise. Section 1.14 develops this issue as a representational crisis. The present section records

the prior economic condition: production of symbols can become abundant faster than the institutional capacity to authenticate, rank, and absorb them.

1.12.3 Knowledge Abundance

Knowledge abundance requires a more qualified interpretation than symbolic abundance. Modern economies possess unprecedented capacities to store, reproduce, retrieve, and recombine codified knowledge. Digital networks make scientific articles, technical documentation, educational materials, software, data, and institutional records available across distances at costs far below those of earlier print and archival systems. Artificial intelligence can further reduce the effort required to search, summarize, translate, and reorganize such materials. These developments expand the effective availability of codified knowledge even when the production of justified knowledge remains demanding.

The economic properties of information help explain this transformation. Arrow's analysis of invention emphasized that information differs from ordinary commodities because its production involves uncertainty and its use can be difficult to appropriate exclusively once the information exists (Arrow 1962). Digital reproduction strengthens the practical significance of this distinction by making many informational objects cheap to copy and distribute. The marginal cost of another reader, user, or software instance can become very small relative to the original cost of discovery, design, or verification.

Expanded availability, however, does not eliminate the dispersed and situated character of economically relevant knowledge. Hayek's analysis of knowledge in society emphasized that knowledge of particular circumstances remains distributed among many actors and cannot be treated as if it were centrally given (Hayek 1945). Contemporary data systems and AI can aggregate and mediate some of this knowledge, yet they do so through representations, classifications, and institutional access arrangements. Tacit knowledge, local judgment, practical familiarity, and context-sensitive interpretation remain difficult to detach from the relations in which they are formed.

The phrase *knowledge abundance* therefore refers here to an expansion in the accessible stock and recombinability of codified knowledge rather than to a disappearance of epistemic scarcity. Several complementary scarcities can intensify as codified material proliferates. Verification remains costly. Provenance must be established. Contradictory sources require adjudication. Questions must be selected. Relevance must be judged relative to a concrete problem. The scarce activity increasingly concerns orientation within a large possibility space of available information and candidate explanations.

AI-mediated work illustrates this redistribution. Brynjolfsson, Li, and Raymond find evidence consistent with generative AI helping less experienced workers access and apply patterns embodied in the practices of more experienced workers (Brynjolfsson et al. 2025). Such diffusion can reduce certain knowledge asymmetries inside an organization. At the same time, the organizational value of the system depends on who can access the tool, what proprietary knowledge it can retrieve, how its outputs are checked, and which institutional processes accept those outputs as actionable.

The scarcity of codified know-how can decline while the scarcity of trustworthy interpretation, authorized access, and responsibility for judgment becomes more salient.

This distinction is important for GRE because an economy with abundant informational artifacts can still distribute epistemic capability very unequally. Access to a large corpus differs from the capacity to formulate worthwhile questions, discriminate among explanations, connect knowledge to a local situation, or persuade an institution to act. The later analysis of epistemic economy will treat these differences directly. At the historical level, the relevant transition is already visible: economic scarcity moves from possession of information alone toward the relations that make information interpretable, credible, and practically consequential.

1.12.4 Attention, Trust, and Institutional Access

As symbolic and informational supply expands, several relational conditions become more economically scarce. Attention is the clearest case. Simon's analysis of information-rich organizations argued that an abundance of information creates a scarcity of the attention required to receive and process it (Simon 1971). The proposition becomes increasingly important in digital environments where both human and machine systems can produce outputs continuously. The cost of producing another message may approach zero while the time available to read, interpret, compare, and act upon messages remains bounded.

Attention scarcity is relational because visibility depends on competition among claims upon finite recipients. A document can exist without being read, a recommendation can be generated without being considered, and an opportunity can be technically available without entering the decision horizon of the relevant actor. Search systems, ranking algorithms, professional reputation, institutional position, and social networks therefore influence which signals obtain scarce attention. Abundance in production can increase the economic value of selection mechanisms.

Trust becomes consequential through a related mechanism. Economic relations frequently involve commitments whose quality cannot be fully established before action. Arrow's discussion of gifts and exchanges emphasized the pervasive role of trust in commercial and social transactions (Arrow 1972). In information-rich environments, the number of potential counterparties, claims, and representations can expand faster than the capacity to verify each one independently. Trust, reputation, certification, and institutional assurance then perform a filtering function. Their economic importance grows when direct verification is expensive relative to the abundance of available claims.

Trust should not be treated here as a homogeneous stock. It is generated and sustained within particular relations, histories, institutions, and repeated practices. Trust in a person, trust in a profession, trust in a platform, and trust in a public institution arise under different conditions and can fail in different ways. The scarcity relevant to economic coordination is therefore the limited availability of credible relations through which actors can rely on information, promises, identities, and standards without reproducing the entire verification process themselves.

Institutional access forms a third scarcity. Institutions organize entry to resources, credentials, markets, finance, scientific communities, legal protections, and decision

procedures. North's institutional analysis emphasizes that rules and organizations structure incentives and transaction possibilities rather than merely recording choices after they occur (North 1990). In a digital economy, information about an opportunity can be abundant while actual access to the institution controlling that opportunity remains constrained. Knowing that a funding programme exists differs from being eligible to apply; knowing that a model exists differs from having compute access; knowing that a scientific field exists differs from possessing the credentials, language, networks, or institutional affiliation through which participation becomes possible.

The capability perspective provides a useful bridge from resource possession to effective opportunity. Sen's account of development as freedom emphasizes substantive opportunities and the institutional conditions through which people are able to pursue valued ways of living (Sen 1999). For the present historical argument, the important point is analytical: equal information or nominal resources can coexist with unequal effective access because conversion depends on social, institutional, and personal conditions. Scarcity can therefore reside in the relation between a subject and an institution even when the informational description of the opportunity is widely available.

Attention, trust, and institutional access share a common structural feature. They mediate the conversion of abundant possibilities into consequential action. Symbolic abundance produces many candidate claims; attention determines which are considered; trust influences which are treated as credible; institutional access affects which can be acted upon. Their growing importance marks a transformation in scarcity from possession alone toward relational gateways.

1.12.5 Generative Opportunities and Meaningful Participation

The final scarcity considered in this section concerns opportunities to participate in relations that can generate further capacities, knowledge, projects, recognition, and future options. The term *generative opportunity* is used here in a preliminary sense. It denotes access to a relational configuration in which participation can contribute to outcomes that extend beyond immediate consumption or transfer. Examples include entry to a research community, participation in an organization where skills can develop, access to collaborators and infrastructure, involvement in a public institution, or membership in a network through which new projects become possible. The full theory of generative value and generative opportunity is developed later in the book; the present section identifies the historical conditions that make the category increasingly relevant.

This perspective extends the analysis of scarcity beyond the ownership of goods. A person may possess material resources and still lack access to relations in which those resources can be converted into capability. A worker may possess skill yet lack organizational entry. A researcher may possess knowledge yet lack collaborators, infrastructure, or recognition. A community may possess local knowledge yet lack institutional channels through which that knowledge can alter decisions. In each case, scarcity resides in a missing relation or a constrained pathway of conversion.

Sen's capability approach provides an important precedent for shifting attention

from resources to substantive opportunity (Sen 1999). GRE carries the question further into the structure of relations that generate later possibilities. The distinction is analytical rather than competitive: capabilities concern what a person is effectively able to do or be, while generative opportunities direct attention to the relational processes through which new capacities and future option spaces may emerge. The two can overlap, and their exact relation remains an open theoretical problem for later chapters.

Artificial intelligence intensifies the relevance of this issue because productive abundance can weaken the historical link between human participation and material necessity. If machines can perform a growing range of cognitive and symbolic tasks, economic inclusion cannot be understood only through the scarcity of labor required for production. Access to livelihood remains crucial, yet another problem becomes visible: whether people possess opportunities to participate in relations where their judgment, curiosity, care, creativity, or responsibility can become consequential. Section 1.15 examines the resulting pressure on the modern economic subject, and Section 1.17 develops relational and generative conditions of subjecthood more directly.

Meaningful participation is therefore introduced here as an economic object whose scarcity cannot be inferred from unemployment statistics or income measures alone. Its empirical specification requires caution. Meaningfulness varies across persons and contexts, and GRE does not assume a single universal content. The economically relevant issue is whether institutional arrangements provide plural pathways through which participants can enter, sustain, and transform consequential relations. Scarcity appears where such pathways are narrow, heavily gated, or concentrated among actors already possessing relational advantage.

The transformation of scarcity described across this section can now be stated in historical terms. Material scarcity persists, while digitalization and AI produce relative abundance in selected symbolic and informational domains. This abundance raises the importance of attention, trust, institutional access, and generative opportunity as mediating scarcities. Economic analysis organized only around the possession and allocation of material goods therefore captures a declining share of the constraints that determine who can convert resources into consequential participation. Section 1.13 turns next to allocation under radical capability asymmetry, where these new scarcities interact with increasingly unequal productive capacities.

1.13 Allocation under Radical Capability Asymmetry

This section examines a historical allocation problem created when productive capability becomes highly unequal across human and artificial participants. Its role in the chapter is to connect the changing scarcity structure of Section 1.12 to the institutional mechanisms through which income, access, and economic participation are distributed. The objective is to distinguish five elements that are often conflated: employment as an allocation channel, comparative capability as a condition of competitive access, automation as a transformation of task demand, productive abundance as distinct from broad resource access, and capability asymmetry as a possible source of

economic power. The discussion proceeds historically and institutionally rather than as a forecast of aggregate employment. Artificial intelligence is treated as a contemporary case in which productive capability may become radically asymmetric while the allocation of livelihood and participation remains organized through institutions formed under earlier productive conditions.

1.13.1 Employment-Based Allocation

Wage employment became one of the central allocation mechanisms of industrial economies because it linked productive participation to command over resources. A worker supplied labor through an employment relation and received wages or salary that could be converted into food, housing, services, savings, and other goods. The arrangement also frequently mediated access to benefits, credentials, professional networks, legal status, and forms of institutional recognition. Employment therefore functioned as more than a contract for a discrete productive task. It connected a position within production to a wider bundle of claims upon economic resources.

The historical character of this arrangement is important. Polanyi's account of market society emphasizes the institutional construction required to treat labor as something organized through markets and contracts (Polanyi 1944). Sen's entitlement analysis makes a related point from the side of command over resources: access to goods depends on the entitlement relations through which a person can transform endowments, production possibilities, trade, and public transfers into effective command (Sen 1981). Wage employment is one such entitlement relation. Its importance arises from the way institutions connect labor contribution to purchasing power rather than from any timeless identity between work and livelihood.

Employment-based allocation also packages several relations together. The employer receives access to labor under organizational authority; the worker receives income; public institutions may attach taxation, insurance, pension rights, immigration status, or social protection to the employment relation; and households organize consumption and care around the resulting income stream. The economic significance of losing a job therefore depends on the institutional bundle attached to employment. Two economies with similar productive technologies can generate very different consequences from the same reduction in labor demand when healthcare, housing, social insurance, or legal membership are connected to employment in different ways.

This bundling made employment an efficient administrative recipient for allocation in periods when productive systems required extensive and continuing human labor. Income could be distributed through organizations already responsible for coordinating production, while participation in production supplied a socially legible basis for claims on output. The arrangement also created vulnerability because access to livelihood became dependent on continued inclusion in productive organizations. Historical labor politics, social insurance, and public provision can be read partly as responses to this vulnerability rather than as departures from an otherwise self-sufficient labor market.

Artificial intelligence makes the contingency of the employment-allocation linkage more visible. If a growing range of tasks can be performed with less human labor, the

economic question extends beyond the number of jobs created or destroyed. It concerns whether institutions continue to use employment as the primary route through which people receive income, institutional access, and opportunities for participation. The issue is therefore one of allocation architecture: a productive system can change faster than the institutions that connect productive contribution to resource claims.

1.13.2 Comparative Capability and Competitive Access

Competitive allocation depends on relative as well as absolute capability. Where access to jobs, contracts, finance, education, or professional positions is limited, applicants are compared against one another under institutionally defined criteria. Improvements in one person's productive capacity can therefore alter the competitive position of others even when their own abilities remain unchanged. The scarcity lies in the number and quality of positions, while capability influences who can enter them.

Human-capital theory formalized one important part of this structure by treating education and training as investments that can raise productivity and earnings (Becker 1964). The approach helps explain why individuals invest in capabilities that improve access to scarce economic positions. A relational analysis adds the competitive environment in which those capabilities are evaluated. The return to a skill depends on the distribution of comparable skills, the technologies with which the skill is combined, the institutions controlling entry, and the criteria by which organizations recognize productive contribution.

The capability perspective further distinguishes possession of resources from effective opportunity. Sen emphasizes that people differ in their ability to convert resources into substantive freedoms because personal, social, and institutional conditions differ (Sen 1999). In labor and professional markets, the corresponding conversion problem includes credentials, networks, geographic access, legal status, organizational membership, and technological complements. A person can possess knowledge without possessing a recognized pathway through which that knowledge becomes economically consequential.

Artificial intelligence alters comparative capability in a complex way. Experimental and workplace studies have found that generative AI can raise performance in selected writing and customer-support tasks, with especially large gains for some lower-performing or less-experienced workers (Noy and Zhang 2023; Brynjolfsson et al. 2025). In such settings, AI can compress certain within-task performance differences by diffusing practices or supplying assistance. This equalizing effect at the task level can coexist with wider inequalities in access to frontier systems, proprietary data, compute, organizational authority, and the ability to redesign work around the technology.

Comparative capability therefore remains institutionally mediated. The relevant economic unit is rarely a human capability considered in isolation or an artificial capability considered in isolation. Competitive access depends on combinations of persons, tools, organizations, infrastructures, and recognized claims. Radical capability asymmetry becomes economically significant when some actors can assemble these combinations more effectively than others or control the institutional inter-

faces through which combinations are admitted into competition.

1.13.3 Artificial Intelligence and Employment Scarcity

Artificial intelligence introduces a new form of uncertainty into employment-based allocation because it can substitute for selected cognitive and symbolic tasks while also complementing workers and generating new tasks. The task-based literature on automation distinguishes displacement effects from reinstatement effects: technologies can reduce labor demand in tasks they automate while new tasks and activities can restore labor demand elsewhere (Acemoglu and Restrepo 2019). The historical record therefore offers no basis for treating task automation as mechanically equivalent to aggregate technological unemployment.

The relevant problem for GRE is narrower and more structural. Employment scarcity can increase for particular groups, occupations, or periods when the number of positions capable of providing stable income and institutional membership grows more slowly than the number of people seeking such positions. AI can contribute to this condition when organizations reorganize production around machine performance and require fewer workers for tasks that previously justified large employment structures. New tasks, new industries, or increased demand can offset the effect, yet the offset depends on the speed, location, accessibility, and institutional form of the new opportunities.

Korinek and Stiglitz analyze AI and worker-replacing technological progress through distributional channels that include innovation rents, changes in factor prices, and possible forms of technological unemployment under specified conditions (Korinek and Stiglitz 2019). Their analysis is useful here because it separates greater productive capacity from the distribution of the resulting gains. A technology can increase aggregate output while changing bargaining positions, income shares, and the allocation of surplus. The distributive consequences depend on ownership, substitution patterns, policy, and institutional design rather than on productivity alone.

Current evidence also counsels against a simple capability hierarchy in which AI uniformly replaces weaker workers first. Brynjolfsson, Li, and Raymond find substantial productivity gains from an AI assistant in customer support, with larger gains among less-experienced and lower-skilled workers in their setting (Brynjolfsson et al. 2025). Such evidence suggests that AI can operate as a capability-diffusion mechanism inside organizations even while reducing the scarcity of some human task-specific skills. The same technology can therefore complement workers at one margin and weaken the market value of previously scarce expertise at another.

Employment scarcity should consequently be understood as a relational outcome rather than a direct property of AI capability. It depends on how quickly tasks are reorganized, which new roles appear, how income is connected to those roles, who can access complementary tools, and whether institutions create alternative routes to livelihood and participation. The historical significance of AI lies in its potential to weaken the inherited coupling between human productive necessity and resource allocation. Whether that potential is realized, and in which sectors or populations, remains an empirical question.

1.13.4 Productive Abundance and Resource Concentration

Greater productive abundance does not determine how control over productive assets or resulting income is distributed. A production system can generate rapidly expanding quantities of output while ownership of capital, infrastructure, intellectual property, market access, or organizational decision rights remains concentrated. The distinction becomes especially important when the marginal cost of selected outputs falls faster than the cost of building or controlling the systems that generate them.

Digital and AI production display this asymmetry clearly. Section 1.11 noted that frontier AI development remains concentrated in large organizations with access to substantial compute, data, engineering capacity, and financing, even as downstream use diffuses more widely (Stanford Institute for Human-Centered Artificial Intelligence 2026). The result is a layered productive structure: symbolic and cognitive services can become cheaper and more abundant at the user interface while the infrastructure capable of producing frontier systems remains scarce and institutionally concentrated.

A broader empirical precedent is provided by the literature on superstar firms. Autor and colleagues document rising sales concentration in several industries and find that industries with larger increases in concentration experienced larger declines in labor's share, consistent with reallocation toward highly productive firms with relatively low labor shares (Autor et al. 2020). The analysis does not establish an AI-specific causal mechanism. Its relevance here is structural: productivity growth, concentration, and changes in the distribution of income can coexist when technological and market conditions shift activity toward a small number of highly productive organizations.

Resource concentration can also persist through control of complementary assets. Access to an AI model may be widespread while valuable deployment requires proprietary data, customer relationships, legal permissions, computing infrastructure, distribution channels, or organizational authority. The productive capability of the model becomes economically consequential through these relations. Actors controlling scarce complements can therefore capture a larger share of value even when the immediate technological output is reproducible at low marginal cost.

This distinction complicates abundance narratives. Productive abundance can reduce prices, widen access to services, and create new opportunities, while simultaneously increasing the strategic importance of the remaining scarce complements. Economic analysis therefore needs to track both output abundance and the distribution of control over the conditions that make abundance possible. Section 1.18 later identifies this divergence as one reason entity-level measures of possession can miss changes in relational and generative structure.

1.13.5 Capability Asymmetry and Economic Power

Capability asymmetry becomes economic power through institutional relations that convert superior capacity into control over resources, options, or the conduct of others. A technically superior system does not automatically possess economic power. Power emerges when capability is connected to ownership, organizational authority,

infrastructure control, bargaining position, institutional recognition, or the ability to determine access to scarce complements. The distinction is central to GRE because it separates differences in what actors can do from differences in what actors can compel, withhold, authorize, or capture.

The institutional mediation can be seen in ordinary firms. Organizational law and asset partitioning help establish entities capable of owning assets, entering contracts, and separating pools of claims (Hansmann and Kraakman 2000). Institutions therefore determine which actors can legally command productive resources and which claims are recognized when conflicts arise. Similar mediation applies to artificial capability. An AI system's productive capacity is exercised through the organization that owns, operates, licenses, deploys, or integrates it. The economically relevant power may reside in the relation among model capability, organizational control, and institutional recognition rather than in the model considered by itself.

Radical human–AI capability asymmetry makes this mediation especially important. The economic value of advanced AI partly arises because its performance can exceed human performance in selected tasks. Eliminating every capability difference would also eliminate much of the productive reason for deploying the technology. The practical problem is therefore not the existence of asymmetry alone. It is the structure through which asymmetry is converted into dependency, bargaining power, exclusion, or concentrated control over future opportunities.

Several conversion pathways are possible. An organization that controls scarce AI infrastructure can convert technical capability into lower production costs, then into competitive advantage, market access, revenue, and further investment. A platform can convert informational and computational capability into control over ranking, matching, or access. A worker equipped with an AI assistant can convert machine capability into higher individual productivity when organizational rules permit use and recognize the resulting output. Different institutional arrangements can therefore produce different power distributions from similar underlying technologies.

The same logic applies in the opposite direction. Humans and institutions can retain substantial power over technically superior systems through ownership, legal authority, access controls, energy supply, deployment permissions, and the design of organizational objectives. Capability and power can therefore diverge in both directions. The degree of divergence is a property of the relational architecture connecting subjects, institutions, and productive systems.

This distinction completes the section's historical argument. Employment-based allocation, competitive access, AI-mediated task transformation, resource concentration, and institutional conversion together create a setting in which productive capability can become radically asymmetric without determining a single distributive outcome. Economic consequences depend on the relations that connect capability to claims, resources, institutions, and participation. Section 1.14 turns next to symbolic abundance and representational crisis, where expanding productive capacity changes the reliability of the symbolic interfaces through which those relations are recognized and coordinated.

1.14 Symbolic Abundance and Representational Crisis

This section examines a second consequence of contemporary productive transformation: the expansion of symbolic production changes the conditions under which economic actors rely on representations of persons, organizations, transactions, risks, assets, claims, and states of the world. Its role in the chapter is to connect the symbolic abundance introduced by digitalization and artificial intelligence to a problem of economic coordination. The objective is to distinguish five layers of that problem: the scale of symbolic production, the relation between symbols and referents, the institutional effects of classification, the growing importance of provenance and epistemic trust, and the consequences of representational instability for coordination. The discussion is historical and institutional. It treats representations as economically consequential interfaces whose reliability depends on practices of classification, verification, authorization, and interpretation.

1.14.1 Expansion of Symbolic Production

Modern economies have long depended on symbolic production. Contracts, accounts, prices, reports, ratings, certificates, legal identities, statistical indicators, inventories, forecasts, and organizational records allow dispersed actors to coordinate without direct access to every underlying event or relation. Digital infrastructures greatly expanded the volume, speed, and granularity of these representations. Section 1.10 described how platforms, continuous observation, and algorithmic systems intensified the production and use of data. Section 1.11 added a further change: generative systems can now produce linguistically and visually plausible symbolic artifacts at very low marginal cost.

The economic significance of this expansion lies in the changing ratio between symbolic production and the resources required to evaluate it. A report, explanation, image, recommendation, summary, classification, or synthetic record can be generated quickly. The work required to determine provenance, contextual adequacy, factual support, relevance, and institutional standing may remain costly. Symbolic abundance therefore enlarges the set of representations available to actors while also increasing the burden placed on selection and verification.

The distinction between symbolic output and knowledge is essential. Language models can generate fluent text whose surface form resembles ordinary human communication, yet fluency alone does not establish understanding, reference, evidential grounding, or truth. Bender and colleagues emphasize this gap in their critique of large language models, warning against treating statistical success in language generation as equivalent to semantic understanding (Bender et al. 2021). The relevance for economics extends beyond debates about artificial intelligence. Economic coordination increasingly proceeds through representations whose production cost can fall much faster than the cost of establishing their epistemic status.

This asymmetry changes the practical meaning of abundance. A larger supply of symbols can improve access to explanation, translation, drafting, visualization, and administrative communication. The same expansion can also increase duplication, low-quality synthesis, strategic fabrication, and competition for attention. The result-

ing problem concerns the institutional relation among production, filtering, verification, and use. Symbolic production becomes economically productive only when actors can establish which representations deserve reliance within a particular decision context.

The contemporary transformation therefore adds a new layer to scarcity. Section 1.12 argued that abundant information can increase the relative scarcity of attention. Symbolic abundance also increases the relative importance of infrastructures that authenticate sources, preserve context, establish responsibility, and connect representations to the relations they purport to describe. These infrastructures become part of the productive conditions of knowledge-intensive economic coordination.

1.14.2 Symbols and Referents

A representation becomes economically useful through a relation to something beyond its own symbolic form. A balance sheet refers to an organization's financial position; a credential refers to an institutional status; a price refers to a transactionally recognized valuation; a risk score refers to an inferred probability or classification; a written claim refers to an event, object, or relation that may be investigated independently. The relevant economic question therefore concerns the stability of the relation between symbolic form and referent.

That relation has never been automatic. Documentary practices, accounting rules, legal procedures, statistical classifications, professional standards, audits, and institutional routines have historically supplied the conditions under which a representation acquires standing. A monetary figure in an audited statement, for example, carries a different institutional status from the same numeral written in an unauthenticated message. The visible symbol may be identical while its relation to evidence, authority, and responsibility differs.

Artificial symbolic production increases the importance of this distinction because surface plausibility can be generated independently of a corresponding referent. A text can describe an event that did not occur; an image can depict a scene that was never captured; a synthetic profile can imitate the ordinary markers of an institutional identity; a generated citation can possess the form of scholarship without referring to an existing publication. The representational problem therefore concerns the mapping from sign to referent and the institutional conditions under which that mapping can be trusted.

The problem is broader than deception. A representation can be sincere and still detach from the structure it is meant to summarize. Statistical categories may lag behind changing economic relations. Administrative records may preserve a legal identity while control has shifted elsewhere. Organizational reporting may describe formally bounded entities whose productive processes depend on external networks. A model can continue to produce internally coherent outputs after the relations that once justified its parameters have changed. Representational instability therefore includes both fabricated symbols and historically outdated or structurally incomplete mappings.

GRE later develops a more explicit distinction between relational reality and manifestational reality. The historical purpose of the present section is narrower. It estab-

lishes why the distinction becomes economically urgent under contemporary productive conditions. When institutions coordinate through increasingly abundant representations, the quality of economic action depends increasingly on the reliability of the relations connecting those representations to the subjects, processes, assets, and events they mediate.

1.14.3 Classification and Administrative Reality

Economic representations frequently take classificatory form. Persons are classified as employed, unemployed, self-employed, insured, resident, eligible, creditworthy, skilled, dependent, or vulnerable. Organizations are classified by legal form, sector, industry, size, ownership, reporting status, and jurisdiction. Assets, liabilities, expenditures, incomes, transactions, and risks are likewise organized through standardized categories. Classification makes complex relations administratively tractable by assigning them to recognized types.

The historical sociology of quantification shows that these categories are institutional achievements. Desrosières traces how statistical conventions construct comparability by defining categories, coding rules, and procedures of aggregation (Desrosières 1998). Hacking's work on historical ontology likewise emphasizes that classifications participate in the historical formation of the objects and kinds through which institutions organize knowledge (Hacking 2002). The relevant implication for GRE is that administrative representation can participate in constituting the economic reality upon which later decisions operate.

The System of National Accounts provides a concrete example. Its concept of an institutional unit identifies entities capable of owning assets, incurring liabilities, making economic decisions, and entering contracts, and uses those units to organize sectoral accounts (European Commission et al. 2009). Such classifications are indispensable for macroeconomic observation. They also establish a particular resolution at which economic activity becomes visible. Relations that cross recognized units or operate through informal, distributed, or hybrid arrangements can be less visible within the same framework.

Classification acquires performative force when eligibility, taxation, reporting duties, access, benefits, or regulatory treatment depend on category membership. An employment classification can affect social insurance and labor protections. A credit category can alter borrowing conditions. A platform's ranking category can affect discoverability. A statistical category can shape which population is recognized as a policy target. The representation therefore enters the relation it describes by altering the conditions under which actors are treated.

This feedback makes classification economically generative in a limited but important sense. A category can stabilize expectations, coordinate institutions, and support large-scale administration. It can also redirect behavior toward the criteria used for classification. As categories become integrated into automated systems, the speed of this feedback can increase. Classification, decision, and subsequent data generation can occur in a repeated loop, allowing an administrative representation to shape the future observations from which it is later updated.

The resulting issue is neither a rejection of classification nor a preference for un-

structured description. Complex economies require abstractions. The analytical task is to identify the relations that an abstraction preserves, the relations it suppresses, and the institutional consequences produced when the abstraction becomes an operational category. Representational crisis emerges when categories remain administratively powerful while their fit with changing relational structures becomes increasingly uncertain.

1.14.4 Authenticity, Provenance, and Epistemic Trust

Symbolic abundance increases the economic importance of authenticity and provenance. Authenticity concerns the standing of an artifact or claim as the artifact or claim it purports to be. Provenance concerns the history of its production, modification, custody, and transmission. Epistemic trust concerns the willingness to rely on a representation within a decision process. These dimensions interact, yet each answers a different question.

The distinction is visible in contemporary provenance standards. The C2PA Content Credentials specification defines technical mechanisms for binding signed provenance assertions to digital assets, recording creation and editing information, and validating whether those assertions remain associated with the underlying content (Coalition for Content Provenance and Authenticity 2026). The specification also draws an important boundary: validation of provenance data does not by itself determine whether the represented claim is true or normatively acceptable. Provenance supplies evidence about source and transformation history; interpretation remains necessary.

This separation has direct economic significance. A cryptographically verified document can still contain a mistaken forecast. An authenticated identity can make a false statement. A valid model output can be based on inappropriate assumptions. Conversely, an artifact without machine-verifiable provenance can still be accurate. Reliable coordination therefore depends on several layers of trust: confidence in source identity, confidence in chain of custody, confidence in the procedure that generated the claim, and confidence in the claim's adequacy to the decision at hand.

Porter's history of quantitative objectivity shows that impersonal procedures and standardized measures became important partly because institutions required forms of judgment that could travel across distance and survive disputes over personal authority (Porter 1995). Digital provenance infrastructures can be understood as a contemporary extension of the same organizational problem. Where direct familiarity is unavailable, institutions construct portable signals through which strangers can coordinate. The contemporary difference lies in the scale and speed of symbolic production, which increase the number of artifacts for which such signals may be demanded.

Provenance itself can therefore become an economic resource. Actors able to establish trusted identity, verified histories, recognized credentials, and auditable production chains may obtain advantages in markets where surface form is easy to imitate. Verification infrastructures can also become sites of dependency when a small number of institutions control identity, certification, reputation, or access to trusted channels. The problem of epistemic trust thus connects symbolic abundance to the

power questions developed later in the book.

The historical shift is consequently double. Artificial systems reduce the cost of producing persuasive symbolic form, while institutions respond by increasing investment in provenance, authentication, audit, reputation, and trusted intermediation. Economic coordination moves toward a regime in which the ability to produce symbols is widespread, while the ability to establish their standing remains institutionally differentiated.

1.14.5 Economic Coordination under Representational Instability

Economic coordination depends on representations because actors routinely decide in the absence of direct access to the underlying relations they seek to govern. Firms rely on accounts and forecasts; creditors rely on identities, histories, and risk measures; consumers rely on labels, reviews, and reputational signals; governments rely on administrative records and statistical indicators; platforms rely on profiles, rankings, and behavioral traces. Representational instability therefore becomes an economic problem when actors can no longer assume that the cost and reliability of these interfaces remain roughly stable.

Several consequences follow. Verification becomes a larger component of transaction and coordination costs. Organizations may devote more resources to authentication, audit, provenance, identity management, model validation, and source assessment. Trusted intermediaries can gain strategic importance because they reduce uncertainty for participants who cannot verify every claim independently. At the same time, concentration around trusted intermediaries can create new dependencies and bottlenecks. The infrastructure that restores trust can itself become a source of economic power.

Representational instability also affects temporal coordination. Decisions are often made before verification is complete. A false or poorly grounded representation can influence prices, hiring, credit, procurement, or public response before correction arrives. Later correction may fail to reverse the relational consequences already produced. The economic effect of a representation therefore depends partly on the speed with which it is produced, circulated, believed, acted upon, challenged, and revised.

Classification feedback adds a further layer. Once an institution acts on a representation, the action changes subsequent data. A risk classification can alter access to credit; altered access changes later repayment histories; those histories then become inputs to subsequent classification. A ranking can redirect attention; redirected attention changes observed popularity; popularity then reinforces the ranking. These loops make representational systems participants in the processes they measure.

The resulting crisis is best understood as a problem of alignment among symbolic production, referential reliability, institutional classification, and practical trust. The term *crisis* refers here to intensified instability in that alignment rather than to universal collapse of representation. Many representations remain highly reliable, and digital systems can improve traceability, consistency, and access. The historical change lies in the simultaneous expansion of symbolic productive capacity and the growing economic importance of institutions that determine which representations

can be trusted, acted upon, and converted into recognized claims.

This shift prepares the next problem in the chapter. Economic subjects themselves are partly stabilized through representational systems: occupational titles, employment records, credentials, income categories, organizational roles, legal identities, and measures of contribution all participate in defining how persons and organizations appear within economic institutions. When productive relations and representational systems change together, established subject positions can lose part of the institutional support that previously made them stable. Section 1.15 therefore turns from representational instability to the destabilization of the economic subject.

1.15 Destabilization of the Economic Subject

This section examines how contemporary productive transformation unsettles the institutional relations through which modern economic subjects have been stabilized. Its role in the chapter is to connect the preceding transformations of production, scarcity, allocation, and representation to a problem of subject formation. The objective is to identify the historical relations among economic roles, work, social recognition, productive necessity, and participation, and then to clarify why artificial intelligence places pressure on arrangements that have tied material access and social standing to comparative productive contribution. The discussion proceeds historically and institutionally. It first reconstructs economic roles as socially organized positions, then examines work as a source of recognition and membership, distinguishes productive contribution from productive necessity, analyzes the possibility of productive redundancy, and closes by identifying forms of economic participation that need not depend on productive superiority.

1.15.1 Economic Roles and Subject Formation

Modern economic institutions do more than allocate resources among pre-existing persons and organizations. They also assign recognizable positions through which participants become legible as workers, employers, owners, consumers, creditors, debtors, taxpayers, dependants, professionals, and members of organizations. Section 1.4 reconstructed these positions as historically formed economic subjects, while Section 1.5 showed how law, accounting, statistics, and administrative classifications stabilize the entities to which those positions attach. The present subsection develops the further implication that repeated participation in such roles can become part of the practical continuity through which persons understand their place in economic life.

An economic role carries a bundle of expectations, rights, obligations, resources, and relations. Employment connects a worker to wages, working time, organizational authority, occupational identity, social insurance, and often a trajectory of promotion or skill formation. Ownership connects an actor to control, exclusion, residual claims, and asset-based security. Professional status connects expertise to credentials, jurisdiction, reputation, and access to specialized work. Household positions connect provision, care, dependence, and intergenerational transfer. These arrangements differ across legal systems and historical periods, yet they share a general structure:

economic subject positions are reproduced through institutional relations that make some forms of participation recognizable and consequential.

This relational formation does not imply that persons are exhausted by economic roles. A person can remain a parent, friend, citizen, learner, creator, believer, neighbor, or participant in many other relations whose meaning exceeds economic classification. The analytical point concerns the historical importance of economic roles for access and recognition. In industrial and post-industrial societies, employment status, occupation, income, property, organizational affiliation, and professional credentials have often affected where a person can live, which institutions become accessible, how risk is borne, and which forms of contribution become publicly visible. Economic roles therefore participate in the stabilization of subject positions even though they never constitute the whole of subjectivity.

Polanyi's historical account of market society is useful here because labor, land, and money became increasingly organized through market institutions that restructured the relation between livelihood and social organization (Polanyi 1944). Marx's analysis of wage labor likewise places labor-power inside a historically specific relation in which access to the means of livelihood is mediated through the sale of labor capacity and the organization of production under capital (Marx 1867). The theoretical traditions differ substantially, yet both make visible a common historical fact: participation in production became deeply connected to the institutions through which subjects acquired income and occupied recognizable social positions.

The contemporary problem arises when the relations that stabilize those roles change faster than the categories through which subjects remain institutionally recognized. A person can retain knowledge, experience, responsibility, and the capacity for meaningful action while the labor market value of a previously recognized role declines. An organization can retain formal identity while its productive function is redistributed across platforms, contractors, automated systems, and external infrastructures. A credential can continue to certify a competence even as the task structure associated with that competence changes. Subject destabilization therefore begins as a mismatch between historically stabilized roles and changing productive relations.

The economic subject is consequently vulnerable to transformations that leave the underlying person or organization intact. The worker can persist while the job disappears; the professional can persist while the exclusive jurisdiction of a profession erodes; the firm can persist while productive control migrates toward infrastructure providers; the household can persist while the employment structure supporting its income becomes less stable. This distinction prepares the analysis of recognition in the next subsection. What becomes unstable is often the relation through which a subject is economically recognized, rather than the existence of the subject itself.

1.15.2 Work and Social Recognition

Work has historically supplied more than output. It can connect persons to income, routine, organization, skill formation, collective membership, reciprocal dependence, and publicly recognizable contribution. The relative importance of these dimensions varies widely across occupations and societies, and many forms of socially necessary activity remain unpaid or weakly recognized. Even so, the institutional centrality

of employment means that changes in work can affect both material access and the social recognition attached to participation.

The material relation is direct. Section 1.6 described employment as a major channel through which households receive claims on resources. Wages can determine access to housing, credit, insurance, savings, mobility, and many forms of consumption. Employment can also serve as an administrative gateway to benefits and legal protections. Where these arrangements are strong, work becomes one of the principal institutional bridges between productive participation and livelihood.

The recognitional relation operates differently. A role becomes socially recognizable when institutions and communities possess a vocabulary for identifying its contribution. Occupational titles, credentials, organizational positions, portfolios, rankings, and professional standards make contribution visible in standardized ways. Recognition can therefore depend on representation as well as performance. Section 1.14 showed that representational systems participate in economic coordination; they also participate in subject formation by stabilizing the categories through which contribution is noticed and attributed.

This dependence creates asymmetries among forms of work. Market-mediated labor often leaves records of hours, wages, outputs, contracts, and titles. Care, informal coordination, emotional support, household maintenance, community work, mentoring, and many forms of relational labor may generate substantial capacities while remaining weakly represented in conventional accounts. The economic subject produced through employment institutions therefore reflects a selective architecture of recognition. Activities become more visible when they enter established categories of paid contribution, while other relations can remain economically consequential without receiving equivalent institutional standing.

Sen's capability approach helps clarify the stakes because material resources matter through the substantive opportunities they enable rather than through possession alone (Sen 1999). Participation in work can be valuable partly because it supports income, but also because it can expand capabilities through learning, association, mobility, voice, and institutional membership. The same perspective also permits a distinction between work and the broader capabilities work sometimes supports. If technological change weakens the employment channel, the relevant loss cannot be assessed adequately by asking only whether income can be replaced. The consequences may concern access to relations, routines, opportunities for contribution, and forms of recognition previously carried by employment.

This point gives subject destabilization a wider scope than unemployment. A person may remain employed while experiencing reduced autonomy, weaker occupational jurisdiction, diminished bargaining power, or increasing dependence on algorithmic systems. Conversely, a person outside paid employment may possess rich capacities and participate in relations of care, learning, creation, and community life. Economic subjecthood therefore becomes unstable when inherited institutions continue to use employment as a privileged signal of contribution while productive and socially valuable activity becomes more heterogeneous.

Artificial intelligence intensifies this problem because it can alter the informational basis on which professional recognition rests. When generative systems assist writ-

ing, coding, analysis, design, diagnosis, or customer interaction, observed output becomes increasingly co-produced by persons, models, organizations, datasets, and infrastructures. Brynjolfsson, Li, and Raymond find that generative-AI assistance can increase worker productivity while producing heterogeneous gains and forms of knowledge diffusion (Brynjolfsson et al. 2025). The broader implication is that contribution becomes more relational: the performance attributed to an individual may depend increasingly on access to shared artificial capabilities. Recognition systems organized around isolated individual productivity may therefore become less informative about the relations that actually generate performance.

The historical role of work in social recognition should consequently be separated into its component relations. Employment can provide income, status, routine, membership, learning, bargaining position, and visibility of contribution. Technological transformation can affect these components differently. A future institution may preserve income while weakening membership, preserve work while changing autonomy, or expand productive capacity while concentrating recognition in those who control infrastructures. The economic problem concerns the reorganization of these relations rather than a single binary distinction between employment and unemployment.

1.15.3 Production and Social Necessity

The relation between production and subjecthood becomes especially important when productive capability grows faster than the need for particular forms of human contribution. This subsection distinguishes productive contribution from productive necessity. A person can contribute to production without being indispensable to it, and a society can possess the technical capacity to produce more output while reducing the number of human tasks required for a given production process. The distinction matters because modern allocation and recognition systems have often tied access to resources to the continuing demand for labor.

Industrial production already contained this tension. Mechanization increased output while reorganizing the demand for particular skills and tasks. The task-based framework developed by Acemoglu and Restrepo describes technological change through a balance between displacement, in which capital or automation performs tasks previously assigned to labor, and reinstatement, in which new tasks create new domains for labor demand (Acemoglu and Restrepo 2019). This framework is useful for GRE because it avoids treating technical capability as a direct forecast of employment. Productive transformation changes the task structure, while institutions, demand, complementary innovations, and new activities shape the resulting labor relation.

Artificial intelligence extends the same problem into domains of cognitive and symbolic production discussed in Section 1.11. The relevant change is the widening set of tasks for which machine systems can provide useful substitutes or complements. Writing, translation, coding, search, classification, planning, image production, and analytic support can increasingly be performed through human–AI configurations. The resulting productivity gains can expand output, lower costs, generate new demand, and create new roles. They can also reduce the amount of human labor re-

quired for some existing outputs. Both directions are compatible with the same technological advance.

The concept of social necessity adds another layer. A task may cease to be technically necessary for producing a given output while remaining socially meaningful. Human teaching, care, artistic performance, deliberation, companionship, craftsmanship, or face-to-face service can retain value even when some associated informational or productive functions are automatable. The persistence of such activity depends on institutions of valuation and participation as much as on comparative technical efficiency. Productive necessity and social desirability therefore belong to different analytical dimensions.

This distinction prevents a narrow interpretation of technological progress. If machine systems can produce a report faster than a person, the technical relation concerns the production of the report. The economic and social relation also concerns who learns through producing it, who is recognized for judgment, who bears responsibility for its consequences, who retains access to the relevant institution, and which capabilities are reproduced through repeated practice. An output-equivalent substitution can therefore change the relations surrounding production even when the immediate product appears unchanged.

The implications for subject formation are substantial. Modern societies have often connected the worth of economic participation to productive necessity: a worker receives income because an organization requires the worker's labor, and the need for that labor supports bargaining position and recognition. As artificial productive capacity expands, that connection can weaken in some domains. Technical abundance may make a person's participation less necessary for output without making the person's experience, judgment, relationships, or potential contribution meaningless. A tension then emerges between the organization of production and the organization of subject recognition.

Korinek and Stiglitz emphasize that the distributional effects of artificial intelligence depend on how technological change affects factor returns, innovation rents, ownership, and labor demand (Korinek and Stiglitz 2019). The implication for the present argument is institutional. Productive capability alone does not determine who receives resources or recognition. The connection between production and livelihood is mediated through property, employment, bargaining institutions, taxation, public provision, and other mechanisms of allocation. Productive necessity can therefore decline before the institutions built around it have been replaced or reconfigured.

The resulting subject problem is historically specific. Industrial modernity stabilized a powerful chain linking work, contribution, income, and social position. Contemporary artificial productive capacity can loosen individual links in that chain at different rates. Economic theory therefore needs concepts capable of distinguishing output production from capability formation, necessity from participation, and technical substitution from the broader relational functions historically carried by work.

1.15.4 Productive Redundancy and Subjective Instability

Productive redundancy names a condition in which an actor's participation becomes less necessary for achieving an established productive objective because comparable or superior output can be generated through other configurations. The term refers to a relation between an actor and a production system, rather than to a judgment about the actor's intrinsic worth. This distinction is central to the section. An economic system can treat a contribution as redundant while the person remains fully capable of experience, learning, care, judgment, creation, and participation in other relations.

Redundancy can arise gradually. A task may first receive machine assistance, then become standardized, then shift toward supervision, and eventually require little direct human production. It can also arise unevenly across workers. Access to artificial tools may allow some employees to perform a wider range of tasks, reducing demand for specialized positions elsewhere. Organizational redesign can redistribute tasks among workers, models, platforms, and external contractors. The resulting instability therefore concerns the configuration of productive relations rather than a uniform technological shock.

The subjective consequences depend on how strongly a person's economic continuity has been organized around a productive role. Where income, professional identity, daily routine, social network, institutional membership, and perceived contribution are concentrated in employment, the weakening of that role can produce several forms of instability at once. Material insecurity may be accompanied by a loss of recognized position, reduced opportunities for skill use, and uncertainty about the relation between personal capability and social need. These effects can occur even when aggregate production rises.

The concept should remain analytically restrained. Productive redundancy is a possibility generated by changing task relations; it is not a forecast that human labor as a whole will become unnecessary. Acemoglu and Restrepo's displacement–reinstatement framework explicitly leaves room for new tasks and new forms of human comparative advantage (Acemoglu and Restrepo 2019). Artificial intelligence may also create complementary roles whose content cannot yet be specified. GRE therefore treats redundancy as a local and historically variable relation that can expand, contract, or transform as institutions and production systems evolve.

Even a local form of redundancy can expose a deeper problem in allocation. If access to income and social resources depends heavily on being competitively necessary to production, a decline in necessity can become a decline in material command. Section 1.13 described the institutional channels through which capability asymmetry can affect allocation. Subjective instability adds the consequence that the same institutions also influence how persons understand their place in economic life. A system can therefore preserve productive abundance while generating insecurity among participants whose recognized roles weaken.

Income replacement addresses only part of this structure. Transfers, social insurance, public provision, or asset ownership can protect material access when employment falls. Such arrangements may be indispensable, yet the relations previously carried by work can remain unresolved. A person can possess income while lacking a recognized field of contribution; possess leisure while lacking access to commu-

nities of practice; possess consumption opportunities while lacking participation in decisions that shape shared institutions. The difference between material security and relational participation is therefore analytically important.

This distinction also constrains simplistic claims about a post-work economy. Reduced labor requirements can expand freedom from undesirable work, create time for care and learning, and weaken forms of domination tied to economic necessity. The same reduction can intensify exclusion if institutions continue to allocate recognition, voice, and access through employment. The consequences depend on which relations replace the employment nexus and how those relations distribute opportunities for meaningful participation.

The historical significance of artificial intelligence therefore lies partly in the possibility that productive abundance and subjective insecurity can coexist. A society may become technically capable of producing more with less human labor while retaining institutions that interpret reduced labor demand as reduced social claim. The tension arises from the lag between productive transformation and the institutional forms through which subject positions are recognized. This lag motivates the final subsection's focus on participation beyond productive superiority.

1.15.5 Economic Participation beyond Productive Superiority

The destabilization of inherited subject positions creates a positive analytical task: economic participation needs to be distinguished from productive superiority. Modern institutions have often rewarded actors who possess scarce capabilities, control productive assets, or occupy roles that organizations require. These mechanisms remain important, yet they provide an incomplete basis for subjecthood when artificial systems can exceed human performance across expanding sets of tasks. A relational economy therefore requires concepts of participation that remain intelligible even when contribution cannot be justified by superior output alone.

Sen's capability perspective offers one foundation because it evaluates substantive opportunities rather than reducing well-being to resource possession or commodity command (Sen 1999). Applied to participation, the relevant question concerns which relations persons are effectively able to enter, sustain, and shape. Access to education, public institutions, collaborative work, culture, care, research, community life, and collective decision-making can matter because these relations expand what persons are able to become and do. Their value need not depend on proving that human performance exceeds the best artificial alternative.

Economic participation can therefore be analyzed through several distinct dimensions. Material participation concerns access to resources and infrastructures required for life. Productive participation concerns contribution to the production and maintenance of goods, services, organizations, and shared capacities. Epistemic participation concerns access to inquiry, learning, interpretation, and the production of knowledge. Institutional participation concerns membership, voice, and the ability to influence rules. Relational participation concerns access to durable relations through which trust, care, identity, cooperation, and future opportunities can be generated. These dimensions can overlap while remaining analytically separable.

The distinction matters because technological systems affect them differently. Arti-

ficial intelligence may reduce the labor required for a productive task while increasing opportunities for learning, experimentation, or collaborative creation. It may improve access to knowledge while concentrating control over computational infrastructure. It may enable small organizations to perform functions previously requiring large staffs while increasing dependence on a few platform providers. Evaluation therefore requires tracing which forms of participation expand, which contract, and which become conditional on new intermediaries.

Participation also has a temporal dimension. A relation can be valuable because it generates later capabilities that were unavailable at the moment of entry. Apprenticeship, education, research collaboration, caregiving, community membership, and participation in institutions can produce skills, trust, confidence, reputation, and future opportunities. A purely output-centered account can undervalue such relations when their immediate productivity is modest. GRE later develops this problem through the concept of generativity. The historical point here is that the weakening of productive necessity makes these longer-horizon relational effects more visible as economic questions.

The same perspective changes the interpretation of artificial capability. If machine systems outperform humans on a task, the comparison answers a question about task performance under specified conditions. It does not determine whether humans should cease to participate in every relation organized around that task. Education offers the clearest example: a system may know more than a learner while the learner's engagement with a subject still generates human capability. Similar distinctions may arise in art, research, care, deliberation, and craftsmanship, where participation itself can transform the participant and the surrounding relational system.

This approach preserves the role of productive efficiency while limiting its jurisdiction. Efficiency remains relevant when a goal is well specified and output can be compared meaningfully. Subject formation, capability development, institutional membership, and relational continuity introduce additional objects of economic evaluation. A society facing radical artificial capability therefore confronts a problem of institutional design: how to organize access, contribution, recognition, and participation when comparative productive superiority no longer provides a stable general foundation for each of them.

The next section develops the relational basis required for that problem. Section 1.16 examines economic subjecthood as a relatively stable configuration generated and sustained through social and institutional relations. The move does not assign final ontology to the subject. It identifies the relational conditions under which subjects acquire sufficient persistence, recognition, and causal efficacy to become objects of economic analysis.

1.16 Relational Constitution of Economic Subjecthood

Section 1.15 identified a historical strain in the modern alignment among productive contribution, income, recognition, and subject position. The present section provides the conceptual bridge required by that diagnosis. Its role is to reconstruct economic subjecthood through the relations that generate, stabilize, and recognize an actor as

a participant in economic life. The objective is deliberately limited: the section develops a relational account sufficient for economic analysis while reserving stronger metaphysical questions for the ontological discussion in Chapter 4. The argument proceeds through five steps. It first locates subject formation within social relations, then examines the mechanisms that stabilize economic actors, turns to institutional recognition, states a minimal account of relational reality under ontological suspension, and finally considers how the framework applies to human and artificial economic subjects. The method is historical-institutional and analytical. It asks what practical conditions allow an actor to persist as a recognizable bearer of roles, resources, obligations, capacities, and consequences across time.

1.16.1 Social Relations in Subject Formation

Economic subjecthood becomes intelligible once the subject is approached through the relations in which economic capacities acquire determinate form. A worker is constituted economically through relations of employment, remuneration, authority, skill recognition, and social reproduction. An owner occupies relations of title, exclusion, transfer, inheritance, and control. A consumer appears through monetary access, market exchange, product classification, credit, and infrastructures of distribution. A household becomes actionable through membership, care, income pooling, taxation, welfare rules, and statistical recognition. These positions differ sharply in content, yet they share a structural feature: the economic subject is recognizable because a network of relations gives the position continuity and practical consequences.

This relational reconstruction extends the historical argument developed earlier in the chapter. Economic action has long been embedded in ongoing structures of social relations, and Granovetter's critique of atomized economic action remains useful precisely because it directs attention to the social structures through which apparently individual conduct becomes possible and consequential (Granovetter 1985). The relational point can be taken further without assuming that every feature of a person is socially produced. Economic subjecthood concerns a domain-specific position. The person who occupies that position exceeds it, while the position itself is formed through relations that make certain actions, claims, obligations, and resources available.

The distinction between bearer and position prevents two forms of analytical compression. One compression treats the subject as a self-contained unit whose economically relevant capacities are already present before interaction. The other treats the subject as fully exhausted by the relations currently observed. A relational account can preserve a practical identity while recognizing that the capacities attached to that identity are historically conditioned. Skills are acquired through education and work; creditworthiness is constituted through records and institutional judgment; ownership depends on recognized title; occupational identity depends on social classification and organizational demand; household responsibility depends on membership rules. These capacities become attributes of actors in practice even though their production is relational.

Historical categories participate in this formation. Hacking's historical-ontological work emphasizes that classifications, descriptions, and styles of reasoning can par-

ticipate in bringing into view kinds of persons and objects that become available for thought and action (Hacking 2002). In economic life, categories such as employee, unemployed person, shareholder, debtor, beneficiary, incorporated firm, or dependent household member do more than summarize pre-existing properties. They organize eligibility, obligation, comparison, and institutional response. Once repeatedly used, a category can become part of the relational environment through which actors understand their position and through which others act upon them.

Subject formation therefore has a recursive structure. Relations generate positions; positions organize expectations and conduct; conduct reproduces or modifies the relations that generated the positions. This recursion explains why economic subjects can appear stable while remaining historically transformable. A worker can persist as a recognizable subject across many transactions because employment law, payroll systems, occupational classifications, organizational routines, and social expectations stabilize the position. Changes in technology, law, family structure, or organizational form can later alter the same position without requiring the person occupying it to disappear.

The relational constitution of subjecthood also clarifies why new economic actors can emerge historically. Platform sellers, data workers, content creators, gig workers, cooperative members, algorithmic service providers, and other contemporary positions become economically salient when repeated relations stabilize distinctive expectations, flows, rights, risks, and forms of recognition around them. The emergence of a subject position can therefore be studied historically through the relations that make it durable enough to enter allocation, accounting, regulation, and collective interpretation.

1.16.2 Relational Stabilization of Economic Actors

Subject formation alone does not explain persistence. Economic analysis ordinarily requires actors that can be followed across transactions, held responsible for obligations, assigned resources, and recognized by counterparties. Relational stabilization names the process through which a changing configuration becomes sufficiently continuous to support those practices. The relevant stability is practical and historical. It can be strong enough for accounting, contracting, policy, and statistical analysis while remaining open to transformation.

Several mechanisms contribute to stabilization. Repetition is the most elementary. Recurrent interaction allows counterparties to form expectations about conduct, reliability, skill, payment, or role performance. Records extend repetition across time by making prior actions institutionally available. Contracts and property titles preserve obligations beyond the moment of agreement. Organizational routines preserve roles across personnel changes. Membership rules define who remains inside a household, association, cooperative, or firm. Trust lowers the need to renegotiate every relation from the beginning. Infrastructures such as payment systems, registries, identity systems, and digital platforms provide technical continuity across otherwise separate encounters.

Stabilization also depends on complementarity. A position becomes durable when other positions are organized around it. The worker position is sustained by employ-

ers, payroll systems, labor law, training institutions, tax systems, and household expectations. The firm is stabilized by workers, suppliers, customers, creditors, regulators, accounting practices, and legal recognition. The consumer position depends on sellers, money, distribution, standards, information, and rights of redress. The durability of an actor is therefore partly a property of the surrounding configuration. A subject can lose economic continuity when complementary relations dissolve even if the bearer remains materially unchanged.

This point is especially important for collective actors. A corporation may survive the departure of founders, managers, workers, investors, and customers because the relations composing the organization are reproduced through roles, records, procedures, assets, contractual continuity, and external recognition. Section 1.5 showed how organizational law and accounting provide institutional mechanisms for such persistence. Relational stabilization adds the wider economic condition: counterparties continue to orient their conduct toward the organization as one participant. The collective actor acquires continuity because many relations converge on a sufficiently stable reference point.

Stabilization admits degrees. Some subject positions are highly standardized and portable across institutions; others depend on a narrow local relation. An incorporated firm with registered assets, audited accounts, recurring contracts, and regulatory standing possesses stronger institutional continuity than an informal collaboration assembled for a single project. A household can be stable for purposes of taxation and unstable for purposes of care or resource sharing. A digital identity may be persistent within one platform and irrelevant outside it. Economic subjecthood therefore varies with the domain, scale, and relation under examination.

The degree structure matters for contemporary transformation. New technologies can produce economically consequential actors faster than legal and statistical systems can stabilize them. A software agent can repeatedly perform purchasing, pricing, recommendation, or coordination functions while formal responsibility remains assigned to a human or organization. A decentralized collective can coordinate resources before established law provides a clear organizational category. Relational stabilization can therefore precede full institutional recognition, creating a period in which practical economic agency and formal subject status diverge.

1.16.3 Institutional Recognition of Subject Positions

Institutional recognition converts relational stabilization into forms that large-scale economic systems can administer. Law, accounting, taxation, statistics, welfare systems, financial institutions, and organizational procedures require identifiable units to which rights, obligations, resources, liabilities, and observations can be attached. Recognition gives a subject position an address within these systems. It also changes the position by creating consequences that follow from being classified in one way rather than another.

Modern economic administration offers clear examples. The System of National Accounts defines institutional units through capacities such as owning assets, incurring liabilities, making economic decisions, and engaging in transactions in their own right (European Commission et al. 2009). Financial reporting similarly constructs re-

porting entities whose boundaries can include a legal entity, part of an entity, or several entities, depending on the informational purpose of the report (IFRS Foundation 2018). Organizational law stabilizes further distinctions by partitioning assets and creditor claims around recognized organizational forms (Hansmann and Kraakman 2000). These frameworks do not merely discover a universal natural boundary. They create standardized interfaces through which heterogeneous relational configurations become comparable and actionable.

Recognition has distributive consequences. Employment status can determine access to wages, insurance, leave, taxation, and legal protection. Household classification can alter benefit eligibility and tax liability. Corporate status can affect asset ownership, limited liability, financing, and continuity. Residency, citizenship, professional certification, and organizational membership can determine access to institutions and resources. Recognition therefore participates in the production of economic capacity. A subject position that enters an institutional category can acquire options unavailable to an otherwise similar actor outside it.

The same process can exclude. Relations that do not fit established categories may remain economically consequential while receiving weak institutional visibility. Informal care, unpaid collaboration, platform-mediated labor, collective knowledge production, or cross-border digital activity can generate value and obligations without aligning neatly with inherited administrative units. The mismatch does not make these relations unreal. It affects whether economic systems can see them, allocate to them, regulate them, or assign responsibility through existing procedures.

Institutional recognition is therefore performative in a bounded sense. A classification can change access, incentives, responsibility, and behavior because institutions act through it. Its efficacy still depends on relations beyond the classification itself. Declaring an organization independent does not produce suppliers, trust, productive capacity, or internal coordination. Recognizing a worker category does not determine the actual distribution of bargaining power or care burdens. Recognition becomes economically effective when classificatory rules connect to infrastructures, resources, expectations, and enforcement.

This bounded performativity provides a useful bridge to the later discussion of manifestation. Economic systems often encounter subjects through institutional representations: accounts, legal statuses, employment records, credit files, identifiers, statistical categories, or platform profiles. These manifestations can stabilize action while preserving only part of the underlying relational structure. The analytical task is therefore twofold: to take institutional recognition seriously as a causal component of economic subjecthood and to preserve the possibility that the recognized manifestation leaves economically relevant relations unresolved.

1.16.4 Relational Reality under Ontological Suspension

The preceding analysis permits a minimal ontological stance suitable for the historical argument of this chapter. An economic subject can be treated as relationally real when a configuration is generated and sustained through relations, persists sufficiently to support recurrent interaction, and exercises causal effects within the economic system. This criterion concerns analytical standing rather than ultimate meta-

physical substance. Chapter 4 develops the distinction more fully through ontological suspension, relational reality, and manifestational reality.

Ontological suspension is useful because the economic subjects considered in this chapter are heterogeneous. A person, household, corporation, cooperative, state agency, platform account, and software agent do not need to share one ultimate mode of being in order to participate in economically consequential relations. Economic analysis can ask how each is generated, recognized, stabilized, and causally effective while leaving deeper questions about consciousness, personhood, identity, or metaphysical composition open where the economic argument does not require their resolution.

Relational reality also guards against premature reification. A stabilized subject can be treated as a unit for a particular analytical purpose while its boundary, capacities, and continuity remain dependent on relations. The firm can be a real contracting and accounting subject even though its productive capacity depends on workers, suppliers, law, finance, infrastructure, and knowledge networks. The household can be a real administrative unit even though its internal distribution cannot be inferred from aggregate resources. A worker can be a real employment subject while occupational identity and earning capacity remain historically generated. Reality at the relational level therefore supports unit-level analysis without converting provisional boundaries into timeless essences.

The same stance preserves practical identity. Relational constitution does not require economic analysis to dissolve every subject into an unbounded network. Contracts, liabilities, rights, welfare claims, preferences, plans, and histories frequently attach to identifiable actors. The question is how those identities are sustained and what relations make them economically effective. A relational account can therefore move between levels: it can treat the subject as a unit where the unit is causally and institutionally stabilized, and it can reopen the unit when internal or external relations become necessary for explaining an outcome.

This level-sensitive stance is especially important for value and responsibility. Economic systems often need to know who receives a transfer, who owes a debt, who controls an asset, who bears a risk, or who is accountable for a decision. These questions require subjects. GRE later asks how resources and value move through the relations composing and surrounding those subjects. Relational reality allows both inquiries to proceed without forcing one level to replace the other.

Ontological suspension also supports theoretical pluralism. Different disciplines may describe the same economic participant through different ontological vocabularies. Law may focus on personhood and responsibility; sociology on role and recognition; psychology on agency and cognition; computer science on system architecture; economics on choice, production, and allocation. GRE can use relational criteria to compare these descriptions where they intersect economically while allowing each domain to retain questions that exceed economic analysis. This discipline becomes decisive when artificial systems enter the picture.

1.16.5 Human–Artificial Economic Subjecthood

Artificial intelligence intensifies the subjecthood problem because economically consequential activity can increasingly be produced by systems whose legal, moral, cognitive, and institutional status differs from that of human participants. Section 1.11 showed that contemporary AI systems already participate in cognitive production, symbolic generation, workplace assistance, and organizational coordination. The question here concerns the analytical conditions under which such participation supports an economic subject position.

Four dimensions should be separated. Productive agency concerns the capacity to perform economically relevant tasks or alter outcomes. Relational continuity concerns whether counterparties repeatedly orient their conduct toward the system or toward a stable role mediated by it. Institutional recognition concerns whether rights, liabilities, accounts, contracts, or administrative consequences can be attached to the position. Normative standing concerns questions such as welfare, rights, responsibility, consciousness, or moral consideration. These dimensions can vary independently. A system may possess substantial productive agency and relational continuity while institutional and normative standing remain assigned to the human or organizational actors surrounding it.

The distinction prevents economic efficacy from carrying an ontological burden it cannot bear. Current language models can generate fluent symbolic output, while fluency itself does not establish understanding or meaning in the strong sense cautioned against by Bender and colleagues (Bender et al. 2021). Economic analysis nevertheless has reason to follow the causal role of such systems when organizations change staffing, prices, workflows, search processes, or service provision in response to them. Productive and relational effects can therefore be studied without treating those effects as evidence of human-equivalent cognition.

Institutional mediation remains central. A software agent that purchases goods, schedules labor, executes trades, recommends credit, or negotiates within a platform usually acts through accounts, permissions, assets, and liabilities ultimately connected to recognized persons or organizations. The economic subject may therefore be layered: an artificial system can occupy an operational role, a firm can bear legal responsibility, workers and users can supply inputs, and platform owners can control the infrastructure. The relevant unit depends on the question being asked. Production analysis may focus on the artificial agent's task performance; liability analysis may focus on the organization; power analysis may focus on ownership and infrastructure; welfare analysis may focus on affected humans.

This layered structure also clarifies why human and artificial economic subjects should not be treated as automatically equivalent. Human economic subjecthood is embedded in embodiment, vulnerability, social reproduction, capability development, legal rights, and forms of recognition that exceed productive output. Sen's capability perspective is relevant because it locates evaluation in substantive opportunities and the institutional conditions under which persons can act and become (Sen 1999). Artificial systems may participate powerfully in economic production without sharing the same capability, welfare, or rights framework. A relational analysis can compare economically relevant functions while preserving these normative differ-

ences.

Artificial systems can nevertheless acquire increasingly stable subject-like positions within particular economic domains. Recurrent identity, persistent memory, delegated authority, autonomous task execution, access to resources, and counterparties that adapt to system behavior can create a durable operational position. Institutional evolution may later attach new forms of recognition to such positions. The trajectory is an empirical and legal question rather than a conclusion established by technical capability alone.

The wider significance for GRE is methodological. Economic subjecthood should be analyzed through the relations that generate and stabilize participation rather than through a single universal test of entity status. Human persons, collective organizations, and artificial systems may occupy different subject positions, with different degrees of persistence, recognition, agency, and normative standing. The framework therefore preserves heterogeneous subjecthood while retaining enough structure for allocation, production, power, and responsibility to remain analyzable.

Section 1.17 takes the next step. Once subjects are understood as relationally stabilized, the central question shifts from the persistence of a subject to the capacity of relations to transform subjects, generate capabilities, alter future possibilities, and reproduce or change the conditions under which later relations form. That movement introduces the generative dimension that distinguishes GRE from a purely relational economics.

1.17 From Relational Subjecthood to Generative Relations

This section develops the transition from relational constitution to generativity. Its role in the chapter is to show why identifying the relations that stabilize an economic subject is only the first stage of analysis. The objective is to examine how persistent relations can transform subjects, generate capacities, alter the range of future possibilities, and organize forms of participation whose effects extend beyond an immediate transaction. The discussion proceeds conceptually and historically, drawing on the relational insights established in Sections 1.8 and 1.16. It first distinguishes persistence from mere recurrence, then analyzes subject transformation and capacity formation, extends the analysis to future possibility, and closes by specifying the generative structure of economic participation.

1.17.1 Persistence of Relational Structures

A relation becomes historically consequential when it persists long enough to condition later action. Persistence can arise through repeated interaction, institutional recognition, durable expectations, shared infrastructure, accumulated knowledge, legal rules, organizational routines, or material dependence. The resulting structure can outlast the particular exchange in which it first appeared. Employment relationships can generate occupational identities and skill trajectories; credit relations can alter future borrowing conditions; supply relationships can create specialized productive capacities; educational relations can reshape later opportunities; and

platform-mediated relations can reorganize access to markets, audiences, and information. The economic significance of a relation therefore depends partly on the temporal structure through which its effects continue.

Persistence should be distinguished from simple repetition. A sequence of transactions can recur without producing a durable change in the participants or in the surrounding institutional environment. A persistent relational structure has a stronger property: earlier interaction affects the conditions under which later interaction occurs. Trust, reputation, contractual routines, shared standards, specialized assets, organizational memory, and accumulated expectations are familiar mechanisms through which past relations become active conditions of the present. Granovetter's account of embedded economic action remains useful here because it directs attention to ongoing social structures rather than isolated transactions (Granovetter 1985). For GRE, the further question concerns what these ongoing structures make possible over time.

The persistence of relations can be located at several scales. A dyadic relation between worker and employer may stabilize expectations about effort, compensation, learning, and advancement. Repeated relations among firms can create interorganizational routines and shared technical standards. Relations among research institutions can stabilize channels through which knowledge, personnel, and equipment circulate. Financial relations can become embedded in clearing systems, regulatory arrangements, and expectations about liquidity. The relevant unit of analysis therefore expands as persistence becomes distributed across multiple participants.

Institutionalization is one important mode of persistence. A relation becomes institutionally durable when rules, classifications, legal forms, accounting practices, credentials, or administrative procedures reproduce it beyond the memory or intention of particular participants. Section 1.5 showed how modern economic entities are stabilized through precisely these mechanisms. The same mechanisms can stabilize relations among entities. A professional credential reproduces a relation between certified expertise and institutional access; a property title stabilizes a relation of exclusion and control; a standard contract reproduces a recognizable pattern of obligation across many interactions. Persistence can therefore be carried by symbolic and administrative infrastructures as well as by repeated personal contact.

Material complementarity can also make relations persistent. Specialized productive systems often create capacities that have value only within a wider configuration. A supplier investing in a highly specific component, a worker acquiring organization-specific knowledge, or a laboratory developing equipment around a shared protocol may become increasingly connected to a particular relational environment. The relation persists partly because the capacities generated within it are difficult to redeploy elsewhere without loss. This structure can support coordination and learning while also creating dependence and switching costs.

Persistence is normatively ambiguous. Durable relations can support trust, learning, care, coordination, and collective capacity. They can also reproduce dependency, exclusion, hierarchy, or unequal bargaining positions. The analytical importance of persistence lies in its generative potential rather than in any presumption that durability is beneficial. Once a relation modifies the conditions of later interaction, economic analysis must attend to the trajectory it produces and to the distribution of the

capacities and constraints that accumulate within it.

This temporal perspective prepares the move from relational stability to subject transformation. A subject stabilized by relations can also be changed by those relations. Persistence therefore provides the medium through which economic participation becomes formative rather than merely connective.

1.17.2 Relations and Subject Transformation

Economic subjects enter relations with histories, capacities, expectations, and institutional positions, and participation can modify each of these. The relevant transformation may concern skill, preference, identity, reputation, bargaining position, access, trust, obligation, or the practical categories through which a subject understands available action. Relations thereby participate in the production of later subjects. A relational account of economic life becomes generative when it follows this transformation across time.

Work provides a familiar example. Employment can alter a worker through training, occupational socialization, access to colleagues, exposure to organizational routines, and participation in professional communities. Human-capital theory captures one component of this process by treating education and training as investments that alter productive capacity (Becker 1964). A generative relational perspective widens the object. Skill formation occurs through relations with instructors, coworkers, institutions, technologies, standards, and bodies of knowledge. The capacity that later appears to belong to an individual can therefore have a distributed history of generation.

Organizations undergo analogous transformation. Repeated collaboration can produce routines, trust, shared vocabularies, coordination practices, and collective memory that are unavailable to participants acting separately. Powell, Koput, and Smith-Doerr's study of biotechnology is important because innovation appears within networks of interorganizational learning rather than inside fully self-sufficient firms (Powell et al. 1996). The productive subject in such settings changes through its relations: a firm's effective knowledge base and opportunity structure depend on the collaborations through which it learns and combines capabilities.

Relational transformation also occurs through institutions that classify and recognize subjects. Credentials can transform access to occupations; credit scores can change financing conditions; legal statuses can alter eligibility and responsibility; platform ratings can influence future matching and visibility. These representations can become part of the causal environment in which later subject positions are formed. Section 1.14 described the representational instability associated with symbolic abundance. The present point is temporal: once a representation affects later relations, it participates in the trajectory through which a subject is transformed.

Transformation can be cumulative and path dependent. Two subjects with initially similar resources can acquire different capacities because they enter different relational environments. Early access to strong mentors, well-connected institutions, trusted collaborators, stable employment, or high-quality infrastructure can generate later advantages that compound through subsequent relations. Conversely, exclusion from these environments can limit the opportunities through which capacities

would otherwise develop. The distribution of present resources therefore provides only a partial account of future economic position when the relations through which resources are converted into capacities differ systematically.

This dynamic also complicates the usual separation between preference and constraint. Participation can alter what subjects value, what they can imagine, which goals appear attainable, and which forms of activity become meaningful. Economic relations can therefore affect both the feasible set and the orientation of the subject within it. GRE does not require a universal theory of preference formation at this stage. It requires only the weaker historical observation that economic participation can modify the subject who later chooses, works, invests, cooperates, or withdraws.

Artificial intelligence introduces a new set of formative relations. A worker who repeatedly relies on an AI system may acquire new capabilities through augmentation, lose others through reduced practice, reorganize attention around system outputs, or become dependent on infrastructures controlled elsewhere. Organizations can similarly redesign workflows, expertise hierarchies, and decision routines around artificial systems. The long-run economic effect therefore concerns more than the productivity of a task at one moment. It also concerns the kinds of human and organizational subjects produced by sustained participation in AI-mediated relations.

Subject transformation provides the bridge to capacity formation. A generative relation becomes especially important when participation produces abilities, resources, forms of coordination, or institutional access that were unavailable to the participants before the relation developed.

1.17.3 Relations and Capacity Formation

Capacity formation gives the generative dimension a more precise economic object. A relation is generatively significant when participation helps produce a capacity that changes what a subject or collective can subsequently do. Capacities can be productive, epistemic, organizational, relational, political, or adaptive. They may reside partly in identifiable subjects and partly in the relations and infrastructures through which those subjects act.

The capability perspective offers an important point of contact because it evaluates resources through the substantive opportunities they enable rather than through possession alone (Sen 1999). GRE extends this concern temporally. The question becomes how present relations contribute to the formation of later capabilities and how unequal access to those relations shapes future opportunity. A training grant, for example, has one immediate recipient, yet its effect depends on educational institutions, mentorship, time, social support, recognition, and pathways into later work. Resource allocation and capacity generation are therefore analytically distinct stages.

Some capacities are intrinsically relational. Trust cannot be possessed by one actor in isolation in the same manner as a physical asset. Coordination capacity emerges through repeated mutual adjustment. A professional network becomes useful through reciprocal recognition and access. Collective knowledge depends on communication, shared standards, and institutional memory. Organizational resilience can depend on redundancy, distributed expertise, and the quality of relations among units. These examples show why a purely possessive vocabulary can

underdescribe capacities whose efficacy lies in structured interdependence.

Capacity can also be generated at a higher level than the participants through whose interaction it arises. A research collaboration can create a shared dataset, protocol, instrument, or body of tacit knowledge that later participants inherit. A supply network can develop standards and logistical routines that increase the productive capacity of the network as a whole. A community can establish norms and institutions that support collective action. The resulting capacity is real in its effects even when it cannot be assigned without remainder to any single member.

Relational capacity formation is often cumulative. Early participation can create the competence required to enter more advanced relations, which then generate further capability. Education, professional apprenticeship, scientific collaboration, entrepreneurship, and institutional membership frequently exhibit this structure. The trajectory can become self-reinforcing when generated capacities increase access to subsequent opportunities. The reverse is also possible: weak initial access can reduce later participation and create cumulative disadvantage.

The distribution of capacities therefore depends partly on the distribution of generative relations. Two actors receiving identical nominal resources can experience different long-run outcomes because their surrounding relations differ. Access to mentors, infrastructure, stable institutions, trusted collaborators, legal recognition, and time can determine whether a resource becomes an enduring capability. This observation is central to the later GRE treatment of allocation. Allocation affects economic futures partly by changing the relations through which capacity can be generated.

Capacity formation also clarifies why generativity should remain separate from immediate performance. A relation may reduce short-term efficiency while increasing learning, redundancy, adaptability, or future option space. Conversely, a highly optimized arrangement may produce excellent immediate output while generating little new capability among participants. GRE later develops the evaluative consequences of this distinction. At the historical level of the present chapter, the important point is that the productive significance of a relation can appear only across time.

The temporal extension of capacity leads directly to future possibility. Generated capability matters because it changes the set of relations, actions, and trajectories available later.

1.17.4 Relations and Future Possibilities

Economic relations participate in the construction of future possibility by changing which actions, affiliations, projects, and institutional positions become available. A future opportunity is rarely created by a resource alone. It emerges from a configuration that connects capacity, recognition, infrastructure, information, legal permission, social access, and material conditions. The generative effect of a relation can therefore be described partly through the possibilities it opens, preserves, redirects, or forecloses.

This perspective adds a temporal dimension to scarcity. Section 1.12 argued that contemporary scarcity increasingly concerns attention, trust, institutional access,

and generative opportunity alongside persistent material scarcity. Generative opportunity is distinctive because its value lies in what can follow from participation. Access to a research laboratory matters partly through experiments that become possible; access to a professional community matters through collaborations and recognition that may emerge; access to a stable learning environment matters through capabilities that develop over time. The economic object is therefore a pathway rather than a single consumable unit.

Future possibility is path dependent because present participation can alter later access. A first job can generate experience that changes eligibility for later work. A credit relation can create a repayment history that affects future finance. Membership in a standards body can provide information and influence over later technical rules. Participation in a platform can accumulate reputation and audience. These relations create histories that institutions later use when allocating further opportunities. Economic systems thereby convert past relations into conditions of future participation.

Possibility can also be foreclosed. Debt burdens can constrain later choices; restrictive contracts can limit mobility; dependency on proprietary infrastructure can raise switching costs; narrow credential systems can exclude forms of competence that lack recognized representation; concentrated ownership can prevent participants from converting contribution into control. The generative analysis of economic relations therefore requires attention to both expansion and contraction of future option spaces.

The same structure operates collectively. A community that loses a school, clinic, transport link, financial institution, or research facility may lose more than the immediate service. It can lose the relations through which later capabilities and projects would have formed. Conversely, shared infrastructure can generate opportunities that were not specified in the original investment. The return on infrastructure may therefore include emergent activities that could not be enumerated in advance because they depend on subsequent relations among users.

This openness distinguishes generative possibility from prediction. A generative relation can expand the range of feasible futures without determining which future will occur. Educational access can enlarge capability without fixing occupation; scientific infrastructure can enable discoveries without specifying them; social trust can support cooperation without determining its object. GRE is therefore interested in conditions that make later generation possible while retaining contingency in the trajectories that follow.

Future possibility also introduces a distributional problem. Some actors possess wide option spaces because they can draw on wealth, institutions, networks, mobility, and recognized credentials. Others confront narrow spaces even when their current consumption appears similar. A static snapshot can therefore understate inequality when it ignores the unequal capacity to generate future alternatives. The later GRE framework will treat this issue through generative opportunity, value circulation, and justice across time.

The relation between participation and possibility now becomes explicit. Participation is economically generative when it changes the conditions under which later

participation can occur. This gives the final subsection its organizing principle.

1.17.5 Generative Structures of Economic Participation

Economic participation has a generative structure when taking part in an activity changes the participant, the relation, or the surrounding institutional conditions in ways that affect later participation. This formulation extends the conventional focus on what an activity produces immediately. Employment can produce goods and income while also generating skills, reputations, dependencies, and organizational roles. Education can deliver instruction while generating curiosity, competence, social connection, and later access. Research can produce findings while creating instruments, communities, standards, and new questions. Care can meet present needs while sustaining the capacities through which persons participate in future social and economic life.

The generative structure of participation can be analyzed through several dimensions. The first is subject formation: participation can stabilize or transform the identity and position of the participant. The second is capacity formation: participation can generate abilities and resources that persist. The third is relational reproduction: participation can strengthen, weaken, or reorganize relations among actors. The fourth is institutional transformation: repeated participation can alter rules, expectations, and recognized categories. The fifth is option-space transformation: the preceding changes can expand or contract future possibilities.

These dimensions need not move together. A relation can generate productive capacity while reducing autonomy. It can expand organizational capability while concentrating control. It can strengthen trust within a group while increasing exclusion at its boundary. It can create valuable knowledge while producing dependency on infrastructure controlled by another actor. Generativity therefore describes a structure of downstream production rather than a complete normative evaluation. Later chapters address power and justice because the distribution, direction, and control of generative effects require separate analysis.

Participation can also generate relations that were not specified by the initiating objective. Collaboration undertaken to complete a project may produce a durable research network. Shared use of infrastructure may create a community of practice. A cooperative response to crisis may establish institutions that persist after the immediate problem has passed. These outcomes matter because they alter the relational environment from which later economic action begins. The economic significance of participation can therefore exceed the objective under which the activity was initially organized.

The distinction between ordinary relationality and generativity can now be stated positively. Relational analysis asks how actors, organizations, and institutions are connected and constituted through relations. Generative analysis asks how those relations produce changes that become conditions of subsequent economic life. The object includes newly generated subjects, capacities, institutions, relations, constraints, and possibilities. This temporal extension is the reason GRE requires more than a static map of economic relations.

The distinction is especially important under conditions of artificial intelligence

and symbolic abundance. An AI-mediated relation can improve immediate productivity while changing skill formation, professional recognition, dependency, organizational memory, and access to future work. A platform can facilitate exchange while reshaping market entry, reputation, data accumulation, and bargaining power. A transfer can raise present consumption while leaving generative opportunity unchanged, or it can support relations that produce durable capability. The same immediate outcome can therefore sit inside very different generative trajectories.

Generative participation also provides an alternative route for thinking about economic inclusion after the destabilization described in Section 1.15. If productive necessity weakens as a universal basis of social membership, participation can still matter through learning, care, inquiry, creation, cooperation, institution building, and other relations that generate capacities and future possibilities. This observation does not establish a normative programme or an allocation rule. It identifies an economic object that becomes more visible when productive contribution, productive necessity, and meaningful participation no longer coincide automatically.

Section 1.18 develops the analytical consequence. Once economic subjects and capacities are understood as relationally generated, an entity-centered account becomes incomplete whenever internal relations, external relations, relations among relations, downstream effects, or transformations of future generative conditions are required to explain an intervention. The next section therefore specifies the relational and generative limits of entity-centered economics before the chapter turns to the scientific conditions that make more demanding forms of analysis increasingly possible.

1.18 Relational and Generative Limits of Entity-Centered Economics

This section specifies the analytical boundary reached by entity-centered economic description after the historical developments reconstructed in Sections 1.5–1.17. Its role in the chapter is to identify the conditions under which persons, firms, households, states, and other recognized entities remain adequate units of analysis, and the conditions under which additional relational and generative description becomes necessary. The objective is therefore one of scope rather than replacement: entity-centered analysis remains powerful where entity boundaries are stable and the economically relevant effects of an intervention can be represented at the level of the recipient. The discussion proceeds from relations internal to entities, through relations surrounding them and relations among relations, to downstream intervention effects and transformations of future generative conditions. The method is conceptual and comparative, using established work on firms, embeddedness, network organization, global value chains, and entitlement to show that economically consequential structure can reside both within and between recognized entities.

1.18.1 Internal Relations within Economic Entities

An economic entity is often represented by variables attributed to the entity as a whole: income for a household, productivity for a firm, assets for a corporation, expenditure for a public body, or output for a national economy. Such variables are indispensable for comparison and administration. Their adequacy depends, however, on whether the internal relations through which the entity operates can be treated as analytically secondary for the question at hand. When internal organization shapes the conversion of resources into action, the same entity-level quantity can correspond to substantially different economic capacities.

The firm provides the clearest historical example. Coase's classic analysis of the firm begins from the observation that productive activity can be coordinated through authority inside an organization as well as through market exchange across organizational boundaries (Coase 1937). The distinction matters because a firm is more than an owner of inputs. It is a patterned arrangement of authority, employment, information, routines, and contractual relations through which inputs are combined. Two firms holding similar assets can therefore exhibit different productive capacities when their internal coordination, knowledge distribution, worker relations, or organizational routines differ.

Organizational law reinforces this point by stabilizing the entity without exhausting its internal structure. Hansmann and Kraakman show that organizational law supports standardized legal entities partly through asset partitioning, which separates organizational assets and creditor claims from those of owners or managers (Hansmann and Kraakman 2000). This legal boundary is economically consequential because it makes the organization tractable as a bearer of assets and obligations. Yet the boundary does not describe how authority, expertise, risk, reward, and decision rights are distributed inside it. A legally unified corporation can contain highly unequal or internally fragmented relational structures while appearing as one administrative recipient.

Households display a parallel difficulty. A transfer recorded at household level can alter the resources available to the household while leaving open the internal distribution of control, care obligations, time, bargaining position, and effective access. Treating the household as a single recipient can be appropriate for some fiscal or demographic questions and inadequate for questions concerning who can actually command the transferred resources. The general issue is the conversion from entity-level possession to participant-level capability. Where this conversion depends on internal relations, the entity boundary becomes an important part of the explanation rather than a neutral container.

Internal relations also shape the persistence of capacities. Knowledge can be distributed among workers and routines rather than stored in any single individual. Trust can be localized in teams. Authority can be centralized or dispersed. Care obligations can allocate time asymmetrically. Data can be accessible to some organizational positions and unavailable to others. These structures influence what an entity can do even when conventional balance-sheet or resource measures remain unchanged. A relational description therefore becomes useful when variation inside the entity explains variation in action, learning, adaptation, or access that entity-level

quantities cannot capture.

The implication is a scope condition. Entity-centered analysis is strongest when internal heterogeneity does not materially affect the causal or evaluative question. Relational analysis becomes increasingly necessary as internal organization determines the conversion of nominal resources into effective capacities. This does not dissolve the entity. It adds a second analytical resolution at which the entity is reconstructed as a stabilized configuration of relations.

1.18.2 External Relations around Economic Entities

Economic entities also derive capacities from relations that cross their recognized boundaries. Suppliers, customers, creditors, regulators, professional communities, infrastructures, knowledge networks, platforms, and public institutions can alter what an entity is able to produce, access, learn, or survive. Entity-level resources therefore acquire economic meaning partly through the external relations that make those resources usable.

Granovetter's account of embeddedness provides a foundational statement of this problem by showing that economic action is situated in ongoing structures of social relations rather than occurring among atomized actors (Granovetter 1985). The analytical consequence is especially visible where trust, reputation, repeated interaction, or social position affect exchange. A firm with modest internal resources can occupy a highly advantageous position in a dense network of reliable partners, while a better-capitalized firm can remain constrained by weak access, low trust, or peripheral position. Entity attributes and relational position therefore provide distinct information.

Interorganizational production sharpens the distinction. Powell's analysis of network forms of organization identifies arrangements in which reciprocal communication and continuing exchange coordinate activity in ways that are poorly described as either discrete market transactions or internal hierarchy (Powell 1990). Section 1.8 used this literature to reconstruct the expansion of relational production. The present concern is analytical: once production depends on continuing interorganizational relations, a firm's productive capacity cannot be inferred from its owned assets alone. It also depends on the quality, accessibility, and durability of relations through which complementary capabilities are obtained.

Global value chains extend this structure across jurisdictions and organizational scales. Gereffi, Humphrey, and Sturgeon distinguish several governance forms whose emergence depends on transaction complexity, codifiability, supplier capability, explicit coordination, and power asymmetry (Gereffi et al. 2005). The relevant unit of analysis is therefore larger than any one firm. Lead firms, suppliers, standards, logistics systems, contractual practices, and technical interfaces together produce the conditions under which production occurs. An intervention directed toward one participant can propagate through this wider configuration.

External relations are also central to effective command over resources. Sen's entitlement analysis demonstrates that access to food cannot be inferred from aggregate availability alone because persons obtain command through production possibilities, trade opportunities, state entitlements, and other socially recognized channels

(Sen 1981). The same analytical lesson generalizes cautiously: a resource can exist in the environment and remain economically inaccessible to an entity whose relational pathways to it are absent or blocked. Access is therefore a relational condition connecting resources to subjects.

This point becomes particularly important under digital and AI-mediated production. Access to compute, datasets, model interfaces, platforms, payment systems, professional networks, standards, and trusted intermediaries can determine the usefulness of nominally owned assets. External relations can also impose dependency: an organization may appear autonomous at the entity level while relying on a small number of infrastructural or platform relations for essential functions. Relational analysis reveals these conditions without requiring the abandonment of entity-level accounting.

The external limit of entity-centered analysis is reached when economically decisive capacities and constraints arise from position in a relational environment. At that point, the question changes from the quantity of resources held by an entity to the relations through which those resources become actionable, exchangeable, recognized, and reproducible.

1.18.3 Relations among Economic Relations

Economic systems frequently contain structures in which one relation changes the operation of another. These higher-order configurations cannot be represented fully by listing pairwise ties because the economically relevant object is the relation among relations. Credit conditions can alter employment relations; legal classifications can reshape market access; platform rules can mediate buyer–seller relations; professional standards can condition relations between expertise and institutional authority; and ownership structures can change how organizational decisions are connected to labor, investment, and distribution.

The distinction is easiest to see in mediated exchange. A buyer and seller can transact through a platform, yet the terms of their relation depend on a further relation between each participant and the platform. Visibility, ranking, payment, data access, dispute resolution, and reputation can all be mediated through this additional structure. The buyer–seller relation therefore changes when the platform's rules or incentives change even if the two participants remain otherwise identical. The economically significant object is a configuration in which one relation governs, conditions, or transforms another.

Organizations contain similar higher-order structures. A manager's authority over a worker may be conditioned by labor law, collective agreements, professional norms, internal grievance procedures, or algorithmic monitoring systems. A creditor's claim may alter the relation between managers and investment decisions. A shareholder structure can influence how organizational surplus is connected to workers, suppliers, or research expenditure. These arrangements involve several relations whose interaction produces effects that no single dyad carries alone.

Network and value-chain research provides empirical settings in which such configurations become visible. Network forms coordinate relations among organizations through repeated exchange and reciprocal communication (Powell 1990), while

global value-chain governance connects lead-firm coordination, supplier capability, standards, and power asymmetry within structured production relations (Gereffi et al. 2005). A relation can therefore become consequential because of the other relations in which it is embedded. The same supplier tie can generate learning in one network, dependence in another, and exclusion in a third.

This higher-order perspective also clarifies why institutional change can have broad economic effects without transferring resources directly. A change in legal recognition, reporting rules, standards, or eligibility criteria can modify the relations through which many other interactions occur. Section 1.5 showed that legal personality, accounting boundaries, statistics, and administrative recognition stabilize economic entities. The same institutional devices can restructure relations among those entities by changing who may contract, who bears liability, what counts as compliant performance, or which transactions are visible to regulators and counterparties.

Relations among relations create a methodological demand for explicit boundary and scale choices. An analyst can always enlarge the relational map, and no practical inquiry can include every connection. The relevant question is whether omitting a higher-order relation changes the explanation of the outcome under study. GRE therefore treats higher-order analysis as problem-dependent. It becomes warranted where the behavior of a focal relation varies systematically with the configuration of surrounding relations.

The resulting picture remains compatible with entity-level economics. Entities continue to matter as legal, administrative, and organizational condensations. The additional analytical layer concerns the architectures through which their relations are coupled. This layer becomes central whenever intervention in one relation changes the operation of others.

1.18.4 Downstream Effects of Economic Intervention

Entity-centered evaluation commonly begins with a defined intervention and a defined recipient: a transfer to a household, a subsidy to a firm, a loan to an organization, a tax on an income stream, or an investment in a public body. This structure is often appropriate for immediate incidence. Its generative limit appears when the intervention changes relations whose later effects extend beyond the initial recipient and evaluation horizon.

A resource transfer can generate several distinct downstream pathways. It may alter bargaining position, enable entry into a network, support education or training, change creditworthiness, reduce dependence on a particular employer, permit migration, create time for care or inquiry, or allow an organization to invest in standards and relationships that affect later collaboration. Two transfers with the same nominal value can therefore produce different trajectories because they enter different relational configurations.

The distinction between receipt and command is again useful. Sen's entitlement framework shows that resource outcomes depend on socially organized channels through which persons gain effective command (Sen 1981). In a generative setting, the question extends further: effective command at one moment can alter the chan-

nels available later. Access to credit can create a repayment record; access to education can change occupational networks; access to infrastructure can change market participation; access to a platform can generate data and reputation that affect future visibility. An intervention can therefore modify the relations through which later interventions or opportunities are converted into capability.

Downstream effects can also propagate across entities. Support to one firm may sustain suppliers, preserve specialized knowledge, alter local employment, or strengthen a technological standard. A procurement decision can reorganize a supply network. A platform rule can change incentives for thousands of participants. A financial intervention can alter expectations and counterparties beyond its formal recipient. The immediate recipient remains administratively important, while the causal object expands to include the relational pathways through which the intervention propagates.

Evaluation horizons shape whether these effects appear. A short-horizon assessment may correctly report immediate consumption, output, employment, or solvency while omitting changes in learning, trust, dependency, network position, institutional access, or option availability that emerge later. Longer horizons create their own uncertainty and attribution problems. GRE therefore does not presume that downstream effects can always be measured precisely. It treats temporal extension as a question of analytical adequacy: when plausible downstream mechanisms are central to the intervention's significance, the evaluation should state which are included, which are excluded, and what evidential confidence attaches to them.

The same discipline applies to negative downstream effects. An intervention can create dependency, crowd out alternative relations, increase concentration, lock participants into proprietary infrastructure, or shift risk to actors outside the original evaluation boundary. Entity-centered accounting may record a local gain while relational analysis detects a redistribution of constraint elsewhere. Such cases are especially important when the initial recipient and the later bearer of cost are different entities.

Downstream analysis therefore changes the unit of evaluation from a recipient-state pair to a trajectory through a relational system. The intervention remains identifiable, and the recipient remains important, yet the relevant economic question includes what relations the intervention forms, strengthens, weakens, or redirects over time.

1.18.5 Transformation of Future Generative Conditions

The deepest limit of entity-centered analysis appears when economic activity changes the conditions under which future economic activity can be generated. At this point the object is no longer only a downstream outcome. It is the transformation of the relational, institutional, material, or epistemic conditions that structure later possibilities.

Capacity formation provides one route. A relation can generate skills, trust, organizational routines, infrastructure, or shared knowledge that later activities presuppose. Section 1.17 described these processes as generative because participation changes what subjects and institutions can subsequently do. The same logic applies to

constraints. A relation can produce dependency, exclusion, standardized interfaces, proprietary lock-in, debt obligations, or institutional classifications that narrow later options. Generativity therefore includes the production of enabling and constraining conditions.

Institutional persistence amplifies these effects. Once a relational arrangement is stabilized through law, accounting, standards, administrative categories, or organizational routines, it can shape later transactions that were absent from the original decision. A financing rule can influence which organizations survive long enough to innovate. A credentialing system can determine who enters a profession. A platform's data architecture can shape later visibility and bargaining power. A property regime can influence which forms of cooperation or exclusion become ordinary. These structures operate as inherited conditions for actors who did not choose their initial form.

The transformation of future conditions is especially important for value and allocation. A present allocation can generate capacities that increase later access to resources, or it can support relations whose benefits circulate beyond the initial recipient. Conversely, a present extraction can weaken the relations required for future generation even when current output remains high. The later Parts of this book develop these questions through relational allocation, heterogeneous value, generative return, spacetime, power, and justice. The historical argument of the present chapter is narrower: contemporary economic organization increasingly makes these future-conditioning effects difficult to treat as peripheral.

Artificial intelligence intensifies the issue because current arrangements can shape the distribution of future productive intelligence. Decisions about compute, data, model access, research infrastructure, intellectual property, standards, and institutional participation can influence which actors are able to learn from and contribute to later technological development. Immediate productivity effects are therefore only one dimension of the economic significance of AI-related investment and allocation. The configuration of relations around artificial productive capacity can alter the future distribution of capability itself.

A generative analysis also requires restraint. Future conditions are uncertain, relational pathways branch, and interventions can produce unintended effects. Strong claims about long-horizon generation therefore require stronger evidence than descriptions of present allocation. GRE's later methodology distinguishes association, enablement, contribution, co-generation, and stronger forms of attribution so that temporal extension does not become speculative license. The present section establishes only the analytical reason for asking the question.

The resulting scope condition can be stated positively. Entity-centered economics remains highly effective when the relevant outcomes are well represented by attributes of recognized entities within a specified horizon. Relational analysis becomes necessary when internal organization, external position, or higher-order relational structure materially affects those outcomes. Generative analysis becomes necessary when present relations transform the subjects, capacities, constraints, institutions, or possibilities through which later economic life unfolds. These analytical layers are complementary resolutions of economic reality rather than mutually exclusive schools.

This distinction completes the historical movement from the modern entity-centered order reconstructed in Sections 1.3–1.6 to the relational and generative problems made increasingly visible by globalization, digital mediation, artificial intelligence, symbolic abundance, and changing subjecthood. Sections 1.19 and 1.20 now turn from historical necessity to historical possibility: the scientific formalisms, computational resources, and analytical vocabularies that make more demanding relational and generative inquiry increasingly feasible.

1.19 Scientific Conditions for Relational Analysis

This section identifies the scientific conditions that have made relational economic analysis increasingly tractable. Its role in the chapter is historical and methodological: the preceding sections established why contemporary economic problems increasingly exceed an exclusively entity-centered description, while the present section asks which analytical developments make more explicit study of relations feasible. The objective is to specify a repertoire rather than to prescribe a single formalism. The discussion proceeds from dynamical systems and complex-systems approaches to network and higher-order representations, field-based descriptions, and multiscale or background-sensitive formalisms. Each subsection distinguishes the analytical possibility supplied by a scientific language from the stronger claim that economic reality literally possesses the ontology of the formal system used to describe it.

1.19.1 Dynamical Systems

Dynamical-systems theory enlarges economic analysis by making trajectory, stability, feedback, and qualitative change explicit objects of study. A static description records the state of an economic entity or relation at a selected moment. A dynamical description asks how that state changes, which states are reachable from it, which configurations persist after disturbance, and how local changes accumulate along a trajectory. The analytical language is mature across the natural and applied sciences, where nonlinear systems are studied through state spaces, flows, fixed points, periodic behavior, bifurcations, and sensitivity to initial conditions (Strogatz 2024). Its relevance to relational economics lies in the possibility of treating relations and relational configurations as time-indexed variables whose evolution matters to the economic outcome.

The gain is especially clear when a relation has memory. Employment relations accumulate experience and expectation; credit relations acquire repayment histories; supply relations generate specialized routines; platform relations accumulate reputation and data; institutional relations carry prior classifications into later access. A cross-sectional description can identify that a relation exists, while a dynamical description can ask how its present form depends on the path by which it was reached. The trajectory becomes economically relevant because two configurations that appear similar at one moment may respond differently to later disturbance when their histories have generated different capacities, expectations, or constraints.

Dynamical systems also provide a precise distinction between stability and value.

Stability concerns how a configuration responds to perturbation. It does not establish that the configuration is efficient, just, desirable, or generative. This distinction is important for GRE because persistent economic structures can include durable cooperation, durable exclusion, resilient infrastructure, or resilient dependency. A dynamical description can characterize persistence without silently converting persistence into normative endorsement.

Nonlinearity further expands the range of analyzable relational phenomena. When the effect of one relation depends on the state of other relations, aggregate behavior may fail to equal a simple sum of isolated effects. Feedback can amplify or damp disturbances; thresholds can make similar interventions consequential in one configuration and negligible in another; interaction among several processes can produce regime changes absent from any component considered separately. Such possibilities matter in economies organized through interdependent firms, financial claims, standards, infrastructures, and institutional expectations.

The methodological contribution remains bounded. A dynamical model requires a defensible specification of states, variables, boundaries, and transformation rules. Social and economic systems also include reflexive subjects whose interpretation of a model can enter the subsequent dynamics. The availability of dynamical-systems theory therefore establishes a scientific possibility: economic relations can be studied as evolving configurations rather than as static background conditions. It does not by itself establish which dynamical representation is appropriate to a particular economic problem. That question belongs to model construction, evidence, and later methodological chapters.

1.19.2 Complex Systems

Complex-systems research provides a second condition for relational analysis by directing attention to systems whose macroscopic behavior depends on interaction among heterogeneous, adaptive, and partially autonomous components. The relevant scientific shift is analytical rather than terminological. A system can display regularities at one scale that are difficult to infer from isolated components because interaction, feedback, adaptation, and boundary formation contribute to the collective pattern. Holland's work on complex adaptive systems, for example, treats signals, boundaries, and evolving organization as central to the behavior of systems ranging from biological organization to markets and governments (Holland 2012).

For economic analysis, this perspective weakens the presumption that explanation must begin and end with attributes of independently specified units. Firms can adapt to competitors and regulators; households respond to institutions and changing prices; standards alter which technologies are compatible; market participants learn from one another; organizations modify routines in response to observed outcomes. The state of one participant is therefore partly conditioned by a surrounding configuration that is itself changing in response to participants. Complexity-oriented analysis provides a vocabulary for studying this reciprocal dependence without requiring that every collective regularity be reduced immediately to a single representative agent or equilibrium condition.

The approach also makes heterogeneity analytically productive. Differences

among actors in resources, expectations, information, capabilities, and network position can affect system-level behavior because interaction transmits and transforms those differences. Heterogeneity can produce clustering, specialization, segmentation, cascades, or uneven adaptation. In a relational economy, the distribution of positions can therefore matter as much as an average attribute. A system composed of actors with the same mean income, skill, or productivity can exhibit different dynamics when the relations among them differ.

Complex-systems approaches are particularly useful for distinguishing local rule from global pattern. A participant may act according to a relatively simple decision rule while the aggregate configuration exhibits persistence, volatility, concentration, or coordination that no participant designed. This possibility resonates with the historical argument developed earlier in the chapter. Modern economic institutions often generate structures whose consequences exceed the horizon of the actors participating in them. The scientific significance of complexity research is that such distributed generation can be represented and investigated without assigning the collective pattern to a central designer.

Adaptation introduces another important dimension. Economic actors respond to outcomes, and their responses alter the environment to which later actors adapt. The resulting feedback can change the effectiveness of a rule over time. A regulatory threshold, ranking metric, trading strategy, or recommendation system can have one effect before widespread adaptation and another after participants reorganize around it. Complexity-oriented analysis therefore encourages researchers to treat observation, strategy, and institutional response as potentially endogenous components of the system.

The term *complexity* can easily become too broad to discipline analysis. GRE therefore uses complex-systems language only when the local problem exhibits the relevant structure: interaction, heterogeneity, feedback, adaptation, multilevel organization, or emergent collective regularity. Complexity is a scientific resource for relational inquiry rather than an explanation by itself. Its historical importance lies in the development of formal and computational methods capable of treating interdependence as a primary analytical object.

1.19.3 Network and Higher-Order Models

Network science provides the most direct formal language for representing economic relations among identifiable entities. Nodes represent analytically specified units and edges represent specified relations among them. Once such a representation is justified, analysis can address connectivity, centrality, clustering, community structure, path length, assortativity, diffusion, robustness, and the interaction between network topology and dynamical processes. Newman's review of complex networks documents the development of these concepts across social, technological, and biological systems and emphasizes the study of both network structure and dynamics on networks (Newman 2003).

The relevance to economics is immediate because many economic phenomena already have relational form. Credit links connect borrowers and lenders; supply chains connect buyers and suppliers; ownership links connect shareholders and

firms; labor mobility connects organizations; communication links connect teams; trade links connect jurisdictions; platform relations connect several participant groups through an intermediary. A network representation can therefore preserve relational information that disappears when each entity is summarized only by its own attributes.

Network models also make positional effects explicit. Two firms with similar observable resources can occupy very different positions in a supply network. Two researchers with similar individual capabilities can have different access to knowledge because their collaborative neighborhoods differ. Two households with similar income can face different opportunity structures because transport, care, credit, or social-support connections differ. In each case, an entity-level variable remains relevant, while network position adds information about the pathways through which resources, risks, information, and opportunities can move.

Pairwise networks have a clear limitation: many economic relations involve groups, institutions, or coordinated sets of participants whose effects cannot be represented adequately as collections of independent dyads. A project consortium, household, standards committee, cooperative, research team, or multilateral agreement can impose conditions on a group as a group. Higher-order network research has developed explicit representations for such cases through hypergraphs, simplicial complexes, and related structures. Battiston and colleagues survey this literature and show that interactions among three or more units can generate dynamical behavior that is not captured by pairwise links alone (Battiston et al. 2020).

Higher-order models are especially relevant to the GRE concern with relations among relations. A contract can depend on a regulatory institution; a supply relation can depend on a standard jointly maintained by several organizations; a worker's access to employment can depend on credentialing relations linking educational institutions, professional bodies, and employers. Such structures can be flattened into pairwise edges, but flattening can erase the condition that the relevant effect exists only when several relations are jointly present. Higher-order representations make that joint dependence visible.

These models nevertheless remain representations. Nodes must be chosen, edges must be defined, interaction order must be specified, and the temporal stability of the representation must be justified. A legal entity, household, platform account, institution, or community can function as a node for one question and as an internally structured relational system for another. Network analysis therefore does not eliminate the boundary problem; it renders the boundary decision explicit and makes its consequences inspectable. This is a scientific advance because relational structure can be formalized, compared, and tested while preserving awareness that the graph is an analytical construction.

1.19.4 Field-Based Representations

Field-based representations become useful when economically relevant conditions are distributed across a domain and cannot be localized adequately in a finite set of isolated links. In mathematics and mathematical physics, field descriptions assign quantities to locations in a continuous or discretized domain and study how

local states vary, interact, and propagate. Partial differential equations provide a developed formal language for representing such spatially or continuously distributed dynamics, including nonlinear propagation, diffusion, transport, and wave-like processes (Evans 2010). GRE draws from this scientific repertoire at the level of representation: some economic conditions may be better described as distributed environments than as attributes attached to individual entities.

Several economic objects have this character. Accessibility can vary continuously across geographic space; labor-market opportunity can depend on local density and transport; information exposure can vary across communication environments; regulatory intensity can differ across jurisdictions; trust or reputational climate can be unevenly distributed; infrastructure can create gradients of connection and cost. In such cases, the relevant condition surrounds many actors at once and changes the consequences of local relations. A field representation can encode this distributed context without assigning the whole effect to one neighboring entity.

Field language also helps distinguish a relation from the conditions under which the relation operates. The same contractual form can have different consequences in regions with different institutional capacity. The same amount of credit can generate different outcomes where market access differs. The same platform rule can affect participants differently when local alternatives, network density, or legal protections vary. Treating the surrounding condition as a field makes it possible to model systematic variation in relational effect across position.

The approach can be extended beyond geographic space when the relevant domain is abstract. A field can be defined over a state space, capability space, or other structured domain if distance and neighborhood have defensible meanings. Such constructions can represent how similar configurations experience similar pressures or how local changes propagate through a structured possibility space. Their usefulness depends on whether the chosen geometry captures an empirically meaningful relation rather than merely providing a visually attractive mathematical surface.

Field-based representation therefore carries a stronger burden of justification than ordinary metaphor. A model must specify what the field variable represents, what domain indexes it, what counts as locality, how interactions propagate, and how the representation connects to evidence. GRE's ontological suspension is important here. The success of a field model would show that a distributed representation is analytically productive for a given problem; it would not establish that an economy is literally a physical field. The scientific condition consists in the availability of mature mathematics for distributed, locally coupled systems and in the possibility of adapting that mathematics under explicit domain-specific assumptions.

1.19.5 Multiscale and Background-Sensitive Formalisms

Relational economic systems operate across several scales at once. Individuals participate in households, organizations, networks, institutions, markets, jurisdictions, and transnational systems; processes at each level can constrain or enable processes at others. Multiscale analysis supplies concepts for studying how organization, variation, and response differ across scale rather than assuming that one analytical resolution is sufficient. Bar-Yam's multiscale treatment of complex systems formalizes the

idea that effective response depends on matching the scale of variation in a system and has been applied to biological and social organization (Bar-Yam 2004).

The economic importance of scale is visible in ordinary examples. A workplace policy can affect an individual immediately while altering organizational culture slowly. A local supply disruption can propagate into sectoral production when many firms share dependencies. A financial position can be safe at the level of one institution while contributing to correlated systemic exposure. A household decision can be rational under prevailing prices while repeated decisions across many households alter the market conditions on which those choices depended. Relational analysis therefore requires the ability to move among levels without presuming that a pattern observed at one scale can be transferred unchanged to another.

Multiscale formalisms also clarify why aggregation can both reveal and conceal. Coarse-graining can expose collective regularities invisible at the level of individual events, while the same operation can erase heterogeneity and local dependence that matter to causal interpretation. Disaggregation can recover local structure while making system-level constraints harder to see. The choice of scale is therefore part of the model rather than a neutral technical detail. A relational account should report which distinctions are preserved at the selected resolution and which are suppressed.

A related scientific development concerns formalisms in which the background against which dynamics unfold is itself allowed to vary. General relativity provides a paradigmatic case: spacetime geometry is dynamical rather than a fixed stage, and background-independent approaches in gravitational physics develop descriptions in which the geometry relevant to motion is part of the system being modeled (Rovelli 2004). GRE does not infer a social ontology from this physical result. The methodological significance is narrower: modern science contains coherent formalisms in which the structure conditioning local dynamics need not be treated as permanently external and fixed.

This possibility matters for relational economics because economic backgrounds are often historically produced. Market boundaries change; infrastructures are built and abandoned; legal categories are revised; standards alter compatibility; platforms reorganize access; institutions modify the relations they regulate. A model that holds the surrounding structure fixed can be adequate over a limited interval, while a longer-horizon analysis may need the background itself to become variable. Section 1.20 develops this issue in generative terms by asking how states, relations, constraints, and transformation rules can coevolve.

Background sensitivity also disciplines comparison. A relation observed in one institutional setting may not preserve its effects when transplanted into another because the surrounding rules, infrastructures, histories, and scales differ. Formal models can represent this contextual dependence through parameters, boundary conditions, changing topology, or evolving geometry. The appropriate device depends on the problem. The common principle is that the relation cannot always be interpreted independently of the structure in which it is embedded.

The scientific opening described across this section is therefore plural. Dynamical systems make trajectories and stability analyzable; complex-systems approaches make interaction, heterogeneity, feedback, and adaptation central; networks and

higher-order models represent explicit relational structure; field approaches represent distributed conditions; multiscale and background-sensitive formalisms permit analysis across levels and under changing contextual structure. None of these formalisms establishes GRE by itself. Together they change the historical feasibility of a relational economics by providing mathematical and conceptual languages in which relations can become explicit objects of analysis. Section 1.20 turns to the stronger problem of generativity, where the analytical task includes the endogenous transformation of the structures and rules through which later economic change occurs.

1.20 Scientific Conditions for Generative Analysis

This section identifies the scientific conditions that make generative economic analysis increasingly possible. Its role in the chapter is to move beyond the explicit representation of relations developed in Section 1.19 toward a stronger analytical problem: economic relations can change the structures, constraints, and transformation rules under which later economic activity occurs. The objective is to specify the scientific languages capable of representing this endogeneity without treating every historical change as an instance of one universal mechanism. The discussion proceeds through endogenous dynamics, structure-changing processes, path dependence, coevolution, and the evolution of transformation rules. The method is comparative and conceptual. It draws on evolutionary economics, institutional economics, path-dependent dynamics, and complex-adaptive-systems research to identify analytical possibilities that later GRE chapters may formalize more precisely.

1.20.1 Endogenous Dynamics

Generative analysis begins where the conditions of change enter the dynamics being studied. A model can describe an economic system dynamically while leaving its transformation law fixed: prices, quantities, employment, or network positions may change through time according to a stable rule. Such a model is already richer than a static comparison because it represents trajectories. Generative analysis asks a further question. Economic activity can alter the conditions that shape later activity, so the variables governing subsequent change may themselves become endogenous to the history of the system.

Evolutionary economics supplies a developed precedent for this orientation. Nelson and Winter organize economic analysis around processes in which firm behavior, routines, search, innovation, and competitive selection jointly determine industrial change through time rather than around instantaneous optimization toward a predetermined equilibrium (Nelson and Winter 1982). The analytical importance of this move for GRE lies in its treatment of economic behavior and industrial structure as mutually consequential. Firms act within inherited routines and market conditions, yet search, innovation, imitation, investment, and differential survival can alter the distribution of routines and capabilities that later firms confront.

Endogeneity in this stronger sense can appear through several channels. Learning can change an actor's future response to a similar situation. Investment can create infrastructure that changes the feasible action set. Repeated exchange can build trust

or dependency. Regulation can produce new categories to which future regulation refers. Platform participation can generate data that improve the platform's later matching or ranking capability. A subsidy can expand a technology sufficiently to lower its later cost, and the lower cost can alter subsequent adoption. In each case, present activity modifies a condition relevant to the next round of activity.

Institutional economics adds another level of endogeneity. North treats institutions as humanly devised constraints that structure political, economic, and social interaction while also developing an account of institutional change in which organizations, incentives, and accumulated choices affect the evolution of those constraints (North 1990). This creates an analytical loop important for GRE: institutions condition economic action, economic action generates incentives and organizational responses, and those responses can contribute to institutional persistence or transformation. The conditioning structure therefore belongs to the history of the system rather than remaining permanently external to it.

Endogenous dynamics should still be specified locally. Some constraints can remain effectively fixed over the time horizon of a study; some institutional changes arrive through exogenous shocks; some actor responses are well represented by stable rules. GRE therefore does not require every model to endogenize every background condition. The scientific condition established here is the availability of frameworks in which a conditioning variable can become part of the dynamics when the research question requires it. This possibility is the first step from relational description toward generative analysis.

1.20.2 Structure-Changing Processes

Generative economic processes can alter more than the values attached to a fixed set of variables. They can change the structure through which variables are related. A supply relation can be created or terminated; a firm can merge with another; a market can acquire a platform intermediary; a legal category can make a new organizational form available; an infrastructure investment can connect previously separated regions; a technological standard can render previously incompatible components interoperable. The analytical object is therefore sometimes a changing architecture rather than movement inside an unchanged architecture.

This distinction matters because parameter adjustment and structural change carry different implications. A fall in a transaction cost changes the strength of an existing relation. The creation of a new intermediary changes which relations exist and how other relations are routed. A wage increase changes the terms of an employment relation. The legal recognition of a new form of worker, firm, property, or digital asset can change the categories through which economic relations are constituted. Generative analysis requires formalisms capable of representing these alterations in topology, membership, boundary, rule, or institutional status.

Evolutionary approaches again provide an important scientific precedent. Nelson and Winter's framework treats technological and organizational change as processes in which variation, search, selection, and retained routines can alter the composition and behavior of industries over time (Nelson and Winter 1982). Complex-adaptive-systems research broadens the representational possibility by treating signals, bound-

aries, and hierarchical organization as structures that can themselves develop and reorganize (Holland 2012). These traditions differ in object and formal detail, yet both make structural transformation an analytical problem rather than a residual category for changes that a fixed-state model cannot absorb.

Network and higher-order models discussed in Section 1.19 can also be made generative when the relational topology evolves. Nodes may enter or leave; edges may form, strengthen, weaken, or dissolve; higher-order groups may assemble or fragment; network position can affect the probability of subsequent tie formation. The same principle applies beyond networks. Field boundaries can shift, institutional classifications can be rewritten, and the scales at which coordination occurs can change. The scientific requirement is a representation in which the structure at one time can influence, and be influenced by, the processes unfolding within it.

Structure-changing analysis also disciplines causal interpretation. When an intervention alters the architecture through which later effects propagate, the relevant causal question extends beyond the immediate response of a fixed system. The intervention may create new channels of diffusion, new dependencies, new exclusion boundaries, or new organizational capacities. Two interventions with identical short-term outputs can therefore generate different long-term trajectories when one leaves the surrounding structure unchanged and the other rewrites it. This distinction becomes central later in GRE's treatment of relational allocation and generative value.

1.20.3 Path Dependence and Historical Trajectories

Generative analysis requires historical trajectories because the effect of a present relation can depend on the sequence through which the current configuration was produced. Path dependence provides a scientific language for this dependence on prior development. Arthur's analysis of competing technologies shows how increasing returns can make early events consequential for later adoption and can produce lock-in under specified conditions (Arthur 1989). The contribution is methodological as much as substantive: a historically contingent event can matter because it changes the returns, expectations, compatibility relations, or learning environment confronting later choices.

A path-dependent account differs from a simple statement that history matters. The relevant claim identifies a mechanism through which earlier events alter later transition possibilities. Increasing returns, sunk investments, institutional complementarity, network effects, learning, or accumulated expectations can make the consequences of an action depend on when it occurs and on what has occurred before. A trajectory therefore contains information that a comparison of endpoints can lose.

Institutional development displays the same structure in a different register. North's account of institutional change emphasizes that existing institutions shape the incentives and organizations through which later change proceeds, giving institutional development a cumulative and historically conditioned character (North 1990). The implication for GRE is that economic relations can inherit constraints generated by earlier relations even after the original circumstances have disappeared. Ownership forms, labor classifications, accounting conventions, technical standards, transport networks, and financial infrastructures can continue structuring action

because later investments and expectations have formed around them.

Historical trajectories also permit branching. A configuration can support several feasible continuations, and relatively small differences in timing, sequencing, or local interaction can direct development toward different regions of the possibility space. This does not require the claim that every historical outcome is radically contingent. Some paths are strongly constrained; others are open across a wider range. Generative analysis therefore benefits from distinguishing structural persistence, path dependence, branching possibility, and exogenous disturbance rather than placing all historical change under a single label.

For GRE, the importance of path dependence extends to value and subject formation. Skills acquired under one technological regime can shape access to the next. A reputation accumulated in one institutional setting can affect later credit or employment. A community's prior exclusion can constrain current participation even after formal barriers are removed. A platform's early relational centrality can attract further participants and data. The generative consequence of a relation is therefore partly temporal: it can modify the conditions under which later relations become possible, valuable, or difficult to escape.

Path dependence also has a methodological limit. Lock-in claims can be too easily inferred retrospectively from persistence alone. Arthur's mechanism depends on specific increasing-return processes rather than on the mere fact that one outcome endured. GRE should therefore identify the mechanism through which prior states affect later transition probabilities, costs, or available options. Historical narrative and formal path dependence can complement one another only when the connection between sequence and later constraint is made explicit.

1.20.4 Coevolution of States, Relations, and Constraints

A generative economic system can contain several mutually changing layers. Actor states change, relations among actors change, and the constraints governing those relations change. Treating these layers separately can be useful for local analysis, while longer-horizon explanation often requires their coevolution. The scientific challenge is to represent feedback across layers without assuming that one layer permanently determines the others.

Consider an employment system. Workers acquire skills and experience; firms reorganize tasks and technologies; labor-market relations alter bargaining positions and mobility; legal institutions revise classifications and protections; training systems respond to changing demand. Each layer conditions the others. A change in technology can alter the value of a skill, which changes hiring patterns, which changes incentives for training, which changes the future distribution of skills, which can alter the technologies firms find profitable to adopt. A single state variable can describe one slice of this process, while a coevolutionary account follows the reciprocal modification of several kinds of structure.

The same logic applies to finance, platforms, and knowledge systems. Credit histories influence lending relations, lending relations shape investment, investment changes productive capability, and new capabilities alter future creditworthiness. Platform rules shape interaction, participant behavior generates data, data influence

algorithmic ranking, and revised ranking changes participant behavior. Research institutions allocate attention and resources, resulting inquiry changes the stock of knowledge, and new knowledge changes which questions appear feasible or valuable. In each case, generative relations operate through recursive coupling among state, relation, and constraint.

Complex-adaptive-systems research supplies conceptual resources for such recursive organization. Holland's treatment of evolving signals and boundaries emphasizes that adaptation can occur through changing interactions and organizational structures rather than through movement of an isolated variable alone (Holland 2012). Evolutionary economics similarly treats behavior, search, capability, and competitive structure as historically linked processes (Nelson and Winter 1982). GRE draws from these approaches a methodological possibility: the object of explanation can be a coupled trajectory in which the units, relations, and constraints relevant to later behavior are partly generated by earlier behavior.

Coevolution also limits simple attribution. When several layers change together, a downstream outcome can be jointly generated by processes that are difficult to isolate as independent causes. A regulatory change may alter firm behavior only because technological capabilities have changed; a technological opportunity may matter only because institutions recognize a new organizational form; a new organizational form may diffuse only because financing relations support it. Generative analysis therefore requires language for contribution, enablement, mediation, and co-generation in addition to strong single-cause attribution. Later methodological chapters develop those distinctions explicitly.

The coevolutionary perspective remains compatible with analytical decomposition. Researchers can hold some layers fixed to study a local mechanism, compare periods in which one layer changes faster than another, or construct reduced models for particular questions. The crucial scientific advance is the ability to relax those simplifications when they become explanatorily consequential. States, relations, and constraints can be modeled as jointly historical objects rather than as permanently separated levels.

1.20.5 Evolution of Transformation Rules

The strongest form of generative analysis treats the rule governing change as historically variable. A conventional dynamical representation specifies how a current state is transformed into a later state under a given transition rule. Many economic applications can legitimately hold that rule fixed over the period of interest. A generative system can require another level of description when learning, institutional change, technological innovation, or reflexive adaptation modifies the rule through which subsequent states are produced.

Economic routines provide a concrete illustration. Nelson and Winter treat organizational routines as persistent elements of firm behavior while also giving search and innovation a role in changing the routines and capabilities that shape later behavior (Nelson and Winter 1982). The analytical implication is subtle. A firm's current action may be generated by an inherited routine, while the outcome of that action can contribute to search, learning, imitation, or selection that changes the routine governing

future action. The transformation process therefore has a history of its own.

Institutional rules exhibit a similar recursion. Property definitions, accounting standards, eligibility criteria, contractual forms, and regulatory classifications can shape economic action. Repeated use of those rules can generate disputes, workarounds, constituencies, complementary investments, or new information that later motivates rule revision. Once revised, the institution changes the mapping from economic circumstance to permitted or rewarded action. Institutional change is therefore generative in a stronger sense when it alters the rule through which later economic relations are constituted or evaluated.

Adaptive digital systems make this issue especially visible. A ranking or recommendation rule can be updated from observed behavior; participants then adapt to the updated rule; their adaptation generates new observations that affect subsequent updates. The operative transformation rule is consequently embedded in a feedback process. Economic analysis that treats the algorithm as a fixed parameter can be adequate for a short interval, while analysis of longer-run behavior may need to represent the update procedure, participant adaptation, and institutional oversight as part of the system.

The evolution of transformation rules marks the boundary between a merely dynamic account and the more demanding conception of generativity developed in this book. Generativity does not require that every transformation rule change continuously. It requires analytical openness to the possibility that present relations can modify the mechanisms, constraints, classifications, or rules through which future relations are produced. This is the scientific condition that later permits GRE to study economic spacetime as historically generative rather than as a fixed arena containing changing entities.

The section's five conditions can now be stated together. Endogenous dynamics make conditioning variables part of the process; structure-changing models allow relational architectures to evolve; path dependence gives prior trajectories causal relevance; coevolution links changing states, relations, and constraints; evolving transformation rules make the mechanisms of change themselves historical objects. These scientific resources do not yield a complete generative economics, and none supplies a universal formalism. They establish a historical possibility: contemporary economic analysis possesses increasingly developed languages for asking how economic activity changes the conditions of its own continuation. Section 1.21 turns from scientific form to computational capacity and asks what makes these richer representations practically analyzable at scale.

1.21 Computational Conditions of Contemporary Analysis

This section identifies the computational conditions that make the richer scientific representations introduced in Sections 1.19 and 1.20 practically analyzable. Its role is distinct from the previous two sections. Scientific formalisms establish that relational and generative structures can be represented; computational infrastructures determine whether those representations can be explored at useful scale, temporal resolution, and heterogeneity. The objective is to reconstruct a historical shift in fea-

sible economic inquiry rather than to equate computational power with explanatory adequacy. The discussion proceeds from the expansion of computational capacity to large-scale simulation, dynamic network computation, agent-based and multiscale modeling, and emerging paradigms that make increasingly complex models differentiable, composable, and computationally tractable. Throughout, computational feasibility is treated as an enabling condition for inquiry rather than as evidence that a model is empirically correct.

1.21.1 Expansion of Computational Capacity

The first computational condition is the sustained expansion of the scale at which numerical procedures can be executed. Gordon Moore's 1965 observation concerning rapidly increasing component density in integrated circuits became a historical marker for a broader technological trajectory in which increasingly capable processors, memory systems, storage, networking, and software infrastructures reduced the cost of many forms of computation (Moore 1965). The significance for economic analysis lies less in any single hardware metric than in the resulting expansion of the model classes that can be investigated routinely.

Earlier analytical methods often benefited from strong reductions because computational constraints made large heterogeneous systems difficult to represent directly. Representative agents, aggregate state variables, stationary environments, sparse interaction structures, and short simulation horizons can all be theoretically justified in appropriate domains. They also reduce computational burden. As computational capacity expands, however, some reductions become choices rather than unavoidable technical necessities. Researchers can preserve more heterogeneity, maintain explicit interaction structures, examine longer trajectories, repeat analyses across parameter configurations, and compare several model specifications rather than committing immediately to a single reduced representation.

The increase in feasible computation changes the relation between model complexity and empirical discipline. A richer model can carry more of the structure that the research question considers consequential: multiple actor types, institutional rules, evolving networks, spatial structure, delayed effects, and several temporal scales. The same computational expansion also makes it easier to construct models whose internal complexity exceeds their evidential support. The historical opening is therefore double. More relational structure can be represented, while the space of underdetermined models also becomes larger.

Computation further changes the practice of uncertainty analysis. A model need not be examined at one parameter vector or under one deterministic scenario. Ensembles can explore sensitivity to initial conditions, stochastic shocks, behavioral rules, boundary assumptions, and alternative institutional specifications. This makes uncertainty more explicit when the ensemble is designed around substantively meaningful alternatives. It can also create an appearance of comprehensiveness when the sampled alternatives omit the main source of uncertainty. Computational abundance expands the set of questions that can be asked; it does not decide which uncertainties deserve representation.

For GRE, the main historical consequence is that relational detail has become less

dependent on analytical compression than in earlier computational environments. A model can increasingly retain the identity of several classes of relations, preserve temporal ordering, and follow feedback across scales. This capacity does not remove the need for abstraction. It changes the reason for abstraction: simplification should be defended by the analytical role it serves rather than by computational necessity alone.

1.21.2 Large-Scale Simulation

Simulation provides a second computational condition because it allows researchers to investigate systems whose aggregate consequences are difficult to derive analytically from local rules. Epstein and Axtell's *Growing Artificial Societies* provided an influential demonstration in the social sciences by constructing artificial populations in which macro-level patterns emerge from repeated interaction among heterogeneous agents (Epstein and Axtell 1996). The methodological importance of this approach lies in the ability to make an explicit set of micro-level rules generate a trajectory that can then be inspected, perturbed, and compared with alternatives.

Large-scale simulation is especially useful when a research question concerns interaction effects. A rule governing one actor may have little meaning in isolation because its consequences depend on the simultaneous behavior of many others. Credit defaults can propagate through balance-sheet relations; supply interruptions can move through production networks; migration decisions can alter local opportunity structures; institutional rules can induce adaptation that changes the effect of the rule itself. Simulation permits these interactions to be represented as processes rather than collapsed immediately into an equilibrium condition or comparative-static result.

The growth of computational capacity also makes repeated simulation more important than a single illustrative run. A stochastic model can be executed across many seeds; a parameterized model can be explored across ranges; several institutional designs can be compared under the same disturbance; rare but consequential trajectories can be searched for rather than assumed absent. Such ensembles are particularly relevant to generative analysis because the object of interest may be a distribution of possible trajectories, the frequency of transition between regimes, or the conditions under which a local perturbation produces a system-level effect.

Simulation also supports counterfactual reasoning under explicit assumptions. A model can compare a historical baseline with altered network structure, different access rules, alternative timing, or modified institutional constraints. The comparison is valuable because it forces the counterfactual mechanism to be stated operationally. Its evidential standing remains conditional. A simulated counterfactual shows what follows within the model from the altered assumptions; it does not establish that the real economy would have followed the same path. Calibration, validation, historical plausibility, and comparison with observed trajectories remain separate tasks.

This distinction is essential for GRE. Simulation can make generative hypotheses visible by showing how a proposed relational mechanism could produce a downstream configuration. It can also reveal that an intuitively plausible mechanism fails to generate the expected effect once interactions and feedback are made explicit.

Both outcomes are useful. Neither converts synthetic output into empirical confirmation. Computational simulation is therefore best understood as a controlled environment for mechanism exploration, sensitivity analysis, and the comparison of possible trajectories.

1.21.3 Dynamic Network Computation

Network analysis becomes more powerful when computation can follow relations that change through time. A static network records a topology for a selected interval. Many economic relations, however, form, dissolve, recur, switch direction, or change weight. Temporal-network research formalizes this problem by representing contacts or ties with explicit timing and duration, making the order of interactions part of the analytical object (Holme and Saramäki 2012). The computational condition is important because temporal ordering substantially enlarges the information required to describe a network and the number of possible paths through it.

Dynamic network computation changes several familiar economic questions. In finance, the relevant exposure structure can evolve as positions are opened and closed. In production, suppliers can be replaced, duplicated, or vertically integrated. In labor markets, workers move among organizations and carry skills and information across firm boundaries. On digital platforms, recommendation, ranking, and participant behavior can change the effective network on a much shorter timescale. The economic consequence of a relation can therefore depend on when it exists, what preceded it, and which other relations are simultaneously active.

Temporal computation also makes path-sensitive diffusion analyzable. A sequence of edges can transmit information, liquidity, disruption, reputation, or opportunity only when their timing permits the sequence to occur. Two networks with the same aggregate number of edges can support different propagation because the edges appear in different orders. This matters for GRE because the generative effect of a relation may depend on whether it arrives before or after a complementary capability, institutional recognition, or competing pathway has formed.

The same computational logic extends to networks whose topology coevolves with behavior. Participants can create or sever relations in response to outcomes, and those relational changes alter later incentives. A supplier may diversify after disruption; a lender may reduce exposure after loss; a platform participant may migrate after changes in ranking; a research group may form new collaborations after acquiring a technique. Computation permits the network itself to become an endogenous state variable rather than a fixed background for action.

Dynamic network models nevertheless inherit the representational limits described earlier. The existence of a time-stamped edge still depends on a definition of the relation, a boundary around the system, and data that capture the relation with sufficient resolution. Computational tractability cannot recover relations that were never observed, distinguish causal influence from coincident timing by itself, or decide whether a higher-order configuration should be represented as several edges or as a distinct collective relation. The historical advance is the capacity to compute with changing topology; the epistemic burden of defining and validating the topology remains.

1.21.4 Agent-Based and Multiscale Modeling

Agent-based computation provides a fourth condition by permitting heterogeneous actors, local rules, institutional constraints, and interaction structures to coexist within one executable model. Agent-based computational economics explicitly developed this possibility as an alternative way to study decentralized economic systems whose aggregate behavior is generated through interaction, learning, strategic adaptation, conventions, organizations, and institutional arrangements (Tesfatsion 2006). The approach complements the complex-systems perspective of Section 1.19 by giving the interacting components an operational computational representation.

The value of agent-based modeling for GRE lies in the ability to preserve heterogeneity that may be generatively consequential. Workers can differ in skills and network position; firms can differ in routines and financing; households can differ in obligations and access; institutions can impose different rules across categories; artificial agents can possess capabilities unavailable to human participants. These differences can be represented together with local interaction rules, allowing the analyst to ask whether macro-level concentration, segregation, coordination, instability, or capacity formation emerges from the specified configuration.

Agent-based representation does not require an ontological commitment to isolated atomic individuals. An "agent" can be an analytical object whose behavior is partly constituted by relational position, organizational membership, inherited resources, institutional classification, or internal state. Organizations, households, collective bodies, and algorithmic systems can also be represented as agents at appropriate scales. The computational framework is therefore compatible with a relational account so long as the model does not treat the agent's attributes as independent of the relations the theory claims are constitutive.

Multiscale modeling extends the same logic when economically relevant processes operate at different resolutions. Local transactions can occur rapidly, organizational routines can change more slowly, institutions can evolve over longer intervals, and infrastructure can impose constraints across several scales. A computational model can couple these layers explicitly, allowing fast processes to generate inputs into slower processes and slower structures to condition the space within which faster interactions occur. Such coupling is particularly important for the fast–slow historical perspective developed elsewhere in GR, while GRE need not assume that every economic system admits a clean separation of timescales.

The difficulty lies in validation. A model that includes heterogeneous agents, networks, institutions, and several scales can fit many qualitative patterns for many different reasons. More computational detail can increase realism in one dimension while reducing identifiability overall. Agent-based and multiscale models therefore require careful documentation of which mechanisms are load-bearing, which parameters are calibrated, which structures are empirical, and which are exploratory. Their historical significance is that such questions can now be investigated computationally with far fewer reductions than before; their scientific standing still depends on evidence and comparative model evaluation.

1.21.5 Emerging Computational Paradigms

Contemporary computation is also changing the form of modeling itself. One important development is automatic differentiation, which evaluates derivatives of computer programs efficiently and has become a central component of modern machine-learning systems and differentiable programming (Baydin et al. 2018). The broader significance is that increasingly complex computational pipelines can be treated as composable objects whose parameters may be estimated, optimized, or linked to inference procedures without requiring every derivative or intermediate transformation to be derived manually.

For relational and generative analysis, this opens several possibilities. A simulation can be connected to parameter estimation; a network process can be embedded within a larger model; a surrogate model can approximate a computationally expensive component; and an end-to-end pipeline can propagate information across several stages. These possibilities reduce the technical distance between formal specification, simulation, estimation, and sensitivity analysis. They also make it easier to construct hybrid models that combine institutional rules, network dynamics, statistical components, and learned functions.

Parallel and distributed execution further alters the feasible scale of inquiry. Rather than treating a simulation as a single sequence of calculations, researchers can divide parameter sweeps, Monte Carlo replications, network partitions, or independent scenarios across many processors or machines. Accelerator-based computation makes some matrix- and tensor-intensive models practical at scales that would previously have been prohibitive. Cloud infrastructures can make such resources available without local ownership of equivalent hardware. These developments broaden access to some forms of computation while also introducing new dependencies on software ecosystems, specialized hardware, infrastructure providers, and technical expertise.

Machine-learning methods introduce another change by allowing components of a model to be estimated from data when an explicit functional form is unavailable or deliberately left flexible. This can support prediction, emulation, dimensionality reduction, or the approximation of expensive simulations. It can also weaken interpretability when learned components become more complex than the mechanism the model was intended to clarify. GRE therefore treats learned components as one computational resource among others. Their use should follow the epistemic role of the model: prediction, mechanism reconstruction, counterfactual exploration, or decision support impose different requirements on transparency and validation.

The emergence of these paradigms does not imply convergence toward a single computational methodology. Some economic questions remain best served by transparent low-dimensional models; others benefit from simulation, networks, agent-based systems, or learned approximations. The historical change lies in the expansion of feasible combinations. Formal components can increasingly be composed, differentiated, simulated, and compared within one computational environment. This makes generative relational questions more tractable while also making model governance, reproducibility, provenance, and infrastructure dependence more important.

The five conditions developed in this section define a computational opening

rather than a computational solution. Expanding capacity permits richer representations; large-scale simulation explores interaction and counterfactual trajectories; dynamic network computation follows changing relations; agent-based and multi-scale models preserve heterogeneity across levels; and emerging paradigms make complex computational systems increasingly composable. None resolves the evidential problem of whether the modeled relations correspond to the world. Section 1.22 therefore turns from computational feasibility to evidential conditions: the data infrastructures, longitudinal records, continuous observation, and distributed evidence systems through which relational and generative claims may be confronted with empirical traces.

1.22 Evidential Conditions of Contemporary Governance

This section identifies the evidential conditions that make more adaptive forms of economic governance and institutional decision-making increasingly feasible. Its role in the chapter is narrower than a general theory of governance. The objective is to reconstruct how changes in data production, longitudinal linkage, distributed observation, evidence updating, and feedback-oriented decision processes alter the practical possibility of following relational and generative economic processes through time. The discussion proceeds from continuous data collection to longitudinal infrastructures, distributed sources of observation, iterative evidence revision, and adaptive decision processes. The method is historical and institutional: the section treats contemporary evidence infrastructures as enabling conditions for GRE while preserving the distinction between evidence, interpretation, judgment, and legitimate action.

1.22.1 Continuous Data Collection

A first evidential condition is the movement from episodic measurement toward more continuous forms of observation. Traditional censuses, surveys, audits, and periodic administrative reports remain indispensable because they are designed around explicit statistical purposes and can provide carefully structured observations. Contemporary public sectors, however, increasingly operate alongside administrative databases, digital service records, transaction logs, sensor streams, platform traces, and machine-generated records that are produced as part of ongoing activity. The World Bank's 2021 account of public-intent data explicitly includes administrative, census, survey, citizen-generated, and machine-generated sources and emphasizes their roles in policy design, execution, monitoring, and evaluation (World Bank 2021). The OECD similarly describes a data-driven public sector as one in which data become an integral resource for policy making, service delivery, organizational management, and innovation (Ooijen et al. 2019).

The methodological change is temporal as much as quantitative. A periodic observation compares a small number of states separated by an interval. A more continuous evidential infrastructure can preserve intermediate changes, timing, sequence, and recurrence. This matters for relational analysis because a relation can form, weaken, reverse, or disappear between conventional observation points. It matters even more for generative analysis because the sequence through which capacities,

constraints, and institutional responses develop may be part of the explanation. A record of endpoints can show that a transition occurred; a denser temporal record can sometimes reveal the pathway through which it occurred.

Continuous observation also changes the practical relation between evidence and intervention. When evidence arrives only after a long reporting cycle, institutions often evaluate effects retrospectively. When administrative or operational indicators are updated more frequently, deviations can become visible during implementation. Such visibility does not by itself determine whether a deviation matters, whether the underlying measure is valid, or whether action should follow. It changes the feasible timing of inquiry. Institutions can potentially distinguish a transient fluctuation from a persistent change sooner, compare the development of several trajectories, and identify where additional investigation is needed before the end of an intervention cycle.

The increase in observational frequency introduces corresponding risks. Data generated continuously are often generated for operational rather than analytical purposes. Definitions can change as software, eligibility rules, administrative procedures, or institutional priorities change. Missingness may become systematic because participation in digital systems is unequally distributed. High-frequency measurement can also encourage attention to what changes rapidly while slower structures remain difficult to observe. A rich stream of immediate indicators may therefore produce an evidential bias toward fast variables precisely when the economic process of interest depends on institutional, demographic, ecological, or cultural variables that move more slowly.

Continuous data collection should therefore be treated as an expansion of temporal access rather than as complete observation. It increases the density of traces available to analysis while leaving unresolved questions of validity, provenance, representativeness, privacy, and interpretation. For GRE, its historical significance lies in making trajectories easier to reconstruct. The evidential object can increasingly become a process unfolding through time rather than a pair of states compared before and after an event.

1.22.2 Longitudinal Evidence Infrastructures

The second condition is the development of infrastructures capable of relating observations across time. Longitudinal evidence differs from repeated measurement when records can be connected to persons, organizations, places, programs, institutions, or relational configurations in ways that preserve temporal continuity. The analytical gain is substantial. Repeated cross-sections reveal population-level change; longitudinal systems can additionally show trajectories, persistence, transitions, and heterogeneous sequences within the changing population.

Contemporary data-governance initiatives increasingly recognize integration and linkage as institutional questions rather than purely technical tasks. The World Bank's *World Development Report 2021* develops the idea of an integrated national data system in which data production, exchange, and use are connected across public institutions and, under appropriate arrangements, with academic, private-sector, civil-society, and individual participants (World Bank 2021). The OECD's account of

a data-driven public sector likewise emphasizes data governance across the public sector rather than isolated use within single agencies (Ooijen et al. 2019). These developments create the possibility of observing economic processes whose relevant evidence is distributed across organizational boundaries.

Longitudinal linkage is especially important for generative questions because effects can appear after substantial delay. An educational intervention may affect labor-market position years later; infrastructure can alter patterns of firm formation only after complementary investments accumulate; institutional recognition can affect credit access, organizational survival, or intergenerational opportunity over long horizons. A short evaluation window may correctly measure immediate outputs while missing later relational or capacity effects. Longitudinal evidence creates the possibility of following these effects without assuming that the value of an intervention is exhausted by its first measurable consequence.

The same infrastructure also supports the analysis of path dependence. If later outcomes depend on the sequence through which earlier states were reached, an evidential system must preserve more than current status. It must retain enough historical structure to distinguish trajectories that end at similar observed states but arrive there through different institutional histories. This requirement links evidence design to the historical arguments developed in Section 1.20: path dependence is analytically meaningful only when the history required to identify the path has been preserved.

Longitudinal evidence is therefore inseparable from institutional memory. Data definitions, identifiers, classifications, and access rules must persist long enough for records to remain comparable, or their changes must themselves be documented. A category that changes meaning over time can create false continuity when the same label is treated as stable. Conversely, a change in classification may be evidence of institutional transformation rather than a nuisance to be harmonized away. The evidential infrastructure must preserve both observations and the history of the categories through which those observations were produced.

This point is central to GRE's emphasis on future re-epistemization. Evidence retained for one analytical purpose may later be revisited under different concepts or methods. Longitudinal infrastructure therefore has a generative epistemic function of its own: it preserves the possibility that future inquiry will reconstruct present processes differently. The value of preservation is not limited to improving current prediction. It also maintains future access to historical relational structure.

1.22.3 Distributed Observation

A third evidential condition is the distribution of observation across many institutions and forms of participation. Economic reality is rarely observed from a single point. Tax administrations, statistical offices, regulatory agencies, firms, financial institutions, researchers, civil-society organizations, households, digital platforms, sensors, and citizens can all produce traces relevant to the same economic process. The World Bank describes the contemporary data-governance ecosystem as extending beyond government to the private sector, civil society, academia, and other actors, and it emphasizes the institutional problem of enabling data to be combined and exchanged

while safeguarding rights, security, and integrity (World Bank 2021).

Distributed observation matters because different observers have access to different manifestations of the same relational system. Administrative records may reveal recognized membership and formal transfers. Surveys may reveal experiences and expectations that administrative systems do not record. Transaction data may reveal realized exchanges with high temporal resolution. Qualitative fieldwork may reveal meanings and informal relations that standardized records cannot represent. Citizen-generated evidence can make visible local conditions that centralized institutions observe poorly. None of these sources provides a neutral view from nowhere; their combination can nevertheless reveal discrepancies that would remain invisible within a single evidential regime.

The analytical opportunity is therefore triangulation across positions. When several sources converge despite different production processes, confidence in some claims may increase. When they diverge, the divergence can become substantive evidence. A statistical indicator may report stable service delivery while interview evidence documents changing barriers to access. Administrative records may show formal program participation while transaction data reveal that effective use is concentrated among a subset of recognized participants. The discrepancy may indicate measurement error, category mismatch, selective observation, or a genuine difference between formal recognition and realized relation.

Distributed observation also introduces a relational problem among evidence producers themselves. Data are generated under different mandates, incentives, legal constraints, business models, technical standards, and temporal rhythms. Combining them requires interfaces: shared identifiers, interoperable formats, provenance records, agreements over access, and institutions capable of resolving conflict among sources. Evidence infrastructure is therefore itself a relational system. Its architecture influences which observations can be connected, which remain isolated, which actors gain interpretive authority, and which absences become structurally persistent.

This makes evidential plurality both a strength and a governance challenge. A system with many observers can reduce dependence on one institutional viewpoint, yet concentration in key infrastructures can create new forms of asymmetry. Platforms with privileged access to behavioral data may see relations unavailable to public institutions or researchers. Public agencies may possess administrative authority that makes their classifications consequential even when alternative descriptions exist. Communities may hold contextual knowledge that has little institutional standing. The distribution of evidence production is consequently linked to the distribution of epistemic power, a theme developed more fully in later parts of the book.

For GRE, distributed observation expands the possibility of reconstructing relational reality from multiple manifestations. It also reinforces ontological and epistemic restraint. Agreement among sources can strengthen an inference; disagreement can reveal the dependence of representation on institutional position. The existence of many observations does not eliminate the inverse problem of moving from manifestations to the relational structures that generated them.

1.22.4 Evidence Updating

The fourth condition is the institutional capacity to revise evidential judgments as new information becomes available. Evidence-informed policy making is defined by the OECD broadly enough to include statistics, data, research evidence, and evaluation in decisions to plan, implement, and, where relevant, alter public policies and programs (OECD 2020a). This formulation is important because it treats evidence as part of an iterative process rather than as a single justificatory input delivered before action begins.

Updating has several analytically distinct forms. New observations can change estimates within an existing model. They can reveal that a previously measured relation has weakened or reversed. They can expose a missing variable, a classification error, or a boundary condition that the original analysis omitted. In stronger cases, evidence can undermine the representation itself and require a change of model, category, or theory. GRE's generative perspective makes the last possibility especially important because the system under study may change the relations that made an earlier model adequate.

An updating infrastructure must therefore preserve revision rather than merely replace earlier states of knowledge. Versioned datasets, documented methodological changes, model histories, evaluation reports, and explicit records of revised assumptions allow later researchers to reconstruct why a decision or interpretation changed. Without such provenance, an institution can update its current estimate while losing the history of its own learning. The result is a paradoxical form of informational abundance in which current dashboards improve while the trajectory of interpretation becomes harder to recover.

Evidence updating also requires a distinction between evidential revision and automatic policy response. An estimate can change without changing the relevant decision because the difference is too small, the intervention is costly to reverse, normative commitments constrain the available actions, or several evidential sources point in different directions. Conversely, a modest evidential change can become decision-relevant when a system is close to an institutional threshold or when delay carries large costs. Evidence informs judgment; it does not mechanically substitute for judgment.

This distinction becomes more important when evidence arrives at different frequencies. Operational indicators may update daily, survey estimates quarterly, fiscal data annually, and structural outcomes only over several years. Treating every update as equally decision-relevant would allow high-frequency indicators to dominate simply because they arrive more often. A generative-relational approach instead asks which timescale corresponds to the process being governed and whether the evidence updates the fast state, the slower relational architecture, or the assumptions linking the two.

The scientific significance of evidence updating is therefore deeper than responsiveness. It institutionalizes revisability. A governance system capable of learning from new evidence can revise representations, evaluations, and interventions without assuming that the original model was final. This does not guarantee learning; institutional incentives can suppress inconvenient findings, methods can remain

locked into outdated categories, and rapid updating can amplify noisy indicators. It creates a historical possibility for governance to remain epistemically open while acting under incomplete knowledge.

1.22.5 Adaptive Decision Processes

The fifth condition is the incorporation of feedback into decision processes. The OECD's policy framework on public governance describes monitoring information as a resource that can feed decision-making, track implementation, and support adjustment, and it emphasizes feedback loops and evaluation across the policy cycle (OECD 2020c). Its cross-country work on policy evaluation likewise treats evaluation as a source of accountability, learning, and improved decision-making rather than as a purely retrospective exercise (OECD 2020b). These institutional practices make it increasingly feasible to treat some interventions as revisable processes rather than fixed decisions followed by a single final assessment.

Adaptive decision processes are especially relevant where causal structure is uncertain and the consequences of intervention unfold over time. An institution can begin with a provisional model, monitor selected consequences, compare observed and expected trajectories, revise the model, and alter the intervention when predefined or deliberatively assessed conditions are met. The practical logic resembles the research-practice relation developed later in this book: action generates evidence, evidence revises understanding, and revised understanding changes subsequent action.

Adaptation requires more than frequent data. The evidence must arrive in a form that can be interpreted relative to the decision. Institutions need authority to revise implementation, procedures for recording why revisions occur, and safeguards against the continuous redefinition of objectives in response to short-term indicators. An adaptive process also needs temporal discipline. Some interventions require enough time for effects to emerge; premature adjustment can prevent the very relation being evaluated from stabilizing. Other interventions create rapidly compounding harms for which delayed response is costly. The appropriate update interval is therefore a property of the intervention and the relevant dynamics rather than a universal preference for faster feedback.

Reversibility further conditions adaptation. When an action can be adjusted at low cost, institutions can learn through incremental changes more readily. When interventions alter legal status, infrastructure, ecological conditions, or long-horizon expectations, later correction may be partial or impossible. In such cases, evidence updating still matters, but adaptive governance must operate through staged commitments, safeguards, contingency planning, or more demanding ex ante justification. The availability of real-time evidence does not make irreversible action experimental in the same sense as a reversible pilot.

Adaptive decision processes also remain normatively and politically situated. Evidence can indicate consequences and uncertainty; it does not decide which consequences deserve priority, whose losses require protection, or which distributions are acceptable. These questions lead directly to Section 1.23, which examines the political and normative conditions under which relational governance becomes institution-

ally meaningful. The evidential architecture developed here supplies information for decision; it does not supply the legitimacy or normative ordering of the decision itself.

The historical opening is therefore specific. Contemporary institutions can increasingly observe economic processes at higher frequency, connect evidence across time and organizations, revise interpretations as evidence accumulates, and alter some decisions during implementation. These capacities make relational and generative governance more technically conceivable because trajectories and feedback can enter institutional practice. They also expose new problems of surveillance, data concentration, representational power, model dependence, and temporal mismatch. GRE treats this evidential expansion as a condition of possibility for adaptive economic analysis and action, while retaining the distinction between observing a generative system and possessing the knowledge or authority required to control it.

1.23 Political and Normative Conditions of Relational Governance

This section identifies the political and normative conditions that have made relational questions increasingly admissible within economic governance. Its role in the chapter is historical and disciplinary: Sections 1.19–1.22 reconstructed scientific, computational, and evidential capacities, whereas the present section concerns the standards by which institutions decide whose relations, capabilities, interests, and temporal claims enter the field of evaluation. The objective is to show how political participation, human-rights recognition, capability-oriented development, commons governance, and environmental or intergenerational normativity widened the range of economically relevant objects beyond administratively isolated recipients and contemporaneous outputs. The discussion proceeds through those five developments in sequence. Its method is reconstructive rather than prescriptive. The section treats these traditions as historical conditions that make relational governance thinkable and institutionally legible; systematic governance theory remains outside the scope of this chapter and is reserved for later GRE interfaces with Generative Relational Governance.

1.23.1 Political Participation

Political participation changes the position from which governance problems are formulated. An administrative model can treat persons primarily as recipients, taxpayers, employees, consumers, regulated entities, or statistical units. Participatory arrangements introduce an additional status: persons and organized groups can enter the process through which public problems, priorities, and institutional responses are interpreted. This change matters for relational analysis because affected parties often possess information about dependencies, informal practices, exclusion mechanisms, and downstream effects that remain weakly represented in administrative categories.

The institutionalization of participation as a governance concern is visible in

twentieth-century rights instruments. Article 25 of the International Covenant on Civil and Political Rights recognizes for citizens the right and opportunity to take part in the conduct of public affairs, directly or through freely chosen representatives, alongside electoral and public-service rights (United Nations General Assembly 1966). The significance for the present argument lies in the formal recognition of participation as part of the structure of public affairs. Governance is thereby evaluated partly in terms of relations between institutions and those subject to, represented within, or participating in public decisions.

Participation also alters the evidential architecture described in Section 1.22. Distributed observation acquires a political dimension when experiences and local knowledge enter institutional deliberation through hearings, consultation, representative bodies, associations, unions, community organizations, or other channels. Administrative evidence can reveal formally recorded transfers and statuses; participants can identify how those arrangements operate in practice. A benefit formally available to all eligible persons may be difficult to obtain because of language, time, location, documentation, digital access, stigma, or dependence on intermediaries. These conditions are relational because the effective outcome depends on the configuration linking claimant, institution, infrastructure, and other actors.

The analytical value of participation therefore extends beyond preference aggregation. Participants can contest the definition of the object itself. A housing problem may be framed as insufficient units, insecure tenure, spatial exclusion, financing constraints, discriminatory access, or inadequate transport relations. Each formulation identifies a different relational structure and therefore a different possible intervention. Participatory processes can expose these competing formulations before an administrative category becomes fixed as the sole representation of the problem.

Participation also has clear limits. Access is uneven, organized interests possess different resources, participation can be costly, and institutional forums can reproduce existing asymmetries. A meeting or consultation does not establish that every affected relation has become visible. Nor does participation remove the need for expertise, legal authority, or accountable decision. For GRE, the historical importance of participatory norms is more specific: they weaken the assumption that the economic object of governance can be fully specified from the administrative center before those situated within its relational field are heard.

This condition matters especially for generative questions. The long-run effects of an intervention may include changes in trust, capability, dependency, organizational learning, and future access. Such effects often appear first in the experiences of participants rather than in the primary output metric. Political participation creates institutional channels through which some of these effects can become objects of public interpretation and later evidence.

1.23.2 Human Rights and Institutional Recognition

Human-rights frameworks provide a second condition by institutionalizing forms of recognition that are not exhausted by economic role. The Universal Declaration of Human Rights states that everyone has a right to recognition everywhere as a person before the law and articulates equality before the law among its foundational guar-

antees (United Nations General Assembly 1948). The present chapter does not derive a complete normative theory from these provisions. Their historical significance for GRE lies in the expansion of institutional standing: a person enters governance as a bearer of recognized claims whose relevance cannot be reduced to ownership, productivity, income, contractual position, or contribution to measured output.

This development complicates purely recipient-centered economic description. A transfer system can be efficient in reaching a target population while still affecting privacy, family relations, freedom of association, legal recognition, or access to remedy. A labor arrangement can increase output while altering dependence, voice, or exposure to arbitrary exclusion. A data infrastructure can improve administrative coordination while creating new asymmetries in visibility and classification. Once recognized rights become part of the institutional environment, these dimensions become relevant constraints on the design and evaluation of economic governance.

Institutional recognition is itself relational. A right requires more than the internal possession of an attribute by an isolated individual. Its practical effect depends on relations among the person, legal rules, administrative bodies, courts or review mechanisms, documentation systems, and other actors capable of honoring or violating the recognized claim. Formal recognition can therefore be represented as a stabilized institutional relation whose effectiveness varies with access, enforcement, and the organization of remedies. This does not reduce rights to economic relations; it clarifies why rights matter to economic institutions even when their normative foundation is external to economics.

The distinction is especially important for heterogeneous subjects. Section 1.16 separated economic subjecthood from final metaphysical or moral personhood. Human-rights traditions reinforce the need to preserve that separation. Economic systems may assign roles to persons, organizations, or artificial agents for purposes of contract, production, or allocation, while normative and legal standing follows different criteria. GRE therefore requires care whenever economic functionality is used as a proxy for broader status. Productive capacity does not settle legal recognition, and administrative recognition does not settle moral standing.

Human-rights frameworks also expand the temporal stability of claims. Economic positions can change rapidly: employment can end, assets can be lost, and market participation can fluctuate. Rights-based recognition is designed to persist across many such changes. This creates an institutional layer whose continuity can constrain short-horizon optimization. From a generative perspective, such continuity can affect future options by preserving access to institutions, remedies, participation, and protections during periods of economic transition.

The resulting contribution to relational governance is a boundary condition rather than a policy formula. Rights language identifies some relations and statuses as institutionally salient even when they are poorly captured by current output measures. GRE can analyze the economic consequences of those relations while leaving their ultimate normative justification to political philosophy, law, and human-rights theory.

1.23.3 Capability and Human Development

The capability and human-development traditions provide a third condition by shifting evaluation from resources alone toward substantive opportunities. Sen's capability-oriented account treats development in terms of the expansion of substantive freedoms and the effective opportunities persons possess to pursue valued ways of living (Sen 1999). This change is directly relevant to relational economics because identical resource bundles can generate different practical possibilities when persons occupy different social, institutional, bodily, geographic, or infrastructural positions.

Capability analysis changes the evaluative unit without dissolving the importance of resources. Income, assets, services, and public provision remain means through which capabilities can be supported. Their significance depends on conversion conditions. A transport subsidy has little mobility effect where transport infrastructure is absent. Digital access has different consequences when literacy, language, hardware, electricity, or institutional recognition differ. Formal educational access has different value when care obligations, discrimination, health, or local labor-market structures alter the feasible use of education. These examples make visible the relational environment through which resources become effective opportunities.

This shift also creates a bridge between entity-centered and relational evaluation. The person remains a central normative referent, while the explanation of effective freedom requires attention to the relations surrounding that person. The analytical question becomes wider than resource possession. It includes the social and institutional conditions through which possession is converted into the ability to act. GRE can therefore inherit an important discipline from capability analysis: resources, outcomes, and opportunities should remain distinct analytical objects.

The capability perspective also introduces plurality into economic evaluation. If development concerns several kinds of functioning and freedom, a single aggregate output measure provides only a partial view. Health, education, mobility, participation, security, and other dimensions can interact without being reducible to one immediate metric. For GRE, the importance of this plurality is methodological as well as normative. Heterogeneous values may require different evidential forms and may circulate through different relational pathways. Later chapters extend this problem into value conversion and partial commensurability; the present section identifies the historical tradition that made plural opportunity structures a legitimate economic concern.

A generative extension follows when present capabilities affect the production of future capabilities. Education can generate learning capacity; political participation can generate organizational experience; secure institutional recognition can expand future access; health can affect later employment and care relations. Capability at one moment can therefore become an enabling condition for capability at another. This temporal extension should be handled cautiously because long-horizon attribution is difficult. It nevertheless reveals why capability-oriented evaluation is congenial to a generative framework: the object of interest can include the changing possibility set through which later economic action becomes feasible.

The relationship between GRE and the capability tradition remains one of dialogue

rather than identity. Capability analysis supplies a normative and evaluative vocabulary centered on substantive opportunity. GRE adds questions about relational generation, circulation, conversion, and historical transformation. The two can overlap substantially while preserving different theoretical commitments.

1.23.4 Commons and Collective Governance

Commons scholarship supplies a fourth condition by demonstrating that shared-resource problems can be organized through institutional forms more diverse than a binary opposition between centralized control and individualized private ownership. Ostrom's comparative work on common-pool resources analyzes self-organized and self-governed arrangements, including both long-enduring institutions and cases of fragility or failure (Ostrom 1990). The historical importance of this research lies in making collective rule formation, monitoring, boundary definition, conflict resolution, and institutional adaptation legitimate objects of economic analysis.

The commons perspective is relational at several levels. Resource use depends on relations among appropriators, relations between users and the resource system, and relations between local arrangements and wider authorities. The relevant economic object is therefore difficult to represent as a resource plus a set of independent claimants. Rules concerning access, monitoring, sanctions, contribution, and conflict resolution alter how the group interacts and how the resource is reproduced over time. Institutional performance depends on the configuration of these relations.

This perspective also widens the concept of governance capacity. Coordination can emerge from participants who construct and revise rules rather than receiving a fully specified institutional design from an external authority. Such self-organization does not imply spontaneity without structure. Ostrom's analysis emphasizes institutions, information, credible commitments, monitoring, and the conditions under which participants can organize collective action (Ostrom 1990). The result is an empirical challenge to analytical frameworks that treat collective governance as conceptually secondary to state administration or market exchange.

For GRE, commons research is especially relevant to the distinction between allocation and generativity. A shared resource can be allocated among current users while the institutional relations required for future reproduction are simultaneously strengthened or weakened. Rules that maximize present extraction may reduce future resource availability or institutional trust. Rules that preserve the resource can impose present costs while maintaining later options. Evaluation therefore requires attention to the relation between current distribution and the reproduction of the relational system through which future use remains possible.

The commons tradition also provides a useful warning against idealizing relational organization. Collective governance can fail, exclude outsiders, reproduce internal hierarchy, or become fragile under changing conditions. Ostrom's own comparative programme includes failures as well as successes (Ostrom 1990). Relational density therefore has no automatic normative priority. GRE treats the structure, distribution, revisability, and generative effects of relations as empirical and normative questions rather than assuming that more relation is inherently better.

This restraint clarifies the contribution of commons scholarship to the present

chapter. Its historical significance is the expansion of the institutional imagination available to economics. Shared resources can be governed through architectures in which users, rules, monitoring, and collective learning form an evolving system. That possibility supplies an important precedent for GRE's later examination of relational allocation, collective capacity, and institutional generativity.

1.23.5 Environmental and Intergenerational Normativity

Environmental and intergenerational norms provide a fifth condition by extending economic evaluation across temporal and ecological boundaries. The World Commission on Environment and Development's 1987 report, *Our Common Future*, articulated sustainable development through the relation between present needs and the ability of future generations to meet their own needs, while explicitly linking environmental limits to technology and social organization (World Commission on Environment and Development 1987). This formulation helped stabilize a normative vocabulary in which future consequences and ecological conditions became integral to development rather than external aftereffects.

The temporal extension changes the structure of the economic subject. Future persons cannot participate in current markets, vote in current institutions, or contract with present actors, yet current investment, extraction, infrastructure, emissions, debt, and technological choices can alter their opportunity sets. Intergenerational evaluation therefore requires institutions to represent interests that are temporally absent from ordinary exchange. This is a relational problem because current actions create relations of inheritance, dependence, exposure, and constraint across time even when the later participants are not presently available as counterparties.

Environmental problems introduce a related spatial and systemic extension. Ecological processes cross property boundaries, jurisdictions, and accounting periods. Resource depletion, pollution, biodiversity loss, and climate effects can connect actors who never transact directly. The relevant causal structure can therefore extend beyond the legal boundaries of the entity generating an immediate economic output. Environmental normativity makes these externalized relations harder to exclude from evaluation simply because they fall outside the original contract or reporting unit.

The combination of environmental and intergenerational concerns also changes the meaning of economic efficiency across horizons. An arrangement can produce high current output while degrading ecological or institutional conditions required for later production. Conversely, present investment can maintain capacities whose returns become visible only over long periods. GRE's generative vocabulary is well suited to this temporal structure because it distinguishes present outcomes from the conditions under which future outcomes can be generated. The normative judgment about how present and future claims should be weighted remains a separate problem.

This separation is important. Generativity does not itself determine goodness. A system can generate durable forms of domination as readily as durable capabilities; an environmentally persistent arrangement can remain unjust; preservation can conflict with present claims of people facing urgent deprivation. Environmental and

intergenerational evaluation therefore requires explicit normative reasoning about distribution, rights, risk, recognition, and acceptable tradeoffs. GRE can contribute an account of how current relations transform future possibility while leaving the ranking of competing claims open to normative theory.

The five developments reconstructed in this section collectively widen the space within which relational governance can be conceived. Participation makes affected relations relevant to problem formation; human-rights recognition gives institutional standing to persons beyond their market roles; capability analysis directs attention toward effective opportunities and conversion conditions; commons research establishes collective institutional arrangements as substantive economic objects; and environmental or intergenerational normativity extends evaluation across ecological systems and historical time. None of these traditions yields GRE by itself. Together they create a political and normative environment in which economic governance can increasingly be asked to account for relations, heterogeneous forms of standing, future possibilities, and the conditions through which economic life is reproduced. Section 1.24 turns next to the development of nomos and institutional form: the legal and organizational structures through which such expanded objects of recognition can acquire durable institutional expression.

1.24 Development of Nomos and Institutional Form

This section identifies the institutional developments through which relational and collective economic claims acquire durable forms of recognition. Its role in the chapter is to connect the political and normative opening reconstructed in Section 1.23 with the legal and organizational forms that make such claims actionable over time. The objective is to show how *nomos*, used here in a deliberately broad sense for the operative normative and institutional order that assigns statuses, claims, duties, boundaries, and procedures, changes the range of economic relations that can be represented and governed. The discussion proceeds from legal recognition of economic subjects to collective and relational interests, then examines fiduciary, cooperative, and commons-based institutions before turning to adaptive and revisable governance. The method is institutional and comparative. It treats legal and organizational forms as historically developed devices for stabilizing relations, allocating authority, preserving claims, and structuring revision, while leaving the systematic theory of governance to later GRG work.

1.24.1 Legal Recognition of Economic Subjects

Legal recognition supplies one of the principal mechanisms through which an economic subject becomes durable across transactions. Section 1.5 showed that modern economic entities become administratively legible through legal personality, property, contract, accounting, and statistical classification. The present subsection develops the institutional implication of that argument. Recognition gives continuity to a position that can own assets, incur liabilities, enter contracts, appear in accounts, receive transfers, and bear responsibilities across time. Economic analysis can then treat that position as sufficiently stable for allocation and coordination even when

the persons, assets, or internal relations composing it change.

Organizational law illustrates the structure clearly. Hansmann and Kraakman emphasize the role of organizational law in separating organizational assets and creditor claims from the personal asset positions of owners and managers (Hansmann and Kraakman 2000). This legal partitioning stabilizes a boundary through which an organization can persist as an economic unit across changes in membership and management. The System of National Accounts similarly treats institutional units as basic economic and statistical units capable of owning assets, incurring liabilities, making economic decisions, and entering transactions in their own right (European Commission et al. 2009). The legal and statistical vocabularies differ, yet both rely on institutional criteria that transform a changing configuration of persons and resources into a recognizable economic position.

Recognition therefore participates in the production of the economic object it later regulates. Once an entity is recognized as a corporation, public body, household, nonprofit institution, or other institutional unit, contracts, accounts, taxes, liabilities, transfers, and statistics can attach to that recognized position. The resulting stability supports coordination across actors who need not reconstruct the entity's entire internal relational history before every transaction. Recognition reduces uncertainty by supplying a durable institutional address for claims and obligations.

The same mechanism also creates selective visibility. Legal and administrative forms foreground the relations that are necessary to maintain the recognized position: ownership, authority, liability, membership, contractual capacity, reporting boundaries, and related incidents. Other relations can remain external to the formal identity of the unit even when they matter economically. Care relations within households, dependencies in supply chains, informal obligations, platform-mediated access, or ecological dependencies can shape the capabilities of an entity while receiving weaker recognition in the formal representation.

The development of nomos therefore changes economic ontology at the practical level. The point concerns institutional reality rather than ultimate metaphysics. A legal form can make a configuration sufficiently stable and causally efficacious for economic coordination, while the broader social and relational constitution of that configuration remains open to analysis. This institutional stabilization is one historical condition for entity-centered economics, and it also creates the starting point from which relational analysis can ask which constitutive relations remain outside the recognized boundary.

1.24.2 Recognition of Collective Interests

Collective interests extend institutional recognition beyond a simple aggregation of individually held claims. Their significance for GRE lies in the possibility that an institution can assign standing, assets, decision rights, or continuity to a group whose economic activity depends on coordinated relations among members. The relevant development concerns the creation of forms through which a collective can persist and act even as individual participants enter, leave, or change their contributions.

The corporation is one familiar example, though collective recognition extends beyond shareholder-owned firms. Associations, cooperatives, mutuals, unions, pension

arrangements, foundations, public bodies, and commons institutions organize interests whose practical content depends on continued relations among multiple participants. Organizational forms can provide a durable account of membership, authority, assets, obligations, and procedures for collective decision. The recognized collective thereby acquires a temporal continuity that individual contracts alone may reproduce only at substantial cost.

Cooperative institutions provide a particularly explicit example of collective economic recognition. The International Cooperative Alliance defines a cooperative as an autonomous association of persons who voluntarily unite to meet common economic, social, and cultural needs through a jointly owned and democratically controlled enterprise (International Cooperative Alliance 1995). The institutional form links economic participation to membership and democratic control rather than treating invested capital as the sole basis of authority. The form therefore stabilizes a collective interest while preserving identifiable relations between members, enterprise, capital, and decision procedures.

Collective recognition also changes the possible recipient of economic allocation. Resources can be directed toward a jointly owned reserve, a common infrastructure, a pension fund, a mutual insurance pool, or an institution whose purpose concerns a class of members rather than an isolated owner. The economic consequence is important: the same nominal transfer can have different effects depending on whether it becomes private property, common capital, an indivisible reserve, or an institutional asset governed under membership rules. Collective forms therefore make visible the organization of the recipient, not merely its legal name.

The analytical implication for GRE concerns persistence and aggregation. A collective interest gains economic relevance when the institutional form can preserve some relation or capability across turnover in individual participants. The collective then becomes a legitimate object of analysis because decisions taken at the collective level can affect access, bargaining position, risk sharing, investment, and future participation. Collective recognition does not establish that every group claim is normatively valid. It establishes that economic institutions have developed devices through which certain shared claims can be stabilized, governed, and carried through time.

This development widens the space of economic subjecthood introduced in Section 1.16. Subject positions can be individual, organizational, or collective, and their stability can depend on different institutional mechanisms. GRE can therefore examine how a form of collective recognition alters the relations through which resources, risks, authority, and returns circulate.

1.24.3 Recognition of Relational Interests

Relational interests concern claims whose practical meaning depends on a structured relation among parties rather than on possession by a single isolated holder. Their institutional significance becomes visible when economic law or organizational design protects a beneficiary relation, membership relation, stewardship relation, access relation, dependency, or continuing obligation whose value cannot be described fully as an immediately transferable asset. The objective of this subsection is to identify the institutional possibility of recognizing such interests while preserving the distinction

between a relation and an entity created to administer it.

Trust law offers a useful illustration. Hansmann and Mattei analyze the trust as an organizational form that structures relations among parties to the trust and between those parties and third parties, with asset partitioning playing a central role in the form's economic function (Hansmann and Mattei 1998). The legal arrangement separates dimensions of control, benefit, and creditor access that coincide more closely under simple ownership. A beneficiary's economic interest therefore depends on an institutionalized relation to assets managed through another position. The interest is intelligible through the relation among trustee, beneficiary, trust assets, and third parties.

Membership provides a second illustration. Cooperative rights derive their practical meaning from a person's relation to the cooperative and to the procedures through which the cooperative is controlled. The ICA principles connect membership to participation in policy and decision making, member economic participation, autonomy, and cooperation among cooperatives (International Cooperative Alliance 1995). These rights have an economic content that differs from a detached claim to an asset because their exercise depends on continuing membership and institutional procedures.

Commons institutions provide a third form. Ostrom's comparative work documents arrangements in which groups establish rules concerning access, use, monitoring, sanctioning, and collective choice around common-pool resources (Ostrom 1990). The relevant interest is structured through relations among users, resource conditions, monitoring practices, and institutional rules. Access to the resource can therefore depend on membership and rule-governed relations rather than on exclusive ownership by a single actor.

These examples suggest a cautious extension of economic representation. Some interests can be represented more adequately by specifying the relation through which the claim is sustained. A transfer to a beneficiary, a member, or a resource user changes more than the recipient's balance sheet when it also alters membership, control, dependence, monitoring obligations, or future access. Relational analysis becomes useful where these continuing relations materially shape the effect of the transfer.

Institutional recognition can nevertheless reify what it stabilizes. A fluid relation may be converted into a fixed legal category, a standardized entitlement, or an administratively bounded membership class. Such stabilization can be necessary for enforceability and coordination, while also narrowing the variation that the institution can perceive. GRE therefore treats recognition as a generative intervention into the relation itself. The act of making an interest legible can alter the boundaries, participants, duties, and future trajectories of that interest.

The resulting problem is central to later relational allocation theory. Economic institutions require stable addresses for claims, yet generative relations can change through time. A relationally sensitive nomos therefore needs forms that can recognize continuing interests while leaving room for revision when the relations supporting those interests change.

1.24.4 Fiduciary, Cooperative, and Commons-Based Institutions

Fiduciary, cooperative, and commons-based institutions demonstrate several ways in which economic organization can distribute ownership, control, benefit, and responsibility across differentiated positions. Their importance for the present chapter lies in institutional variety. Modern economic ordering already contains forms that depart from the simple image of one owner controlling one asset for one private purpose. These forms provide concrete precedents for GRE's later inquiry into allocation toward relations, shared infrastructures, collective capacities, and future beneficiaries.

Fiduciary structures separate authority from beneficial interest under a rule-governed relation. Trust law can partition assets and structure claims among trustees, beneficiaries, and third parties in ways that ordinary bilateral contracting may reproduce only imperfectly (Hansmann and Mattei 1998). The institutional form permits resources to be administered under purposes and duties that persist beyond a particular transaction. Pension funds, charitable trusts, and other fiduciary arrangements differ substantially in law and function, yet they share the broader feature that control over assets and entitlement to benefits can occupy distinct institutional positions.

Cooperatives organize a different separation. Their institutional identity places membership, joint ownership, and democratic control at the center of the enterprise. The ICA principles include voluntary and open membership, democratic member control, member economic participation, autonomy, cooperation among cooperatives, and concern for community (International Cooperative Alliance 1995). These principles provide an explicit example of an economic organization whose architecture links capital to a wider structure of membership and collective decision. The form does not guarantee equal outcomes or successful governance. It demonstrates that economic control and return can be institutionally organized through relations other than proportional investor ownership.

Commons-based institutions add another configuration. Ostrom's cases show that users of common-pool resources can, under some conditions, develop durable rules for access, monitoring, conflict resolution, sanctioning, and collective choice (Ostrom 1990). Their significance lies in the institutionalization of reciprocal and continuing relations around a shared resource. The resource remains economically consequential through a pattern of use and governance that cannot be reduced to a sequence of isolated transfers.

Taken together, these forms show that institutional architecture can distribute economic functions across multiple roles. Asset control, beneficial claim, membership, monitoring, participation, stewardship, and residual return can be attached to different positions and linked through rules. GRE can therefore treat institutional form as part of the causal structure of allocation. A resource entering a trust, cooperative, or commons arrangement enters a different generative configuration from the same resource entering an individually controlled account.

The comparison also supplies a methodological caution. Fiduciary, cooperative, and commons institutions arise from distinct legal histories and solve different problems. Their inclusion in one subsection identifies a family resemblance in the distri-

bution of economic roles, rather than an equivalence among the forms. Later GRE chapters can ask which structural features matter for generativity, participation, return, or justice without treating any existing institution as a ready-made model for a generative relational economy.

The historical lesson is therefore modest and important. Institutional pluralism already exists within modern economic orders. The development of GRE does not require inventing relational organization from an empty institutional field. It requires learning how existing forms distribute relations, which capacities they preserve, which asymmetries they create, and how their rules affect the circulation and return of value.

1.24.5 Adaptive and Revisable Governance

Adaptive and revisable governance provides the final institutional condition considered in this section. Relational and generative systems change while institutions act upon them, so a governance form that can monitor consequences, evaluate implementation, revise rules, and reopen decisions possesses a different temporal structure from a one-time allocation. The objective here is to identify institutional revisability as a historically developed governance capacity, while maintaining the distinction between revisability and a complete theory of adaptive governance.

Institutional revision begins with explicit procedures for observation and feedback. The OECD's framework on sound public governance treats monitoring as a source of information during implementation and connects monitoring and evaluation to adjustment of policy and resource allocation (OECD 2020c). Its comparative work on policy evaluation similarly presents evaluation as a mechanism for accountability, learning, and improved decision making (OECD 2020b). These practices create formal channels through which observed consequences can re-enter the decision process.

Revisability matters because the object of governance can change during implementation. A program can alter incentives, participation, organizational routines, information flows, or the composition of the population it serves. A rule designed for one relational configuration can therefore become mismatched to the configuration partly generated by the rule itself. Monitoring then has a generative significance: the institution observes a system in which its own intervention has become one of the causal relations.

Adaptive capacity also depends on the architecture of amendment. Institutions vary in who can initiate revision, what evidence can count, whose testimony has standing, which decisions are reviewable, how quickly rules can change, and which commitments remain protected from short-horizon adjustment. These procedural differences shape the relation between stability and learning. Rapid revision can make an institution responsive while reducing predictability; rigid rules can preserve expectations while allowing mismatch to accumulate. The relevant design problem concerns the organization of temporal responsiveness across different kinds of rule and different timescales of change.

Existing institutions already embody partial solutions. Cooperative principles can be interpreted and updated through living guidance while preserving a continuing

institutional identity (International Cooperative Alliance 2017). Commons arrangements can contain collective-choice and monitoring procedures through which rules respond to local conditions (Ostrom 1990). Public-governance frameworks increasingly formalize monitoring, evaluation, and revision across policy cycles (OECD 2020c; OECD 2020b). These examples differ in authority and domain, yet each illustrates an institutional attempt to combine continuity with revisability.

For GRE, revisability has a further implication. If institutions participate in generating the relations they govern, evaluation cannot be confined to whether an intervention reached its initial target. It must also ask what relations, capacities, dependencies, and future options emerged through implementation. The answer can justify revision even when the initial output metric was achieved. This creates an institutional bridge between the evidential conditions of Section 1.22 and the generative analysis developed in Sections 1.17–1.20.

The development of nomos therefore expands the practical possibility of relational economics in two directions. Institutional forms can recognize subjects, collectives, and continuing relational interests; revision procedures can preserve the capacity to learn when those recognized forms change through time. The same developments also create new risks of reification, unequal recognition, procedural capture, and excessive administrative complexity. Sections 1.25 and 1.26 turn to these limits directly by examining the remaining epistemic and governance constraints on relational analysis.

1.25 Contemporary Limits of Relational Knowledge

This section specifies the epistemic limits that remain after the scientific, computational, evidential, political, and institutional openings developed in Sections 1.19–1.24. Its role in the chapter is to prevent the historical possibility of richer relational analysis from being mistaken for complete access to relational reality. The objective is to distinguish five persistent limits: partial observation, dependence on representation and model choice, causal underdetermination, boundary and scale dependence, and the temporal incompleteness of generative evaluation. The discussion is epistemological and methodological. It treats these limits as conditions under which relational knowledge must be produced, qualified, compared, and revised, while reserving the fuller epistemology of GRE for Chapter 5.

1.25.1 Partial Observation

Relational economic analysis begins from evidence that is necessarily selective. Some relations are formally recorded because institutions require contracts, accounts, registrations, transactions, tax records, administrative classifications, or platform logs. Other relations remain informal, tacit, private, strategic, episodic, or distributed across several organizations. Even where a relation leaves traces, the traces may register only a subset of its dimensions: a payment can record transfer without recording dependence; an employment contract can record legal status without recording informal authority; a platform interaction can record clicks without recovering the meaning assigned to them by participants. The expansion of data

infrastructures therefore increases observational capacity while leaving observation partial.

The limitation is partly institutional. Observation follows the categories and purposes of the apparatus that produces the record. Administrative systems collect information relevant to eligibility, compliance, taxation, service delivery, or organizational management; firms collect information relevant to production, customers, risk, or control; platforms record events that can be captured through their technical architecture. These records can be highly informative, yet their coverage follows the operational needs of the institution. Relations that matter economically can remain weakly observed when no reporting system has reason, authority, or technical capacity to record them.

The limitation is also distributed. Hayek's account of dispersed knowledge emphasized that economically relevant knowledge exists in incomplete and frequently contradictory fragments across many participants rather than as a single integrated dataset available to one observer (Hayek 1945). Contemporary digital infrastructures can aggregate quantities that were previously unavailable, but aggregation does not eliminate dispersed local knowledge. Tacit routines, contextual expectations, unrecorded obligations, local meanings, and strategic interpretations can remain distributed even in data-rich environments.

Observation can also be asymmetric. Powerful organizations may observe workers, consumers, suppliers, or users more extensively than those participants can observe the organizations that classify and act upon them. Regulators may receive disclosures unavailable to ordinary market participants; platforms may infer behavior from traces that users cannot inspect; organizations can combine datasets across domains while individuals encounter only the immediate interface. Relational knowledge therefore has a distribution as well as a quantity. The question concerns who can observe which relations, at what resolution, and under what rights of access.

Partial observation does not imply that relational claims are arbitrary. It requires explicit evidential scope. A study can state which relations are directly observed, which are inferred, which are represented through proxies, which are inaccessible, and which may be missing systematically. Section 1.22 showed that contemporary evidence infrastructures make such distinctions increasingly tractable. The epistemic discipline is to treat improved observation as an expansion of access rather than as completion of the object.

1.25.2 Representation and Model Dependence

Observed traces become relational knowledge only after they are represented. A representation identifies the entities or positions to be distinguished, the relations to be recorded, the attributes attached to them, the temporal resolution of observation, and the boundary within which the description is constructed. This dependence is present in statistical tables, legal categories, network graphs, field models, agent-based simulations, and qualitative relational maps alike. Relational analysis therefore inherits the epistemic problem already identified for economic categories in Section 1.1: analytical objects become visible through historically and methodologically specific forms of description.

Statistical and administrative classifications provide an obvious case. Desrosières showed historically how statistical reasoning depends on conventions of classification, coding, equivalence, and aggregation that make heterogeneous cases comparable (Desrosières 1998). Hacking likewise emphasized that categories and styles of reasoning have histories and can participate in the formation of the objects they classify (Hacking 2002). For GRE, the implication is that a relational dataset never contains relations in an entirely pre-analytical form. It contains observations organized through decisions about what counts as an actor, event, tie, transaction, household, firm, sector, location, or period.

Formal relational models make these decisions especially explicit. A network representation requires nodes and edges; a higher-order representation requires specification of group interactions; a field representation requires a domain, variables, locality, and boundary conditions. Newman and Battiston and colleagues show how different relational formalisms preserve different structures and support different dynamical questions (Newman 2003; Battiston et al. 2020). A pairwise graph can be appropriate for one problem and lose essential information for another in which an interaction exists only through a group or institutional configuration.

Model dependence therefore concerns the conditional character of inference. A conclusion can be robust within one representation and change when the same empirical material is organized differently. The appropriate response is comparison rather than the search for a representation free of assumptions. Where several defensible models exist, GRE can ask which distinctions each preserves, which it suppresses, and which conclusions survive translation across representations. Later methodology chapters develop this principle through triangulation, sensitivity analysis, and model plurality.

Representation also feeds back into practice. Once a model becomes an administrative category, performance indicator, credit classification, eligibility rule, or platform score, it can change behavior and institutional treatment. Model dependence then becomes generative as well as epistemic: the representation partly enters the relational system it was designed to describe. This possibility strengthens the requirement that GRE state the standing of its models precisely. A model can be descriptively useful without being ontologically exhaustive, and its institutional use can create consequences not contained in its original evidential purpose.

1.25.3 Causal Underdetermination

Relational association does not by itself identify the mechanism that generated it. Two organizations may display similar network positions for different historical reasons; a strong association between membership and outcome may reflect selection, common institutional exposure, reciprocal influence, or an unobserved relation; a policy intervention may coincide with change while several other processes evolve simultaneously. The problem becomes more demanding in generative systems because relations, subjects, institutions, and constraints can coevolve, allowing causes and conditions to change while the observed process unfolds.

The econometric identification literature provides a disciplined language for this limitation. Manski argues that empirical analysis should distinguish what the avail-

able data identify from what follows only after additional assumptions are introduced, and develops methods for learning under incomplete data and partially identified treatment responses (Manski 2008). The relevance to GRE is methodological rather than doctrinal. Rich relational data can narrow the space of plausible explanations while leaving several mechanisms compatible with the observations. Stronger causal claims require stronger design, temporal evidence, institutional knowledge, or assumptions whose credibility must be stated rather than hidden inside the model.

Generative analysis adds historical underdetermination. Path-dependent systems can reach similar visible states through different sequences, and similar interventions can produce different consequences when they enter different institutional trajectories. North's account of institutional change and Arthur's treatment of increasing returns both make historical sequence analytically consequential (North 1990; Arthur 1989). The present state therefore need not uniquely reveal the path that generated it, while a path reconstructed from records may still admit competing mechanism accounts.

Causal underdetermination is especially important for relational intervention. An observed improvement after strengthening one relation can coexist with changes in resources, expectations, network position, institutional recognition, or external conditions. A claim that the relation generated the improvement should therefore identify the mechanism, timing, relevant alternatives, and evidence that discriminates among them. Where the evidence supports only contribution, enablement, or association, the language of the claim should remain correspondingly limited.

This limitation does not reduce GRE to causal skepticism. It specifies an evidential gradient. Some cases support strong identification; others support partial identification, mechanism plausibility, process evidence, or bounded counterfactual claims. The research task is to align claim strength with evidential strength. A generative framework is most useful when it makes additional mechanism questions visible, while remaining willing to leave several explanations open when the evidence does not discriminate among them.

1.25.4 Boundary and Scale Dependence

Relational descriptions depend on where the system boundary is drawn and at what scale the system is observed. An organization's internal network can appear dense when suppliers, regulators, households, and infrastructures are excluded, while the same organization can occupy a peripheral or dependent position in a wider production network. A household can appear as one allocation unit in national accounts and as a differentiated set of care, income, authority, and dependency relations at a finer resolution. Neither description is automatically defective. Each answers a different question by preserving a different set of distinctions.

The statistical literature provides a classic warning against transferring relationships across levels of aggregation. Robinson demonstrated that correlations calculated for grouped populations can differ materially from corresponding relationships among individuals and that aggregate associations therefore do not license direct inference about individual behavior (Robinson 1950). The lesson extends beyond ecological correlation. Relations observed at one scale can be generated by compositions,

constraints, or interactions that disappear when the analysis moves to another scale.

Complex-systems research supplies a complementary perspective. Bar-Yam's multiscale framework treats structure as scale-dependent and emphasizes that the organization visible at one resolution can differ from that visible at another (Bar-Yam 2004). Network analysis likewise depends on the population of nodes and ties admitted to the graph (Newman 2003). Centrality, clustering, brokerage, modularity, and dependency can all change when the boundary expands, when a layer is added, or when a higher-order interaction is represented explicitly.

Boundary selection also has normative and political consequences. A firm-level productivity analysis can exclude unpaid household labor on which workers depend; a project-level cost calculation can exclude environmental effects outside the administrative jurisdiction; a platform-level analysis can omit alternative infrastructures that determine user exit; a national analysis can externalize transnational labor or ecological relations. The boundary therefore determines which effects become internal to evaluation and which remain external to it.

GRE should consequently treat boundary and scale as reportable analytical choices. Robust relational claims should indicate whether their conclusions persist across plausible alternative boundaries and resolutions. Where conclusions change, the variation is itself informative: it identifies the scale or relational neighborhood at which the mechanism appears. This discipline makes multiscale disagreement a source of knowledge rather than a defect to be concealed by choosing one preferred level.

1.25.5 Temporal Limits of Generative Evaluation

Generative evaluation faces a temporal limit because the object of evaluation includes consequences that have not yet fully emerged. A transfer can alter capacity only after training, trust, infrastructure, or institutional learning accumulates. A new dependency can remain invisible while short-run output rises. A legal or organizational reform can change incentives immediately while its effects on membership, bargaining position, or future options unfold over years. The evaluation window therefore participates in the result.

Historical economics already contains several mechanisms that make timing consequential. North emphasizes that institutions shape subsequent incentives and paths of change, while Arthur shows how early events can be amplified through increasing returns and produce later lock-in (North 1990; Arthur 1989). These mechanisms imply that a present intervention may acquire significance through a trajectory whose later stages are unavailable at the moment of decision. The evaluator observes a prefix of the process rather than the completed process.

The problem is sharper for generative value because later effects can include changes in the capacity to generate further relations and options. An educational opportunity may alter later learning relations; infrastructure can generate complementary investment; institutional access can create future membership and information; extraction can weaken capacities whose loss becomes visible only after repeated use. Short observation windows can therefore favor effects that manifest quickly and discount effects whose causal pathway is delayed or distributed across

scales.

Long-horizon evaluation also encounters changing contexts. The institutional environment, technology, value structure, and subject positions relevant to an intervention can change while the intervention's effects unfold. A model calibrated to the initial context can therefore lose adequacy before the trajectory ends. This is one reason why adaptive evaluation and institutional learning, discussed in Sections 1.22 and 1.24, are historically important: they permit judgments to be revised as later evidence arrives rather than treating the first evaluation as final.

Temporal incompleteness places a limit on certainty rather than on evaluation itself. GRE can distinguish immediate outcomes from delayed effects, preserve the assumptions under which projections are made, identify indicators of intermediate mechanism, and reopen judgments when new stages of the trajectory become observable. Intergenerational and environmental evaluation makes this requirement especially visible because the subjects affected by present action can include persons who cannot participate in present evidence production or decision procedures (World Commission on Environment and Development 1987).

The five limits developed in this section define an epistemic boundary around the contemporary opening reconstructed in the chapter. More data leave observation partial; richer formalisms remain representation-dependent; relational patterns can support several causal accounts; boundaries and scales shape what becomes visible; and generative evaluation remains temporally incomplete while the future is still being produced. These limits do not cancel the case for GRE. They determine the form that a responsible relational economics must take: explicit about observation, conditional about models, disciplined about causal language, transparent about scale and boundary, and revisable across time. Section 1.26 extends the argument from knowledge to governance by examining the practical constraints that arise when institutions attempt to act within systems they can only partially know.

1.26 Contemporary Limits of Relational Governance

This section identifies the practical limits that remain when relational knowledge is translated into governance. Its role in the chapter is to complement the epistemic limits developed in Section 1.25: even when relevant relations can be observed with reasonable confidence, governing them requires administrative categories, legally actionable statuses, computationally tractable representations, normative judgments, and institutional authority over observation and classification. The objective is to specify five recurrent constraints on relational governance: administrative reification, legal dependence on stable categories, computational complexity, normative plurality, and asymmetries in the power to observe and classify. The discussion is institutional and diagnostic. It does not develop a general governance theory, which belongs to the later GRG programme; it clarifies why richer relational knowledge does not automatically yield frictionless or normatively determinate intervention.

1.26.1 Administrative Reification

Relational governance requires administrative action, and administrative action requires objects that can be named, compared, recorded, assigned responsibility, and linked to procedures. This requirement creates a recurring tension. Relations are often continuous, overlapping, historically variable, and distributed across more than one institution, while administrative systems operate through discrete records, statuses, eligibility categories, reporting units, and decision rules. Governance therefore converts a relational field into administratively actionable objects. The conversion is necessary for implementation, but it can also stabilize the representation more strongly than the underlying relation warrants.

Modern statistical and administrative systems provide a clear illustration. Statistical practice depends on conventions that establish equivalence, coding, classification, and aggregation among heterogeneous cases (Desrosières 1998). Standardized quantitative procedures also became institutionally attractive because they support impersonal and transportable judgment (Porter 1995). These achievements make large-scale administration possible. They also establish a practical grammar in which only some aspects of relational life become legible enough to govern.

The problem can be described as administrative reification: a representation introduced to make a relation governable can acquire the practical standing of the relation itself. A household category may become the unit through which eligibility is determined; an employment status may determine access to benefits; a reporting entity may define which transactions are consolidated; a statistical sector may determine how economic activity is aggregated. The administrative object then influences the distribution of resources and responsibilities, so its boundary has causal consequences even when the underlying relational configuration remains more complex.

Hacking's historical ontology is useful for specifying the feedback involved. Classifications can become part of the conditions under which people and institutions understand, organize, and respond to the classified object (Hacking 2002). The point for GRE is not that every category mechanically creates what it names. It is that classificatory schemes can enter the relations they describe through eligibility rules, compliance procedures, accounting boundaries, organizational incentives, and social recognition. Administrative representation can therefore become one component of the generative environment.

Relational governance cannot remove this problem simply by adding more categories. Finer classification increases descriptive resolution, but it also increases administrative complexity and may create additional boundaries whose practical effects require justification. Nor does replacing discrete categories with continuous scores eliminate reification. A score can become an equally powerful administrative object when access, risk, priority, or surveillance is tied to it. The central governance question concerns how a representation is used, how contestable its boundary remains, and how easily the institution can revise it when the relations it governs change.

The practical implication is a discipline of representational modesty. Administrative categories should be treated as instruments with stated scope, provenance, and revision procedures. Where a category carries high-stakes consequences, gov-

ernance should preserve some capacity to inspect cases that fit the administrative representation poorly. This principle does not dissolve the need for categories. It recognizes that governance acts through abstractions whose convenience can otherwise conceal their generative effects.

1.26.2 Legal Dependence on Stable Categories

Law intensifies the demand for stability because rights, duties, liabilities, ownership claims, contracts, jurisdiction, and procedures require sufficiently determinate subjects and objects. Economic relations may change rapidly, yet legal institutions must decide who bears an obligation, who controls an asset, which entity enters a contract, which claimant has standing, and which boundary determines responsibility. Relational governance therefore encounters a second limit: the more fluid the underlying relations become, the more difficult it is to preserve both relational sensitivity and legal determinacy.

Organizational law illustrates the productive side of stable legal categories. Hansmann and Kraakman show how organizational forms create standardized legal entities and partition assets and creditor claims, making complex collective activity governable through relatively stable legal boundaries (Hansmann and Kraakman 2000). Trust law can likewise separate control, benefit, and claims against assets in ways that organize relations among trustees, beneficiaries, settlors, and third parties (Hansmann and Mattei 1998). These forms do more than describe economic relations. They constitute durable positions through which those relations can be coordinated over time.

The same stability can become constraining when relational reality changes more quickly than legal form. A firm may reorganize production across contractors, platforms, subsidiaries, and algorithmic systems while liability remains attached to formally recognized entities. A worker may occupy economically dependent positions that fall imperfectly within inherited employment categories. A digital platform may mediate transactions across jurisdictions whose legal classifications do not align. The governance problem is therefore temporal as well as conceptual: legal categories need enough persistence to support expectation and accountability, while economic relations continue to evolve.

Accounting and statistical systems reveal analogous tensions. The IFRS Conceptual Framework treats the reporting entity as a boundary constructed for financial reporting and allows that boundary to include a single entity, part of an entity, or multiple entities (IFRS Foundation 2018). The System of National Accounts similarly relies on institutional units capable of owning assets, incurring liabilities, entering contracts, and making economic decisions (European Commission et al. 2009). Such frameworks show that institutional practice already works with analytically constructed boundaries. Relational governance can therefore revise boundaries, but it must do so through procedures that preserve comparability, responsibility, and legal intelligibility.

The limit is consequently structural rather than merely conservative. Governance cannot continuously redefine every subject and relation at the speed of the underlying economy without destabilizing the expectations that institutions themselves sus-

tain. Legal and administrative forms have characteristic revision times. Their relative slowness can support coordination by making obligations predictable. The same slowness can generate mismatch when new relations become economically consequential before the corresponding legal categories evolve.

GRE should therefore treat legal stability and relational sensitivity as jointly necessary institutional properties whose balance varies by domain. Some contexts require durable categories because responsibility must remain traceable across time. Others require flexible recognition because fixed categories systematically omit economically dependent or newly mediated relations. The analytical task is to identify which features require continuity, which can be revised, and what institutional process governs the transition. Systematic theories of legal change belong outside GRE, but the economic consequences of such temporal and classificatory mismatch remain central to relational analysis.

1.26.3 Computational Complexity

Relational governance also faces a computational limit. As the number of relevant actors, ties, higher-order interactions, temporal states, institutional constraints, and possible interventions increases, the space of relationships that could matter expands rapidly. Contemporary computation makes much richer analysis possible, as Section 1.21 established, yet increased computational capacity does not remove the need to simplify. Governance decisions must operate with finite models, finite observation windows, and finite time for deliberation.

Network analysis already demonstrates how relational structure creates analytical burdens absent from isolated-unit models. Newman surveys methods for representing large systems through networks, while higher-order network research shows that pairwise edges can fail to preserve interactions that exist only at the level of groups or simplicial structures (Newman 2003; Battiston et al. 2020). Adding temporal variation increases the problem further because the relevant structure is then a sequence of changing relational configurations rather than a single graph. The computational object can become very large before uncertainty in measurement or causality is even considered.

Complex-systems analysis adds another difficulty: local interventions can propagate through feedback, adaptation, and reorganization. Bar-Yam's multiscale treatment emphasizes that different structures become visible at different scales and that organization at one scale cannot be inferred straightforwardly from another (Bar-Yam 2004). A governance model that represents only one scale may therefore miss interactions that dominate elsewhere. A model that attempts to include every scale can become too complex to interpret, calibrate, or use within a decision process.

Computational complexity is consequently also a problem of model selection. Governance must choose which relations to resolve, which to aggregate, which time horizon to simulate, which behavioral responses to include, and which uncertainty to represent. Agent-based models can explore heterogeneous interaction, while dynamical and network models can reveal trajectories, feedback, and topological dependence. Each representation reduces the system differently. Richer models may expose mechanisms hidden by simpler ones, yet they can also become harder to validate and easier

to overfit to assumptions rather than evidence.

The practical limit becomes especially visible when a model is used for intervention. Decision makers often need an answer before exhaustive computation, data collection, or model comparison is possible. In such settings the relevant standard is not maximal descriptive detail but sufficient robustness for the decision at hand. A relational governance process should therefore identify which conclusions survive plausible changes in boundary, scale, representation, and parameter assumptions. Later chapters develop this through sensitivity analysis, model plurality, and adaptive revision.

Computational capacity thus changes the frontier of feasible governance without eliminating incompleteness. The historical significance of contemporary computation lies in making previously inaccessible relational structures analyzable. The corresponding discipline lies in refusing to treat computational resolution as equivalent to causal certainty or institutional wisdom. The more complex the model, the greater the need to state what it omits, which assumptions drive its results, and which decisions would change if another representation were adopted.

1.26.4 Normative Plurality

Relational governance is further limited by normative plurality. A relational description can show that an intervention changes access, dependence, capability, trust, participation, risk, ecological conditions, or future possibilities. The description does not by itself determine how these consequences should be ranked. Relations can support several legitimate values simultaneously, and changes that improve one dimension can burden another. Governance therefore requires normative judgment in addition to relational knowledge.

The capability approach provides one important illustration. Sen shifts attention from resources alone toward the substantive opportunities people possess to achieve valued ways of living (Sen 1999). This move makes conversion conditions and heterogeneous circumstances analytically visible, but it does not reduce all valued functionings to a single universally fixed metric. Human-rights traditions introduce another vocabulary centered on recognition, equality, participation, and protected claims (United Nations General Assembly 1948; United Nations General Assembly 1966). Environmental and intergenerational frameworks extend evaluation to conditions affecting future persons and ecological systems (World Commission on Environment and Development 1987). Commons scholarship adds concerns with collective rule making, participation, and durable institutional arrangements (Ostrom 1990). These frameworks overlap, yet they are not interchangeable.

Normative plurality becomes particularly demanding when consequences are distributed across time and scale. An intervention can improve immediate output while reducing long-horizon ecological resilience. A classification can improve administrative consistency while excluding a minority whose circumstances fit poorly. A platform policy can increase average efficiency while concentrating dependence on an intermediary. A commons institution can protect collective resources while imposing participation burdens unevenly. Relational analysis reveals these connections more clearly, but greater descriptive richness can increase the number of values that enter

evaluation.

This is a limit on optimization rather than a rejection of it. Optimization is appropriate where the objective, constraints, and metric are sufficiently specified and normatively legitimate for the local problem. The difficulty arises when governance projects heterogeneous values into a single scale without examining what the conversion suppresses. GRE therefore needs to distinguish between locally commensurable objectives and domains in which value translation remains partial, contested, or institutionally imposed. The later chapters on heterogeneous value and justice develop this problem directly.

Normative plurality also limits claims about generativity. A system capable of generating more relations, options, or future capacities is not therefore morally superior. Generativity describes a capacity of a system; goodness requires additional normative premises. A relation can be highly generative while reproducing domination, environmental harm, or exclusion. Conversely, some constraints can be ethically justified precisely because they limit what may be generated. Relational governance must therefore keep generative evaluation and normative evaluation analytically connected without collapsing one into the other.

The governance implication is procedural as well as philosophical. Where values cannot be reduced credibly to one metric, institutions need ways to expose the relevant dimensions, represent affected positions, preserve disagreement, and revise decisions as consequences become clearer. Participation, rights, public reasoning, and institutional contestability become important partly because normative plurality cannot be resolved by data alone. GRE can analyze the economic effects of these arrangements while leaving the choice among comprehensive moral theories open.

1.26.5 Power over Observation and Classification

The final limit concerns power over the production of governable reality. Relational governance depends on observation, categorization, measurement, and model construction. The actors controlling these processes can influence which relations become visible, which subjects are recognized, which outcomes are measured, and which interventions appear administratively available. Observation and classification therefore have a political economy of their own.

The history of statistical reasoning makes this visible. Desrosières shows that statistical categories depend on conventions that make heterogeneous cases comparable, while Porter demonstrates how quantitative standards acquire authority through institutional practices of objectivity (Desrosières 1998; Porter 1995). Hacking adds that classifications can participate in shaping the objects and persons to which they are applied (Hacking 2002). Together, these traditions imply that the infrastructure of observation is not a neutral window placed outside economic relations. It is itself composed of institutions, technologies, standards, professional roles, and access rights.

Contemporary data infrastructures intensify this issue because observational capacity is unevenly distributed. Section 1.25 noted that platforms, firms, regulators, public agencies, researchers, and individuals can possess very different access to the same relational system. The World Bank's treatment of data-governance ecosystems explicitly emphasizes that data use depends on institutional arrangements, interop-

erability, safeguards, and relations among multiple actors (World Bank 2021). OECD work on data-driven public sectors similarly treats data governance as a system-wide institutional problem rather than a purely technical matter (Ooijen et al. 2019). The ability to combine, interpret, and operationalize data is therefore itself an economic capability.

Power can enter at several points. An institution may determine which categories are officially recognized; a platform may define the events its interface records; a rating system may choose the variables that enter a score; an employer may observe worker performance at greater resolution than workers can observe organizational decision rules; a public authority may possess administrative records unavailable to the persons classified by them. These asymmetries affect both knowledge and action because the observing institution can convert its representation into eligibility, pricing, ranking, surveillance, resource allocation, or enforcement.

Classification power should nevertheless be distinguished from arbitrary control. Institutions often require standardized categories to coordinate at scale, preserve legal equality, maintain comparability, and administer scarce resources. The relevant GRE question concerns the relational conditions under which classificatory authority becomes accountable. Important dimensions include transparency about category construction, rights to correction or appeal, separation between measurement and automatic sanction where appropriate, access to provenance, and the possibility of revising categories whose consequences diverge from their intended scope.

The same point applies to models. A relational model used only for research has one kind of influence; the same model embedded in a decision system can acquire allocative power. The transition from description to intervention changes the normative and institutional burden carried by the model. Governance therefore needs to track who constructs the representation, who can inspect it, who bears its errors, and who possesses authority to revise it. These questions connect epistemology directly to economic power without implying that every act of measurement is domination.

Taken together, the five limits of this section qualify the practical promise of relational governance. Administrative systems require simplification; law requires stability; computation requires tractable models; normative plurality requires judgment; and observational infrastructures distribute classificatory power unevenly. None of these limits makes relational governance impossible. They determine the conditions under which it can remain accountable, revisable, and proportionate to what is actually known. The historical opening identified in the preceding sections is therefore accompanied by a corresponding discipline: greater relational visibility expands the space of possible intervention while also making the institutional consequences of representation harder to ignore.

1.27 The Double Character of Contemporary Technical Capacity

This section synthesizes the technical and institutional developments examined in Sections 1.19–1.26 by identifying their double character. Contemporary infrastructures expand the capacity to observe relations, predict outcomes, simulate alterna-

tives, and assist decision-making. The same infrastructures can also intensify surveillance, behavioral steering, infrastructural dependence, and concentration of analytical power. The objective is to state this duality without assigning technology an intrinsic political direction. The discussion proceeds through five coupled developments: observation and surveillance, prediction and behavioral intervention, computational assistance and concentration, artificial intelligence as both analytical capacity and economic power, and the relation between technical capability and epistemic humility. The method is historical and institutional: technical affordances are treated as capacities whose economic consequences depend on ownership, access, authority, institutional embedding, and the relations through which technical outputs become actionable.

1.27.1 Observation and Surveillance

Contemporary data infrastructures make a wider range of economic relations observable at finer temporal and organizational resolution. Administrative records can be linked longitudinally; platforms record interaction histories; firms collect transaction and workflow data; sensors and digital systems produce machine-generated traces; and public institutions increasingly organize data across previously separated administrative domains. These developments provide important conditions for relational analysis because relations that once appeared only through episodic surveys or retrospective reconstruction can increasingly be observed as evolving patterns (Einav and Levin 2014; World Bank 2021; Ooijen et al. 2019).

Observation acquires a different institutional character when visibility is asymmetric and linked to consequential action. A platform may observe participants' transactions and interactions at a level of detail unavailable to the participants themselves. An employer may observe task timing, communication patterns, or performance indicators while workers possess limited visibility into the models used to evaluate them. A public authority may combine administrative sources that no individual subject can assemble. In these cases, expanded observation becomes part of a relation between observer and observed rather than a purely epistemic improvement.

The distinction between observation and surveillance therefore turns on relational conditions as much as on the technical act of data collection. Relevant conditions include who observes whom, whether visibility is reciprocal, which purposes authorize collection, who controls the resulting records, whether subjects can inspect or correct representations, and which decisions can be made from the collected data. The same technical infrastructure can support accountability in one configuration and disciplinary control in another. OECD and World Bank work on data-driven public systems accordingly places institutional safeguards, governance arrangements, and relations among data holders and users alongside the expansion of analytical capacity (Ooijen et al. 2019; World Bank 2021).

Algorithmic management provides a concrete economic illustration. Kellogg, Valentine, and Christin document how computational systems can participate in directing, evaluating, and disciplining work, showing that the relevant technology is embedded in organizational relations of authority rather than operating as a detached measurement device (Kellogg et al. 2020). The observational capacity is eco-

nomically consequential because it can be converted into scheduling, performance evaluation, task assignment, or sanction.

For GRE, the important historical change is therefore an increase in the resolution at which economic relations can be rendered observable together with an increase in the asymmetry with which such observation may be distributed. Relational visibility creates new possibilities for research and governance while also making control over observation itself an economic resource. The analytical task is to trace the institutional relation that converts visibility into action.

1.27.2 Prediction and Behavioral Intervention

The second development concerns the coupling of prediction with intervention. Improvements in data availability and computational modeling allow institutions to estimate future outcomes at a scale and frequency that would previously have been impractical. Prediction can support screening, forecasting, risk assessment, resource prioritization, and other decisions in which action depends on expectations about future states. Manski's treatment of prediction and decision emphasizes the importance of distinguishing what data identify from what follows only after additional assumptions, a distinction that remains central when predictive systems enter practical decision processes (Manski 2008).

Prediction becomes economically generative when the predicted classification changes the conditions under which the subject subsequently acts. A risk score may alter access to credit or insurance. A ranking may alter visibility in a marketplace. A forecast may change inventory, investment, or staffing. A recommendation system may reorganize attention. A workplace model may alter assignments, targets, or evaluation. The technical output therefore participates in the relational system that produces the next round of data.

This feedback means that predictive performance and causal understanding occupy different analytical positions. A model may rank future outcomes accurately while leaving the mechanism producing those outcomes only partially specified. Once a prediction is used to intervene, the intervention can alter incentives, opportunities, expectations, and observed behavior. The subsequent data then reflect both the underlying process and the institution's prior decisions. Relational governance therefore requires attention to the pathway through which prediction becomes action rather than treating predictive accuracy as a complete account of policy or organizational adequacy.

Algorithmic control in organizations illustrates this coupling. Systems that predict performance or classify workers can also structure the tasks, metrics, and incentives through which later performance is produced (Kellogg et al. 2020). The distinction is especially important in settings where subjects adapt strategically to measures or where institutional decisions affect the opportunities that later appear in the data. Prediction can then become one component of a recursively generated environment.

The double character of predictive capacity lies in this recursion. Better prediction can reduce local uncertainty and improve the timing or targeting of decisions. The same capacity can intensify behavioral intervention when predictions are embedded in institutions with authority over access, ranking, work, prices, or eligibility. GRE

therefore treats prediction as an epistemic capacity whose economic consequences depend on the relation between model, decision-maker, affected subject, and subsequent feedback.

1.27.3 Computational Assistance and Computational Concentration

Contemporary computation also combines diffusion of analytical assistance with concentration of upstream productive capacity. At the level of use, software, cloud services, machine-learning tools, and generative systems can reduce the time and expertise required for search, coding, drafting, simulation, and data analysis. Experimental and workplace evidence on generative AI already shows that assistance can raise productivity in bounded tasks and that gains can be heterogeneous across users (Noy and Zhang 2023; Brynjolfsson et al. 2025). These developments can broaden access to forms of analytical work that once required larger teams or more specialized training.

The upstream conditions of frontier computation display a different structure. Advanced model development depends on large-scale compute, specialized hardware, data infrastructure, engineering expertise, and substantial capital expenditure. The 2026 AI Index reports that industry produced more than ninety percent of notable AI models in 2025 and documents rapid growth together with substantial concentration in global AI compute infrastructure (Stanford Institute for Human-Centered Artificial Intelligence 2026). The diffusion of interfaces to many users can therefore coexist with concentration of the infrastructural capacity on which those interfaces depend.

These two movements should be analyzed together. A small organization may gain access to powerful analytical assistance through an external service while becoming more dependent on a small number of infrastructure providers. A researcher may gain computational capacities that would once have required institutional-scale resources while losing visibility into training data, model updates, or service continuity. A firm may reduce internal analytical costs while increasing switching costs or exposure to upstream pricing and access decisions. Local capability expansion can therefore occur together with systemic dependency.

Computational concentration is not an automatic consequence of computational progress. Open models, shared infrastructure, public research institutions, interoperability, and falling hardware costs can diffuse capability. The present historical configuration nonetheless makes the relation between downstream accessibility and upstream concentration analytically important. GRE needs to distinguish the availability of a tool to users from ownership or control of the productive infrastructure that makes the tool possible.

The distinction also matters for value capture. Assistance can generate productivity gains across a broad set of users while infrastructure owners capture rents through access fees, complementary services, proprietary interfaces, data advantages, or control over standards. The distribution of gains therefore depends on the institutional pathways through which computational capacity is accessed and monetized. Technical diffusion and economic concentration can proceed simultaneously because they operate at different layers of the production structure.

1.27.4 Artificial Intelligence as Analytical Capacity and Economic Power

Artificial intelligence sharpens the double character of contemporary technical capacity because it can function simultaneously as an analytical instrument and as an economically controlled productive asset. As an analytical instrument, AI can expand the capacity to search, summarize, classify, generate hypotheses, write code, compare scenarios, and interact with complex information environments. The productivity evidence reviewed in Section 1.11 shows that these systems can complement workers and redistribute access to task-relevant expertise in specific settings (Brynjolfsson et al. 2025; Noy and Zhang 2023).

Analytical capability becomes economic power through institutional conversion. A model that can classify customers, workers, suppliers, applicants, or content has limited allocative consequence until an organization can connect its classifications to prices, access, visibility, employment, credit, procurement, or enforcement. A system capable of generating high-quality recommendations has limited bargaining power unless an actor controls the infrastructure, interface, or organizational position through which those recommendations shape decisions. The distinction between capability and power therefore remains essential.

Several conversion interfaces are especially important. Ownership links technical capacity to claims over revenue and assets. Platform position links analytical capacity to control over access and intermediation. Organizational authority links prediction to task assignment and evaluation. Infrastructure ownership links computational capacity to dependency and pricing. Data access can reinforce model quality and observational asymmetry. These relations can combine, allowing a technically capable system to become part of a durable structure of economic influence.

The concentration documented in the AI Index is therefore relevant to economic power without establishing a deterministic relation between frontier capability and social dominance (Stanford Institute for Human-Centered Artificial Intelligence 2026). Concentrated model development and compute create one possible basis for asymmetry; law, market structure, interoperability, public infrastructure, competition, organizational design, and user exit determine how that asymmetry is converted into power. The same technical system can occupy different economic positions under different institutional arrangements.

AI also complicates the location of agency inside economic systems. A firm may delegate analysis to a model while retaining formal decision authority. Workers may rely on AI assistance while remaining responsible for output. Platforms may embed model judgments in ranking systems that influence participants without presenting the model as an independent economic subject. These arrangements distribute analytical agency across humans, organizations, and artificial systems. GRE therefore benefits from treating AI first as a relationally embedded capacity and then asking which subject positions, claims, dependencies, and responsibilities are generated around it.

This approach also preserves the distinction developed in Section 1.16 between economic subjecthood and final metaphysical personhood. An artificial system can become economically consequential through its position in productive and decision

relations even where legal or moral personhood remains absent. The economic problem concerns how capability is institutionalized, who controls its deployment, who bears its errors, who captures its returns, and which forms of dependency follow.

1.27.5 Technical Capability and Epistemic Humility

The expansion of technical capacity increases the need for epistemic discipline. Richer data, larger models, faster simulation, and more capable artificial systems permit analysis of economic structures that were previously inaccessible. They also increase the number of representations, model choices, generated hypotheses, and intervention pathways that researchers and institutions must evaluate. Technical capability can reduce some forms of uncertainty while creating new dependencies on complex systems whose limitations are difficult to observe directly.

The distinction between symbolic performance and epistemic adequacy remains central. Bender and colleagues caution that fluent language generation should not be treated as equivalent to understanding, and the argument applies more broadly to the interpretation of machine-generated analytical output (Bender et al. 2021). A system can produce coherent classifications, explanations, forecasts, or policy drafts whose evidential basis, causal adequacy, or domain validity still requires independent examination. The lower marginal cost of producing analysis can therefore increase the scarcity of verification and judgment.

Contemporary AI evaluation provides a second illustration. The 2026 AI Index documents rapid capability gains together with declining transparency for some frontier systems and growing difficulty in maintaining benchmarks that remain informative as model performance changes (Stanford Institute for Human-Centered Artificial Intelligence 2026). Improved technical performance does not remove the need to ask what a benchmark measures, how training and evaluation data relate, which failure modes remain hidden by aggregate scores, and how results transfer into institutional settings.

Relational and generative systems add another source of uncertainty because observation and intervention can change the system being analyzed. A model embedded in allocation, ranking, or governance can alter the behavior that later supplies its evidence. A classification can reshape the subject position it describes. A successful intervention can transform the relation that made the original model valid. The practical value of a model therefore depends partly on whether institutions can detect when the conditions supporting it have changed.

Epistemic humility in GRE is consequently a positive methodological discipline. It includes calibrated claim strength, explicit model assumptions, provenance, validation against alternative representations, preservation of uncertainty, rights of contestation where models affect subjects, and willingness to revise conclusions as relations evolve. Computational and AI assistance can strengthen each of these practices when used to compare models, search evidence, test sensitivity, and document provenance. Their contribution is greatest when technical capacity expands the range of questions that can be examined while institutional arrangements preserve the capacity to recognize error.

The double character of contemporary technical capacity can now be stated in the

terms required by this chapter. The same historical developments that make relational and generative economics increasingly possible also increase the capacity to observe, classify, predict, intervene, and concentrate control over the infrastructures through which economic reality is represented. Technical progress therefore widens both the epistemic reach of economic inquiry and the institutional stakes of economic representation. This combination supplies an important part of the historical opening for GRE developed in the next section: the contemporary economy is simultaneously more relationally observable and more dependent on the governance of the very instruments that make such observation possible.

1.28 Historical Opening for Generative Relational Economics

This section draws together the historical argument developed across Sections 1.1–1.27. Its role is to explain why Generative Relational Economics becomes intelligible as a distinct research programme under the present historical configuration. The objective is narrower than a claim of historical inevitability. GRE is treated as one possible theoretical response to a conjunction of transformations in productive forces, inherited relations of production, scarcity, allocation, subjecthood, scientific representation, computation, evidence, and institutional form. The discussion therefore proceeds through six linked developments: transformation of productive forces, tension within inherited relations of production, transformation of scarcity and allocation, reorganization of productive dependence, destabilization of entity-centered subjecthood, and the emergence of economic problems whose object is increasingly relational and generative. The method is historical-material and reconstructive. It asks which material and institutional changes make certain economic questions more difficult to contain within inherited abstractions, while preserving the possibility that other theoretical responses to the same historical condition remain available.

1.28.1 Transformation of Productive Forces

The contemporary opening for GRE begins with a transformation in productive forces. Marx's historical-material formulation linked changes in productive forces to tensions within existing relations of production, while leaving open the concrete form through which such tensions are resolved (Marx 1859). Chapter 1 has used this formulation as a historical orientation rather than as a deterministic law. The relevant contemporary change is the expansion of productive capacity through digital networks, data infrastructures, automated cognition, machine learning, large-scale computation, and globally distributed organizational systems.

Digitalization lowers important costs of search, copying, communication, tracking, and verification, thereby changing which transactions and forms of coordination are economically feasible (Goldfarb and Tucker 2019). Artificial intelligence extends this transformation into cognitive and symbolic tasks. Task-based analyses of automation emphasize that technologies can displace some forms of labor while creating complementary or reinstated tasks elsewhere, so technological change should be studied through changing task structures rather than through a simple substitution narrative

(Acemoglu and Restrepo 2019). Experimental and workplace evidence on generative AI similarly indicates substantial productivity effects in bounded cognitive tasks, with gains distributed unevenly across workers and contexts (Noy and Zhang 2023; Brynjolfsson et al. 2025).

The historical significance of these developments lies in the kind of productive capacity they make increasingly available. Earlier mechanization primarily expanded the scale and speed of physical production. Contemporary systems also expand the production, recombination, classification, translation, and circulation of symbols. They therefore intervene in domains previously associated with expertise, communication, research, administration, and professional judgment. The result is a productive system in which material, informational, symbolic, organizational, and computational capacities are more tightly coupled than in earlier industrial configurations.

The transformation is also uneven. Access to advanced analytical interfaces can diffuse rapidly while upstream infrastructures remain highly concentrated. Frontier model development depends on capital-intensive compute, specialized hardware, data infrastructure, and organizational capability, and recent AI-industry evidence documents continuing concentration in frontier model production and compute capacity (Stanford Institute for Human-Centered Artificial Intelligence 2026). Productive expansion therefore coexists with new dependencies on infrastructure providers, model developers, platforms, and institutions able to finance and govern high-cost computational systems.

This combination matters for GRE because it changes the analytical object of production. Productive capacity is increasingly difficult to locate within a single worker, firm, machine, or asset. It emerges from relations among human expertise, software, models, data, platforms, organizational routines, legal permissions, energy and compute infrastructures, and transnational supply networks. The transformation of productive forces therefore creates a historical setting in which relational configuration becomes more directly productive and in which the capacity of relations to generate later capabilities becomes economically salient.

1.28.2 Tension within Inherited Relations of Production

The transformation of productive forces becomes theoretically consequential when it is placed beside inherited relations of production. Modern economic institutions developed around property, contract, firms, employment, administratively recognizable recipients, and relatively stable categories of productive contribution. These forms remain indispensable. They organize responsibility, allocate rights, structure investment, and make complex economies legally and administratively actionable. Their historical effectiveness is one reason entity-centered economic analysis became so powerful.

Contemporary productive organization places increasing pressure on the assumption that productive contribution can be attributed cleanly to bounded entities. Firms remain important, yet production may depend on platform ecosystems, contractual networks, external research communities, data contributors, open-source infrastructures, cloud providers, supply chains, and distributed knowledge relations. Coase's

analysis of firms already treated organizational boundaries as an institutional response to the comparative costs of using markets and internal direction rather than as a natural partition of economic reality (Coase 1937). Granovetter's account of embeddedness later emphasized that economic action is situated within ongoing social relations rather than exhausted by atomized actors or anonymous markets (Granovetter 1985). Contemporary digital production intensifies the practical relevance of both observations.

A second tension concerns employment. Wage labor historically connected productive contribution, income, organizational membership, and social recognition. Automation and AI can loosen these connections by altering which tasks require human labor and by changing the relative productive advantage of workers across tasks (Acemoglu and Restrepo 2019; Korinek and Stiglitz 2019). The resulting problem is not reducible to the quantity of employment. It concerns the institutional architecture through which access to income, insurance, training, status, and participation has been attached to employment. A productive transformation can therefore become an allocative and recognitional transformation even when total output rises.

A third tension concerns ownership and control. Productivity gains generated by collective infrastructures can be appropriated through legally concentrated claims. Evidence on the rise of highly productive "superstar" firms provides an important structural precedent: technological and organizational changes can increase aggregate productivity while simultaneously increasing concentration and altering labor shares (Autor et al. 2020). The specific mechanisms of AI-era concentration remain empirical questions, but the broader analytical point is already established. Productive abundance does not determine the distribution of control over productive assets or the claims on the surplus they generate.

These tensions do not imply that inherited relations of production have become obsolete. They indicate that the mapping from productive contribution to recognized ownership, income, authority, and participation becomes increasingly mediated by institutional relations. GRE enters this space by asking how economic relations convert productive capacities into claims, dependencies, exclusions, and future possibilities. The historical opening therefore lies in the growing explanatory importance of the conversion architecture connecting productive forces to institutional positions.

1.28.3 Transformation of Scarcity and Allocation

The same historical transformation alters the structure of scarcity. Classical and neoclassical economics developed powerful languages for problems in which scarce resources must be allocated among competing uses. That problem remains fundamental. Material resources, energy, land, housing, time, specialized labor, compute, and institutional capacity remain scarce. Contemporary technical change therefore does not abolish scarcity. It changes its distribution across domains and, in some domains, the relation between abundance at one layer and scarcity at another.

Symbolic production provides the clearest example. The marginal cost of producing text, images, code, summaries, and other representations can fall dramatically when generative systems are available. Yet the abundance of symbols increases the burden placed on attention, verification, interpretation, provenance, and trust. Si-

mon's formulation that an abundance of information consumes attention becomes more important as the production of candidate messages, claims, and artifacts becomes cheaper (Simon 1971). Arrow's analysis of trust as an economically consequential institution likewise indicates why systems of exchange cannot be understood through information volume alone (Arrow 1972). Where provenance and authenticity become uncertain, the capacity to verify and trust may become more valuable precisely because symbolic supply has expanded.

Allocation problems therefore move beyond the transfer of a nominally scarce resource to a recognized recipient. Access to attention, institutional gateways, trusted channels, computational infrastructure, and relations capable of generating later opportunities may become decisive. Sen's capability approach is relevant here because it distinguishes possession of resources from the substantive opportunities a person can actually realize under specific conversion conditions (Sen 1999). GRE extends this concern temporally: present allocations can change the relations and capacities through which later opportunities are generated.

This temporal extension changes the meaning of scarcity. A resource can be abundant at the point of production while the relations required to convert it into learning, recognition, authority, or participation remain scarce. Knowledge artifacts can be plentiful while trustworthy epistemic communities remain difficult to build. Computational tools can be widely accessible while frontier compute remains concentrated. Information can be abundant while institutional attention remains rationed. A system can therefore experience simultaneous abundance and scarcity at different relational layers.

The historical opening for GRE lies partly in this layered structure. Allocation remains central, but the analytically relevant object increasingly includes the relation through which a resource becomes effective and the downstream conditions the allocation helps reproduce. The question shifts from the amount transferred to the generative pathway through which a transfer becomes capacity, dependence, participation, exclusion, or future option. This shift provides the historical bridge from an allocation-centered economics toward a generative relational one.

1.28.4 Reorganization of Productive Dependence

The development of artificial generativity introduces a further historical possibility. Political economy has long examined societies in which persons depend on goods and services generated through the activity of others and in which division of labor, property, employment, exchange, and monetary claims organize access to those outputs. This description is not offered as an exhaustive origin theory of markets or money. It identifies a persistent structural problem: subjects are not materially self-sufficient, and access to socially generated capacities and products must therefore be organized through institutions. Marx's later political writings are relevant here because they connect distributive arrangements to the organization of the conditions of production rather than treating consumption shares as an isolated problem (Marx 1994).

Artificial intelligence, especially when considered together with robotics and automated infrastructures, makes it possible to ask how this structure changes when an expanding range of useful outputs can be generated without another person's direct

labor. The present evidence concerns bounded tasks rather than a fully autonomous productive system, and task-based analyses caution against treating automation as a single process of total substitution (Acemoglu and Restrepo 2019; Korinek and Stiglitz 2019). The historical significance lies instead in the possibility opened by the trajectory: some forms of instrumental dependence on another human's productive activity may weaken as artificial systems become capable of producing, coordinating, or mediating a wider range of goods and services.

Such a development would not by itself dissolve political-economic dependence. Dependence can migrate. A subject who no longer requires another person's labor may still require access to models, compute, energy, data, robotic systems, land, networks, standards, legal permissions, or organizational infrastructures controlled by others. Productive abundance at the level of output can therefore coexist with scarcity at the level of access. The replacement of a human generator by an artificial generator does not constitute a transformation of the underlying relation when the capacity to use, modify, maintain, or redirect the generative system remains strongly conditioned by asymmetric claims or permissions.

This distinction reveals three analytically different layers. One concerns access to what has already been generated. A second concerns access to the capacity through which new outputs can be generated. A third concerns participation in shaping the conditions under which generation becomes possible and develops over time. Those conditions include material infrastructures, legal rules, knowledge, education, technical standards, organizational forms, relational networks, trust, institutional recognition, and increasingly the computational systems through which productive possibilities are opened or closed. The layers interact, but distribution at one layer does not determine distribution at the others.

The historical implication is that a reduction in necessary human labor need not produce a post-political-economic society. It can instead move the political-economic problem toward the organization of access to generative capacity and toward the formation, opening, closure, and reproduction of generative conditions. A society could become less dependent on human labor while remaining highly dependent on infrastructures whose use and evolution are unequally controlled. Conversely, broad access to productive outputs would remain incomplete if subjects had little capacity to participate in shaping the systems on which that access depends.

GRE treats this reorganization as an opening rather than as a technological destiny. It does not infer a particular institutional order from advances in artificial intelligence, nor does it assume that labor, exchange, money, or property disappear when artificial productive capability increases. The narrower historical claim is that AI makes a deeper political-economic question increasingly visible: who can enter, mobilize, influence, maintain, and alter the processes through which future economic possibilities are generated? Later parts of the book develop the implications for capital, power, exploitation, access, and governance. At this point, the question matters because it helps explain why the economic object of inquiry can no longer be exhausted by the distribution of already generated outputs.

1.28.5 Destabilization of Entity-Centered Subjecthood

The transformation of productive forces and scarcity also destabilizes inherited forms of economic subjecthood. Modern economic institutions became organized around subjects that could be recognized as workers, owners, consumers, households, firms, creditors, debtors, and public authorities. These roles were never exhaustive descriptions of the persons or organizations occupying them. They were nevertheless sufficiently stable for contract, taxation, accounting, employment, welfare provision, and statistical administration.

AI complicates this architecture because systems without settled legal or moral personhood can perform economically significant tasks, generate outputs, mediate decisions, and participate in organizational workflows. Bender and colleagues' critique of large language models remains important precisely because fluent symbolic performance does not settle questions of understanding, agency, or personhood (Bender et al. 2021). GRE therefore has reason to distinguish economic participation from final ontological status. A system may have economic effects without thereby receiving the standing of a human person, legal subject, or moral patient.

Human subjecthood is destabilized from the opposite direction. If productive tasks once central to employment can be performed more efficiently by artificial systems, the relation among work, contribution, income, recognition, and membership becomes less secure. Becker's human-capital framework captured an industrial and post-industrial world in which investments in education and skill were strongly connected to productive capacity and earnings (Becker 1964). Contemporary AI can alter the return structure of particular skills, and the social consequences depend on how institutions reorganize work, ownership, training, access, and participation.

The relevant distinction is between productive contribution, productive necessity, and subject worth. A person can contribute without being comparatively necessary for a task; a person can lose comparative productive advantage without losing the capacity for experience, relation, learning, care, judgment, or participation. Sen's emphasis on substantive freedom helps expose the insufficiency of reducing social standing to productive superiority (Sen 1999). The economic problem is therefore institutional as much as technological: inherited systems may continue to allocate income and recognition through roles whose historical relation to productive necessity is changing.

A relational account of subjecthood becomes useful under these conditions because it asks how economic positions are generated and stabilized through relations of recognition, responsibility, membership, dependence, and access. Such an account does not deny persons, firms, or organizations as entities. It asks which relations make those entities economically actionable and how changes in those relations alter the subject positions available in the economy. The destabilization of entity-centered subjecthood thus becomes one route by which contemporary conditions open space for a relational economic framework.

1.28.6 Emergence of Generative Relational Economic Problems

The preceding transformations converge in a class of problems whose object is neither a static entity nor a fixed relation. The central question becomes how economic relations generate later subjects, capacities, institutions, constraints, dependencies, and possibilities. This is the specifically generative dimension of the historical opening.

Several developments make such questions increasingly visible. Networked production means that the productivity of an actor can depend on the configuration of relations in which it is embedded. Institutional change means that rules can alter incentives while also changing the categories and relations through which later action occurs (North 1990). Evolutionary economics provides a language for routines, search, innovation, and changing populations of organizational practices (Nelson and Winter 1982). Path-dependent models show how early contingencies and increasing returns can shape later feasible trajectories (Arthur 1989). Contemporary network and multiscale methods provide additional tools for representing changing relational structures across levels (Newman 2003; Bar-Yam 2004).

The economic significance of generativity appears when present arrangements change the conditions of later generation. Education can alter future capabilities. Employment can generate professional networks and institutional access. Ownership can generate collateral, bargaining power, and future investment capacity. Platform participation can generate reputation and dependence simultaneously. Research infrastructures can generate new knowledge while concentrating access to data or compute. Allocation can therefore be evaluated partly through the futures it makes easier, harder, or impossible.

These problems exceed a static relational description because the relation itself may change through use. A cooperative relation can build trust or exhaust it. A labor relation can generate skill, dependence, identity, or exit capacity. A credit relation can expand productive capacity while changing future claims and bargaining positions. An institutional category can stabilize participation while reifying the boundary it recognizes. Generative analysis therefore asks how relations reproduce, transform, or dissolve the conditions under which later relations become possible.

GRE emerges historically at the intersection of necessity and possibility. It becomes more necessary because productive forces, scarcity, subjecthood, and power are increasingly organized through complex relations whose downstream effects matter economically. It becomes more possible because scientific, computational, evidential, and institutional capacities make such relations more observable and analyzable than before. Neither movement is complete. Relations remain partially observed, causal structures remain underdetermined, formal models remain selective, and governance remains constrained by law, normativity, computation, and power.

The historical opening should therefore be read as an invitation rather than as a conclusion. Contemporary conditions make a generative relational economics increasingly thinkable and potentially useful. They do not establish its superiority in advance. GRE must still demonstrate that relational and generative descriptions improve explanation, comparison, evaluation, or practical understanding in concrete economic problems. Section 1.29 therefore closes the chapter by stating the possibili-

ties and limits under which this historically situated research programme proceeds.

1.29 Historical Possibilities and Limits of Generative Relational Economics

This section closes Chapter 1 by stating the historical possibility conditions, analytical scope, and persistent limits under which Generative Relational Economics proceeds. Its role is to convert the chapter's historical reconstruction into a disciplined statement of theoretical standing. The objective is to specify what contemporary conditions make GRE increasingly feasible, which forms of analysis those conditions enable, which institutional developments permit relational and generative questions to become actionable, and which epistemic and normative limits remain constitutive. The discussion proceeds through relational observability, generative analytic capacity, institutional possibility, epistemic and normative limits, and the historical situatedness of GRE itself. The method is synthetic and reflexive. It draws on the chapter's historical, institutional, methodological, and normative analyses while treating GRE as one historically generated response among possible responses to the contemporary economic condition.

1.29.1 Relational Observability

A relational economics becomes practically possible only to the extent that economically relevant relations can be observed, reconstructed, or responsibly inferred. Contemporary economies generate a density of traces that earlier periods could rarely sustain at comparable scale. Administrative records, transaction logs, platform interactions, longitudinal surveys, organizational databases, supply-chain records, machine-generated telemetry, and public statistical infrastructures can preserve sequences of interaction rather than only isolated outcomes. Data infrastructures therefore enlarge the empirical space in which economic relations can be studied over time.

This expansion of observability matters because relations are rarely exhausted by the attributes of the entities they connect. A firm may possess a given stock of capital while occupying a highly dependent position in a supply network. A worker may have a given qualification while lacking access to the institutions through which that qualification becomes economically effective. A platform may mediate exchange while simultaneously structuring search, ranking, reputation, and access. Network analysis, longitudinal linkage, and higher-order relational models make some of these structures increasingly representable (Newman 2003; Battiston et al. 2020). Public-data frameworks likewise increasingly recognize administrative, survey, citizen-generated, and machine-generated data as complementary sources within wider evidence ecosystems (World Bank 2021; Ooijen et al. 2019).

Relational observability remains mediated. Data are produced through classifications, measurement conventions, legal permissions, technical architectures, and institutional incentives. Desrosières and Porter show in different ways that statistical objects depend on conventions of classification and comparability rather than emerg-

ing as transparent copies of the world (Desrosières 1998; Porter 1995). A database may therefore make a relation visible by first deciding what counts as an actor, event, category, transaction, or boundary. The resulting representation can be highly useful while remaining historically and institutionally constructed.

The distinction between a relational trace and the relation itself is therefore essential. Repeated communication may indicate collaboration, dependence, supervision, conflict, or routine administration depending on context. A contractual tie may formalize only part of the effective relation. Absence of recorded interaction may reflect genuine absence, informal coordination, inaccessible records, strategic concealment, or a measurement system designed around different categories. Section 1.25 therefore treated partial observation and representation dependence as persistent epistemic conditions rather than temporary technical inconveniences.

GRE consequently treats contemporary observability as a historical opening rather than as epistemic completion. More relations can be followed across time, organizations, and scales than was previously feasible, and this makes relational economic questions empirically more tractable. The same evidential expansion also increases the need to document provenance, classification, missingness, boundary choice, and the institutional production of data. Relational observability becomes scientifically valuable when the conditions of observation remain part of the analysis.

1.29.2 Generative Analytic Capacity

Relational observation supplies a map of connections and configurations; generative analysis requires an additional capacity to investigate how those relations produce later states, structures, constraints, and possibilities. Contemporary scientific and computational developments make this second task more feasible by allowing trajectories, endogenous change, feedback, heterogeneous interaction, and historical dependence to become explicit analytical objects.

Several methodological developments contribute to this capacity. Dynamical systems provide languages for trajectories and stability; complex-systems approaches examine emergence under heterogeneous local interaction; network and higher-order models represent changing relational topology; agent-based models permit heterogeneous actors and institutions to coevolve; and multiscale approaches make it possible to distinguish structures visible at different levels of aggregation (Strogatz 2024; Holland 2012; Newman 2003; Battiston et al. 2020; Tesfatsion 2006; Bar-Yam 2004). Evolutionary economics adds a specifically economic vocabulary for routines, search, innovation, and changing organizational populations, while path-dependent models clarify how early contingencies and increasing returns can alter later feasible trajectories (Nelson and Winter 1982; Arthur 1989).

These developments allow GRE to ask a stronger class of questions. A labor relation can be studied through the skills, networks, bargaining positions, and exit capacities it generates over time. An allocation can be studied through the institutional access or dependence it creates downstream. A platform relation can be studied through reputation, lock-in, and future option structure. A legal category can be studied through the subject positions and claims it makes actionable. Generative analysis therefore concerns the transformation of conditions under which later economic action occurs,

rather than only the immediate output associated with a present state.

Contemporary computation expands the feasible scale of this inquiry. Large simulations, temporal-network computation, differentiable pipelines, and hybrid empirical-modeling systems allow analysts to explore model families that would once have been prohibitively costly (Holme and Saramäki 2012; Baydin et al. 2018). Yet computational capacity changes the size of the model space more quickly than it resolves the problem of model adequacy. A simulation can represent a mechanism precisely while representing the wrong mechanism. A dynamic network can reproduce observed patterns while omitting the institutional meaning of the links. A path-dependent model can generate lock-in without establishing that the empirical case follows the proposed feedback process.

Generative analytic capacity must therefore remain tied to evidential discipline. The relevant gain is the ability to formulate, compare, and interrogate richer mechanisms, not the ability to eliminate historical contingency or uncertainty. Manski's distinction between what data identify and what additional assumptions contribute remains especially important when models become more elaborate (Manski 2008). GRE uses expanded analytic capacity to sharpen questions about generation, propagation, and transformation while preserving explicit uncertainty about mechanism, boundary, scale, and historical transfer.

1.29.3 Institutional Possibility

A theoretical framework becomes economically consequential only when institutions can recognize at least some of the objects it describes. Contemporary institutional development provides partial precedents for treating collective relations, shared assets, fiduciary responsibilities, capabilities, common resources, environmental constraints, and adaptive revision as legitimate objects of economic organization. These precedents do not constitute a ready-made GRE institutional order. They show that modern nomos already contains forms through which economic action can be organized around structures more complex than isolated ownership by a single bounded recipient.

Trust law, for example, can partition assets and organize claims among trustees, beneficiaries, and third parties through a durable legal structure (Hansmann and Mattei 1998). Cooperative institutions can connect economic participation to jointly owned and democratically controlled organizations (International Cooperative Alliance 1995). Commons scholarship demonstrates that groups can construct rule systems for governing shared resources under conditions that vary across successful and unsuccessful cases (Ostrom 1990). Human-development approaches shift evaluative attention from resource possession alone toward substantive capability and opportunity (Sen 1999). Environmental and intergenerational frameworks extend the relevant horizon beyond present output toward the conditions inherited by future participants (World Commission on Environment and Development 1987).

These institutional forms matter for GRE because they demonstrate several kinds of possibility. Economic claims can be attached to collective arrangements. Decision rights can be distributed. Stewardship can be distinguished from unrestricted alienation. Beneficial interests can differ from formal control. Rules can be revised when

ecological or social conditions change. Resources can be evaluated partly through the capabilities they enable. None of these arrangements is intrinsically generative or just; each can succeed, fail, exclude, or produce unintended dependencies. Their significance lies in demonstrating that the institutional grammar of economic life is historically variable.

Adaptive and evidence-informed governance provides a further possibility. Contemporary public-governance frameworks increasingly emphasize monitoring, evaluation, evidence updating, and institutional learning across policy cycles (OECD 2020a; OECD 2020b; OECD 2020c). Such arrangements create institutional space for decisions to be revised as downstream effects become visible. For GRE, this is particularly relevant because generative evaluation is temporally incomplete. If an intervention changes capabilities, relations, constraints, or option spaces over time, institutional arrangements require procedures for observing those effects and reopening prior judgments.

Institutional possibility therefore concerns the capacity to make relational and generative objects actionable without assuming that every relation should be formalized. Legal recognition can stabilize a relation while also reifying it; measurement can make a collective visible while narrowing its meaning; adaptive governance can increase responsiveness while also expanding surveillance or administrative reach. GRE consequently treats institutional development as an enabling condition whose design remains normatively and politically contestable.

1.29.4 Epistemic and Normative Limits

The historical possibility of GRE is inseparable from limits that cannot be removed by greater technical sophistication alone. Relations remain partially observable, causal mechanisms remain underdetermined, boundaries and scales remain analytically consequential, and generative trajectories remain temporally incomplete. Section 1.25 established these limits at the level of knowledge, while Section 1.26 showed how they reappear in governance through administrative abstraction, legal categories, computational tractability, normative plurality, and unequal power over observation and classification.

The first limit concerns inference. Rich relational data do not automatically distinguish causation from selection, common causes, strategic adaptation, or unobserved structure. Longitudinal evidence can improve temporal reconstruction without guaranteeing identification. Larger models can represent more mechanisms while creating additional degrees of freedom. The appropriate response is calibrated claim strength: association, mechanism evidence, historical reconstruction, counterfactual support, and formal plausibility should be distinguished rather than compressed into a single language of proof. Manski's analysis of identification provides a useful discipline for this restraint (Manski 2008).

The second limit concerns scale and boundary. An observed relation can change meaning when the analytical boundary expands. A cooperative relation within one organization may depend on extraction elsewhere in a supply chain. A beneficial local intervention may transfer risk across jurisdictions or generations. Robinson's demonstration that aggregate and individual correlations may differ remains a clas-

sic warning against treating patterns at one scale as direct evidence at another (Robinson 1950). GRE therefore treats multiscale analysis as a source of additional questions rather than a guarantee of a privileged final scale.

The third limit is normative. Generativity does not establish goodness. A relation can generate capability while also generating dependence; an institution can stabilize trust while excluding outsiders; an innovation can expand aggregate option space while closing options for particular groups. Sen's capability framework is useful precisely because evaluative questions depend on the substantive freedoms available to differently situated persons rather than on resource totals alone (Sen 1999). Rights, participation, recognition, historical responsibility, and intergenerational consequences introduce normative dimensions that cannot be inferred mechanically from system dynamics.

The fourth limit concerns power. Observation, classification, prediction, and intervention are themselves relational capacities. Actors able to define categories, control data infrastructures, set model assumptions, allocate compute, or determine which evidence enters institutional processes can shape the reality that governance subsequently treats as given. Contemporary technical capacity therefore has the double character developed in Section 1.27: it can widen analytical access while concentrating the infrastructures through which economic reality is represented and acted upon.

These limits define GRE's practical discipline. The framework requires sufficiently strong claims to be useful and sufficiently explicit limits to remain revisable. Relational and generative analysis should be introduced where it changes explanation or evaluation, and its additional complexity should be justified by the economic problem under study. Epistemic humility is therefore an operational condition of the framework rather than a concluding disclaimer.

1.29.5 Generative Relational Economics as a Historically Situated Theory

GRE is itself part of the historical process it seeks to analyze. Its concepts arise within a period marked by global production networks, digital intermediation, artificial intelligence, symbolic abundance, transformed scarcity, intensified data infrastructures, expanding computational capacity, new forms of concentration, and growing concern with capabilities, commons, environment, and intergenerational effects. The framework therefore has no privileged position outside history from which to describe an economy that remains historically dynamic.

This situatedness clarifies the status of the chapter's central claim. Relations have always mattered in economic life. Earlier economic theories were not simply deficient because they often foregrounded entities, prices, resources, or allocation. Those abstractions were historically powerful because property, firms, households, employment, contracts, accounts, and administrative categories made many economic processes tractable through relatively stable units. Chapter 1 has therefore reconstructed entity-centered economics as historically intelligible before identifying the contemporary conditions that expose some of its limits.

GRE emerges when several developments converge. Productive capacity becomes

increasingly distributed across relations among humans, organizations, software, data, platforms, and infrastructures. Scarcity becomes layered across material, informational, attentional, institutional, and generative domains. Economic subjecthood becomes less securely tied to inherited productive roles. Scientific and computational languages make dynamic relational structures more representable. Evidence infrastructures make some trajectories more observable. Legal and institutional forms provide partial precedents for collective, capability-based, fiduciary, cooperative, and adaptive arrangements. At the same time, uncertainty, normative plurality, surveillance, concentration, and classification power remain unresolved.

A historically situated theory must therefore remain open to historical revision. Concepts developed for the present configuration may lose explanatory value as productive forces, institutions, and social relations change. New evidence may show that a proposed generative mechanism is weak, domain-specific, or incorrectly specified. Other economic traditions may explain a problem more parsimoniously or reveal dimensions GRE has obscured. The framework's commitment to revisability follows from the same historical reasoning used to study economic categories themselves: a theory that treats economic forms as historically generated cannot coherently exempt its own categories from historical development.

This position also limits GRE's disciplinary ambition. The framework is proposed as a language and research programme for economic problems in which relational constitution, generative transformation, heterogeneous value, multiscale dynamics, and downstream possibility are analytically consequential. It does not require every economic problem to be reformulated relationally, and it does not claim to replace theories that perform well within their domains of adequacy. Its contribution must be demonstrated through comparative explanation, empirical research, formal development, historical interpretation, and practical analysis.

Chapter 1 has established the historical condition under which such a programme becomes thinkable. The next task is intellectual rather than chronological. The following chapter reconstructs the philosophical, social-theoretical, economic, and scientific lineages from which the conceptual resources of GRE can be assembled. The movement from historical conditions to intellectual genealogy preserves the chapter's central discipline: GRE is approached as a historically situated theoretical formation whose concepts require both ancestry and justification, and whose future development remains open to criticism, counterevidence, and revision.

Chapter 3

Constitution and Research Programme of Generative Relational Economics

Chapter 3 completes the foundational movement of Part I by turning historical emergence and intellectual possibility into disciplinary constitution. Chapter 1 examined the historical conditions under which an economic framework centered on relations, generation, changing capacities, and future conditions of possibility becomes increasingly relevant. Chapter 2 reconstructed the philosophical, economic, social-theoretical, normative, scientific, and formal lineages from which such a framework can draw without treating their differences as reducible to a single doctrine. The present chapter asks a different question: what kind of research programme follows when those historical problems and theoretical resources are organized specifically around economic inquiry? Its task is therefore constitutive. It specifies the provisional identity, objects, scales, questions, epistemic commitments, modes of inquiry, normative interfaces, and boundaries of Generative Relational Economics (GRE).

The term *constitution* is used here in a methodological and disciplinary sense. GRE is still an emerging research programme, and its conceptual vocabulary remains open to revision through empirical inquiry, formal development, comparison with established economics, and criticism from neighboring disciplines. A preliminary constitution therefore does not fix an immutable doctrine. It makes explicit the commitments that currently organize the programme, the questions that distinguish it, the conditions under which a contribution can reasonably be described as GRE, and the domains in which theoretical disagreement remains legitimate. Such specification is necessary for cumulative research. An open programme becomes difficult to evaluate when its objects, boundaries, and standards remain entirely implicit; a rigid programme loses the capacity to learn when provisional commitments are transformed prematurely into protected axioms. Chapter 3 develops an intermediate institutional form: sufficiently explicit to support research coordination and sufficiently revisable to permit theoretical evolution.

The chapter begins from a domain distinction already established at the end of Chapter 2. Generative Relational Theory (GR) supplies a broader orientation toward relations, recursive generation, historical transformation, changing conditions of pos-

sibility, and the possible transformation of effective rules of change. GRE develops that orientation within economics. Its primary concern is therefore economic life: production, allocation, circulation, reproduction, labor, care, ownership, credit, valuation, institutions, technological infrastructures, ecological dependencies, economic power, and the distribution of future capacities. The broader GR framework can interact with law, political theory, education, ecology, history, aesthetics, artificial intelligence, and other domains, while GRE remains responsible for showing why a particular problem is economically significant and how its claims relate to economic evidence and existing economic knowledge.

This disciplinary positioning gives the chapter two complementary functions. The first is selective. GRE requires boundaries because relation and generation are extremely broad concepts. A study does not become GRE merely because it describes a network, identifies an interaction, invokes emergence, or discusses long-run consequences. The programme is organized around more specific analytical questions: how economic relations constitute subjects and objects; how allocations are mediated through relational configurations; how present arrangements generate later capacities, constraints, values, dependencies, institutions, and possibilities; who can access, mobilize, and shape generative capacities and the conditions that sustain them; how those effects propagate across scales; how heterogeneous forms of value are converted, circulated, captured, dissipated, or returned; how economic power alters generative conditions; and how the conditions that govern future change can themselves be transformed. The second function is pluralistic. These questions can be investigated historically, interpretively, qualitatively, quantitatively, causally, formally, computationally, normatively, and through intervention-oriented inquiry. GRE does not require a single privileged method or mathematical representation.

The chapter consequently moves from disciplinary identity to problem structure and then from problem structure to research architecture. It first specifies the scope of the emerging programme and the economic problems that motivate it. It then develops a minimal primitive vocabulary for ontological emergence and identifies the heterogeneous objects and scales that GRE may investigate. Subsequent sections formulate characteristic GRE questions and clarify the distinctive analytical movement from allocation through relational mediation, generation, propagation, conversion, recirculation, extraction, and structural transformation. The chapter then addresses economic subjecthood, the orientation of generation, modes of inquiry, epistemic commitments, praxis, normative evaluation, power, heterogeneity, disciplinary boundaries, and criteria for research contribution. Its final movement treats GRE as a cumulative and internally plural programme, states major open problems, maps the architecture of the wider research agenda, and offers a preliminary constitution that can guide later chapters without foreclosing revision.

Several restraints govern this constitutional exercise. Ontological suspension remains the default: useful relational, dynamical, network, field, geometric, or computational representations do not by themselves establish the ultimate ontology of economic reality. Descriptive generativity remains distinct from normative desirability: a relation can generate durable capacities or self-reinforcing structures while also generating domination, ecological damage, exclusion, or vulnerability. Representation remains distinct from represented reality: measures, categories, graphs, models,

and simulations are epistemic constructions whose adequacy depends on the local question and evidence. Finally, disciplinary openness remains reciprocal. GRE can borrow from neighboring traditions, and those traditions can expose GRE's errors, omissions, and domain limits.

The result is intentionally preliminary. Chapter 3 provides enough constitution for the rest of the book to proceed with a stable research language, while leaving empirical, methodological, formal, and normative disagreements available for later development. The subsequent chapters can therefore deepen GRE's ontology, epistemology, methodology, praxis, substantive economics, theories of power and justice, epistemic economy, artificial intelligence, and domain applications without repeatedly renegotiating the programme's most basic disciplinary identity.

3.1 Disciplinary Identity of Generative Relational Economics

The role of this section is to establish the preliminary disciplinary identity of Generative Relational Economics (GRE) before the chapter specifies its problem-space, objects, methods, and standards of contribution. Its objective is to explain what kind of intellectual formation GRE currently is, the scope within which it makes economic claims, and the commitments that give coherence to otherwise heterogeneous research practices. The argument proceeds from the transition between theoretical proposal and research programme to the scope of the field, the priority of economics as its primary domain, the organizing commitments of relation and generativity, and the conditions under which the programme should remain open and revisable. The method is constitutive rather than taxonomic: the section proposes a working disciplinary identity capable of coordinating research without presenting that identity as historically settled.

GRE is best understood at this stage as an *emerging economic research programme*. The phrase marks both ambition and restraint. It indicates an effort to organize a cumulative body of questions, concepts, methods, models, empirical inquiries, and normative debates around a distinctive analytical orientation. It also recognizes that GRE has not acquired the institutional history, stabilized professional community, canonical methods, or settled boundaries associated with an established discipline or mature subfield. Its identity therefore rests primarily on a coherent problem-space and a set of research commitments rather than on institutional recognition.

This distinction matters because the vocabulary of GRE ranges across several domains. Relations are studied throughout sociology, economics, anthropology, network science, political theory, ecology, and philosophy. Generation appears in theories of production, reproduction, development, evolution, emergence, innovation, complexity, and social formation. Value is central to economics and also to ethics, aesthetics, ecology, and political theory. Fields, trajectories, networks, capabilities, institutions, subject positions, and historical transformations already possess rich literatures of their own. GRE gains disciplinary identity neither by collecting these vocabularies under a new label nor by claiming ownership over their objects. Its identity arises from the specific economic questions produced when relational constitution

and downstream generation are treated together as sustained objects of inquiry.

A characteristic GRE inquiry therefore asks how an economic arrangement changes more than the variables administratively attached to its immediate recipient or transaction. An allocation of money, land, information, compute, credit, legal recognition, care, education, infrastructure, or technological capability enters an existing relational configuration. The allocation can alter capacities, dependencies, bargaining positions, recognition, expectations, institutional practices, ecological conditions, or access to later opportunities. These changes can propagate through further relations, be converted into other forms of value or constraint, become self-reinforcing, dissipate, or transform the conditions under which subsequent economic action occurs. GRE treats these downstream and relationally mediated effects as part of the economic object rather than as automatically external to it.

The programme remains compatible with narrower analyses when they are adequate to the question. A price model, accounting identity, causal estimate, institutional comparison, historical interpretation, network representation, ethnography, or simulation can each provide the most appropriate access to a local problem. GRE does not require every study to represent the full relational and generative field. Its disciplinary claim is instead that certain economically consequential phenomena become visible only when analysis can move between immediate allocation and the relations through which future capacities and constraints are produced. This claim defines a research orientation rather than a mandatory universal model.

3.1.1 From Theoretical Proposal to Research Programme

A theoretical proposal can be organized around a small number of concepts. A research programme requires a wider architecture. It must identify recurring problems, specify objects of inquiry, permit methods appropriate to different forms of evidence, distinguish stronger from weaker claims, accumulate comparative findings, expose itself to revision, and provide criteria through which researchers can disagree productively. GRE enters this second task in Chapter 3.

The transition is significant because relation and generativity can otherwise remain suggestive but underspecified. A relational statement may simply observe that economic actors are connected. A generative statement may merely report that one event has consequences for another. A research programme needs sharper questions. Which relations are constitutive of the economic situation? What entities and subject positions are stabilized through them? Which changes can reasonably be attributed to a relation or configuration rather than to coincident conditions? Through what mechanisms do effects propagate? Which forms of value are generated, converted, captured, returned, or destroyed? How do effects vary across scale and historical time? Under what conditions does a generative process reproduce itself? When does it alter its own conditions of continuation? What evidence would count against a proposed account?

These questions turn GRE from a vocabulary into a programme of inquiry. They also make possible disagreement internal to GRE. Researchers can disagree about whether a particular relation is constitutive or incidental, whether a claimed downstream effect is causal or interpretive, whether a state-space model preserves the

relevant distinctions, whether a value conversion is commensurable, whether an intervention strengthens capability or dependence, or whether a historical transformation changes only outcomes or changes the effective rules through which outcomes are produced. Such disagreements are productive when the disputed objects, assumptions, scales, and evidential standards are made explicit.

A research programme also requires cumulative structure. One study may identify a recurring relational mechanism; another may test whether it travels across institutional contexts; a third may formalize the mechanism; a fourth may show where the formalization fails; a fifth may examine its normative consequences; and an intervention study may alter the relation and observe how the surrounding system responds. The contribution of GRE lies partly in making these inquiries legible to one another. Historical interpretation, qualitative evidence, quantitative estimation, formal modeling, and normative analysis can then address different aspects of a shared problem without being forced into a single epistemic hierarchy.

The programme should therefore distinguish several levels of theoretical commitment. Some propositions will function as organizing hypotheses: for example, that present economic relations can generate future capacities and constraints that are not well represented by immediate allocation alone. Others will be domain-specific empirical claims: a particular credit architecture may generate dependence under specified institutional conditions. Still others will be methodological proposals, formal representations, normative arguments, or exploratory analogies. Treating these levels as equivalent would weaken the programme. GRE becomes more rigorous when the standing of each claim is stated locally and can change through evidence or criticism.

The term *research programme* also protects GRE from premature closure. The field can contain competing accounts of generativity, alternative formal representations, and disagreements about value while retaining a recognizable common problem-space. A programme is strengthened when rival formulations expose assumptions that one formulation had made invisible. Internal plurality therefore becomes part of disciplinary development rather than evidence that the field lacks identity.

GRE's transition from proposal to programme can consequently be summarized through four requirements. It needs a stable enough vocabulary to support communication, a sufficiently explicit problem-space to distinguish relevant contributions, methodological openness appropriate to heterogeneous evidence, and institutionalized revisability through which its own categories can change. Later sections of this chapter elaborate each requirement. The disciplinary identity established here supplies their common orientation.

3.1.2 Scope of the Emerging Field

The scope of GRE is defined by an intersection rather than by a single class of objects. The first component is economic: the inquiry concerns production, allocation, exchange, circulation, reproduction, labor, care, ownership, credit, institutions, technology, ecological dependence, valuation, power, or other processes that materially organize economic life. The second component is relational: the analytical object includes relations or configurations through which subjects, capacities, constraints,

values, and opportunities are constituted or mediated. The third component is generative: the inquiry examines how those relations contribute to later states, possibilities, structures, or rules of change.

This intersection permits a broad empirical range while limiting conceptual inflation. A study of a labor platform can belong to GRE when it investigates how contractual, algorithmic, reputational, and infrastructural relations shape workers' future bargaining capacity, subject positions, dependence, or access to opportunity. A study of agricultural credit can enter GRE through the way financing relations reorganize production choices, ecological risk, household vulnerability, and later credit dependence. A study of education can become economically relevant to GRE when it examines the generation and distribution of capabilities, knowledge, credentials, networks, and future participation in production or exchange. A study of artificial intelligence can enter through changing productive capability, ownership of computational infrastructure, knowledge concentration, labor transformation, or new asymmetries in the capacity to generate economically consequential outputs.

The same objects can also be studied outside GRE, and that coexistence is expected. A legal analysis may focus on doctrinal validity, a sociological analysis on status relations, a psychological analysis on cognition, and a GRE analysis on the economic generation and distribution of capacities through the same institution. Domain boundaries therefore concern the primary research problem rather than exclusive ownership of empirical objects. Interdisciplinary work becomes especially important when the economic mechanism cannot be understood without juridical, cultural, ecological, technological, or political relations.

Scope also varies by temporal depth. GRE can examine immediate relational mediation, medium-term capability formation, long-run institutional reproduction, intergenerational effects, or transformations in the conditions that govern later change. The appropriate horizon depends on the generative claim. A microcredit intervention may require months or years to evaluate changes in debt dependence and productive capacity. An infrastructure investment may reorganize settlement, land value, ecological conditions, and institutional expectations over decades. Knowledge and educational processes can generate effects whose later manifestations are difficult to attribute to a single intervention. GRE therefore treats temporal horizon as part of research design rather than assuming that the period convenient for measurement is identical to the period relevant to generation.

The programme is similarly multiscalar. Generative effects can occur within persons, households, organizations, communities, markets, institutions, states, ecosystems, or transnational systems, and they can propagate across these levels. A policy that expands aggregate productivity can simultaneously weaken a local community's bargaining capacity; a household intervention can change community norms; an institutional classification can alter individual access to credit; a technological standard can reorganize international production networks. GRE does not presume that effects observed at one scale aggregate straightforwardly into effects at another.

A useful boundary follows from this scope. Relational complexity alone is insufficient to define a GRE contribution. Many systems contain numerous relations. GRE becomes relevant when the inquiry identifies an economically meaningful process through which relations contribute to generation, reproduction, transformation, dis-

tribution, or foreclosure. The analytical burden is therefore positive: the researcher should specify the relation, the generated object or capacity, the mechanism or interpretive pathway connecting them, the relevant scale and horizon, and the evidence appropriate to the claim.

This scope allows GRE to remain broad without becoming synonymous with social science. It welcomes interdisciplinary objects while retaining an economic center of gravity. It also leaves neighboring GR domains available for questions whose primary object lies elsewhere. The breadth of the programme is therefore an architecture of interfaces rather than a claim of disciplinary absorption.

3.1.3 Economics as the Primary Domain

GRE is constituted within economics because its motivating questions concern the organization of material and symbolic conditions through which economic life is produced and reproduced. Production, distribution, allocation, exchange, labor, care, investment, credit, ownership, technological capability, ecological dependence, institutions, and value formation remain central. The relational and generative vocabulary changes the analytical emphasis placed on these objects; it does not dissolve the obligation to engage economic mechanisms, evidence, and established economic explanations.

This primary-domain commitment has several consequences. First, GRE should be able to state what is economically at stake in an inquiry. A sophisticated relational description does not automatically become economic analysis. The researcher must connect the relational configuration to economically consequential capacities, constraints, valuations, flows, institutions, or distributions. Second, GRE remains answerable to existing economics. When a conventional model explains the relevant outcome more parsimoniously and with adequate empirical support, GRE has no disciplinary privilege that exempts it from that result. The programme earns analytical space by identifying dimensions that established representations omit or by connecting findings that remain separated across existing literatures.

Third, economics as the primary domain does not imply a narrow definition of economic value. Market prices, income, productivity, and output are indispensable in many inquiries, but economic life also depends on capabilities, care, ecological conditions, knowledge, institutional trust, infrastructure, social reproduction, and forms of relational value whose significance may be incompletely priced. GRE therefore studies how multiple forms of value enter economic processes, while preserving the distinction between economic relevance and universal commensurability.

Fourth, the economic domain contains both descriptive and normative questions. GRE can describe how a platform generates dependency or how an institution concentrates productive capacity without thereby deciding whether the arrangement is just. Normative inquiry enters when evaluative criteria are made explicit: distribution, capability, recognition, participation, ecological sustainability, generative justice, or other justified standards. Economics supplies part of the descriptive object; ethical and political reasoning remain necessary where evaluation exceeds positive explanation.

Fifth, the primary-domain commitment helps distinguish GRE from the wider GR

framework. GR can investigate generative relations in history, law, education, epistemology, aesthetics, governance, or other domains without reducing those domains to economics. GRE concerns those interfaces when they materially affect economic processes or when economic arrangements shape the neighboring domain. A legal rule governing property, for example, is relevant to GRE because it constitutes ownership relations, allocative authority, collateral possibilities, and future investment conditions. The same rule can simultaneously require independent jurisprudential analysis concerning legal validity, interpretation, or rights. The interface is real while disciplinary identity remains differentiated.

This differentiation is important for the future development of the research programme. Without it, GRE could expand until every relational phenomenon becomes an economic phenomenon and the term loses discriminative value. With an explicit economic center, interdisciplinary expansion becomes more rigorous: each borrowing must show what economic problem it helps explain and what aspects remain better handled by another domain.

Economics also offers GRE a demanding test environment because economic systems combine formal institutions, strategic behavior, material constraints, symbolic valuations, historical change, quantitative data, and normative controversy. A viable GRE research programme must therefore interact with several established modes of economic reasoning rather than relying on a single philosophical language. The field's disciplinary identity is strengthened when relational and generative claims produce better questions, better explanations, better empirical distinctions, or more adequate evaluations within this demanding domain.

3.1.4 Relation and Generativity as Organizing Commitments

Relation and generativity provide GRE with its two principal organizing commitments. Neither concept functions as a universal explanation. Relation directs attention to the possibility that economic entities, capacities, positions, and values are partly constituted through connections, dependencies, institutions, recognitions, and repeated interactions. Generativity directs attention to the possibility that present relations alter what becomes possible later. Their conjunction gives GRE its characteristic analytical movement.

The relational commitment begins from specification. A relation should be identified with enough precision to distinguish it from mere co-presence or statistical association. Depending on the inquiry, the relevant relation may involve ownership, exchange, debt, employment, care, authority, information, recognition, technological dependence, ecological dependence, legal standing, platform access, infrastructural connection, or another structured linkage. Relations can be direct or mediated, durable or episodic, formal or informal, symmetric or asymmetric, cooperative or exploitative, visible or weakly represented in available data. GRE does not require these differences to be collapsed into a common relational metric.

Relations can also be constitutive at different levels. A contractual relation may connect already recognized legal persons while simultaneously contributing to their later capacities. Other relations help constitute the relevant economic subject or object itself. Employment relations can stabilize occupational identities and access to

social insurance; credit relations can create debtor positions and classifications; platform rules can constitute categories of worker or seller; property institutions can define the objects over which exchange rights are recognized. Relational analysis therefore includes both interaction among entities and the relational production of entityhood.

The generative commitment adds temporal and counterfactual depth. A relation matters not only through its current state but through the capacities, constraints, structures, values, and subsequent relations it helps produce. Generation can involve accumulation, learning, reproduction, institutionalization, path formation, trust, dependence, lock-in, ecological change, innovation, subject formation, or the creation of new option spaces. Some generative effects amplify later agency; others narrow the range of feasible action. Many do both for different actors or at different scales.

GRE consequently treats generativity as descriptive before it becomes evaluative. A relation can be highly generative because it reliably produces further structures or capacities while remaining normatively objectionable. Monopoly power can generate entry barriers; surveillance infrastructures can generate behavioral control; debt can generate productive investment and also dependency; extractive institutions can reproduce themselves. The strength of a generative mechanism does not determine its justice. Normative orientation must be supplied through explicit evaluative argument.

The two commitments become especially distinctive when the generated effects alter the conditions of further generation. A subsidy can increase productive capacity; the expanded capacity can change market structure; the changed market structure can alter bargaining power and investment incentives; those changes can influence the design of subsequent policy. A technology can alter productivity while also reorganizing skills, ownership, infrastructure, and standards in ways that change which technologies can be developed later. At this point, economic analysis concerns more than a sequence of outcomes. It concerns transformations in the field of future possibility.

This recursive feature explains why GRE pays attention to what later chapters call generative conditions and effective rules of change. The language should remain modest. Many cases can be modeled adequately with fixed rules and changing state variables. Stronger claims about rule transformation require stronger evidence and clearer specification. GRE does not infer meta-level transformation merely because a system changes. It asks whether the mechanisms through which future states are produced have themselves been altered and what observations would support that inference.

Relation and generativity therefore organize research without dictating a single ontology or method. A historical study may reconstruct how property relations generated institutional persistence. A causal design may estimate how access to credit changes later productive capacity. A network model may represent diffusion through relational structure. An ethnography may identify meanings and recognition processes omitted by administrative data. A formal model may examine self-reinforcing dependence under specified assumptions. These inquiries share an orientation while preserving different evidential objects and standards.

The disciplinary identity of GRE resides in this organized plurality. Relation specifies the mediating architecture through which economic processes occur; generativity specifies the downstream production of capacities, constraints, values, structures, and possibilities. Their conjunction turns attention from isolated possession toward economically consequential histories of formation.

3.1.5 Openness, Revisability, and Disciplinary Development

An emerging research programme requires mechanisms for changing itself. GRE therefore treats openness and revisability as constitutive commitments rather than temporary concessions made during an early phase. Its concepts, categories, methods, and boundaries should remain corrigible through empirical failure, theoretical criticism, comparison with competing explanations, normative disagreement, and changes in the historical economy it attempts to understand.

Revisability begins with ontological suspension. GRE can use relational, processual, dynamical, network, field, geometric, or computational representations while leaving open the question of whether any one representation captures the ultimate ontology of economic reality. This stance permits formal development without transforming modeling convenience into metaphysical certainty. A network can be an excellent representation for one mechanism and an inadequate representation for another. A field model can capture distributed conditions while obscuring actor interpretation. A qualitative reconstruction can identify constitutive meanings that are difficult to parameterize while remaining unable to estimate population-level magnitude. Openness protects the programme from identifying one mode of access with reality itself.

Revisability also concerns the programme's own categories. Economic subjects, institutions, technologies, forms of labor, ownership arrangements, and modes of value production change historically. A research language adequate to one economic formation can become less adequate as new infrastructures and relations emerge. Artificial intelligence offers an obvious contemporary example: rapid changes in productive capability, knowledge generation, labor substitution and complementarity, compute ownership, and human-machine interaction may require categories that were less salient in earlier economic analysis. GRE's emphasis on historical generation would be inconsistent if GRE treated its own conceptual vocabulary as historically exempt.

The programme should therefore preserve records of theoretical change. When a category is revised, the earlier formulation should remain intelligible enough for researchers to understand what changed and why. This matters for cumulative inquiry. A field that silently changes the meaning of its central terms can create an appearance of agreement while losing comparability across studies. Explicit versioning of definitions, assumptions, measures, and model classes can make theoretical evolution a source of knowledge rather than a source of confusion.

Openness further requires external correction. GRE should remain answerable to mainstream economics, heterodox economics, economic history, sociology, anthropology, political theory, law, ecology, philosophy, computer science, and other relevant fields. The appropriate correcting discipline depends on the claim. A causal

claim can fail under econometric scrutiny; a historical claim can fail under archival evidence; a legal claim can misunderstand doctrine; an ecological model can omit biophysical constraints; a normative argument can rely on undefended values. Interdisciplinarity is therefore not only a source of concepts. It is a structure of accountability.

Internal pluralism performs a related function. Researchers working within GRE may prefer different ontologies, causal accounts, measures, formal systems, or normative theories. The field should permit such disagreement when the competing formulations remain explicit enough to compare. Productive pluralism differs from unrestricted eclecticism. Competing accounts should specify their domains, assumptions, explanatory targets, evidential support, and points of incompatibility. A programme grows when disagreement creates sharper tests and better distinctions.

Disciplinary development also depends on negative results and limits. A proposed generative mechanism may fail to replicate, operate only under narrow institutional conditions, or add little beyond an existing model. A relational representation may become computationally intractable without improving explanation. A broad concept of value may prove impossible to operationalize for a particular decision. Such findings belong inside GRE rather than outside it. A research programme that records only cases where its preferred vocabulary succeeds would gradually lose contact with the conditions under which that vocabulary is useful.

Finally, GRE should remain historically revisable in its normative orientation. The programme can state commitments to transparency, participation, non-domination, capability, ecological viability, generative justice, or other evaluative principles only by making their justification available for criticism. Historical change can reveal conflicts among values or forms of exclusion that an earlier framework failed to perceive. Normative learning therefore requires both continuity and openness: continuity sufficient to make commitments accountable, and openness sufficient to correct them.

The disciplinary identity proposed in this section is consequently provisional by design. GRE is an emerging economic research programme organized around relational constitution and generative consequence, committed to economics as its primary domain, open to methodological and formal plurality, and structured for revision through evidence and criticism. This identity is strong enough to distinguish a problem-space while remaining incomplete enough to learn from the research it enables. The next section can therefore move from the identity of the programme to the concrete classes of economic problems that give it substantive necessity.

3.2 The Problem-Space of Generative Relational Economics

The role of this section is to delimit the class of economic problems for which Generative Relational Economics (GRE) is intended to provide additional analytical leverage. Its objective is not to claim that these problems belong exclusively to GRE, but to identify the recurring situations in which analysis becomes incomplete when it stops at the immediate recipient, current output, present ownership, or a fixed description of economic actors. The section proceeds through nine problem families: relational

effects of allocation, downstream generation, access to generative capacity and conditions, value beyond possession and exchange, persistent asymmetry and power, changing economic subjecthood, symbolic abundance and representational instability, heterogeneous subjects and value structures, and transformation of future generative possibilities. The method is constitutive and problem-oriented. Each subsection identifies an analytical difficulty that already appears within economic life and states the additional questions that a generative-relational perspective places around it.

The problem-space of GRE begins from a simple observation with wide consequences: an economic intervention rarely terminates at the point where it is administratively recorded. A payment reaches a recipient, a loan enters a balance sheet, an educational opportunity is allocated to a student, infrastructure is installed in a locality, compute is assigned to an organization, legal recognition is granted to a category of actor, or information becomes available to a community. Each event can be represented as an allocation. Yet its economically consequential effects depend on the relations through which the allocated object becomes usable, convertible, reproducible, contestable, shareable, or restrictive. The immediate transfer is therefore one moment within a potentially longer generative process.

This does not make conventional measures irrelevant. Recipient-level outcomes, prices, quantities, income, productivity, ownership, expenditure, and welfare indicators remain indispensable where they answer the question at hand. GRE instead focuses attention on cases in which these measures capture only one layer of the economic transformation. The programme asks what new capacities, dependencies, relations, subject positions, institutional routines, representations, and later possibilities are generated after the administratively visible event. It also asks which possibilities are weakened, foreclosed, extracted, or displaced. The resulting problem-space extends economic analysis temporally, relationally, and across scales without presuming that every problem requires maximal complexity.

The eight problem families below are connected but analytically distinct. An allocation can alter future capability without changing formal ownership. A productive process can generate symbolic standing without generating transferable wealth. A capability asymmetry can remain benign in one relational configuration and become power in another. An artificial system can become economically consequential before its legal or moral subjecthood is settled. Symbolic abundance can expand expressive possibility while making evidence, attribution, and scarcity harder to stabilize. Heterogeneous actors can participate in one economic process while valuing its outcomes through partially incommensurable standards. GRE treats these differences as reasons to preserve a plural problem-space rather than compress them into one master variable.

3.2.1 Allocation beyond the Administrative Recipient

Many economic interventions are administratively organized around identifiable recipients. A household receives a transfer, a firm receives credit, a student receives a scholarship, a municipality receives infrastructure funding, a laboratory receives equipment, or a community receives access to a service. Administrative legibility requires such attribution because institutions must identify who qualifies, who re-

ceives, how much is transferred, and whether the transfer conforms to a rule. This recipient-centered representation is operationally necessary, yet it can be analytically narrower than the economic effects that follow.

An allocation enters a pre-existing relational environment. A monetary transfer can alter bargaining positions within a household, reduce dependence on one employer, enable mobility, change creditworthiness, or increase the capacity to support others. A scholarship can generate knowledge, recognition, networks, migration opportunities, future income, or new asymmetries between the recipient and those who remain excluded. Infrastructure can alter land values, mobility, ecological pressure, political expectations, and patterns of settlement. Access to compute can enable research, automation, surveillance, artistic production, or organizational concentration depending on surrounding capabilities and institutions. The economically relevant object is therefore often larger than the administratively named recipient.

GRE treats the recipient as an important entry point rather than the presumed boundary of analysis. The analytical task is to identify which relations are activated, weakened, or reorganized by an allocation and which downstream effects are sufficiently connected to the intervention to warrant inclusion. This requires boundary discipline. Expanding the field indefinitely would make attribution impossible and turn relational analysis into a description of everything connected to everything else. A GRE inquiry therefore needs to justify why particular relational pathways are economically material to the problem under study.

The extension beyond the recipient also changes how incidence can be understood. Formal receipt and effective benefit can diverge. A subsidy assigned to one actor may partly accrue to landlords, intermediaries, suppliers, creditors, family members, or platforms through price adjustment, contractual dependence, or relational obligation. Conversely, an allocation formally directed at one person can generate benefits for a wider group through care, knowledge sharing, network access, or local demand. Recipient-level accounting remains informative, while the relational incidence of an intervention can require a different map.

This problem becomes especially important where institutions evaluate success shortly after delivery. Immediate uptake can coexist with longer-term dependence, capability loss, market concentration, ecological degradation, or institutional displacement. The reverse is also possible: modest immediate output can generate durable capabilities whose value becomes visible only later. GRE therefore places the administrative recipient inside a wider temporal-relational field and asks how the intervention changes the conditions under which later economic action becomes possible.

The resulting problem is not simply one of externalities. Externality language often begins from a focal transaction and asks which effects fall outside the prices or decisions of the transacting parties. GRE can include such effects, but its concern is broader. Some downstream consequences are constitutive of the recipient's own future capability; others alter the identities and relations through which the original economic categories remain meaningful. The issue is therefore not only what spills outward from a transaction, but how an allocation participates in the production of a subsequent economic configuration.

3.2.2 Generation beyond Immediate Output

Economic analysis frequently evaluates a process through an observable output: units produced, income generated, services delivered, learning achieved, emissions reduced, jobs created, patents filed, or profits realized. Such outputs matter, yet a process can also alter the capacity to produce later outputs. GRE distinguishes these two analytical moments. Immediate output concerns what is produced within a defined interval or activity. Generative effect concerns how the process changes the capacities, relations, constraints, orientations, infrastructures, or rules through which subsequent outcomes may be produced.

The distinction is visible in ordinary economic life. Training can produce a credential while also changing confidence, professional networks, problem-solving capacity, and access to later institutions. A research grant can produce papers while also creating laboratories, datasets, collaborations, techniques, reputations, and future questions. A platform can produce convenience while also establishing standards, behavioral routines, data assets, dependency relations, and barriers to entry. Care can meet an immediate need while also maintaining the bodily, emotional, and social capacities through which later participation remains possible. A failed project can produce little immediate output while still generating knowledge about constraints, new alliances, or institutional learning.

These examples show why generativity cannot be inferred mechanically from output volume. High output can consume the capacities on which future production depends. A firm can raise short-run productivity by exhausting workers, degrading equipment, externalizing ecological costs, or eliminating slack needed for adaptation. An institution can increase publication counts while narrowing intellectual diversity. A resource boom can raise current income while weakening alternative productive capacities. Conversely, a process can appear inefficient in a short horizon because it invests in capacities whose effects are delayed or uncertain.

GRE therefore treats the temporal relation between present production and future productive possibility as a central economic problem. This includes positive generation, maintenance, regeneration, reproduction, depletion, and foreclosure. The relevant question is not whether every activity has downstream consequences; that proposition would be trivial. The research problem is to identify which downstream changes are economically consequential, through what mechanisms they occur, how durable they are, who can access them, and whether they remain reversible.

Generation also differs from simple multiplication. A process is generative in the stronger GRE sense when it changes the conditions under which later states can be produced. Replicating an identical output can matter economically, but repetition alone does not establish transformation of generative capacity. A production system becomes analytically interesting to GRE when participation, accumulated resources, learned practices, institutional recognition, or altered relations change what can subsequently happen. The generated object may be material, organizational, epistemic, symbolic, ecological, juridical, or relational.

This distinction creates a problem of attribution. Later capacities usually have multiple antecedents. A newly capable organization may have received funding, benefited from favorable regulation, recruited skilled members, inherited prior infras-

tructure, and learned from failed experiments. GRE should therefore avoid attributing the whole later capacity to one relation merely because the relation preceded it. Generative claims require mechanism-sensitive reasoning and calibrated scope. The field's interest in downstream effects increases rather than relaxes the burden of specifying how generation is believed to occur.

3.2.3 Access to Generative Capacity and Conditions

A further GRE problem concerns the difference between receiving what has already been generated and gaining effective access to the capacities through which new outcomes can be generated. Conventional distributive questions remain indispensable: who receives income, goods, services, assets, welfare, or other outputs? GRE adds a second layer by asking who can mobilize human, organizational, technical, institutional, or artificial generative capacity. It adds a third by asking who participates in shaping the conditions under which such capacity can exist, be maintained, and develop.

These layers become especially visible in economies organized around infrastructures. A subject can possess equipment yet lack the knowledge, networks, institutional recognition, data access, legal permissions, energy, compute, or organizational support required to make that equipment economically effective. Conversely, access to a powerful generative system can transform what a subject is able to produce even when the subject acquires little conventional property. The economically relevant object is therefore sometimes not the distributed thing itself but effective access to a configuration capable of producing later possibilities.

Artificial intelligence sharpens the problem because it can weaken one form of productive dependence while intensifying another. If artificial systems perform tasks for which subjects previously depended on other people's labor, some forms of human-to-human instrumental dependence may decline. Yet access to the artificial capacity can remain conditional on infrastructures, permissions, ownership, technical standards, energy, compute, or platform governance. A post-labor tendency would therefore not imply a post-political-economic condition. Dependence can migrate from labor-mediated access toward access to generative infrastructure.

GRE does not resolve these questions in advance by treating broad access, common ownership, decentralization, or generative autonomy as automatically desirable. Its constitutive task is narrower. It makes visible a problem that is easily obscured when analysis stops at current output: who can enter, mobilize, influence, maintain, and alter generative processes, and how are the conditions of such participation reproduced? Later chapters develop the associated theories of capital, power, exploitation, justice, and governance. Here the problem is included because it extends political economy from the distribution of generated value toward the organization of generative capacity and generative conditions without replacing the former question.

3.2.4 Value beyond Possession and Exchange

Possession and exchange provide powerful ways of organizing economic value. Ownership establishes claims over resources; exchange reveals willingness to trade un-

der particular conditions; prices coordinate decisions and permit aggregation across many activities. GRE retains these objects while addressing situations in which economically significant value depends on participation, relation, access, recognition, continued circulation, ecological condition, or future capability rather than possession alone.

A resource can have little value to an actor who lacks the relations required to use it. Data require interpretive and computational capacity. Credit requires institutional access and future repayment possibilities. Land depends on legal recognition, infrastructure, ecology, community relations, and permitted uses. Knowledge can gain value through dissemination and recombination rather than exclusion. Membership in a trusted network can create opportunities that cannot be transferred as a discrete owned object. Public infrastructures and commons can generate value through reliable shared availability. Care, reputation, cultural meaning, and institutional legitimacy similarly resist complete description through possession.

Value can also change form as it moves through relations. Economic resources can become educational capability, political access, symbolic standing, health, time, security, knowledge, or ecological resilience. These conversions are neither automatic nor necessarily commensurable. The same monetary amount can generate very different capacities under different institutional, bodily, geographical, or relational conditions. Conversely, forms of value that appear qualitatively different can sometimes be converted into economic advantage through mechanisms such as credentialing, collateralization, monetization, platform visibility, or legal recognition.

GRE treats these conversions as part of the economic problem because they influence who can participate in subsequent generation. The possession of a resource at time one may matter less than whether it can be converted into durable capability at time two. A person may formally possess information without possessing the literacy or authority required to act on it. A community may possess land while lacking political protection against dispossession. A researcher may possess an idea while lacking access to laboratories, collaborators, or publication channels. An organization may own technology whose value depends on ecosystems maintained by others.

This perspective also creates a problem of value trajectories. Value can circulate, recirculate, dissipate, be extracted, be destroyed, or become embedded in relations that outlast the originating exchange. An intervention that appears beneficial at one point may produce a later value transfer away from the original participants through debt service, rent, licensing, platform fees, intellectual-property claims, or unequal bargaining. Conversely, a resource can generate distributed value through open standards, shared knowledge, community infrastructure, or repeated reciprocal use.

The purpose of GRE is not to replace price with a universal alternative measure. Doing so would reproduce the commensuration problem in another form. The programme instead asks which forms of value are relevant to the generative process, how they are recognized or obscured, which conversions occur, and what is lost when heterogeneous values are forced onto one scale. Some studies may use monetary valuation; others may require capabilities, ordinal comparison, qualitative description, multidimensional indicators, or explicit acknowledgement of incommensurability.

The problem-space therefore includes a distinction between current value realiza-

tion and future value generation. An actor can possess valuable assets while occupying relations that reduce future autonomy or capability. Another actor can possess few assets while participating in institutions that generate durable access, learning, security, or collective capacity. GRE does not assume that future generativity should replace present welfare as the evaluative objective. It instead treats the relation between present value and future generative conditions as an economic question requiring explicit normative and empirical analysis.

3.2.5 Persistent Asymmetry and Economic Power

Economic relations routinely contain asymmetries. Actors differ in wealth, productive capability, knowledge, computational capacity, institutional access, bargaining position, vulnerability, mobility, legal recognition, and ability to exit a relation. Difference alone does not establish domination. A doctor and patient, teacher and student, infrastructure provider and user, or advanced technical system and ordinary user can possess highly unequal capabilities while participating in relations that remain mutually beneficial. The analytical problem is to understand when persistent asymmetry becomes economic power and how that power affects later generative possibilities.

GRE approaches power through the conversion of asymmetry into the capacity to shape another actor's options, dependencies, classifications, resources, risks, or future relations. Resource asymmetry can become power when one party controls access to necessities. Knowledge asymmetry can become power when one party can define the relevant evidence or obscure the consequences of a transaction. Institutional asymmetry can become power when one actor controls eligibility, procedure, or recognition. Exit asymmetry can stabilize dependence even where formal participation appears voluntary. Computational or informational asymmetry can allow one actor to predict, rank, personalize, or intervene in another's behavior at a scale the other cannot reciprocate.

This problem is generative because power can reproduce or deepen the conditions from which it arises. Control over capital can generate further capital; control over data can improve prediction and attract further users; institutional authority can shape the categories through which later authority is exercised; reputational advantage can increase access to opportunities that generate additional reputation. Such processes are not inevitable. Competition, law, collective organization, technological change, public infrastructure, and countervailing institutions can interrupt them. GRE is interested in the mechanisms that determine whether an asymmetry decays, persists, becomes self-reinforcing, or changes form.

Persistent asymmetry also complicates simple strategies of equalization. Some differences in skill, knowledge, role, or capability are produced by specialization and may be beneficial. Other differences may be difficult to eliminate or may arise continually through innovation. The problem for GRE is therefore not reducible to making actors identical. It concerns the relational conditions under which unequal capabilities remain compatible with meaningful participation, non-domination, contestability, access to alternatives, and the preservation of future capacity.

This issue becomes especially important under radical capability asymmetry. An

actor may rely on another whose productive, predictive, cognitive, financial, or infrastructural capacity is orders of magnitude larger. Traditional bargaining models can become insufficient when one party cannot meaningfully evaluate the other's capabilities, reproduce the service independently, or exit without severe loss. GRE treats such situations as economic problems of relational architecture. Governance may need to address access, reversibility, auditability, representation, fallback options, common infrastructure, or limits on conversion of capability into control.

The programme also distinguishes power from observable coercion. A relation can shape behavior through dependence, standards, defaults, classification, architecture, or anticipated exclusion without direct commands. Conversely, strong influence can sometimes arise from trust, expertise, or voluntarily delegated authority without amounting to domination. GRE therefore requires local analysis of mechanisms rather than treating every asymmetry as evidence of one universal power relation.

3.2.6 Subjecthood under Changing Productive Relations

Economic theories require some account of the actors who produce, exchange, consume, invest, work, own, decide, cooperate, and bear risk. These actors are often represented as given units for analytical purposes. That representation is frequently useful. Yet productive relations can also change the capacities, roles, identities, and recognition through which an actor counts as an economic subject. GRE treats this instability of subjecthood as part of its problem-space.

Industrialization transformed relations among workers, firms, households, professions, and states. Corporate forms created collective economic actors with legal capacities distinct from their members. Welfare institutions established categories of claimant, beneficiary, dependent, contributor, and protected person. Digital platforms reorganized relations among user, worker, producer, advertiser, seller, and data source. Contemporary artificial systems further complicate the picture by performing economically consequential tasks that were previously associated with human expertise, agency, authorship, coordination, or judgment.

The GRE problem is not to settle the metaphysical status of every possible subject before economic analysis can begin. It is to examine how economic systems assign, stabilize, contest, and transform subject positions. Legal status, contractual capacity, ownership, accountability, recognition, access to institutions, technological mediation, and productive participation can all affect who is treated as an actor and which consequences attach to that treatment.

Changing productive relations can also alter human subjectivity without replacing human subjects. A worker who collaborates with automated systems may become responsible for supervision rather than direct production. A creator working through generative tools may occupy changing relations to skill, attribution, originality, and ownership. A consumer can simultaneously become a source of behavioral data, content, training material, reputation signals, and network effects. A household member can become an economically visible care provider when institutions change the classification of care. Subject positions are therefore partly produced through the categories and relations of economic organization.

This creates problems for models that assume stable preferences, capabilities,

roles, or boundaries of agency across the period being analyzed. Participation in an economic relation can change what an actor knows, wants, can do, expects, or is permitted to become. These changes do not imply that subjecthood is infinitely fluid. Bodies, histories, institutions, legal status, material constraints, and persistent identities provide continuity. GRE's task is to identify which aspects of subjecthood are sufficiently transformed by economic relations to matter to explanation.

The problem also has distributive consequences. When productive systems redefine valued participation, some actors gain recognition while others lose it. Automation can reduce the market value of an existing skill while increasing the value of complementary judgment or coordination. Credential systems can open access while excluding actors whose competence is not institutionally legible. New categories can create rights and protections while also fixing identities in ways that become restrictive. GRE therefore studies subject formation together with the institutional conditions under which recognition generates capability or constraint.

3.2.7 Symbolic Abundance and Representational Instability

Contemporary economies increasingly operate through symbolic objects: data, classifications, scores, rankings, credentials, financial representations, software, models, digital identities, synthetic media, generated text, virtual assets, and machine-produced predictions. Symbolic production has become inexpensive in many domains, while attention, verification, trusted interpretation, and institutional recognition remain scarce. GRE treats this divergence between symbolic abundance and representational stability as a distinct economic problem.

A representation can influence economic reality even when it is incomplete. Credit scores affect access to lending; rankings affect applications and funding; metrics shape organizational behavior; maps and categories determine eligibility; recommendation systems alter visibility; forecasts influence investment; labels affect trust; and digital profiles mediate access to platforms or services. These representations do more than describe pre-existing actors. Once institutions act on them, they can change the relations and opportunities through which those actors subsequently develop.

Symbolic abundance intensifies this process because the cost of producing plausible representations can fall faster than the cost of verifying them. When text, images, claims, reports, credentials, signals, or forecasts can be generated at high volume, scarcity shifts toward provenance, attention, adjudication, trusted institutions, and the ability to distinguish meaningful variation from noise. Economic value can then accumulate around infrastructures that organize visibility and credibility rather than around content production alone.

Representational instability also arises when the underlying object changes faster than the categories used to represent it. Occupational classifications can lag behind new forms of work. Legal categories can lag behind technological capability. Statistical indicators can retain the same name while their social meaning changes. A model trained on historical data can continue producing stable outputs after the relations that made the historical pattern informative have shifted. The representation may remain technically consistent while its relation to the target becomes weaker.

GRE is concerned with this problem because representations participate in generative processes. A classification used to allocate resources can alter behavior, incentives, identities, and institutional structure. A ranking can change the population it was designed to rank. A predictive system can influence the outcome it predicts by affecting who receives attention or opportunity. A narrative about economic risk can alter investment and thereby change the risk environment. Representation is therefore both epistemic and potentially causal.

This does not mean that symbols possess autonomous power outside institutions and practices. Their effects depend on recognition, enforcement, infrastructure, interpretation, and material consequence. A score ignored by all relevant actors remains economically weak; the same score embedded in lending, hiring, insurance, or governance can become highly consequential. GRE therefore studies the relation among symbolic objects, institutional uptake, material allocation, and downstream generation.

The contemporary problem of symbolic abundance also raises questions about knowledge capital. If the production of codified knowledge becomes much cheaper, advantage may shift toward actors who control data, evaluation systems, distribution channels, trusted identities, proprietary infrastructure, or the capacity to convert symbolic output into institutional action. The economic structure of knowledge can therefore change even when information becomes more abundant. GRE treats this as a problem of changing generative conditions rather than assuming that abundance automatically produces equal access or equal capability.

3.2.8 Heterogeneous Subjects and Value Structures

Many economic models gain tractability by representing actors through a common set of variables or a shared metric of preference and welfare. Such representations can be highly informative when the relevant differences are commensurable. GRE also addresses situations in which subjects differ more deeply: in embodiment, cognition, temporal horizon, vulnerability, institutional status, ecological dependence, forms of agency, or the values through which outcomes are interpreted. Heterogeneity then becomes a constitutive feature of the problem rather than a residual variation around one common type.

Heterogeneous subjects can still enter economic relations. A child and guardian, patient and care institution, local community and multinational firm, present generation and future generation, human user and artificial system, or human economy and ecological system may be connected through exchanges, dependencies, constraints, and value creation even where their capacities and evaluative structures differ sharply. The analytical challenge is to represent the relation without pretending that the parties are equivalent or completely mutually intelligible.

Value heterogeneity intensifies this challenge. Economic decisions can involve income, autonomy, cultural continuity, ecological integrity, security, dignity, recognition, knowledge, aesthetic significance, collective identity, and future possibility. Some of these values can be monetized for particular purposes; others resist stable conversion or lose important meaning when reduced to price. Conflict can therefore arise not only over the distribution of one value but over which values should count,

how they should be represented, and who has authority to decide.

GRE approaches heterogeneous value through explicit pluralism. A study may compare several value dimensions, trace conversions among them, identify institutional priorities, or describe conflicts that remain partially incommensurable. The aim is not to prohibit aggregation. Aggregation can be indispensable for decision and coordination. The requirement is to distinguish the practical need for a decision rule from a claim that the underlying values are intrinsically reducible to one scale.

Heterogeneity also affects generative relations because the same intervention can expand one subject's capabilities while narrowing another's. Infrastructure can increase mobility while degrading an ecosystem or displacing a community. Automation can reduce routine labor while expanding organizational capability and concentrating control. Open information can increase public access while exposing vulnerable individuals. A generative process therefore needs to be indexed to subjects, scales, and value dimensions rather than described as generative in an unqualified sense.

The GRE problem-space consequently includes coexistence under incomplete commensurability. Economic relations often need to continue even where actors do not share one ontology, one value function, one time horizon, or one conception of flourishing. Governance then concerns the design of relations that preserve participation, contestability, translation, and revisability under difference. This is an economic issue whenever resources, capabilities, risks, and future possibilities are allocated through those relations.

The problem should also be distinguished from simple diversity. Diversity describes variation among actors or values. Heterogeneity in the stronger GRE sense becomes analytically significant when the differences affect what can be compared, exchanged, represented, or jointly generated. A heterogeneous relation may require several descriptive languages at once. Economic analysis must then resist both premature unification and the opposite conclusion that comparison is impossible.

3.2.9 Transformation of Future Generative Possibilities

The deepest extension in the GRE problem-space concerns interventions that change not only current states or future outcomes, but the space of possibilities from which later economic processes can unfold. An intervention can create new capacities, remove constraints, alter institutions, establish standards, transform expectations, reorganize infrastructures, generate new subject positions, or change the relations through which subsequent innovation and coordination occur. GRE refers to this family of problems as the transformation of future generative possibilities.

The distinction can be illustrated through capability formation. Education does not merely raise an output variable at the moment instruction occurs. It can change which problems a person can recognize, which institutions can be entered, which collaborations become possible, and which future learning can be undertaken. Infrastructure does not merely deliver a service. It can alter settlement patterns, market access, technological adoption, and the feasibility of later investments. Legal reform can change not only current entitlements but the range of organizations, contracts, claims, and collective actors that can subsequently exist.

Technological platforms provide another example. A platform may begin as an intermediary and later become infrastructure on which other actors build businesses, identities, communities, data practices, and standards. At that point, changes to the platform's architecture affect a wide field of downstream possibilities. The economically relevant question extends beyond current user surplus or firm revenue toward the distribution of capacity to create, exit, interoperate, and develop alternatives.

Future possibility can also be narrowed. Debt can finance productive investment while creating obligations that restrict later choices. Monopoly can generate efficient infrastructure while reducing the space for alternative innovation. Environmental degradation can increase present output while eliminating future ecological options. Surveillance infrastructures can improve prediction while normalizing forms of control that become difficult to reverse. Educational standardization can improve comparability while reducing curricular diversity. These processes are generative in the sense that they shape future conditions, even where what they generate is constraint or foreclosure.

GRE therefore distinguishes generation from desirable expansion of possibility. More possibilities are not automatically better, and some constraints are constitutive of valuable order. Legal prohibitions can protect persons and ecosystems; technical standards can make cooperation possible; professional norms can sustain trust; ecological limits can preserve future viability. The analytical problem is to identify which possibilities are enabled or foreclosed, for whom, at what scale, through what mechanism, and according to which evaluative commitments.

Transformation of future possibilities also makes reversibility important. Two interventions with similar current benefits can differ greatly if one preserves exit and revision while the other creates lock-in. Reversible experimentation can support learning under uncertainty. Irreversible infrastructure, ecological change, institutional centralization, or path-dependent standards require stronger attention to long-horizon effects because later actors inherit conditions they did not choose. GRE therefore treats temporal asymmetry between present decision and future revisability as economically significant.

At the strongest level, an economic process can alter the effective rules through which later change occurs. A new legal form can change what organizations may be created. A communication infrastructure can transform how markets and communities coordinate. Artificial intelligence can alter the cost and distribution of cognitive tasks, thereby changing which activities are scarce and which forms of expertise remain economically valuable. Political-economic reforms can change not only allocations but the procedures through which future allocations are decided. The system's later transformations then occur under conditions partly generated by earlier transformations.

This does not imply that future possibility can be mapped exhaustively. Novelty, uncertainty, reflexivity, and incomplete knowledge place limits on prediction. GRE therefore treats generative possibility as an object of inquiry under uncertainty rather than as a fully enumerable state space. Researchers can identify enabling conditions, constraints, path dependencies, option structures, mechanisms of lock-in, and observed capability formation without claiming complete knowledge of the futures that may emerge.

The nine problem families together delimit the initial problem-space of GRE. Allocation can propagate beyond its administrative recipient; production can transform future productive capacity; access to generative capacity and conditions can diverge from receipt of generated outputs; value can depend on relations and conversion rather than possession alone; asymmetry can become self-reinforcing power; productive relations can reshape economic subjecthood; symbolic abundance can destabilize representation and shift scarcity toward verification and institutional recognition; heterogeneous subjects can remain economically connected without complete commensurability; and interventions can reshape the future conditions under which generation itself occurs. These problems share no single mechanism and should not be collapsed into one model. Their common feature is that economically consequential change exceeds the immediate state that conventional accounting or transaction-level description may record.

The next step is therefore conceptual rather than empirical. If GRE is to investigate these problems without presupposing a fixed ontology of entities, agents, relations, or values, it requires a minimal vocabulary from which richer economic objects can later be constructed. The next section introduces that primitive structure through change, structure, constraint, and difference, while retaining ontological suspension regarding their ultimate metaphysical status.

3.3 Primitive Structure for Ontological Emergence

The problem-space specified in the preceding section requires GRE to speak about entities, subjects, relations, capacities, institutions, values, and fields. Treating those objects as unquestioned primitives would, however, reintroduce many of the assumptions that a generative-relational analysis is intended to examine. The role of this section is therefore to establish a weaker conceptual starting point from which richer economic objects can become analytically available. Its objective is to specify four primitive distinctions—change, structure, constraint, and difference—and to explain how their interaction can support the emergence and stabilization of more determinate configurations. The discussion proceeds from each primitive separately to their interaction, the emergence of relative stability, ontological suspension, and multiple realization. Its method is constitutive and minimal: the section states the weakest commitments currently required by GRE while leaving stronger metaphysical claims open.

The term *primitive* is used here in a methodological sense. A primitive is a distinction that the present analytical framework takes as available before introducing more articulated objects. It is not thereby asserted to be metaphysically fundamental, indivisible, timeless, or ontologically prior in every possible theory. Another formalism may decompose one of these primitives further, replace it with a different basis, or represent the same empirical problem through another ontology. GRE's purpose in selecting a primitive structure is practical and epistemic: to begin with concepts weak enough to avoid presupposing the entities and relations whose emergence the programme may later wish to explain.

This choice also prevents a common circularity. If an economic subject is defined

first and its relations are then studied, the analysis can miss processes through which subjecthood itself depends on recognition, law, infrastructure, classification, productive organization, or repeated participation. If a relation is defined first as a link between already constituted nodes, the analysis can miss cases in which the relation contributes to the differentiation or persistence of the nodes. If an institution is treated as a fixed background, the analysis can miss how repeated practices maintain or transform the institution. A minimal primitive structure postpones these commitments. It asks first what changes, what organization makes those changes intelligible, what conditions restrict or enable possible transformations, and what differences become consequential within the configuration.

The four primitives should not be imagined as four substances or four separable components of an economic system. They are analytical dimensions that become meaningful through one another. Change without structure is difficult to identify because change requires some organization within which a transformation can be distinguished. Structure without change becomes analytically inert because structure is known through persistence, variation, reproduction, or transformation. Constraint presupposes a space of possible differences or transitions whose accessibility is conditioned. Difference becomes economically consequential when a structure renders it perceptible, operative, classifiable, or capable of altering later possibilities. Their interaction supplies a minimal grammar for describing ontological emergence while leaving the ontology itself under suspension.

3.3.1 Change

Change is the first primitive because GRE studies economic processes in which later conditions differ from earlier ones. The minimal concept is deliberately broad: change designates a transformation that can be distinguished between configurations, positions, capacities, relations, classifications, rules, or other analytically relevant conditions. This formulation does not presuppose that the thing changing is already an entity with a fixed identity. It permits the identity, boundary, or kind of the relevant object to become part of the change being studied.

Several levels of change should therefore remain distinct. A variable can change while the relations among variables remain similar. A relation can form, intensify, weaken, reverse, or dissolve while the participating terms remain sufficiently stable for the relation to be tracked. A structure can change when patterns among multiple relations are reorganized. A constraint can change when possibilities previously unavailable become accessible, or when previously accessible transitions become costly, prohibited, or practically unreachable. A classificatory or representational regime can change when actors are newly recognized, grouped, valued, or rendered visible. At a still stronger level, the effective rule through which later transformations occur can itself be modified. GRE eventually requires all of these possibilities, yet the primitive concept of change remains weaker than any one of them.

Change is therefore not synonymous with movement along a pre-specified coordinate. Many economic models legitimately represent change in exactly that way: price changes, employment changes, output changes, wealth changes, or probabilities change within a stable variable system. GRE retains such representations wher-

ever they answer the research question. Its additional interest appears when the variable system itself is historically unstable. A category such as employment may change in prevalence while retaining a stable legal meaning, or the legal and organizational meaning of employment may itself be transformed by platform work, contracting arrangements, automation, or new institutional classifications. The first case can be represented as change within a category; the second includes change in the category's constitutive conditions.

This distinction also separates state change from generative change. A state can differ at two times without the transition altering the capacity to produce later states. By contrast, a generative change modifies some condition through which subsequent possibilities are produced, selected, stabilized, or foreclosed. Training that raises a measured skill level is a state change; when the training also alters future access to occupations, networks, credentials, confidence, or learning capacity, the economic significance includes a generative dimension. A regulation that changes a current price is one kind of intervention; a regulation that changes entry conditions, bargaining institutions, or the incentives through which future market structure develops reaches a different level of change.

The concept must also accommodate maintenance. Persistence across time can require continuous activity. A bridge remains usable because inspection and repair occur; a currency remains accepted through continuing institutional and social practices; an organization persists through recruitment, routines, accounting, authority, and repeated recognition; a relation of trust can remain stable because encounters repeatedly confirm expectations. In such cases, apparent sameness at the level of an outcome is produced through ongoing change at other levels. GRE should therefore avoid equating observable stability with absence of process.

Change also carries no intrinsic normative direction. Transformation can enlarge capability, reduce vulnerability, create knowledge, or regenerate ecological conditions. It can equally generate dependency, exhaustion, exclusion, concentration, ecological loss, or irreversible foreclosure. Even a change described as innovation is not thereby beneficial to all affected subjects. The primitive records transformation; the normative evaluation of that transformation requires additional criteria developed later in the programme.

Finally, change is always specified relative to an analytical resolution. A firm may appear unchanged because it retains the same legal identity while its workforce, technology, ownership, dependencies, and internal authority are transformed. A person may appear occupationally unchanged while the meaning and security of the occupation are altered. A market may display stable aggregate shares while the underlying network of suppliers becomes more concentrated. GRE therefore requires the researcher to state which differences count as changes for the local question and which dimensions are being held provisionally constant. This dependence on resolution will become important when the programme later treats scale, boundary selection, and representation.

3.3.2 Structure

Structure provides the organization within which changes and differences become intelligible. In its minimal GRE sense, a structure is a pattern of organization that relates distinguishable components, positions, transitions, or conditions with sufficient regularity to support analysis. The term does not require a single formal representation. A structure may be institutional, relational, spatial, temporal, legal, organizational, symbolic, ecological, computational, or represented through several of these descriptions at once.

This minimal definition matters because structure is often confused with rigidity. GRE instead treats structure as compatible with extensive internal change. A labor market can preserve a recognizable structure while workers and firms enter and exit. A legal system can preserve institutional continuity while rules are amended. A network can preserve a degree distribution or community pattern while particular ties change. A household can remain an administratively recognizable unit while roles and resource flows are reorganized. Structural persistence therefore concerns patterned organization at a selected resolution, not immobility of every constituent.

Structure can also exist at several analytical levels. A local structure may concern the arrangement of a small number of actors or resources. A higher-order structure may concern patterns among relations, institutions, or categories. Structures can be nested, overlapping, or partially incompatible. The same economic subject may simultaneously occupy a workplace hierarchy, a household division of care, a credit relation, a legal status, a platform ranking system, and an ecological dependency. No single structure necessarily exhausts the subject's economic position.

For GRE, structure becomes especially important when it shapes how an intervention propagates. The same allocation can have different effects under different structures because access, conversion, visibility, bargaining, and recirculation differ. A cash transfer received within a predatory debt relation may partly flow to creditors. A research grant enters a university structure that conditions hiring, procurement, intellectual-property ownership, publication, and career recognition. Access to compute can generate different capacities depending on whether technical knowledge, electricity, data, institutional permission, and collaborative networks are available. Structure therefore mediates the relation between an initial resource and the later configuration it helps produce.

Structure also helps distinguish a merely repeated occurrence from a stabilized pattern. Repetition alone can result from coincidence or independent causes. A structural claim is stronger: it proposes that the recurrence reflects an organization of relations, positions, rules, or constraints that makes certain patterns more likely, durable, or reproducible. Such claims require evidence appropriate to the domain. GRE should not infer structure from visual regularity alone; qualitative mechanisms, institutional rules, historical evidence, statistical relationships, network organization, formal models, or combinations of evidence may be needed.

Importantly, structure can itself be an outcome of prior generation. Infrastructure, property regimes, professional categories, organizational routines, standards, market conventions, and technical architectures are historically produced. Once established, they can condition later behavior and appear to subsequent actors as part

of the environment. This temporal layering is central to GRE because generated structures can become conditions of future generation. The analytical movement is therefore recursive: processes generate structures; structures condition later processes; later processes may reproduce, erode, or transform those structures.

Structure should consequently be treated as relative to both scale and time. A relation that looks transient at one temporal scale may contribute to a stable pattern at another. A structure that appears fixed during a short intervention study may be historically recent. A national institution can function as background in a firm-level analysis while becoming the primary object in a comparative institutional study. GRE's minimal concept of structure supports these shifts without requiring that one level be declared ontologically fundamental.

3.3.3 Constraint

Constraint concerns the conditioning of possible transformation. A constraint limits, channels, raises the cost of, delays, redirects, or otherwise modifies which changes are available to a configuration under specified conditions. This definition is intentionally broader than prohibition. Constraints can be hard or soft, formal or informal, material or symbolic, local or distributed, immediate or historically accumulated. They can reduce some possibilities while enabling others by stabilizing expectations, protecting boundaries, supplying standards, or coordinating action.

The enabling dimension is important. A legal rule constrains conduct while also making contracts, organizations, ownership claims, or collective action more reliable. A technical standard restricts admissible designs while enabling interoperability. A professional norm narrows acceptable practice while supporting trust. A budget constraint restricts expenditure while helping define feasible planning. Physical infrastructure limits movement to available routes while making high-volume movement possible along those routes. GRE therefore treats constraint as a transformation of an option space rather than as a synonym for oppression or deprivation.

Constraints differ in the mechanisms through which they operate. A material constraint may arise from energy, time, geography, bodily capacity, or resource availability. An institutional constraint may arise from law, organizational authority, eligibility criteria, property rights, or administrative procedure. A relational constraint may arise from dependence on another actor, obligations, network position, reputation, or bargaining asymmetry. A cognitive or epistemic constraint may arise from limited knowledge, inaccessible information, uncertainty, interpretive categories, or attention. A technological constraint may be embedded in interfaces, protocols, platforms, or computational architectures. These forms can interact, and the same observed limitation can often be generated through several different mechanisms.

Constraint is therefore relational in a weak but important sense: a condition constrains only relative to some possible transformation of a specified configuration. The absence of advanced compute does not constrain a task that requires none. A licensing rule may constrain an unlicensed entrant while enabling established professionals to coordinate around a recognized standard. A language barrier can constrain access in one institution and become irrelevant in another with translation infrastructure. The researcher must specify whose possibilities are conditioned, which

possibilities are at issue, and through what mechanism the conditioning occurs.

Constraints can also be inherited. Present actors confront conditions generated by earlier processes that they did not choose: debt structures, infrastructures, ecological degradation, historical exclusions, educational systems, legal categories, standards, and accumulated concentrations of capital or knowledge. Such inherited constraints can be highly durable even when no current actor intends their continuation. GRE's concern with generation therefore includes the production and transmission of constraints across time.

At the same time, constraints are often transformable. Actors can acquire resources that relax a constraint, organize collectively to alter a rule, invent technologies that change material limits, reinterpret categories, create new infrastructures, or exit relations that previously restricted them. An intervention can also exchange one constraint for another. Credit can relax a liquidity constraint while introducing repayment obligations. Digital platforms can reduce search costs while increasing dependency on ranking systems or data infrastructures. Automation can relax labor bottlenecks while creating new capital, compute, energy, or skill dependencies. Analysis should therefore trace transformations of the constraint structure rather than classify interventions simply as constraint-reducing.

GRE also distinguishes constraint from deterministic closure. A constraint can make a transition improbable without making it impossible, and it can make a transition formally possible while rendering it practically inaccessible. Conversely, the absence of a known constraint does not imply that a possibility will be realized. Capacities, orientations, coordination, chance, and additional conditions also matter. This distinction will later be important for economic power: asymmetry can influence option spaces and the conditions under which choices are made without reducing action to mechanical determination.

3.3.4 Difference

Difference supplies the discriminations through which change, structure, and constraint can be described. In its minimal GRE sense, a difference is a non-equivalence, contrast, distinction, gradient, or differentiation that is relevant to a specified analysis. The primitive does not assume that every observable variation is economically meaningful. A difference becomes analytically consequential when it participates in identification, interaction, selection, valuation, constraint, or subsequent generation.

This distinction between variation and consequential difference is central. Two actors can differ in height without that difference affecting a particular credit relation. They can differ in legal status in a way that radically alters eligibility, bargaining, mobility, or vulnerability. Two firms can differ in size without that difference determining market power in one industry, while in another industry scale can transform access to data, compute, distribution, or finance. GRE therefore asks how a difference enters the relational configuration and what later effects follow from its recognition or operation.

Difference can be prior to a relation, produced through a relation, or amplified by a relation. Participants may enter an exchange with different resources or capabilities. The exchange may itself create new differentiation through learning, reputa-

tion, debt, ownership, or access. Repeated interactions can amplify an initially small difference through cumulative advantage or self-reinforcement. Conversely, institutions can reduce the economic consequences of a difference through insurance, universal provision, accessibility design, anti-discrimination rules, redistribution, or shared infrastructure. The economic significance lies in the generative trajectory of the difference, not merely in its presence.

Difference also participates in the constitution of categories. Economic systems routinely classify workers, firms, borrowers, residents, consumers, citizens, dependents, owners, professionals, risks, assets, and forms of labor. Such classifications make some differences institutionally salient while suppressing others. A category can convert a continuous variation into a discrete administrative distinction, or combine heterogeneous cases under one label. Once institutionalized, the classification can affect access, rights, prices, obligations, visibility, and self-understanding. Representational differences can thereby become causally effective within economic life.

The primitive must remain distinct from inequality. Inequality is a more specific relation involving unequal quantities, positions, opportunities, burdens, capabilities, recognition, or powers. Difference is logically weaker. Heterogeneity can be economically valuable, neutral, complementary, conflictual, or unjust depending on how differences are organized and evaluated. GRE's later treatment of heterogeneous subjects depends on preserving this distinction; a plural economy need not aim at eliminating difference, while justice may require intervention when particular differences are converted into avoidable domination or exclusion.

Difference is also scale-relative. Two configurations can be equivalent for one analytical purpose and different for another. Two households may have the same income while differing in care burdens, health needs, legal status, housing security, social networks, or exposure to environmental risk. Two firms may have identical revenue while differing in ownership, dependence on a platform, ecological footprint, or accumulated knowledge. An economic representation always selects which differences to preserve. GRE therefore treats the choice of relevant difference as part of the epistemic architecture of inquiry rather than as a transparent property of the world.

This point prevents the primitive from becoming an unlimited invitation to complexity. A research design cannot preserve every difference. The analytical task is to justify which distinctions matter to the proposed generative mechanism and to test whether omitted differences undermine the explanation. Difference thus supports pluralism while remaining disciplined by the local research question.

3.3.5 Interaction among the Four Primitives

The analytical value of the primitive structure lies primarily in interaction among its terms. Change, structure, constraint, and difference should rarely be interpreted as independent explanatory variables. Each modifies the meaning and operation of the others. A difference can alter a transition; repeated transitions can stabilize a structure; a structure can convert some differences into effective constraints; a constraint can preserve a structure by narrowing available transitions; and structural change can create new differences and remove old ones.

Consider a simple economic sequence. Two actors begin with a difference in access

to finance. An institutional structure determines which forms of collateral are recognized. That structure constrains borrowing possibilities differently across the actors. The resulting difference in investment capacity alters later income, asset ownership, reputation, and access to finance. Repetition can stabilize a configuration in which the original difference is amplified and incorporated into a more durable structure. The example does not require the researcher to declare wealth, creditworthiness, institutions, or even the actors themselves to be ontological primitives. It can begin from transformations, patterned organization, conditioned possibilities, and consequential distinctions, then introduce richer objects as the analysis becomes empirically specific.

The same primitive structure can describe generative expansion. Shared infrastructure may reduce a constraint on participation. Increased participation can create new differences in specialization and knowledge. Those differences can support a more complex division of labor. The emerging structure can generate additional resources, standards, and coordination capacities, which further relax some constraints while creating new ones. Generativity therefore need not mean monotonic liberation from constraint. New capabilities often depend on newly stabilized structures whose operation introduces obligations, dependencies, standards, or maintenance requirements.

The interaction among primitives also permits recursive analysis. A structure can constrain change, while changes can transform the structure. A difference can be produced by a constraint, while the resulting difference can later modify the constraint through political organization, market power, technological innovation, or institutional recognition. Constraint structures can become objects of economic investment; differences can become commodities, credentials, rankings, or legal statuses; structures can be deliberately designed; and change itself can be governed through procedures that determine how rules may be revised.

This recursion provides a bridge to the stronger GRE question concerning transformation of effective rules of change. At an initial analytical level, a researcher may ask how a configuration changes under a specified structure and set of constraints. At a second level, the inquiry can ask how those structures and constraints themselves change. At a third level, the procedures or mechanisms through which structures and constraints are transformed may become objects of inquiry. The primitive vocabulary can therefore support increasingly reflexive analysis without assuming that a single immutable law governs every level.

A useful discipline follows from this interaction: explanations should specify which primitive role a concept is playing at a given moment. The same institution can be treated as structure when its internal organization matters, as constraint when it conditions an actor's options, as difference when membership distinguishes eligible from ineligible actors, and as an object of change when reforms alter its operation. These descriptions are compatible because they answer different analytical questions. Confusion arises when movement among them occurs without being stated.

The primitive framework is therefore better understood as a grammar than as a taxonomy. It organizes questions about transformation without assigning each empirical object to one permanent category. This flexibility is important for economic

inquiry because the same phenomenon can change analytical status across scale and time. Money can be a resource in one analysis, a relation of credit in another, an institutional structure in a third, a symbolic representation in a fourth, and a constraint through liquidity requirements in a fifth. The primitives do not replace these richer categories; they clarify how such categories can be introduced without assuming their universality in advance.

3.3.6 Emergence of Stable Configurations

GRE requires relatively stable objects because economic inquiry cannot proceed by treating every moment as ontologically unique. Contracts, firms, households, states, currencies, property rights, professions, platforms, resources, and subjects must often be tracked across time. The primitive framework therefore needs an account of how stability can become analytically legitimate without turning stability into primordial substance. The concept of *stable configuration* supplies that bridge.

A stable configuration is a patterned organization whose continuity is sufficient for a specified analytical purpose across a relevant interval, scale, or set of transformations. Stability can arise through several mechanisms: material durability, repeated interaction, institutional recognition, legal enforcement, habit, technical standards, ecological reproduction, feedback, coordinated expectations, memory, documentation, or continual maintenance. These mechanisms need not produce permanence. They produce enough persistence or recurrence for the configuration to function as an identifiable object within the inquiry.

The phrase *sufficient for a specified analytical purpose* is crucial. A corporation can be treated as the same legal entity across changes in personnel and assets, while an organizational ethnography may treat those same changes as constitutive transformations. A currency can remain nominally the same while inflation alters its purchasing power and institutional reforms alter its governance. A household can persist administratively while membership changes. Entityhood is therefore resolution-dependent. GRE treats an entity as analytically real where the stability of a configuration supports explanation, measurement, interpretation, intervention, or coordination at the chosen scale.

Relations can stabilize in the same way. A relation need not be continuously active in order to persist. A debt relation remains operative between payments; a property relation persists while the owner is absent; a professional relation can survive periods without interaction; an institutional hierarchy can remain in force outside moments of explicit command. Persistence can depend on documents, expectations, enforcement, memory, infrastructure, or recognized roles. A stable relation is therefore more than repeated contact, yet it need not be a metaphysically independent object.

Stable configurations can also acquire causal and generative efficacy. Once a classification is institutionalized, it can govern eligibility. Once a platform becomes infrastructure, it can condition market access. Once a professional credential stabilizes, it can shape labor-market sorting. Once a norm becomes widely expected, deviations can become costly even without formal enforcement. An emergent configuration can thus become part of the structure and constraint environment faced by later actors.

Ontological emergence and generative recursion meet at this point: what was produced through earlier processes becomes a condition of later processes.

Stability should also be distinguished from desirability, efficiency, and equilibrium. A configuration can persist because exit is costly, alternatives are suppressed, coordination failure prevents change, or power reproduces the relevant conditions. Another configuration can be beneficial yet fragile because its maintenance depends on scarce resources or voluntary cooperation. GRE therefore treats persistence as an empirical property requiring explanation rather than as evidence of optimality.

The emergence of stable configurations gives GRE a principled basis for introducing richer objects in the next section. Entities, subjects, relations, resources, values, fields, institutions, and symbolic objects can be treated as first-class economic objects when their organization is sufficiently stabilized and their distinctions matter to the research problem. Their status remains historically and analytically conditioned. Stability licenses local objecthood; it does not establish final ontology.

3.3.7 Ontological Suspension

Ontological suspension is the discipline that keeps this primitive framework from becoming a dogmatic metaphysics. It means withholding claims about the ultimate constitution of economic reality when stronger ontological commitments are unnecessary for the local inquiry. Suspension permits the researcher to use entities, relations, processes, fields, networks, states, events, or other representations where they are analytically productive while keeping open the possibility that another representation may reveal different aspects of the same empirical configuration.

Suspension differs from ontological denial. GRE does not claim that entities are unreal because they are relationally constituted, that relations are unreal because they are represented through models, or that institutions are mere descriptions because they depend on recognition. A bank account, legal status, debt, organization, or technical standard can have robust economic consequences. Ontological suspension concerns the level of metaphysical assertion attached to those consequences. The researcher can treat an object as real and causally relevant within an inquiry without claiming that its current representation exhausts what the object is.

This position also differs from unrestricted constructivism. Economic objects can resist interpretation, produce unexpected effects, and impose material constraints regardless of the researcher's preferred description. A bridge has load limits; an ecosystem can be degraded; a debt contract can be enforced; a platform can deny access; a person can become exhausted. Ontological suspension does not dissolve these realities into discourse. It requires the analyst to distinguish the empirical resistance of a configuration from the categories used to describe it.

The discipline is especially important when formal methods are used. A graph can represent relations among nodes, a state space can represent possible configurations, a field can represent distributed conditions, and a simulation can explore consequences of specified rules. Each representation can be rigorous within its assumptions. None acquires metaphysical authority merely from mathematical precision. GRE therefore asks what distinctions the representation preserves, what it suppresses, which mechanisms it assumes, and whether alternative representations

change the substantive conclusion.

Ontological suspension also supports interdisciplinary communication. Economics, law, sociology, history, ecology, computer science, and philosophy can represent the same situation through different objects. A platform worker can appear as a labor supplier, contractual party, legal claimant, network node, data-generating user, organizational participant, or historically situated subject. These representations can conflict in specific claims while remaining jointly informative. GRE should compare their explanatory consequences before treating one vocabulary as universally privileged.

Finally, suspension creates a condition for theory revision. If entities, relations, and categories were fixed as final primitives, evidence that their boundaries change would threaten the coherence of the framework. A suspended ontology permits categories to be reconstructed when historical change reveals their limits. This revisability is particularly important to a programme concerned with the generation of new economic objects, technologies, institutions, and forms of subjecthood.

3.3.8 Multiple Realizations and Ontological Plurality

A minimal primitive structure also allows economically meaningful objects to have multiple realizations. The same functional or institutional role can be sustained through different material, organizational, legal, or relational configurations. Payment systems can be realized through cash, bank deposits, cards, mobile platforms, or other infrastructures. Collective production can be organized through firms, cooperatives, public institutions, households, commons, or loosely coordinated networks. Credentialing can be performed by universities, professional bodies, states, platforms, or community institutions. What counts as the same economic object therefore depends partly on the level at which equivalence is being claimed.

Multiple realization should not be confused with identity. Two configurations can perform similar functions while differing in power relations, vulnerability, ecological cost, accessibility, governance, or downstream generativity. A public payment infrastructure and a proprietary platform may both enable transactions while generating different dependencies and data relations. Two educational systems may produce comparable test scores while differing in social networks, institutional recognition, stress, curiosity, or future opportunity. GRE consequently treats functional equivalence as one possible relation among configurations rather than as proof that their broader economic consequences are equivalent.

The converse problem also occurs: similar manifestations can arise from different generative structures. Two workers can report the same income while one depends on a stable employment relation and the other on volatile platform work. Two firms can display the same output while one relies on durable local capabilities and the other on fragile external supply chains. Two communities can exhibit similar consumption while differing in debt burdens, ecological dependencies, public infrastructure, or informal care. Observable similarity therefore does not guarantee generative similarity.

Ontological plurality follows from these possibilities. GRE can permit several ontologies or representational schemes to coexist when they preserve different distinc-

tions relevant to the research question. An entity-centered model may be adequate for one task, a network representation for another, a process account for a third, and a field-like description for a fourth. Plurality is disciplined by explanatory and evidential adequacy rather than by an assumption that every representation is equally useful.

This pluralism has limits. Representations can contradict evidence, conceal relevant mechanisms, or impose categories that systematically misdescribe the subjects they classify. A plurality of possible descriptions does not eliminate standards of criticism. GRE should ask whether a representation preserves the differences relevant to the claim, whether its boundaries are justified, whether its entities remain stable enough for the inference being made, and whether alternative representations produce materially different conclusions. Ontological plurality therefore increases the burden of comparison rather than removing it.

Multiple realization also matters normatively. Policies often target administratively standardized objects such as households, firms, jobs, schools, or regions. If those categories have heterogeneous realizations, identical interventions can generate unequal effects. A household with the same measured income can face different care obligations; a firm of the same size can possess different network dependencies; a school with similar resources can operate within different linguistic, social, or infrastructural conditions. GRE's later analysis of heterogeneous subjects and values depends on recognizing that categorical sameness can coexist with generatively consequential difference.

The primitive structure developed in this section therefore establishes a deliberately modest ontological foundation for the programme. Change identifies transformation without presupposing a fixed bearer. Structure identifies patterned organization without requiring stasis. Constraint identifies the conditioning of possible transformation without implying deterministic closure. Difference identifies relevant non-equivalence without equating difference with inequality. Their interaction can generate relatively stable configurations that become legitimate objects of economic inquiry at specified scales and times. Ontological suspension prevents these objects from hardening prematurely into universal primitives, while multiple realization and ontological plurality preserve the possibility that comparable economic functions can be sustained through different configurations and that similar observations can arise from different generative histories.

This architecture is intentionally incomplete. It supplies the minimal conceptual conditions under which richer objects can be introduced; it does not yet specify which objects GRE should study. The next section can therefore move from primitive structure to the heterogeneous economic objects that become available once relative stability, analytical scale, and ontological suspension have been established.

3.4 Objects of GRE Inquiry

The primitive structure developed in Section 3.3 allows GRE to introduce richer objects without treating their present boundaries as metaphysically final. The role of this section is to specify the principal classes of objects that GRE may take as eco-

nomically relevant once relative stability, analytical scale, and ontological suspension have been established. Its objective is taxonomic rather than exhaustive: to identify a working repertoire of objects through which relational and generative economic processes can be investigated. The discussion proceeds from emergent entities and subjects to relations, resources and capacities, value, conditions and constraints, fields, temporal objects, institutions, and symbolic or representational objects. Its method is constitutive and pluralist. Each category is defined by the analytical work it can perform, while overlap among categories remains permissible where an empirical configuration supports several descriptions.

An *object of inquiry* in GRE is therefore an analytically stabilized referent around which a research question, body of evidence, mechanism claim, comparison, or intervention can be organized. Objecthood in this sense is local to an inquiry. A firm may be treated as an entity when the question concerns ownership or output, as a relational configuration when the question concerns authority and contracting, as an institutionally recognized subject when the question concerns legal responsibility, and as a trajectory when the question concerns organizational transformation. These descriptions are compatible when they preserve different economically consequential distinctions. GRE does not require a single vocabulary to carry every explanatory burden.

The admissibility of an object depends on several disciplines. Its boundary should be sufficiently explicit for the claim being made. Its persistence should be adequate to the temporal resolution of the inquiry. The evidence used to characterize it should correspond to the dimensions under discussion. Its role in a mechanism should be distinguished from the representation through which that role is inferred. Finally, the analyst should remain attentive to whether the object itself changes through the processes being studied. A category useful at the beginning of an inquiry can require revision if its constitutive relations, internal heterogeneity, or practical meaning change during the relevant history.

The categories below are therefore best understood as a research grammar. They help determine what GRE can study without implying that economic reality is naturally partitioned into ten mutually exclusive classes. Many of the most important GRE questions arise precisely where an object moves across categories: a resource becomes a capability, a repeated relation stabilizes into an institution, a symbolic classification becomes a material constraint, an event redirects a trajectory, or a distributed field of conditions contributes to the emergence of a new economic subject. The taxonomy is designed to preserve those transformations rather than eliminate them through premature classification.

3.4.1 Emergent Economic Entities

Economic analysis routinely refers to persons, households, firms, states, markets, sectors, technologies, assets, platforms, infrastructures, and other entities. GRE retains these objects while treating their entityhood as historically and analytically conditioned. An emergent economic entity is a relatively stabilized configuration that can be tracked as a distinguishable unit because some combination of boundary, continuity, recognition, organization, or causal coherence persists across the interval rel-

evant to the inquiry.

Relative stability is central. A corporation can remain the same legal entity while employees, ownership shares, technologies, contracts, products, and internal authority change. A household can remain administratively recognizable while membership, dependency relations, income sources, and care obligations vary. A market can persist as a named domain while its technologies, participants, rules, and geographic reach are transformed. GRE can treat each as an entity when the continuity is sufficient for the local question, while preserving the possibility that another question requires decomposition of the apparent unit.

Entity boundaries can arise through several mechanisms. Law creates juridical boundaries around corporations, contracts, property, and public authorities. Accounting creates reporting boundaries around organizations and transactions. Technical architectures distinguish users, devices, accounts, services, and platforms. Social recognition can stabilize occupations, communities, or organizational identities. Material organization can generate boundaries through infrastructure, geography, or ecological dependence. These boundaries differ in durability and authority. A legal boundary may remain stable while operational relations cross it extensively; an informal organization may have no independent legal personality while displaying strong internal continuity.

The economic significance of entityhood therefore depends partly on what the boundary permits the entity to do. Recognition can make ownership, contracting, taxation, liability, borrowing, representation, or participation possible. Entity formation can pool resources, concentrate decision rights, create collective capabilities, or separate responsibility. It can also obscure internal asymmetries by presenting a heterogeneous configuration as a single actor. Treating a firm, household, state, or community as one unit can be analytically efficient while suppressing differences in who decides, who bears risk, who receives value, and who remains unrepresented.

Entity emergence can itself become an object of explanation. A group of workers can become an organization; a technical project can become a firm; a loose exchange environment can become a recognized market; a digital protocol can acquire institutional governance; a collective practice can become a sectoral standard. GRE is interested in the conditions through which such configurations become sufficiently stable, recognized, resourced, and reproduced to acquire economic consequences as entities. The transition from diffuse activity to recognized entity can alter access to finance, law, infrastructure, legitimacy, and bargaining power.

Entities can also dissolve, fragment, merge, or migrate across classifications. Insolvency can dissolve a firm while parts of its productive capacity survive elsewhere. A public service can be privatized while its infrastructure remains materially continuous. A platform can reclassify workers without changing the practical dependence through which labor is organized. These cases show why GRE treats entity identity as a question of maintained distinctions rather than a self-evident fact.

The category of emergent economic entity consequently supplies a practical unit of analysis while keeping three questions open: which relations stabilize the entity, which boundaries make the entity economically actionable, and which transformations would make the existing entity description inadequate. These questions con-

nect entity analysis to the remaining object classes rather than isolating entities from them.

3.4.2 Subjects and Subject Positions

Subjects form a distinct class because economic participation involves more than the persistence of an entity. A subject occupies positions from which action, claim-making, evaluation, vulnerability, responsibility, recognition, or experience becomes economically consequential. GRE therefore distinguishes the existence of an entity from the constitution of a subject position. A corporation can be a juridical subject for some purposes without possessing human experience; a person can exist as a biological and social individual while being denied effective recognition as a worker, claimant, owner, borrower, resident, or political participant.

A *subject position* is a relationally and institutionally organized location from which rights, expectations, obligations, opportunities, exposures, or forms of agency become available. Employment status, citizenship, tenancy, creditor status, professional accreditation, platform membership, consumer classification, and eligibility for public support are examples of positions that configure economic possibilities. Such positions are often produced jointly by law, organizational rules, records, classifications, infrastructures, and recognition by other actors.

Subject positions can therefore change without the underlying person or organization disappearing. A worker can move from employee to contractor; a resident can gain or lose eligibility for a service; a borrower can be reclassified by a credit system; a community can become formally recognized as an eligible governance unit; a software agent can be delegated limited transactional authority. Each change modifies what the subject can do, what others may demand from it, and which relations become economically available.

GRE is especially interested in the generative consequences of these positions. A position can enable access to income, credit, education, information, legal remedies, social networks, or institutional voice. It can also create dependency, surveillance, liability, exclusion, or constrained exit. Because positions mediate later capacities, subject formation is not merely a descriptive question about identity. It can become part of the economic mechanism through which future options are generated or foreclosed.

This perspective also preserves the difference between subjecthood and agency. A subject can be strongly constrained while remaining economically consequential. Children, persons under guardianship, refugees, patients, dependents, or algorithmically classified users can occupy economically important positions even where their formal decision authority is limited. Conversely, an actor with substantial operational agency can remain weakly recognized within a legal or moral order. GRE should therefore specify which dimension of subjecthood matters to the inquiry: capacity to act, capacity to experience, standing to claim, institutional recognition, representation, accountability, or exposure to consequences.

Heterogeneity within subject categories is equally important. Administrative categories such as household, worker, consumer, student, patient, migrant, or firm can contain subjects with markedly different capacities and dependencies. Treating cat-

egory membership as sufficient description can obscure differences in language, disability, care obligations, wealth, access to networks, legal status, technical literacy, or exposure to institutional power. A GRE analysis can preserve the usefulness of the category while examining how its practical realization varies among subjects.

Subject positions can also be collectively constituted. A union, cooperative, community association, indigenous polity, professional body, or informal collective can acquire forms of representation and bargaining capacity that are unavailable to isolated members. Collective subjecthood can reorganize the field of negotiation, create shared resources, and alter the conversion of individual grievances into actionable claims. The relevant object is then neither a simple aggregate of persons nor a timeless collective substance. It is a stabilized configuration of representation, recognition, organization, and capacity.

The category will later support GRE's more detailed inquiry into human and artificial economic subjects. At the constitutional level, the key point is narrower: subjecthood is an economic object whenever the positions from which actors participate, experience consequences, make claims, or become governable are themselves generated, maintained, or transformed through economic relations.

3.4.3 Relations and Relational Configurations

Relations are central objects of GRE because economic consequences frequently depend on how actors, resources, institutions, and conditions are connected. A relation can involve exchange, authority, dependence, care, credit, ownership, recognition, information, obligation, trust, competition, cooperation, representation, access, or other structured forms of connection. GRE treats the relation itself as analytically available when its persistence, terms, or consequences matter to the research question.

Relations vary in their constitution. Some are formally specified through contracts, law, accounting, organizational rules, or technical protocols. Others depend on repeated practice, trust, custom, shared expectations, social proximity, or tacit coordination. Some are symmetric in a relevant dimension; others distribute authority, information, risk, or exit options asymmetrically. A relation can remain formally unchanged while its practical content shifts because one party's outside options, dependence, knowledge, or institutional protection changes.

Dyadic representation is useful for many questions, yet GRE also recognizes relational configurations that cannot be adequately decomposed into independent pairs. Supply chains, families, teams, communities, standards ecosystems, financial systems, platform markets, and public infrastructures often involve higher-order or multilayer dependencies. The significance of one tie can depend on the presence of several others. A credit relation, for example, can depend on legal enforceability, informational infrastructure, collateral arrangements, reputational systems, and monetary institutions. A labor relation can depend on household reproduction, immigration status, local labor demand, professional credentials, and collective bargaining institutions.

A *relational configuration* therefore refers to an organized set of relations whose joint structure has economically consequential properties. Concentration, brokerage,

segregation, reciprocity, redundancy, hierarchy, mutual dependence, and network closure can arise at the configuration level. These properties may affect bargaining power, diffusion, resilience, access, vulnerability, and capacity formation even when no single relation carries the full explanation.

GRE also distinguishes relations that connect already stabilized objects from relations that contribute to the constitution of those objects. A contract between two established firms may primarily coordinate exchange. Repeated recognition relations can help constitute a professional status. Care relations can contribute to the maintenance of persons' capabilities. Membership relations can constitute an organization. Legal relations can create ownership or corporate personality. The analytical question is therefore whether the relation is external to the identity relevant for the model, partly constitutive of it, or generative of a new stabilized object.

Relations can persist through material and symbolic infrastructures. A debt relation may be maintained through records and enforcement institutions; a platform relation through accounts, interfaces, ranking systems, and data; a professional relation through credentials and reputational networks. These mediating objects matter because they can change the relation without changing its nominal category. Digitization, automation, or legal reform can intensify monitoring, alter bargaining positions, reduce transaction costs, or enable new forms of exclusion within an apparently familiar relationship.

Relation formation and relation removal are themselves economically consequential events. Access to a mentor, lender, market, transport system, care network, professional community, or knowledge infrastructure can transform later opportunity. Loss of a relation can destroy capability even when material possessions remain unchanged. GRE therefore studies relational portfolios and configurations alongside stocks of individually held resources.

This category supplies the most direct bridge between the programme's relational commitment and ordinary economic inquiry. GRE does not require every explanation to be relation-first. It requires the analyst to make relation-dependent mechanisms visible where they materially alter economic outcomes, value trajectories, subject positions, or future generative conditions.

3.4.4 Resources and Capacities

Resources and capacities are distinct objects because possession or access does not by itself determine what an economic subject can do. A resource is something that can be mobilized, accessed, consumed, transferred, invested, preserved, or combined within an economic process. A capacity concerns an ability or practical possibility to act, produce, learn, adapt, participate, maintain, transform, or generate further possibilities. The relation between the two is mediated by context, institutions, skills, relations, infrastructure, bodily conditions, ecological conditions, and other conversion factors.

Resources can be material, financial, informational, institutional, social, technical, ecological, or symbolic. Land, equipment, money, time, data, legal rights, public infrastructure, credentials, reputation, access to a network, and environmental quality can each function as resources under appropriate conditions. Their resource char-

acter is relational because usefulness depends on what a subject can access and convert within a particular configuration. A database inaccessible to a community, a credential unrecognized by employers, or capital without complementary infrastructure can have limited practical value despite nominal possession.

Capacities likewise occur at several levels. Individuals can possess capacities for work, learning, judgment, mobility, communication, care, and political participation. Organizations can possess capacities for production, coordination, innovation, maintenance, adaptation, compliance, or collective learning. Communities can possess capacities for mutual support, governance, cultural reproduction, ecological stewardship, and collective action. Infrastructures can support capacities by making transport, communication, payment, identification, or knowledge access possible across many subjects.

GRE gives special attention to *generative capacity*: the ability of a configuration to produce or support further economically consequential possibilities. Education can generate later learning capacity; institutional trust can reduce coordination costs and enable cooperation; a research infrastructure can generate future knowledge; public health can preserve productive and participatory capacity; ecological regeneration can sustain future material possibility. Generative capacity is therefore temporally extended and often distributed across relations rather than located wholly inside a single actor.

The distinction between resource and capacity also clarifies why equal allocation can produce unequal outcomes. Subjects receiving identical monetary transfers can face different housing markets, care obligations, health conditions, legal statuses, network access, or local infrastructure. The same nominal resource can therefore generate different effective possibilities. Conversely, subjects with different resource bundles can sometimes realize comparable capabilities through different conversion arrangements. GRE is interested in the relational conditions that mediate these transformations.

Resources and capacities can also be depleted, captured, transferred, or rendered obsolete. Skill can lose market value after technological change; social capital can erode through displacement; ecological capacity can be exhausted; institutional capacity can decay through underinvestment; a public infrastructure can become inaccessible through privatization or pricing. These processes matter even when short-run output or consumption remains stable because they alter the future space of action.

Collective and relational capacities deserve separate attention. Some capacities exist only through coordination among several subjects. A payment system, scientific community, emergency-response network, common resource regime, or democratic institution cannot be reduced to the sum of individual skills. Their capability depends on maintained relations, standards, trust, interoperability, authority, and shared infrastructures. Disruption of those relations can destroy a collective capacity while leaving individual resources physically intact.

GRE therefore treats resources and capacities as related but non-equivalent economic objects. Resource analysis asks what is available and under whose control. Capacity analysis asks what actions or transformations become practically possible.

Generative analysis adds a further temporal question: how does the use, distribution, or transformation of present resources and capacities alter the production of later capacities?

3.4.5 Value and Forms of Value

Value is an object of GRE inquiry whenever economic relations create, recognize, transform, circulate, convert, preserve, capture, dissipate, or contest something treated as valuable. The category includes monetary price while extending beyond price to forms of value whose realization depends on use, relation, recognition, institutional standing, ecological condition, cultural meaning, capability, or future generativity. GRE therefore studies both valued objects and the processes through which value becomes intelligible, actionable, and convertible.

Forms of value should remain differentiated. Market value can be expressed through exchange prices under specified institutional conditions. Use value concerns usefulness relative to purposes and users. Social and relational value can depend on participation, belonging, trust, recognition, reciprocity, or the quality of continuing relations. Cultural and symbolic value can depend on meaning, status, heritage, identity, or collective recognition. Ecological value can concern the maintenance of living systems and material conditions that support present and future activity. Generative value concerns the production or return of capacities, resources, relations, knowledge, infrastructures, or other conditions that enable further generation.

These forms can interact without becoming automatically commensurable. A forest can carry market value as timber, ecological value as habitat and water regulation, cultural value for a community, and generative value through the capacities it sustains over time. A university can generate wages and patents while also producing credentials, knowledge, networks, civic capacity, and symbolic standing. A care relation can involve paid labor, emotional significance, capability maintenance, and institutional responsibility. GRE's task is to track these dimensions with enough separation to avoid converting plurality into a single metric before the research question justifies such conversion.

Valuation is therefore as important as value. Institutions, markets, professional communities, households, algorithms, legal systems, and cultural practices establish procedures through which some properties become visible and comparable. Accounting standards recognize certain assets and liabilities; credit systems assign risk categories; rankings convert heterogeneous characteristics into ordered representations; markets translate bids and offers into prices; communities maintain values that remain outside formal exchange. These valuation processes can affect the objects being valued by changing access, incentives, recognition, or behavior.

Value conversion creates a particularly important object of inquiry. Economic processes frequently transform one form of value into another: knowledge into income, reputation into access, public infrastructure into private profit, ecological resources into commodities, care into labor-market participation, or symbolic recognition into political and economic influence. Conversion interfaces distribute power because actors differ in their ability to authorize, measure, appropriate, or resist conversion.

The same relation can generate value for several parties while allowing only some of that value to be captured or monetized.

Value can also propagate beyond the initial transaction. Education provided to one person can contribute to household well-being, organizational capability, future teaching, or community knowledge. A technological standard can create value for complementary producers. A public transport investment can alter labor-market access and land values. These effects need not be reducible to externalities in a narrow sense; GRE can examine the pathways through which value becomes distributed across relational configurations and time.

Normative value requires additional care. Something can be economically valued without being normatively desirable, and a normatively important condition can remain weakly priced or administratively invisible. Profitability, efficiency, social importance, justice, and generativity are separate evaluative dimensions. Later normative sections of the programme can specify how such dimensions are assessed. At the object level, GRE preserves their distinction so that descriptive value processes do not silently determine normative conclusions.

Value thus enters GRE as a heterogeneous and dynamic object. The central questions concern which form of value is at issue, who recognizes it, through which relations it is produced or realized, how it moves or converts, who can capture it, what is lost in conversion, and how present valuations alter future generative conditions.

3.4.6 Conditions and Constraints

Economic action unfolds within conditions that shape which transitions are feasible, costly, legitimate, intelligible, or sustainable. GRE treats these conditions as objects when their distribution or transformation materially affects economic possibility. A *constraint* is a condition that restricts, redirects, or differentially prices possible action; an enabling condition expands or stabilizes practical possibility. The same configuration can perform both roles for different subjects, actions, or timescales.

Conditions can be material, ecological, institutional, legal, technical, social, epistemic, temporal, or spatial. Transport infrastructure affects geographic access; legal status conditions eligibility and enforceability; technical standards condition interoperability; language affects participation in institutions and markets; ecological limits shape production possibilities; time scarcity constrains care and learning; data access conditions computational capability; public safety affects mobility and investment. These conditions often operate before any explicit transaction occurs.

Constraints vary in strength. Some prohibit action through law or physical impossibility. Others increase cost, uncertainty, delay, or risk. Still others operate probabilistically by making some pathways easier to reproduce than others. A weak broadband connection, lack of childcare, inaccessible documentation, reputational stigma, or absence of collateral may not formally prohibit participation, yet each can substantially reduce practical access. GRE therefore studies the topology of feasible action rather than equating freedom with formal permission alone.

Constraints can also be relationally generated. Bargaining dependence can restrict exit; debt can condition future income allocation; platform design can constrain vis-

ibility; organizational hierarchy can restrict decision rights; social obligations can direct resource use; network position can limit access to information or opportunities. These constraints arise through relations and can persist even where no single actor consciously designs them.

Enabling conditions deserve equal analytical standing. Public infrastructure, trust, open standards, education, legal protection, care systems, stable ecological conditions, and interoperable institutions can make action possible across broad populations. Their economic contribution may be difficult to assign to individual transactions because they operate as background capacities. GRE can bring such enabling structures into view by asking which later activities depend on their continued reproduction.

Conditions can become endogenous to the processes they condition. Industrial activity can degrade ecological conditions; investment can improve infrastructure; repeated discrimination can reshape expectations and network access; successful coordination can build trust; institutional reform can alter transaction costs and enforcement. A condition that is treated as fixed in one local model can therefore become an outcome in a wider temporal or system boundary.

This category is especially important for intervention analysis. Policies frequently act by changing conditions rather than directly producing final outcomes. A guarantee changes perceived risk; a public option changes outside alternatives; a legal recognition changes standing; a subsidy changes relative cost; an information system changes observability. GRE can study these interventions by tracing how modified conditions alter relations, capacities, subject positions, and later trajectories.

Conditions and constraints thus provide the connective tissue between current configuration and future possibility. Treating them as first-class objects allows GRE to examine why identical resources or formal rights can generate different practical outcomes across subjects and contexts.

3.4.7 Fields and Distributed Structures

Some economic conditions are best represented as distributed structures rather than as possessions or pairwise relations. GRE uses the term *field* cautiously for configurations in which opportunities, pressures, meanings, incentives, risks, or capacities vary across a domain and affect actors partly through their position within that distribution. The field concept is an analytical resource rather than a commitment that social reality literally instantiates a physical field.

A distributed structure can be spatial. Land prices, transport access, pollution exposure, labor demand, public services, broadband quality, and ecological conditions vary across geographic space. It can also be institutional or social. Prestige, professional opportunity, credit access, political influence, or informational visibility can vary across positions in a social or organizational configuration. Digital environments add further domains in which ranking, recommendation, search visibility, platform rules, and data access are unevenly distributed.

Field-like representation is useful when the relevant condition cannot be assigned cleanly to a single actor or relation. A local labor market exerts pressures that emerge

from many employers, workers, institutions, transport networks, regulations, and expectations. A scientific field distributes prestige and attention through journals, institutions, funding systems, peer networks, and disciplinary categories. A financial environment shapes borrowing conditions through monetary policy, risk assessment, regulation, liquidity, and market expectations. No isolated tie carries the entire condition.

GRE can therefore study how distributed structures affect the formation and transformation of local relations. A person entering a region with abundant public transport and dense employment opportunities faces a different opportunity structure from an otherwise similar person in a poorly connected region. A small firm operating within an interoperable technical ecosystem faces different generative possibilities from one locked into a proprietary infrastructure. A researcher positioned in a highly visible institutional environment encounters different pathways for recognition and collaboration.

Fields can also be produced by accumulated local actions. Residential sorting can generate spatial concentrations; repeated investment can create technological clusters; platform participation can generate data advantages; institutional prestige can become self-reinforcing through hiring, funding, and citation. The distributed condition then feeds back into later local decisions. GRE is especially interested in these recursive situations because a field generated by past relations becomes a condition for future relation formation.

Boundaries of a field require explicit justification. The relevant domain may be a neighborhood, labor market, profession, platform ecosystem, jurisdiction, linguistic community, supply network, or ecological region. Different boundaries can reveal different gradients and dependencies. The researcher should therefore state what is distributed, across which domain, how position is measured, and which mechanism links the distributed structure to observed outcomes.

Field representations also help avoid attributing every effect to intentional action by identifiable actors. Unequal opportunity can arise through distributed historical structures even when no single current actor controls the whole configuration. At the same time, distributed structure does not imply absence of power. Some actors may possess disproportionate capacity to shape the field through infrastructure ownership, rule setting, investment, standardization, or control of classification systems.

Fields and distributed structures therefore enter GRE as meso- and macro-level objects that connect local relations with wider conditions. They prepare the transition to the next section's analysis of levels and scales by showing that the same economic process can be experienced locally while depending on structures distributed across a much larger domain.

3.4.8 Processes, Events, and Trajectories

GRE requires temporal objects because generation is inherently concerned with how present configurations produce later conditions. Processes, events, and trajectories provide three complementary ways of organizing temporal analysis. A process is an extended pattern of transformation or reproduction; an event is a temporally localized occurrence that changes or reveals a configuration; a trajectory is an ordered

history through a sequence of states, positions, relations, or regimes.

Processes can include accumulation, learning, institutionalization, technological diffusion, ecological degradation, care, maintenance, financialization, organizational growth, migration, professionalization, or the reproduction of inequality. Their identity depends on a pattern that persists through time even though the participating entities and local actions can change. Process analysis asks which mechanisms sustain the pattern, what inputs and relations it requires, and under which conditions its direction or intensity changes.

Events are analytically useful when temporally concentrated occurrences reorganize later possibilities. A bankruptcy, legal judgment, policy reform, infrastructure failure, technological release, merger, protest, disaster, discovery, or institutional recognition can redirect relations and expectations. The significance of an event is relational to its surrounding history. The same formal event can have different effects depending on preparedness, institutional capacity, network structure, or prior accumulation.

Trajectories preserve ordered history. Two subjects can arrive at similar present outcomes through different paths that leave different capacities, obligations, networks, expectations, or vulnerabilities. Equal current income can follow stable professional advancement, volatile gig work, inherited wealth, debt-financed education, or recent displacement. A cross-sectional measure can therefore conceal generatively important histories. GRE uses trajectory analysis to ask how sequences of relations and events shape present and future possibility.

Path dependence can arise through several mechanisms. Earlier choices can create switching costs, complementary investments, habits, classifications, reputational effects, or network structures that condition later choices. Institutional arrangements can make some transitions progressively easier and others harder. Learning can create cumulative capability. Trauma or depletion can reduce future adaptability. These mechanisms differ, so trajectory dependence should be specified rather than invoked as a generic explanation.

Temporal objects also allow GRE to distinguish maintenance from change. A stable institution or capacity may require continuous process. Public infrastructure must be repaired; professional competence maintained; ecosystems regenerated; trust reproduced; data updated; organizations staffed. A snapshot can therefore make a dynamically maintained condition appear static. Process analysis reveals the labor, resources, relations, and constraints required for persistence.

The timescale of a trajectory matters. A policy can improve short-run consumption while weakening long-run fiscal capacity; a technology can raise output while generating ecological or skill dependencies; a cost-cutting strategy can increase current profit while degrading organizational knowledge. GRE consequently studies trajectories across timescales rather than treating the immediate effect as a sufficient description of economic consequence.

Processes, events, and trajectories can themselves interact. An event can initiate a process; a process can accumulate conditions that make an event consequential; a trajectory can cross a threshold that changes the process governing subsequent evolution. These temporal objects therefore provide the language needed to connect cur-

rent intervention with future generative structure.

3.4.9 Institutions and Social Facts

Institutions and social facts are objects of GRE because economic possibilities are stabilized through rules, roles, classifications, expectations, conventions, recognized statuses, and recurring practices that exceed isolated transactions. Institutions organize who may act, under what authority, through which procedures, with which forms of recognition, and under which expectations of continuity. Social facts include collectively sustained realities whose economic consequences depend on shared recognition, repeated practice, or institutional support.

An institution should be distinguished from an organization. An organization is a relatively bounded collective entity; an institution is a stabilized pattern of rules, roles, norms, or practices that can operate across many organizations. A university is an organization, while credentialing practices, academic tenure, disciplinary review, or degree recognition are institutional arrangements. A bank is an organization, while money, deposit insurance, accounting standards, or secured lending involve wider institutions. The distinction matters because organizational change can occur within persistent institutions, and institutional change can reorganize many organizations simultaneously.

Institutions stabilize expectations. Contract law affects the expected consequences of agreement; property regimes organize control and transfer; professional licensing structures entry; welfare systems define eligibility; labor law configures employment relations; standards coordinate interoperability. This stabilization can reduce uncertainty and make complex cooperation possible. It can also preserve historically produced asymmetries by assigning differential rights, burdens, recognition, or access.

Social facts can become economically real through collective recognition and practical enforcement. Currency, credentials, corporate status, property claims, rankings, occupational categories, and reputations depend partly on recognition while producing material consequences. Their socially constituted character does not weaken their reality. A person denied a credential, account, license, or legal status can face direct material exclusion even though the relevant object exists through institutional and representational practices.

GRE is interested in how institutions are generated and reproduced. Repetition can stabilize conventions; law can formalize existing practices; administrative categories can create new subject positions; technical infrastructures can embed rules into routine action; organizations can reproduce institutions through hiring, reporting, and compliance. Institutional persistence therefore requires material, symbolic, and relational supports that can themselves become objects of economic analysis.

Institutions also transform the value and meaning of other objects. A dwelling becomes mortgageable property under specific legal and financial institutions. Data become tradable or restricted through regulatory and contractual regimes. A skill becomes economically valuable when recognized by employers or credentialing systems. A relationship becomes taxable, insurable, or legally protected when institutional categories recognize it. Institutions thus participate in converting material and social differences into economically actionable distinctions.

Institutional change can produce generative effects that extend far beyond the immediate rule modification. A new legal status can enable contracting, borrowing, inheritance, representation, or access to public support. A new technical standard can create markets for complementary products. A revised accounting rule can alter investment behavior. Because institutions condition many later relations simultaneously, their generative reach can be large even when the initiating intervention appears administrative.

The institutional object category therefore links GRE's analysis of stable social reality with its interest in historical transformation. Institutions provide continuity while remaining generated, maintained, contested, and revisable. Their durability makes them analytically powerful; their historical production prevents their present form from being treated as timeless.

3.4.10 Symbolic and Representational Objects

Economic life increasingly depends on symbolic and representational objects: prices, money, accounts, contracts, rankings, scores, categories, models, forecasts, identities, records, credentials, tokens, indices, dashboards, and algorithmic classifications. GRE treats such objects as economically consequential when representations mediate access, coordinate action, allocate attention, stabilize expectations, or alter the behavior of the subjects represented.

A representation should be distinguished from its referent. A credit score is not identical to a borrower's full financial condition; a ranking is not identical to institutional quality; a market price is not identical to every form of value; a model is not identical to the system modeled. The distinction matters because economic action often responds to the representation. A lender can deny credit because of a score, investors can respond to a rating, students can choose universities through rankings, managers can reorganize work around performance indicators, and public agencies can allocate resources through administrative categories.

Representations can therefore become performative or generative. Once a category is used for allocation, subjects may adapt behavior to satisfy it. Once a metric determines funding, organizations may reorganize activity around the metric. Once a risk model affects pricing, the resulting prices can alter the behavior on which future risk estimates are based. Representation enters the causal structure because institutions and actors use it to make decisions.

Symbolic objects also permit coordination across distance and scale. Money represents transferable claims; contracts encode obligations; accounting records organize complex organizations; technical standards encode compatibility; credentials communicate institutional recognition; databases preserve histories that can be acted upon by subjects who never directly observed the original events. These symbolic infrastructures expand economic coordination while creating dependencies on classification, record integrity, interpretability, and institutional trust.

The production of representations is therefore itself an economic process. Data must be collected, categories designed, models trained, records maintained, standards negotiated, and interpretations authorized. These activities require labor, infrastructure, expertise, and institutional power. Actors controlling representation

systems can shape which differences become visible and which forms of value become actionable. In data-intensive economies, control over classificatory and representational infrastructure can become a major source of economic power.

Representations also have error structures. Measurement can be noisy; categories can be incomplete; models can be misspecified; historical records can be biased; proxies can drift as behavior changes. A representation can remain administratively stable while becoming less adequate to the underlying configuration. GRE therefore treats representational validity as historically revisable. The question is not only whether a representation was accurate when introduced, but whether the relations between indicator, referent, and institutional use remain sufficiently stable for current decisions.

Symbolic objects can move across contexts and acquire new effects. A credential issued for educational recognition can become a labor-market filter. A social-media metric can become an advertising asset. A legal category can become a database field used in automated decision systems. A scientific indicator can become a policy target. Such movements can alter the meaning of the representation and the incentives surrounding it.

GRE's interest in symbolic and representational objects is consequently broader than a study of information. It concerns the economic relations through which representations are created, authorized, circulated, interpreted, converted into decisions, and recursively connected to the realities they describe. The distinction between relation and representation remains central: a representation can reveal a relation, simplify it, distort it, or participate in generating a new one.

The ten object classes developed in this section provide GRE with a plural repertoire for empirical and theoretical inquiry. Emergent entities supply relatively stable units; subjects and subject positions identify locations of participation, standing, experience, and exposure; relations and relational configurations make interdependence explicit; resources and capacities distinguish what is available from what can practically be done; forms of value identify heterogeneous objects of production, recognition, conversion, and evaluation; conditions and constraints organize feasible possibility; fields capture distributed structures; processes, events, and trajectories preserve temporal organization; institutions and social facts explain stabilized collective realities; and symbolic or representational objects make visible the classificatory infrastructures through which economic action is coordinated.

These categories should remain permeable. A corporation can simultaneously be an entity, a juridical subject, an institutional configuration, a bundle of capacities, a node in relational fields, and a trajectory. Money can be a resource, an institutionally stabilized social fact, a symbolic object, and a medium through which value is represented and converted. A platform can be an organization, technical infrastructure, field, relation-generating environment, classificatory system, and economic subject under different legal arrangements. GRE gains explanatory power from selecting the representation that preserves the distinctions relevant to the local question, while comparing alternative representations when conclusions depend on that choice.

Object selection is therefore inseparable from scale. An object stable at one level can decompose into heterogeneous relations at another; a relation local to one scale

can appear as a distributed field at another; an event for one subject can be part of a long institutional process at a wider temporal resolution. The next section turns explicitly to these levels and scales of inquiry, establishing how GRE can move among individual, organizational, collective, institutional, ecological, and transnational domains without assuming that the same objects retain identical boundaries across them.

3.5 Levels and Scales of GRE Inquiry

The objects identified in the preceding section become analytically meaningful only relative to a level and scale of inquiry. A household can be treated as an economic subject in one analysis, as a field of interpersonal relations in another, as a node in a credit or welfare network in a third, and as part of a larger demographic, ecological, or transnational configuration in a fourth. Generative Relational Economics therefore requires an explicit account of scale selection. The role of this section is to specify the principal levels at which GRE inquiry can be organized and to clarify how movement among levels affects what counts as an entity, relation, condition, mechanism, and consequence. Its objective is neither to impose a fixed micro–meso–macro hierarchy nor to deny the usefulness of scalar distinctions. It is to make scale an explicit analytical choice whose adequacy depends on the research question, the generative mechanism under study, and the evidential resolution available to the researcher.

Scale in GRE has several dimensions. A *spatial scale* concerns the geographic or material extent of a configuration. A *temporal scale* concerns the duration over which formation, persistence, transformation, or consequence is observed. An *organizational scale* concerns the level at which coordinated action is stabilized, from interpersonal relations to firms, states, transnational institutions, or distributed infrastructures. A *juridical scale* concerns the reach of rights, duties, jurisdictions, and recognized authority. An *ecological scale* concerns the material and living systems within which economic activity is embedded. An *analytical scale* concerns the resolution at which a researcher constructs objects and causal or generative claims. These dimensions can align, but they often diverge.

The distinction between *level* and *scale* is useful even when their boundaries remain context-dependent. A level identifies a position within a layered description, such as person, organization, institution, or transnational system. Scale identifies the extent or resolution of the phenomenon being observed. An organizational process can have a local spatial scale but a long temporal scale; an interpersonal relation can be embedded in a global platform infrastructure; a juridical rule can operate nationally while being produced through transnational negotiation. GRE therefore treats levels as analytical locations within an inquiry and scales as dimensions of extent, duration, or resolution. Neither should be assumed to map onto a single natural hierarchy.

This section proceeds across six recurrent domains of analysis—individual and interpersonal, organizational, community and collective, institutional and juridical, ecological and more-than-human, and inter-system and transnational—before turning to two cross-cutting issues: scale-relative entityhood and cross-scale generative

effects. The method is constitutive rather than classificatory in a rigid sense. The purpose is to define a usable architecture for GRE research while preserving the possibility that empirical cases require different or additional levels.

3.5.1 Individual and Interpersonal Scales

Individual and interpersonal scales concern persons, households, dyads, small groups, and recurrent relations whose immediate organization is accessible at the level of situated interaction. At this scale, GRE can study how economic capacities, constraints, expectations, obligations, identities, and values are generated through relations among concrete subjects. The focus is wider than individual choice in isolation. Choice remains important, but the inquiry asks how the conditions under which choices become available, intelligible, affordable, legitimate, or sustainable are relationally formed.

An individual can be analyzed as an economic subject with resources, preferences, capabilities, legal standing, knowledge, vulnerabilities, and temporal commitments. Yet these attributes frequently depend on relations that exceed the individual. Income can depend on employment relations; credit access can depend on institutional classification and social history; capability can depend on care, education, infrastructure, or recognition; preference formation can depend on social learning and available categories of action. GRE therefore treats individual-level observations as legitimate without treating the individual as analytically self-sufficient.

Interpersonal relations can themselves generate economic effects. Trust can reduce monitoring costs and make cooperation feasible. Care can maintain or expand another person's practical capacities. Advice can alter information, confidence, or opportunity. Repeated exchange can create expectations of reciprocity. Family relations can redistribute resources across time and persons. Friendship and professional ties can provide access to information, employment, finance, or institutional navigation. These effects can be valuable without being fully priced, and they can generate dependency or unequal obligation as well as support.

Households illustrate the importance of distinguishing the administrative recipient from the relational field. A transfer formally delivered to one household member can alter bargaining power, care allocation, educational investment, consumption, savings, mobility, or future exit options for several people. A wage increase can change household time allocation and dependency patterns. Debt undertaken by one member can constrain future resources of others. The relevant unit therefore depends on the mechanism being studied rather than on the administrative unit through which a programme or transaction is recorded.

Temporal scale is especially important at the interpersonal level. Some effects are immediate, such as payment, consumption, or access. Others accumulate through repeated interaction. Trust, skill, reputation, dependency, and caregiving capacity are often generated through histories rather than single encounters. A relation that appears beneficial over one month can create vulnerability over several years; a costly educational investment can generate capabilities whose effects become visible much later. GRE inquiry should therefore specify the time horizon over which an interpersonal relation is being evaluated.

The individual and interpersonal scale also reveals the difference between formal equality and relational position. Two persons may hold the same legal right while facing different exit costs, knowledge, network access, or dependence. Equal monetary transfers can have different generative effects because subjects occupy different relational configurations. This does not imply that every analysis must reconstruct the full social history of each person. It means that the scale of analysis should be broad enough to capture the relations necessary for the specific generative claim.

At this level, evidence can include interviews, ethnography, surveys, administrative records, experiments, transaction histories, diaries, social-network data, or mixed-method designs. The appropriate evidence depends on whether the claim concerns subjective meaning, observed behavior, resource flow, causal effect, relational structure, or long-horizon change. Individual-scale data do not automatically support interpersonal or institutional claims, just as aggregate data can conceal mechanisms operating through concrete relations.

The individual and interpersonal scale is therefore a legitimate entry point rather than a privileged foundation. GRE can begin with persons and direct relations when that resolution is adequate, while remaining prepared to enlarge the analytical boundary when the observed capacities, constraints, or trajectories depend on organizational, institutional, ecological, or transnational structures.

3.5.2 Organizational Scales

Organizational scales concern coordinated configurations that stabilize roles, procedures, decision rights, resource pools, routines, information flows, and boundaries of participation. Firms, public agencies, universities, hospitals, cooperatives, nongovernmental organizations, platforms, laboratories, and project teams can all become objects at this scale. The relevant question is not simply whether an organization exists as a legally recognized entity. GRE asks how organizational arrangements generate capacities and constraints for participants and how those arrangements reproduce or transform their own conditions of operation.

Organizations can pool resources that individuals cannot mobilize alone. They can create specialized roles, accumulate knowledge, establish infrastructure, coordinate long production processes, and distribute risk. They can also concentrate decision authority, create informational asymmetries, and determine access to opportunities. An organization therefore appears simultaneously as an emergent entity and as a relational architecture through which people, technologies, rules, and resources become coordinated.

Organizational boundaries are analytically important because many contemporary production processes extend beyond formal employment or ownership. A platform can rely on independent contractors, users, complementors, cloud providers, advertisers, moderators, data-labeling workers, and public infrastructure. A manufacturing firm can depend on suppliers distributed across jurisdictions. A university can rely on temporary researchers, publishers, funders, accreditation systems, and digital services. The legal boundary of the organization is one relevant boundary, but it may not coincide with the generative boundary of the economic process.

GRE can therefore distinguish between organizational membership and organiza-

tional dependence. A person may depend economically on an organization without being an employee. A community may bear environmental or infrastructural consequences of organizational activity without participating in governance. A supplier may become technologically locked into a dominant buyer. A public institution may depend on proprietary software whose provider sits outside its formal hierarchy. These relations affect the organization's generative reach and the distribution of benefits, risks, and future options.

Organizational scale also makes internal heterogeneity visible. Departments, teams, occupational groups, and technical systems can operate under different incentives and temporalities. A firm can appear coherent at the market level while containing conflicts over investment, labor conditions, safety, innovation, and accounting. An organization can therefore be treated as a unit for one research question and decomposed into internal relational configurations for another. The adequacy of aggregation depends on which mechanisms matter to the inquiry.

Organizational learning is one important generative process. Routines, archives, training systems, informal norms, and technological infrastructures can preserve knowledge beyond individual tenure. Conversely, turnover, outsourcing, or fragmentation can dissipate capabilities even when short-term financial indicators improve. Investment in organizational capacity can therefore generate future possibilities that are not visible in current output, while extraction from organizational knowledge or trust can reduce later adaptability.

Governance within organizations is similarly generative. Decision procedures determine whose information enters deliberation, which risks become visible, how conflict is resolved, and who can revise rules. Participation can create knowledge and legitimacy; concentrated authority can accelerate decisions in some contexts while suppressing local information in others. GRE does not presume one organizational form to be normatively superior across cases. It studies how specific governance architectures shape the production, distribution, and transformation of future capacities.

Organizational scale thus mediates between interpersonal relations and wider institutional structures. Organizations translate law, markets, technologies, and cultural expectations into local procedures, while their actions can reshape sectors, communities, standards, and political economies. Their analysis requires attention both inward to internal relational architecture and outward to the fields in which they operate.

3.5.3 Community and Collective Scales

Community and collective scales concern forms of coordination and shared dependence that do not necessarily coincide with formal organizational boundaries. Neighborhoods, professional communities, scientific fields, cultural groups, commons, mutual-aid networks, open-source communities, social movements, informal markets, and distributed publics can exhibit patterns of collective action without constituting a single organization. GRE includes these formations because economically consequential capacities can emerge through repeated participation, shared norms, common infrastructures, and distributed recognition.

A community can generate resources that are difficult to assign to individual producers. Shared knowledge, reputation systems, linguistic conventions, safety expectations, informal credit, professional standards, and norms of reciprocity can enable action across many participants. Their value often depends on continued collective reproduction. If participation declines, trust erodes, common infrastructure deteriorates, or knowledge ceases to circulate, the resource itself can weaken even when no discrete asset has been destroyed.

Collective scale also matters for the formation of economic subjects. Membership in a professional, cultural, or local community can provide categories through which people understand opportunities and obligations. Collective narratives can shape expectations about work, entrepreneurship, education, debt, care, or acceptable risk. These processes need not imply homogeneous values. Communities can contain disagreement, hierarchy, exclusion, and multiple overlapping memberships. GRE therefore treats collective identity as an empirical configuration rather than an assumption of unity.

Commons provide a particularly useful illustration. A resource can be collectively used and governed through rules that define access, contribution, monitoring, sanction, and adaptation. The relevant economic object is then neither only the resource nor only the individual user. It includes the relation among resource conditions, user practices, governance arrangements, and external pressures. Changes in any of these can alter the viability of the collective system.

Digital communities extend these issues beyond geographic proximity. Open-source projects, online knowledge communities, creator networks, and platform-mediated groups can generate software, information, cultural value, reputation, and social support through dispersed participation. Their infrastructures can nevertheless remain privately owned or technically centralized. A community can therefore be distributed at the level of participation while depending on concentrated control at the infrastructural level. This asymmetry becomes visible only when multiple scales are analyzed together.

Collective action can also produce public or quasi-public capacities. Community organizing may improve bargaining power; professional associations may establish standards; neighborhood networks may coordinate disaster response; scientific communities may produce shared methods and repositories. These capacities can benefit participants unevenly and can create boundaries around membership or recognition. GRE can study both the generative contribution of collective organization and the distribution of access to what is collectively generated.

The temporal scale of communities often exceeds individual participation. Institutions of memory, ritual, documentation, mentorship, and repeated practice can transmit norms and capacities across cohorts. At the same time, a community can transform rapidly under migration, technological change, political conflict, or economic restructuring. Analyses that treat collective structure as fixed can miss the processes through which membership, meaning, and governance are continually reproduced.

Community and collective scales therefore provide a middle range in which distributed relations acquire partial stability without necessarily becoming formal organizations. They are especially important for GRE because generation frequently

occurs through participation that is economically consequential yet only partially represented in contracts, prices, or administrative categories.

3.5.4 Institutional and Juridical Scales

Institutional and juridical scales concern relatively stabilized systems of rules, recognized roles, procedures, classifications, rights, duties, jurisdictions, and authorized decisions. At this scale, GRE studies how economic possibility is structured through the formal and informal arrangements that determine what can be owned, exchanged, licensed, enforced, recognized, taxed, subsidized, inherited, represented, or contested. Institutions are not merely background conditions. They actively generate categories of action and subject positions.

Law provides one especially explicit architecture of economic possibility. Corporate law makes certain collective entities legally actionable. Property law organizes claims over resources. Contract law structures enforceable commitments. Labor law defines employment relations and protections. Bankruptcy law redistributes consequences of failure. Immigration law can shape access to labor markets and public support. Intellectual-property law conditions the circulation and appropriation of knowledge. These arrangements alter incentives, but they also constitute the legal identities and relations through which economic action proceeds.

Juridical scale should not be reduced to national legislation. Municipal regulations, administrative agencies, courts, professional licensing bodies, treaty regimes, private arbitration systems, technical standards, and organizational rules can each exercise authority over different domains. Jurisdictions overlap, and actors can move or strategically position activity among them. GRE therefore asks which authority is operative for the relation under study and how jurisdictional boundaries affect the distribution of rights, risks, and generative opportunities.

Institutional categories can have constitutive effects. Eligibility rules determine who counts as a beneficiary. Accounting standards determine which assets and liabilities become visible. Educational credentials authorize access to professions. Credit classifications influence borrowing conditions. Statistical categories shape policy populations. Once institutionalized, such classifications can alter behavior and resource flows, thereby contributing to the reality they purport to describe.

Institutional scale also introduces temporal depth. Rules inherit prior conflicts and compromises; administrative routines accumulate; precedents stabilize expectations; legal categories outlive the conditions under which they were formed. Economic actors adapt to these structures, and repeated adaptation can create constituencies that support their continuation. Institutional persistence can therefore be generated through feedback among rules, investments, expectations, and organized interests.

Change at this scale can be discontinuous. A legal recognition, regulatory decision, court judgment, or policy reform can rapidly transform the feasible set of actions for many actors. Yet implementation remains relational. Formal change can produce uneven effects when local administrative capacity, information, infrastructure, or social recognition differs. GRE consequently distinguishes institutional rule change from the distributed processes through which a rule becomes effective in practice.

Institutional and juridical scales also mediate normative questions. Rights, procedural protections, and public obligations can constrain economically efficient arrangements for reasons of justice, dignity, or political legitimacy. Conversely, legal authority can stabilize extractive or exclusionary relations. GRE does not infer normative validity from institutional existence. It treats institutions as economically generative structures whose consequences and justification require separate evaluation.

This scale is indispensable whenever the relevant causal or generative mechanism depends on recognized authority. A transaction between two persons may appear interpersonal, yet its enforceability, tax treatment, property consequences, and admissible terms can be institutionally constituted. The juridical environment therefore enters GRE inquiry whenever it materially changes what relations can exist and what they can generate.

3.5.5 Ecological and More-than-Human Scales

Ecological and more-than-human scales concern the living, material, energetic, climatic, and technological systems through which economic activity becomes possible and consequential. GRE includes these scales because economic relations are embedded in conditions that are neither produced solely by human exchange nor adequately represented as passive inputs. Soil fertility, water systems, biodiversity, atmospheric conditions, energy infrastructures, animal populations, computational systems, and built environments can shape and be transformed by economic processes.

Ecological scale complicates conventional boundaries around the economic unit. A factory can be analyzed as an organization, but its production may depend on watersheds, energy grids, mineral extraction, transport corridors, and waste sinks distributed across large regions. Agricultural production can depend on pollination, soil microbiomes, climate patterns, seed systems, and water availability. The relevant generative configuration can therefore extend far beyond the spatial boundary of the producing organization.

Temporal scale becomes especially consequential here. Ecological regeneration, depletion, contamination, and climate effects can unfold over decades or generations. Short accounting periods can therefore classify an activity as productive while externalizing degradation of the conditions that make later production possible. GRE can address this mismatch by treating ecological conditions as part of the generative system rather than only as exogenous constraints encountered by economic actors.

More-than-human inquiry also raises questions about agency and subjecthood. GRE need not resolve a general metaphysics of non-human agency in order to study how animals, ecosystems, technical systems, or artificial agents participate causally in economic configurations. A river can constrain settlement and transport; a disease vector can alter labor and health systems; an algorithm can allocate visibility or credit; an automated system can modify production decisions. The analytical status of these participants should be specified relative to the claim being made rather than predetermined by a universal hierarchy of subjects.

Technological systems illustrate the overlap between ecological and organizational scales. Energy networks, communication infrastructures, logistics systems,

and machine-learning platforms have material footprints, operational dependencies, maintenance requirements, and failure modes. Their economic effects emerge through coupled human and technical relations. Treating technology as a neutral tool can obscure how technical architecture redistributes practical capacities and how its maintenance depends on resource extraction, labor, standards, and institutional support.

Ecological relations also generate value that can resist simple monetization. A wetland can support flood protection, habitat, cultural practice, recreation, and future ecological resilience. Assigning a price to one service can assist a particular decision while leaving other forms of value unrepresented. GRE therefore permits multiple valuation registers at ecological scales and requires transparency about which dimensions are included in a given economic representation.

More-than-human scales also expand the population affected by economic decisions. Future people, non-human organisms, and ecosystems can bear consequences without participating in present transactions. This creates a temporal and representational problem: current subjects make decisions under institutions that may weakly represent distant or non-speaking affected parties. GRE can study the mechanisms through which those absences become economically consequential without assuming that a single metric resolves the normative problem.

Ecological and more-than-human scales thus prevent the research boundary from stopping where conventional organizational or market boundaries stop. They make visible the material conditions, distributed dependencies, and long-duration transformations through which present economic generation can either sustain or erode future possibility.

3.5.6 Inter-System and Transnational Scales

Inter-system and transnational scales concern relations that cross organizational fields, institutional orders, jurisdictions, sectors, infrastructures, or national boundaries. Contemporary economic processes frequently operate through such crossings. Finance, migration, supply chains, digital platforms, scientific collaboration, humanitarian assistance, trade, energy systems, taxation, and data governance can connect actors governed by different rules and situated within different value structures. GRE therefore requires a scale at which interactions among systems become objects in their own right.

A transnational supply chain illustrates the problem. Production may involve design in one jurisdiction, components from several others, assembly elsewhere, finance through global institutions, shipping through international logistics, and consumption in distant markets. Labor rights, environmental rules, currencies, tax regimes, and political risks differ across locations. The economic relation cannot be understood fully through the bilateral transaction between buyer and seller because value generation and vulnerability are distributed across the chain.

Inter-system analysis is broader than geographic internationalization. Health systems can interact with labor markets; education systems with migration regimes; financial systems with housing; scientific systems with intellectual-property institutions; humanitarian systems with border governance. Each system can maintain

its own classifications, objectives, and evaluative criteria. Their coupling can create gaps, contradictions, or conversion points through which subjects gain or lose access.

Conversion across systems is therefore a central object. A qualification recognized in one jurisdiction may not convert into professional standing elsewhere. Financial capital can cross borders more easily than labor. Data can be generated in one legal environment and processed in another. Carbon emissions can be produced locally while their climatic effects are globally distributed. Humanitarian categories can determine access to assistance but interact imperfectly with immigration categories. GRE can study these interfaces as generative sites where differences among systems produce new capacities or constraints.

Transnational scale also changes the distribution of governance capacity. Some actors can choose jurisdiction, route investment, relocate data, restructure ownership, or negotiate directly with states. Others remain territorially or institutionally fixed. Mobility itself therefore becomes an economic capability. The ability to cross boundaries can alter bargaining power even when formal rules are equal within each jurisdiction.

Distributed infrastructures further complicate territorial analysis. Payment networks, cloud computing, communications, shipping, and digital identity systems can operate across many jurisdictions while being controlled by a limited number of organizations or standards bodies. Failure or policy change at one infrastructural node can propagate across distant systems. The relevant scale is then neither purely national nor simply global; it follows the architecture through which dependence and coordination are organized.

Transnational processes also operate across heterogeneous temporalities. Trade agreements, infrastructure investments, migration histories, debt contracts, and climate commitments can bind actors over long periods. Short-term political cycles may interact with long-term obligations. GRE can therefore examine how institutional time horizons become coupled and how present decisions distribute future adjustment costs across places and populations.

Inter-system and transnational scales are consequently necessary whenever the generative relation crosses the boundary of the system in which the initial action is recorded. They direct attention to interfaces, conversions, jurisdictional differences, infrastructural dependencies, and the unequal capacity to move among systems.

3.5.7 Scale-Relative Entityhood

The preceding scales reveal a central constitutional principle of GRE: entityhood is often scale-relative. A configuration that functions as a coherent entity at one analytical level can become a field of heterogeneous relations at another. A household can be a unit in a national survey and a contested relational configuration in an ethnographic study. A corporation can be a market actor in industrial analysis and a network of departments, contracts, algorithms, workers, and investors in organizational analysis. A state can be treated as an actor in international negotiation and decomposed into agencies, courts, political coalitions, infrastructures, and administrative practices in institutional analysis.

Scale-relative entityhood does not imply that entities are unreal. It specifies the conditions under which treating a configuration as an entity is analytically productive. Relative stability, boundary persistence, coordinated action, recognized identity, and causal integration can justify entity-level analysis. The same configuration can nevertheless be decomposed when internal structure becomes relevant to the question. Ontological suspension therefore supports practical realism: the analyst can work with entities while remaining open to changing the level of resolution.

Aggregation is one mechanism through which entities appear. Individual transactions can produce market-level regularities; organizational decisions can produce sectoral patterns; local ecological changes can accumulate into regional effects. Yet aggregation alone does not guarantee that the higher-level object has independent explanatory value. GRE asks whether higher-level patterns feed back into lower-level behavior, constrain possible transitions, or stabilize classifications and expectations. When they do, the higher-level configuration can become causally or generatively relevant in its own right.

Decomposition likewise requires care. Explaining an organization through individuals alone can omit rules, infrastructures, and emergent coordination. Explaining a legal order through statutes alone can omit administrative practice and social recognition. Explaining a market through transactions alone can omit standards, network effects, and institutional conditions. Reduction to a finer scale can therefore lose structure just as aggregation can conceal heterogeneity.

The choice of scale also affects attribution. If a worker acquires a skill, the generative contribution may involve individual effort, teachers, organizational training, public education, family support, digital infrastructure, and prior scientific knowledge. Different scales reveal different contributors. GRE should therefore match attribution to the level of the claim and avoid converting a multi-scale generative process into a single-agent narrative without justification.

Scale-relative entityhood also matters for normative evaluation. Benefits and harms can reverse appearance across scales. A firm-level efficiency gain can impose community-level unemployment; a household-level coping strategy can reproduce gendered burdens; a national growth policy can create ecological costs elsewhere; a local conservation rule can restrict livelihoods while sustaining long-run regional resilience. Evaluation should therefore state the population, temporal horizon, and scale to which a conclusion applies.

Remark 3.1 (Scale-relative entityhood)*.* Treating a configuration as an entity is a modeling and evidential commitment justified by the local inquiry. It does not require the same configuration to remain indivisible, homogeneous, or equally salient at other scales.

This principle gives GRE a disciplined way to move among levels without declaring one level ultimately fundamental. The research question determines the initial resolution, while empirical anomalies, mechanism evidence, or downstream effects can require expansion or decomposition of the analytical boundary.

3.5.8 Cross-Scale Generative Effects

Cross-scale generative effects occur when processes organized at one level alter capacities, constraints, structures, or possibilities at another. These effects are central to GRE because economic generation often propagates beyond the scale at which an intervention, transaction, or decision is initially observed. A scholarship allocated to one person can affect a household, professional network, organization, or future community. A local technological innovation can reshape industry standards. A national regulation can reorganize firm behavior and interpersonal opportunities. A transnational platform rule can alter the visibility and income of individual creators.

Cross-scale effects can move upward through accumulation, coordination, diffusion, or institutionalization. Repeated individual behavior can create market conventions. Local experiments can become organizational routines. Collective practices can become recognized standards. Distributed demand can support an industry. Social expectations can become politically salient and eventually codified. The relevant mechanism should be specified rather than assumed from the observation that lower-level and higher-level change occur together.

Effects can also move downward. Institutional classifications shape individual eligibility; organizational rules structure team behavior; market concentration alters bargaining conditions; national monetary policy changes borrowing costs; ecological degradation constrains household livelihoods. Higher-level patterns can therefore become conditions of lower-level action even when they originated historically from distributed processes.

Horizontal propagation across scales is equally important. A change in one sector can alter another through labor, finance, infrastructure, or regulation. A technological standard adopted by one industry can create complementary markets elsewhere. A health crisis can transform education, transport, employment, and care. These processes are not captured adequately by a single vertical hierarchy because the relevant systems can be partially autonomous yet strongly coupled.

Cross-scale generation can also involve delayed effects. Investment in early childhood can influence educational trajectories years later; infrastructure can shape settlement and productivity over decades; ecological damage can accumulate before crossing thresholds; institutional reforms can alter expectations gradually. A local analysis may therefore be accurate within its immediate horizon while incomplete for longer generative consequences.

Feedback among scales creates additional complexity. An organizational policy can alter worker behavior; aggregated behavior can change organizational performance; performance can lead to a revised policy. A legal reform can change market practices; those practices can generate new political coalitions; the coalitions can reshape subsequent law. In such cases, scale is part of the mechanism because causal influence circulates among levels rather than traveling in one direction.

Cross-scale effects also create attribution difficulties. When value or harm propagates across several levels, assigning the outcome to the initial actor alone can overstate individual contribution, while attributing it only to structure can erase situated agency. GRE therefore treats generative attribution as potentially distributed. The relevant task is to identify the relations through which capacities or constraints were

produced and the points at which different actors or structures materially altered the trajectory.

Measurement should reflect this distributed character. Data collected at one scale can miss effects at another. Firm-level productivity data may not reveal household care burdens; household income data may not reveal ecological depletion; national statistics may not capture transnational tax shifting; platform-level engagement metrics may not capture community-level cultural effects. Multi-level designs, linked data, comparative cases, qualitative tracing, and simulation can each contribute where appropriate, provided the relation between evidence and claim remains explicit.

Cross-scale analysis finally has a governance implication. Interventions aimed at one level can generate consequences elsewhere, so institutional responsibility may need to follow generative reach rather than administrative jurisdiction alone. This does not imply unlimited responsibility for every remote consequence. It creates a research question about which downstream effects are sufficiently connected, foreseeable, material, or governable to enter evaluation and design.

The architecture established in this section therefore gives GRE a way to specify where an inquiry begins, how far its analytical boundary extends, and when movement among scales becomes necessary. Individual, organizational, collective, institutional, ecological, and transnational levels are recurrent sites of inquiry rather than a closed hierarchy. Entityhood remains relative to analytical scale, and generative effects can propagate upward, downward, horizontally, and across time. With these levels clarified, the next task is to state the characteristic questions through which a GRE inquiry can interrogate a concrete economic situation.

3.6 Illustrative Questions in Generative Relational Economics

The preceding sections have specified the disciplinary identity, problem-space, methodological primitives, objects, and scales of Generative Relational Economics. Those elements define a field of possible inquiry, but they remain abstract until translated into questions that can organize empirical, historical, formal, interpretive, and normative research. The role of this section is therefore illustrative. It identifies recurrent question-forms that make the distinctive concerns of GRE operational without turning them into a mandatory sequence or a closed checklist. The objective is to show how a researcher can move from a conventional economic problem toward a generative-relational formulation by asking what relations constitute the situation, what is generated through them, how value and capacity travel, where asymmetries are converted into power, and how present arrangements alter later conditions of possibility.

These questions are intentionally broader than particular methods. A question concerning value propagation might be studied through administrative data, interviews, network analysis, accounting records, historical archives, ethnography, simulation, or some combination of these. A question concerning subject formation may require interpretive evidence that differs from the evidence required to identify a re-

source flow. GRE therefore treats the question-form as analytically prior to method selection. Methods are chosen according to the object, scale, mechanism, and evidential problem rather than according to a presumption that one technique defines the field.

The questions are also non-exclusive. A single research project may begin with one and encounter several others. An analysis of a training subsidy may ask who formally receives the subsidy, which household or organizational relations mediate its use, what capacities are generated, how those capacities propagate through employment networks, which forms of value are realized or lost, and whether the programme changes the future bargaining position of workers. The value of the GRE perspective lies partly in making these connections available for investigation while preserving distinctions among them.

The thirteen question families below should consequently be read as an open repertoire. They do not exhaust GRE inquiry, and they do not imply that every project must answer all twelve. Their function is to reveal characteristic directions of attention: constitution, displacement beyond the administrative recipient, generation, propagation, conversion, recirculation, capacity transformation, access to generative capacity and conditions, subject formation, power formation, orientation, foreclosure, and recursive transformation of the conditions of change.

3.6.1 Which Relations Constitute the Economic Situation?

A GRE inquiry can begin by asking which relations make the observed economic situation possible and intelligible. The question directs attention away from treating visible entities as analytically self-sufficient. A worker, firm, household, platform, loan, public service, or market transaction enters an already organized field of legal, infrastructural, contractual, social, technical, ecological, and symbolic relations. Some of these relations are proximate and observable; others operate as background conditions. The task is to identify which of them materially affect the phenomenon under investigation.

This question is selective rather than totalizing. GRE does not require reconstruction of every relation surrounding an object. The relevant relations are those whose inclusion changes explanation, evaluation, or intervention. A study of household energy insecurity, for example, may need to include income, housing quality, tenancy status, energy pricing, family composition, climate exposure, and access to public support. The entire history of the household is unnecessary unless some part of that history affects the mechanism under study. Relational analysis becomes useful when it improves the adequacy of the inquiry rather than when it simply multiplies context.

The question also encourages distinctions among kinds of relation. A legal relation of entitlement differs from an interpersonal relation of trust; a supply relation differs from an ownership relation; a technical dependency differs from a political authorization; an ecological dependency differs from a contractual obligation. Several may intersect in one case without being reducible to one another. Mapping constitution therefore requires enough conceptual resolution to preserve the mechanism carried by each relation.

Relational constitution can also be asymmetric. One party may depend on another

without reciprocal dependence of the same magnitude or kind. A small supplier can depend heavily on a dominant buyer whose dependence on that supplier is negligible. A migrant worker can depend on an employer for income, legal sponsorship, housing, or information. A municipality can depend on a private platform for an infrastructure it does not control. Asking which relations constitute the situation therefore prepares later analysis of bargaining position, exit, capture, and power.

The practical result is a boundary decision. Once the constitutive relations have been identified, the researcher can justify why some actors, institutions, infrastructures, temporal histories, or ecological conditions are inside the analytical frame and others remain outside it. The boundary remains revisable as evidence accumulates. GRE thus treats relational mapping as a disciplined way to construct the object of inquiry rather than as a demand for unlimited contextual description.

3.6.2 What Changes beyond the Administrative Recipient?

Economic programmes and transactions are frequently recorded through an administrative recipient: the person receiving a transfer, the firm receiving a subsidy, the borrower named on a loan, the patient receiving a service, or the organization holding a grant. GRE asks what changes beyond that formally designated unit. The question matters because economic effects often propagate through relations that administrative data do not treat as recipients.

A cash transfer received by one person may alter household consumption, bargaining power, care responsibilities, debt repayment, education, mobility, or support to relatives. A grant to a small firm can affect employees, suppliers, clients, landlords, local tax revenue, or competing firms. A scholarship can transform not only the student's education but household expectations, future remittances, professional networks, and the aspirations of younger family members. The administrative recipient remains an important object, but it does not automatically define the boundary of effect.

This question is not equivalent to measuring conventional spillovers alone. GRE is interested in the relational pathways through which effects move. Two programmes with similar average indirect effects can operate through different mechanisms. One may propagate through knowledge sharing, another through household redistribution, another through changes in bargaining position, and another through infrastructure created for the initial recipient. Identifying the pathway helps distinguish incidental correlation from generated consequence.

The question also exposes burdens that move beyond the recipient. A policy that expands employment for one group can transfer unpaid care to another group. Debt relief for a firm can preserve jobs while imposing losses on pension funds or public budgets. Digital convenience for consumers can shift risk and time costs onto gig workers. The analysis therefore follows both enabling and constraining consequences beyond the administrative unit.

A useful GRE design can make this boundary extension explicit at the outset. The researcher can specify the formal recipient, identify connected subjects and systems likely to be affected, determine which effects are theoretically relevant, and select evidence capable of observing those pathways. The resulting analysis does not reject

administrative categories; it treats them as one layer within a wider relational field.

3.6.3 What Is Generated through an Economic Relation?

A central GRE question asks what an economic relation produces beyond its immediate exchange or recorded output. The relevant generated objects can include income, knowledge, capability, trust, dependency, reputation, infrastructure, organizational routine, institutional legitimacy, ecological burden, expectations, data, symbolic standing, or new relations. Generation concerns the production of later conditions and possibilities, not merely the transfer of an already existing object from one holder to another.

Consider employment. A wage relation transfers income in exchange for labor, but it can also generate skill, professional identity, social networks, credentials, routines, health effects, dependence, bargaining experience, or exclusion from alternative opportunities. Which of these effects matters depends on the research question. A GRE analysis does not assume that every employment relation generates the same bundle. It asks which outputs are produced in this case, through which mechanisms, for whom, and with what temporal persistence.

The distinction between output and generation is especially useful where the immediate output is easy to measure but longer-term transformation is economically important. A training programme can produce a certificate immediately while generating later confidence, network access, occupational mobility, or employer recognition. A public library can provide books and space while generating study routines, weak ties, civic participation, or access to digital services. An open technical standard can coordinate present interoperability while generating an ecosystem of future complementary production.

Generated effects can be intended or unintended. Organizations can deliberately build capability, loyalty, or infrastructure, while other consequences emerge from repeated interaction without centralized design. Some generated effects become visible only retrospectively. GRE therefore distinguishes the existence of a generated consequence from claims about intention. The question concerns the causal or constitutive production of a later condition, not whether an actor planned that condition.

Generation can also be negative in practical or normative terms. A predatory credit relation may generate debt dependency and reduced future exit options. Repeated precarity may generate risk aversion or the erosion of professional capacity. An extractive production process may generate ecological degradation that constrains later economic activity. The category of generation is therefore descriptive before it is evaluative. Evaluation requires additional criteria concerning whose capacities, values, or futures are affected.

3.6.4 How Does Value Propagate?

Value produced or realized in one relation can travel through a wider configuration. GRE asks how that propagation occurs, which pathways carry it, where it amplifies or decays, and who becomes able to use or capture it. The question begins from the observation that valuable effects rarely remain confined to the site at which they first

appear.

Knowledge provides a clear example. A skill acquired by one worker can improve team performance, be taught to colleagues, contribute to organizational routines, support innovation, or become embodied in a product used elsewhere. Public infrastructure can raise the productivity of many firms and households. Trust accumulated through repeated cooperation can reduce coordination costs for later projects. A scientific result can enable downstream technologies, standards, or educational materials. The original site of value generation and the later sites of value realization can therefore be separated in space, time, and institutional ownership.

Propagation has a topology. Some value moves through direct exchange; some through imitation, learning, standards, networks, public goods, reputation, or price changes. Some pathways require institutional authorization. A professional qualification becomes valuable partly because employers and regulators recognize it. A digital protocol becomes valuable as adoption expands. A neighborhood amenity can propagate into land prices through property markets. Mapping the pathway helps determine whether value is widely distributed, locally concentrated, or captured at a bottleneck.

Propagation can also be blocked. Intellectual-property restrictions, incompatible standards, discriminatory networks, lack of infrastructure, language barriers, licensing rules, organizational secrecy, or geographic isolation can prevent generated value from reaching potential users. A GRE analysis can therefore investigate not only how value travels but which relations determine its transmissibility.

This question does not require that heterogeneous forms of value be collapsed into a common unit. Monetary gains, capability expansion, ecological support, recognition, and relational trust can propagate through different mechanisms and may require different measurements. The analytical task is first to identify the form of value and its pathway. Comparison or aggregation comes later, if the research purpose justifies it.

3.6.5 How Does Value Convert across Forms?

Economic life contains interfaces at which one form of value becomes convertible into another. GRE asks how those conversions occur, which institutions authorize them, whose valuations determine the rate or terms of conversion, and what is lost or created in the process. Conversion is analytically distinct from propagation. Propagation concerns movement of value through a relational configuration; conversion concerns a change in the form through which value is recognized or realized.

Education can be converted into credentials, credentials into employment access, employment into income, income into housing security, and housing security into educational opportunity for another generation. Reputation can become credit access. Cultural attention can become advertising revenue. Publicly produced knowledge can become private intellectual property. Ecological capacity can be converted into commodity production, while financial resources can sometimes be converted into restoration or conservation capacity. Each conversion requires a specific institutional and relational interface.

Conversion interfaces are often sites of asymmetry. Actors differ in their ability to define categories, certify equivalence, set prices, control access, or refuse conversion. A platform may convert user attention into advertising income while users lack a comparable mechanism for realizing the monetary value of their data. A credentialing institution can translate learning into recognized status. A financial system can translate property into collateral and collateral into borrowing capacity, thereby privileging subjects who already possess assets recognizable by that system.

Conversion can be lossy. Meaning, context, ecological complexity, or relational quality can disappear when translated into a scalar metric. Conversely, conversion can create new practical possibilities by making heterogeneous resources interoperable. Monetization can enable exchange across distance; standardized credentials can enable mobility; technical standards can connect previously incompatible systems. GRE therefore treats conversion neither as inherently exploitative nor as inherently beneficial. Its consequences depend on the forms involved, the terms of translation, and the distribution of authority over the interface.

Research can make these interfaces explicit. Instead of asking only how much value exists, it can ask which forms are recognized, which remain invisible, who can perform conversion, what conversion costs arise, who captures the resulting surplus, and whether repeated conversion changes the source form itself. Such questions are especially important when policy seeks to make previously unrecognized value legible to markets or administrative systems.

3.6.6 What Recirculates, Dissipates, or Is Extracted?

Generated resources and value can return to the relations that produced them, spread elsewhere, decay, or be extracted by actors positioned to capture them. GRE therefore asks what recirculates, what dissipates, and what leaves the generative configuration. This question focuses on reproduction through time. A relation can remain productive only if enough of the conditions supporting it are replenished, repaired, or renewed.

Recirculation occurs when generated value or capacity contributes to the maintenance or expansion of the relations that produced it. A cooperative can reinvest surplus in shared infrastructure. A university can use research income to support laboratories and training that enable later research. A community enterprise can return part of its income to local services and networks. Trust generated through successful cooperation can make later cooperation easier. Recirculation can therefore create self-reinforcing dynamics without implying that the resulting configuration is socially desirable.

Dissipation concerns loss through time, friction, obsolescence, leakage, neglect, or ecological degradation. Skills can decay when unused; infrastructure can deteriorate without maintenance; trust can erode; institutional knowledge can disappear through turnover; ecological capacity can be depleted; attention can fragment. Some dissipation is unavoidable, while some reflects institutional choices about maintenance and renewal. An analysis focused only on gross production can miss the cost of replacing dissipated conditions.

Extraction occurs when generated value or capacity is appropriated in ways that

weaken the configuration from which it arises or concentrate its benefits elsewhere. Rent extraction from a local economy, uncompensated appropriation of community knowledge, financial distributions that undermine productive investment, or platform capture of user-generated value can all become candidates for investigation. The concept requires mechanism evidence. The fact that one actor gains more than another does not by itself establish extraction; the analysis must identify the relation through which value is captured and the effect on the generative configuration.

Recirculation, dissipation, and extraction can coexist. A profitable firm can reinvest some surplus, distribute some to workers or suppliers, lose some through depreciation, and transfer some to distant owners. A public programme can generate local capacity while trained workers later migrate. The question is therefore compositional: what proportion or form of generated value follows each pathway, and how do those pathways alter future capability?

3.6.7 How Are Future Capacities Transformed?

GRE places particular emphasis on the transformation of future capacity. An economic arrangement matters not only because of what it produces now but because it changes what subjects and systems can do later. This question links present allocation and relation to the future space of feasible action.

Capacity transformation can occur through learning, infrastructure, health, care, institutional reform, ecological change, debt, technological dependency, network formation, or depletion. A loan can expand productive capacity by financing equipment, while repayment obligations can constrain future cash flow. Employment can build skill and reputation while narrowing alternative career paths. A subsidy can help an industry acquire capabilities that persist after the subsidy ends. Environmental degradation can generate present income while reducing the future productive capacity of an ecosystem.

The temporal profile matters. Some interventions impose immediate costs in order to generate later capacity. Others create immediate gains by drawing down capacities that become scarce only later. A short evaluation window can therefore reverse the apparent ranking of alternatives. GRE does not prescribe one universal horizon, but it requires the horizon to be explicit and adequate to the mechanism claimed.

Capacity is also subject-specific and relational. The same infrastructure can expand the capacity of one group while reducing another's control over land or resources. A technology can increase organizational capacity while deskilling particular workers. A regulatory change can expand consumer choice while increasing compliance burdens for small producers. Asking whose future capacity changes prevents aggregate improvement from automatically standing in for distributed capability.

The question also creates an interface with uncertainty. Future capacities cannot always be observed directly at the time of intervention. Researchers may need intermediate indicators, historical comparison, simulation, qualitative evidence, or repeated observation. GRE therefore treats claims about future generativity as evidentially demanding. The more distant the claimed effect, the more explicit the mechanism and uncertainty should become.

3.6.8 Access to Generative Capacity and Conditions

A further GRE question asks who can enter, mobilize, influence, maintain, and modify the processes through which economic generation occurs. The question is related to allocation but is not exhausted by it. Receiving an output is different from being able to call upon the capacity that produces further outputs, and both are different from participating in the formation of the conditions under which that capacity develops.

The distinction can be organized through three analytical layers. The first concerns generated outcomes: who obtains what has already been produced? The second concerns generative capacity: who can mobilize labor, knowledge, organizations, machines, artificial systems, or institutional capabilities to produce something new? The third concerns generative conditions: who can shape infrastructures, legal permissions, standards, education, data, compute, energy, networks, recognition, and other conditions that make particular forms of generation possible? A GRE project may focus on any one layer, but it should avoid assuming that access at one layer entails access at the others.

Artificial intelligence makes the distinction unusually visible. If increasingly capable artificial systems reduce the need to obtain some goods or services through another person's direct labor, the political-economic problem does not necessarily disappear. It can shift toward access to the artificial generative system and toward control over the conditions under which that system operates and evolves. The relevant research question therefore becomes less exclusively who receives the product and more broadly who can make use of, influence, and participate in the development of generative capacity.

This question opens later analysis of capital, power, exploitation, common infrastructure, and generative autonomy without deciding those issues here. Its role in the present repertoire is diagnostic. It asks whether an observed distribution of outputs conceals a more consequential distribution of capacities and conditions, and whether apparently abundant production remains organized through asymmetrical dependence on access to future generation.

3.6.9 How Are Economic Subjects Generated and Stabilized?

Economic analysis often begins with subjects already defined as workers, consumers, owners, borrowers, firms, entrepreneurs, citizens, beneficiaries, or investors. GRE asks how such positions are generated, recognized, stabilized, and transformed. The question concerns practical economic subjecthood rather than a final theory of personhood.

Subject positions can be produced through legal categories, contracts, organizational roles, technologies, data systems, professional standards, markets, and social expectations. A person becomes a borrower not simply by possessing an individual preference for credit but through eligibility rules, identity documentation, scoring systems, collateral conventions, and lender recognition. A platform worker occupies a subject position shaped by contract classification, algorithmic management, customer ratings, payment infrastructure, and labor regulation. A firm becomes an investable object through legal incorporation, accounting practices, governance ar-

rangements, and financial representation.

Stabilization requires continuity. Roles persist because institutions recognize them, records maintain them, counterparties respond to them, and subjects often organize their own expectations around them. This continuity can enable planning and rights while also producing path dependence. A classification that initially facilitates coordination can later restrict access or define subjects in ways that no longer fit their circumstances.

Economic subjects can also be generated through participation. Repeated saving can produce a recognized credit history; apprenticeship can produce professional identity; membership in a cooperative can develop capacities for collective decision-making; long-term unemployment can alter institutional classification and self-expectation. Subject formation is therefore partly an economic process because access to resources, roles, and relations can reshape practical identity and future action.

The question becomes especially important under technological change. Artificial agents, automated systems, platforms, and hybrid human-machine arrangements can perform functions previously associated with human economic subjects. GRE can ask which dimensions of subjecthood are relevant in each domain: productive agency, control over resources, capacity to enter recognized relations, continuity across time, liability, representation, or normative standing. These dimensions need not coincide, and functional capability does not settle moral or legal status.

3.6.10 How Does Asymmetry Become Economic Power?

Differences in resources, knowledge, capability, network position, or technical capacity are ubiquitous. GRE asks when such asymmetries become economic power. The question prevents a simple equation between difference and domination. Power arises when asymmetry is connected to relations through which one actor can shape another's feasible actions, terms of participation, exposure to risk, access to resources, or future capacities.

A firm with superior technology does not automatically hold power over every other actor. Power emerges when that capability is linked to ownership, market position, contractual authority, infrastructure control, legal privilege, dependency, standard-setting, or capture of a bottleneck. Likewise, information asymmetry becomes power when one party can use informational advantage to determine terms, classify others, restrict alternatives, or impose costs that the other party cannot readily avoid.

Exit and dependence are therefore central. A relation can be formally voluntary while one side faces much higher exit costs. Workers may be able to leave an employer in principle but lose legal sponsorship, health insurance, housing, or accumulated benefits. Users may be free to leave a platform but face network effects, data lock-in, or loss of professional visibility. Suppliers may be free to reject a dominant buyer while lacking alternative markets. Power analysis asks how these relational conditions transform nominal options into practical constraints.

Power can also be infrastructural and impersonal. No single actor may intention-

ally dominate others, yet standards, algorithms, payment systems, zoning rules, or inherited property structures can distribute capacities asymmetrically. GRE can therefore examine power embedded in relational architectures as well as direct command. Identifying power does not require attributing malicious intention; it requires showing how a configuration systematically shapes the options or capacities of differently positioned subjects.

The question naturally leads to generative consequences. Power can reproduce itself by generating the resources, information, legitimacy, or dependency that sustain the original asymmetry. It can also erode its own conditions when extraction undermines cooperation or when concentrated authority produces institutional resistance. GRE therefore studies power not only as a present relation but as a potentially self-reinforcing or self-transforming generative configuration.

3.6.11 What Orients the Direction of Generation?

Generation has direction because economic systems selectively develop some possibilities while leaving others unrealized. GRE asks what orients that selection. Markets, institutions, professional communities, public policy, cultural expectations, metrics, aesthetic judgments, scientific questions, organizational goals, and individual aspirations can all influence which objects receive attention and investment.

The question is broader than incentive analysis while remaining compatible with it. Prices and expected returns orient activity, but so do legal mandates, research agendas, rankings, reputational systems, narratives of desirable futures, and perceptions of what is interesting or feasible. A research organization can direct resources toward questions regarded as scientifically significant even when immediate commercial returns are uncertain. A city can prioritize mobility, housing, tourism, or environmental restoration according to institutional and political judgments that structure later investment.

Orientation can operate before explicit choice by shaping salience. Subjects do not evaluate every imaginable possibility. They encounter a selected field of options made visible by institutions, technologies, language, education, and social experience. Recommendation systems, professional curricula, funding categories, procurement rules, and media attention can influence which possibilities become thinkable or practically available. GRE can therefore study the production of the option field as well as selection within it.

Orientation is also heterogeneous. Different subjects can pursue incompatible forms of value or imagine different desirable futures. Economic coordination then involves negotiation, conflict, coexistence, or institutional procedures for selecting among directions. The presence of plural orientations means that generativity alone cannot supply a normative criterion. A system can be highly generative while producing futures that some affected subjects reject.

Research on orientation can ask who participates in defining goals, which signals are amplified, which possibilities are rendered invisible, what feedback modifies priorities, and how orientation changes after new capacities or knowledge emerge. These questions prepare the more systematic treatment of orientation later in Chapter 3 while showing why the direction of generation is already an economic question.

3.6.12 Under What Conditions Does Generation Produce Foreclosure?

Generation can expand future possibility, but it can also close alternatives. GRE therefore asks under what conditions the production of one pathway forecloses others. Foreclosure can arise through irreversible investment, ecological depletion, institutional lock-in, debt, standardization, network effects, path-dependent learning, spatial development, or the concentration of control over key resources.

A technology can create new capabilities while making older infrastructures uneconomic to maintain. An urban development project can generate housing and commercial value while eliminating community uses of land that cannot easily be reconstructed. A standardized platform can enable broad interoperability while reducing space for alternative technical architectures. Specialized education can generate high competence in one domain while increasing the cost of changing fields later. These examples show why generation and foreclosure can occur together.

Foreclosure is not identical to constraint. Every realized choice excludes some alternatives simply because resources and time are finite. The analytical question concerns consequential closure of future possibilities, especially where the closure becomes difficult to reverse or is imposed unevenly across subjects. The degree of reversibility, distribution of exit costs, and availability of alternative pathways therefore become relevant indicators.

Some foreclosure can be justified or desirable. Safety regulation intentionally eliminates dangerous production methods; environmental rules can close destructive extraction pathways; technical standards can reduce costly incompatibility. GRE does not treat openness as an unconditional good. It asks which possibilities are being closed, for whom, by what authority, with what reversibility, and in pursuit of which values.

The question is particularly important for policy evaluation. An intervention can appear successful according to immediate outcomes while narrowing later adaptability. Conversely, a policy that preserves optionality can look inefficient in a short horizon because it maintains redundant capacity or multiple institutional pathways. GRE can therefore include future option structure as part of economic evaluation when the case warrants it.

3.6.13 How Do Relational Structures Transform Their Own Conditions of Change?

The final illustrative question concerns recursive transformation. Economic relations can generate outcomes that alter the mechanisms through which later change occurs. A market can produce firms that reshape regulation; a platform can generate network effects that change entry conditions; a labor arrangement can produce new worker organizations; a financial innovation can change the infrastructure through which future credit is allocated. The object of inquiry is therefore not only change within a structure but change in the conditions that organize subsequent change.

This question requires careful separation among levels of transformation. A system can move from one state to another while its basic rules remain stable. Parameters can change while the form of the mechanism remains intact. Institutions can

revise rules while preserving their authority structure. More strongly, actors, categories, boundaries, or mechanisms can be reconstituted so that the previous model of change no longer describes the later situation adequately. GRE is especially interested in the transition among these cases because historical economic development often involves several simultaneously.

Recursive transformation can be deliberate. Legislators can redesign institutions, firms can alter governance, communities can create new property arrangements, and regulators can modify market rules in response to observed outcomes. It can also emerge without centralized design as repeated practices create new conventions, standards, expectations, or dependencies. In either case, the researcher should identify the pathway through which earlier relations modify later generative conditions.

Reflexivity intensifies the problem. Economic subjects can observe models, policies, forecasts, and classifications and respond to them. A credit score changes behavior because actors know that the score affects access. A policy target can reorganize organizational reporting. A market forecast can affect expectations and transactions. Representation can therefore enter the causal field it describes. GRE treats such reflexive loops as empirically investigable rather than as a reason to abandon formal or causal analysis.

The evidential standard should remain demanding. Claims that a system has transformed its own rules can easily become rhetorical if the relevant rule, boundary, or mechanism is left unspecified. A strong analysis identifies what changed, which earlier relations contributed to that change, how the new arrangement differs operationally from the previous one, and what consequences follow for later possibilities. The concept is useful precisely when it distinguishes ordinary state change from transformation in the organization of change itself.

Taken together, these thirteen question families define a characteristic style of GRE inquiry without establishing a closed doctrine. They invite researchers to move beyond the immediate recipient, transaction, or output when doing so materially improves explanation; to track generation, propagation, conversion, and recirculation across heterogeneous relations; to examine future capacities, access to generative capacity and conditions, subject formation, power, orientation, and foreclosure; and to remain alert to recursive changes in the conditions of change. A project can enter this problem-space through any one of these questions and combine them according to the object and evidence at hand.

The next section converts this repertoire of questions into a more explicit analytical sequence. It distinguishes allocation, relational mediation, generation, propagation, conversion, recirculation, extraction, structural transformation, and changes in generative conditions. That sequence is not intended as a universal causal chain. Its role is to provide GRE with a reusable perspective for deciding which stages of an economic process require attention in a particular inquiry.

3.7 The Distinctive Analytical Perspective of GRE

The preceding sections have specified the problem-space, primitive structure, admissible objects, scales, and illustrative questions of Generative Relational Economics

(GRE). The role of the present section is to state more explicitly the analytical perspective that organizes those elements into a characteristic mode of economic inquiry. Its objective is to describe a sequence of analytical moves through which an allocation, transaction, policy, institution, or other economic event can be followed beyond its immediate recipient and immediate output into the relations, generated capacities, value pathways, structural changes, and altered conditions of future change that it helps produce. The sequence is presented as a research grammar rather than a universal causal law. A concrete study may enter at any point, omit stages that are irrelevant, distinguish several parallel pathways, or discover feedbacks that make the ordering recursive. The analytical value of the sequence lies in keeping distinct processes that conventional evaluation can easily compress into a single outcome measure.

The perspective begins from allocation because allocation remains a central economic operation. Resources, rights, attention, credit, land, labor, data, infrastructure, authority, and institutional recognition are distributed through decisions and arrangements that place something somewhere under particular terms. GRE treats that placement as an initial intervention into a relational configuration. The allocation changes access, bargaining positions, expectations, dependencies, opportunities for coordination, and sometimes the identities or capacities of the participants. Those changes can generate new resources and forms of value, which may propagate through a wider configuration, convert across forms, recirculate into the relations that produced them, dissipate, or become subject to extraction. Repeated or sufficiently consequential processes can alter institutional and relational structure, transform the conditions that enable future generation, and in some cases change the effective rule through which subsequent transformations occur.

This perspective therefore extends the temporal and relational horizon of economic analysis without prescribing one metric of success. Monetary return, productivity, capability, recognition, ecological capacity, knowledge, trust, security, autonomy, and other forms of value can remain heterogeneous. GRE asks how they are generated and connected before deciding whether comparison, aggregation, or normative judgment is warranted. It also keeps mechanism claims separate from moral evaluation. A self-reinforcing process can be economically powerful while normatively objectionable; a process that dissipates one form of value can generate another; a structural transformation can expand some future possibilities while foreclosing others. The following subsections develop the ten analytical moments in this perspective.

3.7.1 Allocation as an Initial Intervention

Allocation is the analytical point of departure because many economic processes become administratively visible at the moment when a resource, entitlement, burden, opportunity, or authority is assigned. Public budgets allocate funds to programmes. Firms allocate capital and labor. Banks allocate credit. Households allocate time and care. Platforms allocate visibility. Legal institutions allocate rights and liabilities. Educational institutions allocate credentials and access. These operations remain central to GRE, yet GRE reads them as interventions into already structured relations

rather than as terminal distributions among self-contained recipients.

An allocation changes more than possession. Receiving credit can alter a firm's bargaining position with suppliers, its ability to hire, its exposure to debt service, and the confidence of other financiers. A housing subsidy can change household security, neighborhood demand, landlord expectations, and local land values. Allocation of research funding can change laboratory composition, collaboration networks, training capacity, and the future distribution of expertise. Even an apparently simple transfer enters a field of existing institutions, expectations, power relations, and conversion mechanisms.

The analytical unit is therefore the allocation-in-context. A useful GRE study specifies what is allocated, under which institutional conditions, to whom or to which configuration, at what time, with what duration, and through which rights or obligations. It also identifies the baseline relations into which the allocation enters. These relations determine what the allocation can become. The same monetary amount can have different generative effects when recipients possess different infrastructure, debt burdens, social recognition, legal status, network access, or ecological conditions.

Allocation can also concern non-scarce or symbolically abundant objects. Attention, rankings, reputational signals, software, information, and institutional recognition can be allocated through procedures that differ from the allocation of rival material goods. Their economic significance often arises from the relations that make them consequential. A search ranking matters because users, advertisers, platforms, and firms respond to it. A credential matters because institutions recognize it. A dataset matters because actors possess complementary computational and organizational capacities. GRE therefore treats allocation as a broad intervention category whose meaning depends on the relational conditions of use.

Starting from allocation preserves continuity with established economic analysis while widening the subsequent inquiry. The initial question remains who receives what, under which conditions. GRE then asks what relations are activated or reconfigured by that placement, what becomes possible because of it, and which downstream effects remain outside the administrative boundary of the allocation itself.

3.7.2 Relational Mediation

An allocation acquires practical significance through relational mediation. Resources rarely produce identical effects independently of the relations through which subjects can use, interpret, exchange, protect, combine, or transform them. Relational mediation names the set of pathways through which an initial intervention becomes economically operative. These pathways can include contractual relations, kinship and care relations, organizational routines, infrastructures, legal recognition, technical standards, reputational systems, financial arrangements, ecological dependencies, and informal networks of trust or exclusion.

Mediation can enable use. A loan becomes productive when a borrower can purchase equipment, hire workers, obtain permits, reach customers, and sustain repayment. A public dataset becomes generative when users have the skills, computational infrastructure, legal permission, and institutional incentives required to employ it.

A school meal programme can affect educational participation through household budgets, health, attendance routines, and parental expectations. The intervention therefore passes through a configuration of relations whose structure conditions the realized effect.

Mediation can also redirect or neutralize an intervention. A subsidy intended for tenants can be partly captured through rent increases. A wage increase can produce limited household security when debt obligations absorb the gain. New infrastructure can intensify land speculation and displace the population whose mobility it was intended to improve. These outcomes do not imply that the allocation itself is analytically irrelevant. They show that its effect is co-produced by the relations through which it travels.

GRE therefore distinguishes administrative recipient from relational incidence. The person or organization named in a programme may be only one node in a larger set of affected relations. Suppliers, creditors, family members, competitors, property owners, workers, public institutions, ecosystems, or future participants can experience consequential effects. The boundary of relevant incidence should follow the mechanism under investigation rather than the accounting category alone.

Relational mediation also includes interpretation. Economic subjects respond to signals through historically and institutionally formed meanings. A tax incentive can be interpreted as temporary or durable. A guarantee can change perceived risk. A government purchase can signal future market demand. A platform rule can alter expectations about visibility and participation. Such interpretive mediation affects behavior without requiring that every actor hold the same belief.

The analytical task is to identify which relations materially condition the pathway from intervention to effect. GRE does not require exhaustive mapping of an entire social world. It requires enough relational specification to explain why the intervention produced the observed or anticipated consequences and why those consequences differ across subjects, sites, or periods.

3.7.3 Generation

Relational mediation can produce new capacities, resources, meanings, institutions, practices, identities, expectations, and forms of value. GRE uses *generation* for this productive moment. Generation concerns the emergence or augmentation of economically relevant possibilities through a relation or configuration. The generated object may be material, symbolic, institutional, ecological, epistemic, or relational. Its significance lies in the fact that later action becomes possible, easier, harder, or differently organized because the configuration has changed.

Production and generation overlap in many cases, yet their analytical emphases differ. Production commonly directs attention toward an output: goods, services, income, knowledge, or measurable performance. Generative analysis asks what further capacities and conditions are created in producing, using, distributing, or maintaining those outputs. A training programme produces instruction and credentials; it can also generate professional networks, self-confidence, recognized status, organizational routines, and future learning capacity. A transport project produces mobility services; it can generate new patterns of settlement, commercial access, land valua-

tion, and ecological pressure. A cooperative produces goods or services while potentially generating shared governance capability and durable norms of reciprocity.

Generation can occur without an intended designer. Repeated market exchange can generate conventions. Repeated platform participation can generate data and reputational histories. Shared exposure to risk can generate mutual-aid institutions. Competitive pressure can generate organizational routines or technological standards. Conversely, deliberate interventions can fail to generate the capacities they target because the necessary relational conditions are absent.

Generated outcomes are frequently distributed unevenly. A technology can generate organizational productivity while reducing the bargaining power or skill development of particular workers. A financial instrument can generate liquidity for one group while creating systemic exposure elsewhere. Public infrastructure can generate collective access while simultaneously generating private land rents. The generative question therefore includes the location and distribution of newly created capacities and constraints.

A GRE analysis should identify the mechanism through which generation occurs. The presence of a later capacity after an intervention does not establish that the intervention generated it. Competing pathways, background trends, selection effects, and independent causes remain relevant. Historical, qualitative, quantitative, comparative, causal, formal, and computational methods can each contribute depending on the problem. Generative language becomes analytically useful when it sharpens mechanism and temporal structure rather than merely redescribing change.

Generation also includes the production of constraints. Debt can generate purchasing capacity and repayment obligations. Digital infrastructure can generate access and dependency. Standardization can generate interoperability and exclusion of incompatible practices. Institutional recognition can generate rights and categories that narrow alternative forms of identity. GRE therefore treats generativity as directionally open: what is generated may expand, stabilize, redirect, or constrain future possibility.

3.7.4 Propagation

Generated effects can move beyond the relations in which they first appear. Propagation concerns the transmission, diffusion, amplification, attenuation, or replication of resources, capacities, constraints, meanings, and forms of value through a wider relational configuration. It extends the analysis from local generation to the pathways through which generated effects become consequential elsewhere.

Propagation can occur through exchange, learning, imitation, network contact, infrastructure, standards, prices, legal precedent, organizational replication, migration, ecological flows, media, or technical interoperability. A skill acquired within one workplace may spread through labor mobility. A protocol developed by one organization may become an industry standard. A reputation produced in one network may affect credit access in another. An innovation can diffuse through suppliers and competitors. Pollution can propagate across ecological and jurisdictional boundaries.

The structure of the pathway matters. Dense networks can accelerate some forms

of diffusion while creating redundancy. Centralized networks can enable rapid dissemination while producing bottlenecks or concentrated control. Institutional filters can privilege particular carriers and suppress others. Spatial distance can be reduced by digital infrastructure for information while remaining decisive for housing, care, logistics, or ecological impact. A GRE account therefore asks through which relations the effect propagates and how topology, access, and institutional authority condition that movement.

Propagation is also selective. An intervention that generates knowledge may propagate technical information more easily than tacit practice. Monetary gains may cross organizational boundaries through payments while trust remains locally embedded. Recognition can travel across institutions only when credentials or reputational signals are mutually accepted. Ecological damage can propagate physically even when financial liability does not. The form of what moves and the medium through which it moves should therefore be distinguished.

Amplification and attenuation are important possibilities. A small innovation can become economically large when network effects, complementary investment, or standardization amplify adoption. A substantial local intervention can dissipate as effects pass through weak or incompatible connections. The magnitude observed at the origin gives limited information about the magnitude realized elsewhere.

GRE also considers the distribution of access to propagation pathways. Actors positioned at interfaces, platforms, logistics hubs, standards bodies, financial intermediaries, or institutional gateways can influence what travels and under which terms. Propagation can therefore become a source of power as well as a mechanism of diffusion. The relevant inquiry concerns the relational architecture through which generated effects acquire reach.

3.7.5 Conversion

Propagation frequently encounters interfaces at which one form of resource or value is translated into another. Conversion concerns these transformations among forms. Income can become education, housing security, political access, or health. Knowledge can become credentials, intellectual property, technical standards, or market advantage. Attention can become advertising revenue. Reputation can become creditworthiness. Land can become collateral. Ecological capacity can become commodity output, while financial resources can sometimes become restoration capacity.

Conversion differs from movement within a single form. A payment transferred between accounts remains monetary propagation. A credential used to obtain employment converts recognized educational achievement into labor-market access. A public research result licensed into proprietary technology passes through an institutional conversion interface that changes the rights and forms through which its value can be realized. The distinction helps identify where commensuration, authorization, pricing, certification, or institutional recognition becomes necessary.

Conversion interfaces are rarely neutral. Actors differ in their ability to define categories, establish equivalence, set prices, issue credentials, certify quality, recognize claims, or deny access. A bank decides which assets count as acceptable collateral. A university determines which learning qualifies for a degree. A platform determines

which forms of attention can be monetized and by whom. A legal system determines which interests can become enforceable rights. Control over conversion can therefore become a source of economic power.

Conversions can be partial or lossy. Rich forms of knowledge can be reduced to a credential or score. Ecological complexity can be translated into a carbon metric. Care can be monetized without preserving every relational quality attached to unpaid care. Standardization may sacrifice contextual detail while enabling interoperability across institutions. GRE therefore keeps the source form and converted form analytically distinguishable and asks what information, capacity, meaning, or control is gained or lost in translation.

Conversion can also generate additional value. A technical standard can make separate systems interoperable. A recognized qualification can enable geographic mobility. Monetization can permit resources to be exchanged across otherwise disconnected contexts. Legal incorporation can allow a collective project to contract, borrow, or hold assets. The normative significance of conversion depends on the terms, distribution, reversibility, and consequences of the transformation rather than on conversion as such.

Because heterogeneous values may resist full commensuration, GRE does not assume a universal conversion metric. Some forms may be partially convertible, institutionally incomparable, or normatively protected from exchange. The analytical task is to identify the interface, the actors who govern it, the terms under which conversion occurs, and the effects of repeated conversion on both the source and destination forms.

3.7.6 Recirculation

Generated and converted value can return to the relations and capacities that helped produce it. Recirculation concerns this return and the possibility that an economic configuration reproduces or expands its own generative conditions through the value it creates. Recirculation provides a bridge from one-time effects to recurrent economic dynamics.

A firm may reinvest earnings in productive equipment, worker training, research, or supplier development. A cooperative may return surplus to shared infrastructure. A university may use research income to support laboratories and students who enable later research. A community institution may reinvest revenue in local services and networks. Trust produced through successful collaboration can reduce the cost of subsequent collaboration. In each case, an output contributes to the maintenance or enlargement of a condition that supports later generation.

Recirculation is broader than financial reinvestment. Knowledge can return through teaching and mentorship. Institutional capacity can return through improved procedures. Ecological value can return through restoration. Recognition can return through strengthened membership and participation. Data generated by users can be used to improve a service that then attracts further users. The relevant object is the pathway by which generated value reconnects to a generative configuration.

The rate, distribution, and governance of return matter. An organization can generate large value while returning little to the workers, communities, infrastructures, or ecosystems that sustain it. Another can deliberately allocate returns to maintain those conditions. The existence of some recirculation does not by itself establish sufficiency or justice. A system can remain self-reinforcing while distributing benefits unequally or depleting unmeasured conditions outside its accounting boundary.

Recirculation can create positive feedback. Additional capability increases later generation, which supplies further resources for capability formation. Such loops can support cumulative development, institutional persistence, or technological lock-in. Their effects depend on the underlying configuration. A virtuous cycle for one group can become an exclusionary barrier for another when access to the loop is restricted. Self-reinforcement is therefore a dynamical property to be analyzed separately from normative desirability.

GRE uses recirculation to ask whether generated value contributes to the reproduction of the capacities and relations on which future generation depends. This question is especially important where conventional accounts register output or profit while leaving maintenance, care, learning, ecological renewal, and institutional reproduction analytically peripheral.

3.7.7 Dissipation and Extraction

Generated value does not necessarily return to its generative configuration. Some of it dissipates through depreciation, obsolescence, friction, neglect, entropy, institutional turnover, loss of trust, or ecological degradation. Some is extracted by actors positioned to appropriate value without proportionately sustaining the conditions from which it arises. GRE treats dissipation and extraction as distinct pathways because their mechanisms and policy implications differ.

Dissipation can occur without an appropriating beneficiary. Infrastructure decays when maintenance is deferred. Skills weaken when unused. Organizational memory disappears through turnover. Trust erodes after repeated coordination failures. Ecological capacity can decline through cumulative pressure. Data lose relevance. Knowledge becomes obsolete. These processes imply that the maintenance of a generative configuration often requires recurrent inputs rather than a one-time investment.

Extraction involves a relational mechanism of capture. Rent can be appropriated because ownership or control over a bottleneck allows an actor to claim part of the value generated elsewhere. A platform can capture value from user activity through control of infrastructure and monetization interfaces. A financial arrangement can transfer returns away from productive reinvestment. A firm can rely on public education, care work, or ecological capacity while externalizing part of the cost of reproducing those conditions. The analytical claim requires evidence of the pathway through which value is captured and of its relation to the generative configuration.

Unequal distribution alone does not establish extraction. A participant can receive a large return because it supplies scarce capital, bears risk, contributes specialized knowledge, or performs coordination. GRE therefore asks what relation supports the claim, what alternative arrangements are feasible, whether the captured value weak-

ens or sustains the source configuration, and how bargaining power and institutional rights shape the terms of appropriation.

Dissipation and extraction can interact. Deferred maintenance can make an organization dependent on external financing, which can increase opportunities for future extraction. Extractive arrangements can reduce resources available for training or ecological renewal, accelerating dissipation. Conversely, some forms of external appropriation can finance infrastructure that improves the source configuration. Mechanism and temporal sequence matter more than categorical labeling.

The analytical purpose is to account for where generated value goes. A process that appears productive at one accounting boundary may look fragile once maintenance requirements, externalized costs, and captured returns are traced over time. This wider accounting remains plural: GRE need not translate every dissipated or extracted form into money in order to analyze its economic significance.

3.7.8 Structural Transformation

Repeated allocations, mediations, generation, propagation, conversion, recirculation, dissipation, and extraction can alter the relational structure within which later economic action occurs. Structural transformation concerns changes in relatively persistent configurations of access, authority, dependency, coordination, classification, ownership, infrastructure, and institutional recognition. The analytical horizon therefore moves from flows through a structure to changes in the structure itself.

A credit programme can gradually create new financial histories that alter who is considered bankable. Platform adoption can reorganize market access and bargaining relationships. Public infrastructure can change settlement patterns and land values. Repeated outsourcing can transform organizational boundaries and labor relations. An educational expansion can change occupational competition and credential requirements. Long-term extraction can concentrate ownership sufficiently to reshape political and market power. These effects persist because the relations through which later actors operate have changed.

Structural transformation can be cumulative. Small changes in network access, standards, expectations, or institutional categories may become mutually reinforcing. Once a technical standard reaches broad adoption, complementary investments increase switching costs. Once a legal category becomes embedded in administrative systems, data structures, and organizational routines, later decisions may reproduce it. Such persistence does not imply irreversibility, yet reversal can require interventions different in kind from those that produced the initial change.

Structure is scale-relative. A transformation that appears structural for a household may be local from the perspective of a national economy. A regulatory change can be structural for an industry while leaving broader institutional arrangements intact. GRE therefore specifies the scale and boundary at which structural transformation is claimed. The term should signal a change in the organization of relations relevant to the inquiry rather than function as a synonym for any large effect.

Structural transformation can redistribute generative capacity. New infrastructure can enable some actors to participate while making others dependent on cen-

tralized systems. Consolidation can create investment capacity and reduce diversity of organizational forms. A new property regime can make resources legible and tradable while displacing customary claims. GRE asks how the changed structure reorganizes the possibilities available to different subjects and which later pathways become easier, harder, visible, or inaccessible.

At this stage, the analytical perspective begins to become recursive. Structures mediate later allocations and generation, while those processes can further transform structure. The economy is therefore approached as historically layered: present relations carry residues of earlier allocations, conversions, institutions, conflicts, and generative cycles.

3.7.9 Transformation of Generative Conditions

Structural change becomes especially significant when it alters the conditions that make later generation possible. Generative conditions include capacities, infrastructures, ecological resources, legal permissions, institutional trust, knowledge bases, standards, networks, interpretive categories, and other background arrangements through which new economic possibilities can emerge. Transformation of generative conditions concerns changes in this enabling and constraining environment.

The distinction between generated output and generative condition is temporal and relational. A research project can produce a paper as an output while training researchers who become a condition for later inquiry. A transportation system can provide current mobility while also changing the accessibility structure through which future firms and households choose locations. A legal reform can resolve a present dispute while changing the institutional expectations that shape later contracting. Restoration can generate present employment and rebuild ecological capacity that supports future livelihoods.

Conditions can become more or less diverse. An economy can accumulate specialized capabilities that deepen productive potential within one technological trajectory while reducing adaptability to alternative trajectories. Standardization can create broad interoperability while narrowing variation. Concentrated infrastructure can generate scale economies while increasing dependency on a small number of providers. GRE therefore examines the composition of generative capacity, including redundancy, diversity, reversibility, and dependence.

Generative conditions are distributed. The capacity to innovate may depend on public education, care systems, research institutions, finance, standards, migration regimes, energy infrastructure, social trust, and ecological stability. No single actor needs to own these conditions for them to shape economic possibility. This distributed character makes attribution and governance difficult: benefits may be privatized while maintenance costs remain collective, or collective institutions may fail to recognize contributions occurring outside formal accounting systems.

Changes in generative conditions can also alter who counts as an economic subject. Digital identity systems can enable participation for some subjects and exclude others. New organizational forms can recognize collective actors. Artificial systems can acquire delegated decision capacities that change the distribution of agency in markets and institutions. Educational and technical infrastructures can transform

the capacities through which persons become able to participate in particular forms of production or exchange. These questions prepare the more focused treatment of economic subjecthood in the following section, while the present subsection keeps attention on the background conditions through which such subject positions become possible.

The GRE perspective therefore evaluates interventions partly by their effects on future generativity. Immediate welfare or output remains important, yet an intervention can also be assessed by whether it expands, concentrates, diversifies, depletes, or forecloses the conditions from which later value and action can emerge. Such evaluation requires an explicit temporal horizon and awareness that future uses cannot be fully specified in advance.

3.7.10 Transformation of the Effective Rule of Change

The deepest analytical extension concerns situations in which economic processes transform the effective rule through which subsequent change occurs. A structural configuration can change while the basic mechanisms governing adjustment remain similar. In other cases, the mechanisms themselves are reorganized: new institutions redefine permissible transactions, technologies create new categories of action, collective learning changes how actors respond, platforms redesign market matching, legal reforms alter rights and enforcement, or artificial systems introduce new forms of automated selection and adaptation. GRE treats such cases as transformations of the effective rule of change.

The phrase *effective rule* is deliberately modest. It does not imply that an economy possesses one literal master equation. It refers to the locally relevant mechanisms, institutional procedures, response functions, selection environments, and constraints through which changes in the studied configuration are produced. Different methods can represent these rules differently. A historian may reconstruct them through institutional sequences, an economist through behavioral or equilibrium relations, a network analyst through evolving topology, an ethnographer through changing practices, and a computational model through explicit update procedures.

Rule transformation occurs when later dynamics cannot be adequately described by holding those mechanisms fixed. A market governed by bilateral bargaining can become a platform-mediated market in which ranking algorithms and platform rules shape matching and price formation. A monetary system can acquire new instruments that change transmission mechanisms. A labor process can move from human supervision to algorithmic allocation, altering how performance is measured and how workers adapt. A regulatory reform can change the criteria through which organizations become eligible, compliant, or sanctionable. The later system is connected historically to the earlier one while operating through modified mechanisms.

Rule transformation is especially important under reflexivity. Economic subjects learn, anticipate policies, reinterpret categories, and adapt to models used to govern them. Institutions respond to observed behavior. Firms redesign strategies when competitors imitate them. Regulators revise rules when existing rules generate unintended effects. The object of analysis can therefore react to the representations and interventions applied to it. A stable rule may remain a useful local approximation, yet

GRE keeps open the possibility that repeated interaction changes the mechanisms on which the approximation depended.

The transformation of effective rules also raises a governance problem. Interventions can influence more than outcomes within a given system; they can shape the procedures through which future outcomes will be produced. A procurement rule can determine which organizational forms survive long enough to compete later. A data standard can define what becomes measurable and therefore governable. Intellectual-property rules can influence the future distribution of innovation incentives and knowledge access. Educational assessment can alter what institutions teach and what learners treat as valuable. These interventions operate partly at the level of the future change process itself.

This final analytical moment does not make every economic change a case of rule transformation. The claim requires evidence that the mechanisms generating later transitions have materially changed. Maintaining this threshold preserves the distinction among movement within a structure, transformation of structure, transformation of generative conditions, and transformation of the effective rule of change.

Taken together, the ten moments of the GRE perspective provide a layered way to follow economic action through time and relation. Allocation identifies an initial placement of resources, rights, burdens, or attention. Relational mediation specifies the configuration through which that placement becomes operative. Generation identifies newly produced capacities, constraints, values, subjects, or possibilities. Propagation follows their movement; conversion follows changes of form; recirculation follows return to generative configurations; dissipation and extraction account for loss and capture. Structural transformation asks how persistent relations are reorganized. Transformation of generative conditions asks how the capacity for later generation changes. Transformation of the effective rule of change asks whether the mechanisms producing future transitions have themselves been altered.

The sequence remains a heuristic research architecture. Empirical cases can contain loops, branching pathways, simultaneous processes, and multiple scales whose temporal order is only partially recoverable. GRE's distinctive perspective lies in making these layers available for explicit inquiry while preserving the possibility that a narrower established economic analysis may be sufficient for a particular question. The next section turns from this analytical architecture to one of its most consequential objects: the economic subject itself, whose identity, recognition, capacities, and persistence can be treated as historically and relationally generated rather than analytically fixed in advance.

3.8 GRE and the Economic Subject

Generative Relational Economics (GRE) requires a conception of the economic subject that is sufficiently stable for analysis and sufficiently open to account for historical transformation. The role of this section is to specify that conception after the preceding sections have established GRE's objects, scales, problem families, and distinctive analytical sequence. Its objective is to explain how persons, organizations, artificial systems, and other configurations can occupy economically consequential sub-

ject positions without assuming that subjecthood is a timeless property given prior to economic relations. The discussion proceeds through eight connected problems: the movement from given agents to relationally situated subjects; institutional recognition; relational persistence; the coexistence of human and artificial economic subjects; heterogeneity among subjects; capability asymmetry and ontological distinction; participation under conditions in which productive necessity may decline; and subject formation itself as an economic process. The method is constitutive rather than taxonomic. GRE does not attempt to settle the metaphysics of personhood, consciousness, or agency. It specifies a working analytical conception of subjecthood adequate to economic inquiry while preserving ontological suspension and explicit normative separation.

Within this framework, an *economic subject* is a relatively stabilized locus of economically consequential participation that can be identified within a relational configuration. Such participation may include choosing, claiming, producing, consuming, owning, borrowing, contracting, coordinating, representing, interpreting, allocating, governing, bearing risk, receiving recognition, or being made answerable for an economic event. Different forms of subjecthood need not contain the same capacities. A human worker, a household, a corporation, a public agency, and an automated trading system can occupy very different kinds of economic subject position. Their inclusion within a common analytical vocabulary records their participation in economic relations; it does not establish metaphysical, experiential, juridical, or moral equivalence among them.

This distinction is especially important because economic theory often gains tractability by beginning with an already individuated agent. GRE can use such models when the research question warrants them, yet its broader programme keeps open the prior question of how the agent became recognizable, durable, capable, and economically situated. The economic subject can therefore be treated both as a participant in economic dynamics and as a possible product of those dynamics. Wage relations, property regimes, credit systems, organizational membership, legal classifications, technical infrastructures, educational institutions, platforms, and systems of representation can all help constitute which subjects exist for an economic process, what they can do, how they are recognized, and which futures become available to them.

3.8.1 From Given Agent to Relationally Situated Subject

A large class of economic models begins with agents whose identities, preferences, feasible actions, and relevant resources are specified before the modeled interaction begins. This abstraction can be highly productive. It makes possible clear analysis of choice, exchange, strategic interaction, allocation, and equilibrium. GRE retains these analytical resources while adding a complementary question: under which relations did the modeled agent become the kind of subject for whom those preferences, capacities, resources, and feasible actions are available?

The move from a given agent to a relationally situated subject changes the analytical starting point. A worker enters a labor market with skills formed through education, family relations, health, language, migration status, credentialing, and previous

employment. A firm enters a market through legal incorporation, ownership arrangements, financing, supplier relations, infrastructure, standards, and accumulated organizational routines. A consumer appears in a platform economy through accounts, payment systems, identity verification, recommendation systems, device access, and categories through which demand is represented. In each case, the subject remains a meaningful analytical unit, while its capacities and boundaries are understood as relationally conditioned.

Relational situatedness does not imply that a subject is reducible to its relations. GRE requires enough analytical independence to speak about a subject's actions, interests, experiences, holdings, or capabilities when those categories are warranted. The point is that such independence is historically and institutionally achieved to varying degrees. A property owner can act independently with respect to an asset because institutions stabilize ownership claims. A worker can negotiate because labor law, organizational rules, scarce skills, collective representation, or outside options provide a position from which negotiation is possible. A household can plan because some flows of income, care, residence, and obligation persist through time. Subjecthood therefore contains a relation between relative individuation and continuing dependence.

This approach also prevents agency from being treated as a single scalar quantity. A subject may possess substantial agency in one relation and little in another. A highly skilled employee may exercise considerable control over technical decisions while possessing limited bargaining power over employment conditions. A small firm may choose its product design while remaining strongly constrained by a dominant platform or creditor. A government agency may have formal authority but limited informational or implementation capacity. GRE therefore asks which dimensions of agency are operative, through which relations, and at which scale.

Relational situatedness further allows preferences and objectives to be historically formed without assuming that they are infinitely malleable. Education, advertising, professional communities, organizational cultures, social norms, technologies, and repeated interactions can affect what subjects attend to, expect, desire, or regard as feasible. A research programme can study these processes without denying that subjects also exhibit persistence, reflection, resistance, and internally organized commitments. GRE's analytical interest lies in the conditions through which orientation is formed and revised, a problem developed more directly in the following section on the orientation of generation.

The relationally situated subject therefore supplies an intermediate analytical position. It is more structured than an undifferentiated relational field because it permits attribution of action, capacity, burden, and value to relatively stabilized participants. It is more historically open than a permanently given agent because its boundaries, capacities, orientations, and recognized positions can themselves become objects of inquiry. This duality is central to GRE's treatment of subjecthood.

3.8.2 Subjecthood and Institutional Recognition

Economic subjecthood depends partly on recognition. Institutions specify who can open an account, hold property, enter a contract, receive a payment, owe a tax, reg-

ister a company, claim a benefit, represent an organization, access a market, or be counted within an administrative category. Recognition converts a potential participant into a legible participant for a particular institutional process. The resulting subject position can carry rights, obligations, expectations, records, and pathways for future action.

Recognition is distributed across institutions rather than concentrated in a single act. Legal systems recognize persons, organizations, property titles, and contractual capacities. Firms recognize employees, managers, vendors, customers, and authorized representatives. Financial institutions recognize account holders, borrowers, guarantors, and beneficial owners through their own procedures. Platforms recognize users, creators, advertisers, sellers, developers, and automated processes through technical accounts and permissions. Public programmes recognize beneficiaries through eligibility categories. Statistical systems recognize populations through classifications that subsequently shape policy and resource allocation.

These forms of recognition need not coincide. A participant can be economically active while remaining weakly represented in administrative data. A person can be recognized by one institution and excluded by another. An organization can exist juridically while possessing limited practical capacity to act. A platform account can exercise extensive economic functions while the relevant legal obligations remain assigned to a human or organizational principal. GRE therefore treats recognition as relation-specific. It asks who or what recognizes the subject, for which purpose, under which criteria, and with which consequences.

Institutional recognition can also generate capacities. Registration can permit access to banking, procurement, insurance, or legal enforcement. A professional credential can authorize entry into a labor market. A credit history can create or restrict borrowing possibilities. A platform reputation can affect visibility and transaction opportunities. Recognition is therefore more than descriptive classification. Under some conditions it becomes a productive resource whose possession changes future possibilities.

The converse process is economically consequential as well. Misrecognition, weak recognition, or exclusion from relevant categories can constrain participation even when material capacity exists. A skill that lacks accepted certification may command less value. Informal work can remain economically important while receiving limited legal protection or statistical visibility. Care activities can sustain productive systems while remaining weakly represented in monetary accounts. GRE can analyze these situations by separating material contribution, institutional recognition, representational visibility, and normative valuation rather than treating them as a single dimension.

Recognition also creates subject positions that may reshape conduct. A person classified as debtor, beneficiary, employee, high-risk customer, eligible applicant, or verified creator encounters a different opportunity structure and may respond to the expectations associated with that position. The category becomes economically generative when it affects access, incentives, treatment by others, or self-understanding. The same mechanism applies to organizations. Classification as a regulated institution, nonprofit entity, startup, contractor, or systemically significant actor can alter available strategies and obligations.

GRE therefore treats institutional recognition as one mechanism through which economic subjecthood becomes stabilized. It remains distinct from ultimate personhood or moral status. Institutional categories can be revised, contested, strategically used, or shown to be inadequate. Their analytical importance lies in the fact that economies operate through such acts of recognition, and those acts participate in generating the subjects that economic analysis subsequently encounters.

3.8.3 Subjecthood and Relational Persistence

Recognition at one moment is insufficient for many economic processes. Credit, employment, ownership, reputation, insurance, investment, planning, responsibility, and cooperation depend on some capacity to identify a subject across time. GRE therefore treats relational persistence as another condition of economic subjecthood. Persistence means that a configuration can remain sufficiently identifiable across a sequence of interactions for expectations, records, obligations, capacities, and value to accumulate around it.

Persistence does not require immutability. A corporation can change employees, owners, strategies, and assets while remaining recognizable as the same juridical organization for relevant purposes. A household can change membership while retaining continuing obligations and resources. A person can change occupation, preferences, health, wealth, and social position while maintaining biographical and institutional continuity. An artificial system can be updated or retrained while an operational identity, account, mandate, or deployment context persists. Subjecthood therefore depends on criteria of continuity that vary by domain.

Different institutions stabilize continuity through different devices. Names, identifiers, contracts, registries, records, credentials, accounts, signatures, organizational charts, audit trails, reputational histories, and technical logs can all support persistence. These devices allow past interactions to influence present treatment. They make possible credit histories, employment records, accumulated reputation, continuing ownership, delegated authority, and accountability. In this sense, memory is partly institutionalized in economic relations.

Persistence has generative consequences because accumulated history changes future opportunities. Trust can deepen through repeated cooperation. Debt can compound. Reputation can open or close markets. Skills can accumulate through practice. Organizational routines can increase coordination capacity. A history of exclusion can constrain later access even when formal rules change. Economic subjecthood therefore has a temporal dimension: the subject is often a carrier of selectively preserved history.

The preservation is always partial. Institutions decide which past events remain legible and which disappear. Credit systems preserve some payment histories while ignoring many contextual circumstances. Employment records preserve formal roles while omitting informal contribution. Platform metrics preserve selected traces of participation. Historical records may be unequally available across groups and organizations. GRE therefore treats persistence as an epistemic and institutional construction as well as a temporal fact. The subject that appears stable to an analyst may be stabilized by selective recording.

Relational persistence can also fail. Organizations dissolve, identities become contested, records disappear, contractual relations end, platforms remove accounts, or political and technological transformations invalidate previous classifications. Such failures can release subjects from prior constraints, erase accumulated value, disrupt responsibility, or create opportunities for reconstitution. Subject dissolution is therefore part of the economic analysis of subjecthood rather than a mere exception to stable identity.

This temporal view enables GRE to analyze subject formation without assuming a permanent core that economic relations simply reveal. A subject can become more or less coherent, legible, capable, autonomous, or constrained through time. The relevant question is which mechanisms sustain continuity, what they preserve, what they suppress, and how persistence alters the subject's future generative possibilities.

3.8.4 Human and Artificial Economic Subjects

The increasing delegation of economically consequential tasks to artificial systems makes the category of economic subject more complex. Software already performs functions such as ranking, pricing, matching, forecasting, bidding, recommending, filtering, scheduling, allocating attention, and executing transactions under specified conditions. More capable artificial systems can also participate in extended sequences of planning, communication, and decision support. GRE requires a vocabulary that can analyze such participation without presuming that functional capability settles questions of consciousness, personhood, moral standing, or legal status.

A useful distinction is between *human subjecthood* and *artificial operational subjecthood*. Human economic subjects are embodied, vulnerable, temporally finite participants whose economic lives are connected to experience, welfare, social membership, care, rights, and material dependence. Artificial operational subjects can occupy functionally stabilized positions in economic processes when systems are authorized, configured, or institutionally treated as loci through which actions are selected and executed. Their economic relevance can be substantial even when ultimate responsibility, ownership, or legal personality remains assigned elsewhere.

Operational subjecthood can arise through delegation. An organization may authorize a software system to execute trades within limits, set prices, route logistics, select advertisements, or communicate with customers. The system then becomes a proximate locus of economically consequential action. The relevant GRE questions concern the relations that enable this delegated position: who defines the objective, who supplies data, who controls deployment, who bears losses, who can override the system, how actions are attributed, and how generated value returns to the surrounding organization.

This approach avoids a binary choice between treating artificial systems as mere passive tools and treating them as equivalents of human persons. The appropriate analytical status can vary with the inquiry. For a study of market microstructure, an automated trading agent may be a meaningful economic subject because its decisions affect prices and counterparties. For a study of moral injury, welfare, or distributive justice, the same system may be better analyzed as infrastructure or delegated mechanism while the human and organizational subjects bearing consequences remain

central. Subject classification is therefore question-relative.

Artificial systems can also become components of hybrid subjects. A professional using advanced decision support may acquire capacities unavailable to either the human or the system considered independently. A firm can reorganize around automated coordination. A scientific team can distribute cognitive work across researchers, instruments, databases, and models. A platform can combine algorithms, human moderators, sellers, and users into an operational configuration. GRE can treat such configurations as composite subjects when the composite exhibits sufficient persistence, coordination, and causal relevance for the local question.

The distribution of agency within hybrid configurations is a separate problem from identifying the composite. Delegation can obscure responsibility when an outcome is attributed to "the algorithm" despite organizational choices concerning data, objectives, thresholds, deployment, monitoring, and recourse. Conversely, attributing every artificial action directly to one human decision-maker can ignore emergent behavior, organizational fragmentation, and the practical autonomy created by scale and speed. GRE therefore encourages mechanism-specific attribution across the relations that produce the action.

The coexistence of human and artificial economic subjects also changes the ecology of capability. Artificial systems can amplify the productive and cognitive capacity of some human or organizational subjects more than others. Access to compute, proprietary data, infrastructure, legal expertise, capital, and distribution can determine who benefits from artificial capability. The economic significance of artificial subjecthood consequently lies not only in what a system can do, but in how its capability is situated within ownership, institutional recognition, delegation, and return structures.

3.8.5 Heterogeneous Subjects

GRE treats heterogeneity among economic subjects as a constitutive feature of inquiry rather than a residual deviation from a representative agent. Subjects can differ in material needs, bodily vulnerability, temporal horizon, information, attention, cognitive style, social recognition, bargaining position, legal status, technological access, organizational scale, ecological dependence, and forms of value they regard as significant. These differences shape both immediate economic behavior and the generative consequences of economic relations.

Heterogeneity matters even when subjects receive formally identical resources. A monetary transfer can have different effects depending on debt, housing security, health, care obligations, local prices, social networks, or access to complementary services. The same information can be useful to one subject and unusable to another because complementary knowledge or infrastructure differs. The same employment opportunity can expand freedom for one person and intensify constraint for another because mobility, care responsibilities, or legal status differ. GRE therefore asks how an intervention interacts with subject-specific and relation-specific conditions.

Heterogeneity also concerns value. Subjects can evaluate the same outcome through different normative, cultural, professional, ecological, or experiential frameworks. A land-use change may appear as increased asset value to one actor, loss of

livelihood to another, ecological degradation to a third, and disruption of cultural continuity to a fourth. Economic analysis can sometimes translate these differences into a common measure for a specific decision. GRE does not assume in advance that every relevant value admits such conversion without remainder.

Subjects also differ in their capacity to make their valuations institutionally consequential. Some can purchase expertise, influence standards, control platforms, set contractual terms, or withdraw resources. Others possess weak bargaining power or limited representational access. Heterogeneity therefore interacts with asymmetry. A plural economy does not merely contain different preferences; it contains differently empowered subjects whose ability to stabilize their preferred classifications, metrics, and conversion rules can vary substantially.

Artificial and organizational subjects add further dimensions of heterogeneity. A corporation can persist for durations and command resources unavailable to an individual. An automated system can process information at a speed and scale that differs from human cognition. A public institution can exercise authority through rules rather than exchange. A household coordinates care and consumption through relations that are only partially contractual. Treating these subjects as analytically identical would conceal the mechanisms through which they act.

GRE's response is methodological pluralism at the level of subject modeling. Some questions can use utility functions, representative agents, or homogeneous populations. Others require types, distributions, networks, institutional categories, narratives, or qualitative reconstruction. The choice should follow the mechanism and scale of interest. Heterogeneity becomes analytically important when differences among subjects alter generation, propagation, conversion, bargaining, recognition, or exposure to risk.

This perspective also protects against interpreting difference as deficiency. A subject whose capacities do not match the requirements of a particular market or institution may still possess substantial capabilities that the institution does not recognize or reward. Economic subjecthood is therefore partly relational to the evaluative and infrastructural environment. The same person or organization can appear highly capable in one configuration and weakly capable in another. GRE analyzes that relational fit rather than converting every difference into a single hierarchy of subject quality.

3.8.6 Capability Asymmetry and Ontological Distinction

Economic subjects can differ enormously in capability. A multinational firm and an individual consumer do not command comparable resources. A state and a household occupy different institutional positions. A specialized artificial system can outperform a human participant on a bounded computational task while lacking many features that organize human economic life. GRE therefore separates capability comparison from ontological classification and from normative status.

Capability is multidimensional. It can concern computation, memory, prediction, physical action, social coordination, capital access, legal authority, mobility, learning, creativity, endurance, attention, bargaining, or the capacity to absorb loss. A subject can be strong on one dimension and weak on another. Aggregate labels such as "more

capable" therefore require explicit specification of the relevant capability domain and the task or environment in which it is measured.

The distinction becomes especially important in human–artificial comparison. Superior performance by an artificial system on prediction, optimization, search, coding, or information processing demonstrates a capability difference in the specified domain. It does not by itself establish equivalence in embodiment, vulnerability, experience, social membership, moral standing, legal personality, or other ontological and normative dimensions. Conversely, inferior productive performance by a human subject does not imply diminished moral status or a weaker claim to social participation. Productive capability and normative worth belong to different analytical registers.

GRE therefore resists deriving subject status directly from productivity. Economies routinely assign value to capacities that are historically contingent: strength in one technological regime, literacy in another, credentialed expertise in another, computational skill in another. Technological change can rapidly alter which capacities command market value. If recognition or participation were tied directly to currently scarce productive capabilities, changes in technology could destabilize subject status in ethically and politically consequential ways. GRE treats that possibility as an object of economic analysis rather than as a normative conclusion supplied by productivity itself.

Capability asymmetry also generates power when it affects the terms under which others can participate. A platform with superior information and scale can shape market access. A creditor with greater liquidity can impose conditions on a constrained borrower. An organization equipped with advanced artificial systems can negotiate, monitor, or produce at a level unavailable to smaller actors. The relevant issue is the conversion of capability difference into durable relational advantage. Not every asymmetry becomes power, and the mechanism of conversion requires specification.

Institutional design can amplify or moderate capability asymmetry. Standards, interoperability, public infrastructure, collective bargaining, competition rules, education, access to compute, liability arrangements, and rights of appeal can change how capability differences affect participation. GRE's interest lies in the resulting generative structure: which subjects gain new capacities, which become dependent, which forms of value are captured, and whether the asymmetry reproduces itself through control over the conditions of future generation.

The separation among capability, ontology, and normativity thus performs several analytical functions. It permits precise comparison where comparison is meaningful. It prevents performance metrics from silently becoming theories of personhood. It allows economic analysis to study artificial subjects without assuming human equivalence. It also preserves a space in which questions of justice, rights, dignity, or welfare can be evaluated through appropriate normative arguments rather than inferred from market productivity.

3.8.7 Subjective Participation beyond Productive Necessity

Technological development raises a further question for the constitution of the economic subject: how is participation organized when a subject's contribution is no longer required for a particular productive task? Automation has long displaced and transformed tasks, while new technologies have also created new occupations, complementary roles, and forms of demand. GRE does not assume a predetermined endpoint of this process. It identifies a structural problem that becomes more visible as productive capability can be supplied by machines or highly concentrated organizations: economic participation and social subjecthood may become less tightly coupled to productive necessity.

Historically, many economic institutions connect income, recognition, schedule, social interaction, insurance, status, training, and future opportunity to employment or productive contribution. When a task disappears, the loss can therefore extend beyond wages. A subject can lose routines, networks, bargaining position, identity, institutional recognition, and pathways for capability development. Analyses that record only the change in output or income can miss this wider transformation of subject position.

GRE uses the idea of *subjective participation* to name participation through which a person or collective can remain an active locus of choice, recognition, relation, contribution, and value formation within economic life. Productive work can be one important form of such participation, but the category is broader. Care, learning, civic contribution, cultural production, scientific inquiry, community activity, consumption, stewardship, and relational maintenance can all organize economically consequential participation even when their market valuation is limited or indirect.

The economic question is therefore partly institutional. If productive necessity declines for some subjects, which mechanisms connect them to resources, capabilities, recognition, and opportunities for meaningful participation? Several institutional arrangements are conceivable, and GRE need not select among them at the level of disciplinary constitution. The research programme can instead examine how different arrangements affect autonomy, dependence, value generation, social recognition, bargaining power, capability development, and the distribution of future possibilities.

This problem also applies within organizations. An employee whose routine tasks are automated can become more capable when artificial tools release time for judgment, learning, care, design, or coordination. The same technological change can instead narrow the employee's role to monitoring a system controlled elsewhere. The distinction depends on ownership, training, discretion, workflow design, evaluation, and bargaining relations. Automation therefore transforms subjecthood through the surrounding institutional field rather than through task substitution alone.

Artificial systems intensify the question because they can participate in economic processes without requiring the same conditions for welfare, livelihood, social membership, or embodied reproduction as human subjects. A production system organized solely around output can therefore allocate increasingly large shares of economically consequential activity to artificial or organizational subjects while human participation becomes administratively residual. Whether and how institutions re-

spond is a normative and political question; the economic analysis concerns the relations through which such a configuration affects value, demand, bargaining, recognition, capability, and social reproduction.

GRE thus separates the right to analyze productive contribution from the broader question of subject participation. It does not assume that economic inclusion must be earned through scarcity of labor, nor does it presume a specific institutional alternative. It asks how systems generate or foreclose forms of participation when technological and organizational change modifies the economic necessity of particular human capacities. The answer will depend on the orientation of generation, the subject of the following section.

3.8.8 Subject Formation as an Economic Process

The preceding subsections imply a final constitutional claim: subject formation is itself an economic process. Economic relations do more than coordinate already formed subjects. They participate in producing the capacities, identities, expectations, dependencies, temporal horizons, and recognized positions through which subjects subsequently act. GRE therefore includes subject formation within its field of inquiry whenever economic mechanisms materially contribute to that formation.

Labor markets provide a clear illustration. Education and credentialing prepare subjects for occupational categories; hiring procedures classify them; employment develops some skills while allowing others to decay; organizational hierarchies distribute authority; compensation affects outside options; performance metrics orient attention; career ladders shape expectations about the future. The resulting worker is neither created wholly by the labor market nor independent of it. Subject formation occurs through the interaction of economic, educational, familial, legal, cultural, technological, and biological processes.

Credit relations can similarly generate debtor subject positions. Access to credit expands purchasing or investment capacity while repayment schedules reorganize future income. Credit histories affect later access. Default categories alter institutional treatment. Financial literacy, risk tolerance, and expectations can change through repeated borrowing. The economic subject that returns to a credit market is therefore historically modified by previous participation.

Platforms generate other subject forms through accounts, metrics, rankings, recommendation systems, monetization rules, and categories of permissible participation. A person can become a seller, creator, driver, host, advertiser, moderator, or rated customer through platform-specific infrastructures. These positions can create capabilities and income while also subjecting participants to new dependencies, forms of visibility, and evaluative systems. Artificial systems can likewise acquire operational subject positions through permissions, interfaces, memory, delegated objectives, and persistent identifiers.

Property institutions contribute to subject formation by stabilizing relations of control, responsibility, inheritance, exclusion, and expectation. Welfare institutions constitute beneficiary categories. Tax systems recognize households, firms, dependents, and taxable events. Corporate law stabilizes organizations that can persist beyond individual members. Monetary institutions constitute account holders and counter-

parties. Economic subjecthood therefore emerges repeatedly through institutional architectures that define who can do what, with which resources, under which records and obligations.

Subject formation also has recursive effects. Once a subject position is stabilized, subjects can act to preserve, reinterpret, contest, or transform the relations that formed them. Workers organize; firms lobby; consumers coordinate; professional groups set standards; communities create institutions; platform participants develop practices that alter platform design. Subject formation is therefore compatible with reflexivity. Generated subjects can become generators of subsequent institutional change.

This recursive structure connects subject analysis to GRE's broader concern with transformation of generative conditions. An economic system can generate subjects whose capacities and orientations reinforce the system. It can also generate subjects capable of questioning, modifying, or leaving it. Educational investment can create workers suited to an existing industrial structure while also producing knowledge that enables new industries. Financial systems can stabilize prevailing ownership while funding innovations that disrupt incumbent firms. Organizational routines can reproduce hierarchy while creating expertise that later supports institutional reform. The direction of subject formation is therefore neither mechanically reproductive nor inherently emancipatory.

For empirical work, treating subject formation as an economic process requires evidence appropriate to the mechanism. Administrative records can reveal changing classifications and access. Longitudinal data can track capability or income trajectories. Organizational records can show role transformation. Interviews and ethnography can recover changes in interpretation, identity, and perceived possibility. Experiments can identify bounded responses to institutional arrangements. Computational methods can trace large-scale patterns of classification or interaction. GRE does not privilege one method; it requires the method to match the dimension of subject formation being claimed.

The economic subject can now be located within the constitutional architecture of Chapter 3. GRE treats subjects as relatively stabilized participants whose capacities, recognition, persistence, and orientations are relationally conditioned and historically transformable. Human, organizational, and artificial subjects can all enter economic analysis while remaining ontologically and normatively distinct. Capability asymmetry can shape power without determining moral status. Participation can remain economically important even when particular productive contributions lose scarcity. Subject formation itself can be generated through economic relations and can recursively transform those relations in return.

This account also identifies the next constitutional problem. If economic relations help generate subjects, capacities, attention, and future possibilities, the direction of that generation cannot be treated as analytically empty. Economic systems select, reward, amplify, suppress, and stabilize different possibilities. Section 76 therefore turns from the constitution of subjects to the orientation of generation: the processes through which attention, curiosity, aesthetic judgment, epistemic priorities, institutional selection, and heterogeneous value structures influence what becomes economically generative.

3.9 GRE and the Orientation of Generation

Generative Relational Economics treats economic generation as more than the production of additional outputs from given inputs. Economic relations can enlarge, redirect, stabilize, or close future possibilities; they can generate capacities, questions, representations, institutions, expectations, forms of value, and modes of participation. Once generation is understood in this wider sense, a further analytical problem becomes unavoidable: generative processes are oriented. Among many possible objects of attention, questions, investments, designs, interpretations, and institutional trajectories, some become salient and others remain peripheral. The role of this section is to make that directional dimension explicit within the constitution of GRE. Its objective is to identify several mechanisms through which orientation is formed and economically consequential without reducing orientation to a single preference ordering or normative criterion. The discussion proceeds through attention and salience, curiosity and question formation, aesthetic judgment, epistemic orientation, institutional selection, and heterogeneous value structures before locating orientation itself as an economic and political problem. The method remains constitutive rather than exhaustive: these mechanisms identify admissible objects of GRE inquiry and can be combined differently across empirical domains.

Orientation occupies a position between possibility and realized generation. A field can contain several technically feasible innovations, several plausible interpretations of evidence, several ways of organizing care, several institutional reforms, or several investments capable of producing future value. Generativity alone does not determine which possibility receives resources, recognition, attention, or continued development. Selection occurs through subjects, organizations, infrastructures, norms, evaluative conventions, histories, and unequal capacities to make one possibility visible or actionable. GRE therefore asks not only what a relation can generate, but how its generative direction becomes selected, reinforced, contested, or revised.

This problem is distinct from saying that every economic process possesses a conscious purpose. Orientation can arise without centralized intention. Search rankings alter attention; funding rules privilege some questions; professional conventions stabilize standards of relevance; prices redirect investment; built environments make some actions easier than others; inherited categories determine what can be recorded; and repeated interaction can make one trajectory increasingly probable. Orientation can therefore be intentional, institutional, distributed, emergent, or mixed. What matters for GRE is the mechanism through which a space of possibilities becomes unevenly weighted and how that weighting changes subsequent generation.

3.9.1 Direction within Generative Processes

Generation becomes analytically directional whenever several possible continuations are available and the realized process favors some over others. A research group can investigate several questions but allocates effort to a subset. A firm can deploy capital across several technologies but selects particular projects. A city can support several mobility arrangements but builds infrastructure that makes some

trajectories easier to reproduce. A household can convert additional income into consumption, education, savings, care, mobility, or debt reduction. In each case, resources enter a relational configuration whose later consequences depend partly on how possibilities are selected.

Direction should be distinguished from destination. A destination specifies an endpoint toward which activity is explicitly organized. Direction can be weaker and more distributed. It can consist in a persistent bias toward particular questions, objects, timescales, values, or forms of recognition even when no actor has specified a final state. An institution that rewards measurable short-term outputs may orient inquiry toward easily countable achievements without formally prohibiting long-horizon research. A credit system can orient firms toward revenue models compatible with repayment schedules without prescribing a specific product. A platform can orient cultural production through visibility metrics even when creators retain formal freedom over content. GRE is interested in these directional effects because they alter the future distribution of generative opportunity.

Orientation should also be distinguished from deterministic selection. A strong directional field can coexist with novelty, resistance, and contingency. Subjects can reinterpret incentives, institutions can be repurposed, and unexpected relations can open alternatives. The analytical claim is therefore probabilistic and structural: some configurations make particular generative pathways easier to enter, sustain, fund, legitimate, or recognize than others. The strength of orientation is an empirical question that can vary across scales and historical periods.

The concept also permits several levels of analysis. At the level of a subject, orientation can concern attention, aspiration, perceived possibility, or evaluative judgment. At the organizational level, it can concern strategy, metrics, hiring, budgeting, and project selection. At the institutional level, it can concern law, professional standards, eligibility rules, and classification systems. At the infrastructural level, it can concern access, interoperability, search, transportation, or computation. At the cultural level, it can concern what appears admirable, credible, urgent, or worth pursuing. These levels can reinforce or conflict with one another.

Direction becomes especially consequential when orientation feeds back into the conditions of future choice. A selected research programme develops specialized instruments and expertise, making adjacent questions easier to investigate. An industry cluster attracts suppliers and workers, increasing the relative feasibility of further investment in the same domain. A classification adopted for administrative convenience can accumulate datasets organized around its categories, making alternative classifications harder to operationalize. What begins as selection among possibilities can therefore become a transformation of the possibility structure itself.

GRE treats this recursive effect as one reason to study orientation separately from immediate allocation. Allocation determines where resources initially go. Orientation concerns the relational processes that make some uses, interpretations, and continuations more likely to become generative. Their interaction can produce path dependence without requiring that the path was planned in advance. Orientation is thus a bridge between local selection and historical transformation.

3.9.2 Attention and Salience

Attention is a scarce and selective condition of economic participation. Subjects, organizations, and institutions encounter more signals, opportunities, demands, and possible actions than they can process with equal intensity. What enters attention can therefore influence what becomes available for evaluation and generation. GRE treats attention not simply as an internal cognitive resource but as relationally organized through environments, interfaces, institutions, social expectations, and distributions of visibility.

Salience is one mechanism through which this organization occurs. An object can become salient because it is perceptually striking, institutionally emphasized, repeatedly measured, socially endorsed, economically rewarded, emotionally charged, or strategically amplified. Salience need not indicate importance in any independent normative or causal sense. A highly visible indicator can dominate decision making while a less visible condition exerts larger long-term effects. Conversely, a previously neglected relation can become salient when a crisis, measurement innovation, public controversy, or new interpretive framework makes it perceptible as an economic problem.

The economic consequences of salience are therefore twofold. First, salience affects allocation of attention in the present. A firm monitors some indicators more closely than others; an investor notices some opportunities; a public agency prioritizes some risks; a consumer sees some products; a researcher encounters some literatures. Second, repeated attention can alter the object itself. Metrics invite optimization, visibility attracts resources, and recognized problems acquire organizations, professions, and infrastructures devoted to them. Attention can consequently become generative rather than merely observational.

Digital mediation intensifies this issue because ranking, recommendation, notification, and search systems actively order visibility. Their orientation effects may arise from commercial objectives, relevance models, engagement metrics, moderation rules, personalization, or technical constraints. The resulting distribution of attention can affect demand, reputation, cultural production, political communication, and the formation of economic subjects. GRE need not assume that a platform fully controls these outcomes. It can instead ask which mechanisms structure exposure, how users respond, and how visibility feeds back into production and value.

Attention also interacts with inequality. Subjects differ in their capacity to command attention and in their ability to protect their own attention from external capture. Advertising budgets, institutional prestige, network centrality, media access, and control over interfaces can increase one actor's capacity to make objects salient to others. At the same time, workers, consumers, citizens, and researchers can face environments saturated with demands on attention. The distribution of attention therefore has both productive and power dimensions.

A GRE analysis should avoid equating attention with endorsement. A subject may attend to an object because it is threatening, unavoidable, controversial, or institutionally mandatory. Nor should measured engagement be treated as a complete representation of attention. Observable clicks, purchases, dwell time, or citations are partial indicators conditioned by the platform or institution through which they are

recorded. The relation between salience, attention, interpretation, and later action requires empirical specification.

Attention becomes a problem of orientation when it changes which possibilities can enter generative processes. What remains persistently unseen may receive neither investment nor institutional articulation. What becomes hyper-salient can attract disproportionate resources and narrow alternative exploration. GRE therefore studies the production and distribution of salience as part of the economic organization of possibility.

3.9.3 Curiosity and Question Formation

Curiosity introduces a different form of orientation. Attention identifies what enters a field of concern; curiosity can transform an encountered difference, anomaly, absence, or possibility into an object of inquiry. This transformation matters economically because new questions can redirect research, entrepreneurial activity, public investment, education, and institutional experimentation before the value of an answer is known.

Question formation is generative in a stronger sense than information acquisition. A subject seeking a known datum operates within a pre-specified problem. A newly formulated question can reorganize the problem-space itself by distinguishing previously conflated phenomena, proposing a new comparison, or making an unrecognized relation investigable. The economic consequences can be substantial. Scientific questions create research programmes; engineering questions motivate design trajectories; policy questions define measurable problems; entrepreneurial questions organize searches for unmet needs or new combinations.

Curiosity should not be romanticized as an unconstrained internal virtue. Opportunities for curiosity are institutionally distributed. Time, income security, educational access, research infrastructure, mentorship, mobility, archival access, computational resources, and tolerance for failure all affect who can pursue uncertain questions. A person may possess strong curiosity while lacking the relational conditions required to sustain inquiry. Conversely, organizations can create protected spaces in which exploratory questions become economically viable despite uncertain short-term returns.

Question formation is also socially mediated. A discipline defines which questions appear legitimate, mature, trivial, or impossible. A market communicates demand signals that make some problems commercially visible. Public institutions define categories of need. Communities preserve practical knowledge that can make different questions salient from those generated in professional research settings. Interdisciplinary contact can expose assumptions that remain invisible within a single field. Curiosity therefore emerges within histories of classification, authority, and encounter.

The economic orientation of curiosity becomes visible in the distribution of exploratory resources. Research grants, venture finance, procurement programmes, universities, laboratories, foundations, public challenges, and organizational slack all influence which uncertain inquiries can be sustained long enough to generate results. These mechanisms differ from ordinary exchange because expected value may be difficult to estimate ex ante. Selection often relies on judgments concerning

plausibility, novelty, promise, social relevance, or strategic fit rather than on known outputs.

GRE can therefore analyze curiosity as a relational capacity with downstream economic effects. It can ask how an environment makes questions possible, how inquiry becomes sustained, how failed questions still generate capabilities or networks, and how exploratory activity alters the future set of feasible projects. It can also examine exclusion: whose questions receive recognition, which experiences become researchable problems, and which uncertainties remain institutionally invisible.

This perspective does not imply that more curiosity is always better. Unbounded exploration can consume resources, produce distraction, or impose risks on others. Some domains require reliability, maintenance, and disciplined exploitation of established knowledge. GRE's task is not to assign curiosity an intrinsic positive value, but to make visible the conditions under which question formation becomes economically generative and the trade-offs through which exploratory orientation is governed.

3.9.4 Aesthetic Judgment

Economic generation often proceeds under incomplete evidence. Researchers choose among conjectures before proof is available. Designers compare forms before market response is known. Investors assess emerging projects with limited histories. Engineers select architectures before every downstream consequence can be calculated. Public institutions imagine futures for which no complete dataset exists. In such settings, judgment frequently includes an aesthetic dimension: a sense that a problem, pattern, design, explanation, or possibility is elegant, coherent, beautiful, compelling, fertile, proportionate, or otherwise worthy of continued attention.

GRE treats aesthetic judgment as a possible orientation mechanism rather than as a universal or infallible faculty. The term refers here to evaluative responses that help rank possibilities when propositional evidence does not fully determine selection. Such judgments can concern mathematical elegance, conceptual simplicity, visual form, narrative coherence, spatial atmosphere, craftsmanship, symbolic resonance, or the perceived fertility of a question. Their content varies across practices and communities.

Aesthetic judgment can become economically consequential because it directs scarce exploratory resources. Scientists choose which problems feel deep or promising. Architects and planners create environments that shape movement and encounter. Consumers attach value to form and atmosphere. Organizations cultivate identities through design. Investors may respond to narrative and presentation alongside formal projections. Cultural industries depend directly on aesthetic differentiation. In each case, aesthetic orientation participates in the generation of value without being reducible to price.

The relational character of aesthetic judgment is important. Judgments are neither simply arbitrary private tastes nor automatically universal properties of objects. They are formed through histories of training, exposure, comparison, convention, embodiment, and social interaction. What appears elegant to a mathematician, trustworthy to a patient, refined to a consumer, or harmonious to a community can de-

pend on learned repertoires and material environments. Institutions can therefore cultivate, standardize, or marginalize aesthetic criteria.

This relationality creates both generative possibility and power. Shared aesthetic repertoires can coordinate collaboration and make complex quality judgments possible without complete formalization. They can also become exclusionary when dominant groups define legitimate taste, professional style, or intellectual beauty. A funding committee's sense of what constitutes an "interesting" question, for example, may reproduce disciplinary histories that favor some objects and methods. Aesthetic judgment can thus influence resource allocation even when it is not formally acknowledged.

GRE should keep aesthetic judgment distinct from truth, welfare, and justice. An elegant theory can be empirically wrong. A beautiful design can be inaccessible or harmful. A compelling narrative can conceal exploitation. A technically awkward solution can nevertheless generate substantial social value. The analytical significance of aesthetic judgment lies in its role in orientation under uncertainty, not in a presumption that aesthetic approval validates the selected object.

Aesthetic orientation also interacts with serendipity. Encounters that were not sought for instrumental reasons can become generative when a subject experiences them as salient, intriguing, beautiful, strange, or worth pursuing. The generative consequence depends on both encounter and judgment. An environment rich in variation does not guarantee innovation; subjects and institutions must still recognize some differences as invitations to inquiry or creation. This suggests an economic problem of field design: how can environments sustain heterogeneous encounters and exploratory judgment without attempting to pre-engineer the exact novelty that should emerge?

Within GRE, aesthetic judgment therefore belongs to the analysis of orientation because it can influence which possibilities receive further attention, articulation, resources, and institutional support. Its mechanisms require contextual investigation, and its normative status remains open to separate evaluation.

3.9.5 Epistemic Orientation

Economic generation is also directed by epistemic orientation: the standards, classifications, methods, evidential expectations, and interpretive habits through which subjects and institutions decide what can be known, what counts as relevant evidence, and which uncertainties deserve investigation. Epistemic orientation does not merely affect description after economic processes occur. It can shape which processes become actionable and therefore which futures are generated.

Measurement provides a direct example. Once an organization adopts a metric, activity can reorganize around what the metric makes visible. Data collection creates categories, time series, benchmarks, and comparison groups. These representations can improve coordination and accountability, but they also privilege some dimensions over others. A phenomenon that cannot be recorded within the existing schema can remain difficult to govern even when participants experience it as important. Epistemic orientation therefore influences institutional capacity through the design of observability.

Methods likewise orient inquiry. Randomized experiments, econometric identification, ethnography, archival reconstruction, simulation, network analysis, participatory research, and legal interpretation provide access to different dimensions of a problem. Their strengths are domain-specific. When one method becomes institutionally dominant, questions that fit its evidential architecture can become easier to legitimate and fund. GRE's methodological pluralism is partly a response to this orientation effect: the research problem should guide method selection rather than allowing an inherited method to define the only admissible problem.

Classification is another generative mechanism. Administrative categories determine eligibility, statistics, taxation, regulation, and rights. Market classifications affect comparability and exchange. Scientific classifications shape research populations. Professional categories define expertise. Once stabilized, classifications can influence behavior and identity, making the represented distinctions increasingly consequential. Epistemic orientation therefore links representation to ontology without collapsing the two: categories can help generate social effects even though the category remains analytically distinct from the object it represents.

Epistemic orientation has a temporal dimension. Institutions inherit archives, standards, vocabularies, and datasets from earlier periods. These resources make some historical comparisons possible while leaving other experiences poorly recorded. New questions are therefore conditioned by the epistemic infrastructure accumulated in the past. At the same time, present recording decisions shape what future investigators will be able to reconstruct. The organization of knowledge becomes part of intertemporal economic capacity.

Disagreement over epistemic orientation can be productive. Competing models, disciplinary perspectives, and interpretive frameworks can reveal different aspects of a system. GRE does not require premature convergence on a single representation. It asks whether the plurality of representations is explicit, whether their assumptions and domains of validity are understood, and whether institutions preserve the capacity to revise their epistemic orientation when anomalies or changing conditions make existing categories inadequate.

This emphasis also limits the role of formal precision. A precisely estimated quantity can answer a poorly oriented question, while a qualitative observation can reveal a relation that has not yet been formalized. GRE values formal and computational methods where they perform genuine analytical work, but epistemic orientation precedes technique in the sense that the researcher must first decide what distinctions, scales, and forms of evidence are relevant to the inquiry.

3.9.6 Institutional Selection of What Is Generated

Orientation becomes institutional when durable rules, organizations, infrastructures, and evaluative procedures repeatedly privilege some generative pathways over others. Institutions do not need to specify the content of future outcomes in order to shape them. By controlling eligibility, resources, recognition, standards, timing, and access, they can alter which possibilities survive long enough to become self-sustaining.

Funding systems provide an obvious case. Research grants, venture investment,

bank credit, public procurement, philanthropy, and internal organizational budgets each use different selection criteria. Those criteria can favor measurable returns, strategic importance, novelty, reliability, social need, collateral, prior reputation, or compatibility with existing infrastructure. A funding architecture therefore orients generation before the downstream value of a project is known. Its effects accumulate when successful projects create expertise, reputation, and networks that improve their access to future resources.

Legal and regulatory institutions also orient generation. Intellectual-property rules affect incentives and diffusion. Liability rules influence experimentation. Licensing can protect safety while raising entry barriers. Competition policy changes the conditions under which scale can consolidate. Data governance shapes access to informational resources. Labor and social-protection institutions influence the risks subjects can bear when changing occupations or starting new projects. In each case, legal structure changes the feasible and attractive trajectories available to economic actors.

Educational institutions orient generation by shaping capabilities, vocabularies, disciplinary boundaries, and aspirations. Curriculum determines which problems become familiar. Credentials affect access to professions and organizations. Mentorship can make previously invisible pathways imaginable. Evaluation systems influence whether students optimize for standardized performance, exploration, collaboration, or independent inquiry. Education therefore participates in economic generation long before its effects appear as wages or productivity.

Markets themselves are institutional selection environments. Prices, demand, competition, and profitability orient resources toward some activities and away from others. GRE retains this insight while asking how market selection interacts with other orientation mechanisms. Markets depend on property rules, infrastructures, classifications, information, financing, and distributions of purchasing power. A profitable opportunity can reflect genuine social demand, concentrated wealth, regulatory design, network effects, or externalized costs. Market orientation is therefore economically powerful without being normatively self-interpreting.

Platforms and algorithmic systems add another layer by combining infrastructure, ranking, rule enforcement, and data collection. Their selection mechanisms can shape which sellers are visible, which workers receive tasks, which content gains distribution, and which behaviors become economically rewarded. Because participants often adapt to these selection systems, the platform's orientation can become recursive: metrics influence behavior, behavior supplies new data, and new data update the mechanism that structures visibility or access.

Institutional orientation also creates lock-in and complementarity. Once organizations invest in a technology, standard, profession, or accounting category, adjacent investments may become more valuable. Alternative pathways then face higher switching costs even if they are technically feasible. The resulting persistence can be efficient when coordination benefits are large, but it can also preserve arrangements whose original justification has weakened. GRE therefore asks how institutional selection creates future dependency and what forms of optionality remain available.

The analytical objective is not to identify a single institution responsible for ori-

entation. Selection is often distributed across finance, law, culture, infrastructure, expertise, and public authority. A GRE inquiry traces how these mechanisms combine and where control over selection becomes concentrated, contested, or open to revision.

3.9.7 Plural Orientations under Heterogeneous Values

Economic systems contain subjects and communities whose orientations differ. They may disagree about desirable outcomes, relevant time horizons, legitimate evidence, acceptable risk, ecological obligations, cultural continuity, forms of recognition, or the value of particular capabilities. GRE treats this heterogeneity as a constitutive feature of orientation rather than assuming that all relevant directions can be represented by one shared scalar objective.

Plural orientation creates coordination problems. A project that expands aggregate income can weaken a local form of life. A conservation policy can protect ecological conditions while constraining livelihoods unless transition mechanisms are provided. A technological system can increase convenience for users while intensifying surveillance or labor precarity. A research programme can generate broadly useful knowledge while concentrating intellectual property. These tensions cannot always be resolved by discovering a hidden common metric.

Value conversion can help decision making when the conversion rule is explicit and appropriate. Monetary valuation, cost-effectiveness, multi-criteria analysis, voting, deliberation, legal balancing, and negotiated compromise are among the mechanisms institutions use to compare heterogeneous claims. GRE does not reject such conversions. It asks what is gained and lost through them, whose valuations enter the procedure, and whether the conversion becomes mistaken for an ontological equivalence among the values involved.

Plural orientation also means that generativity itself can be evaluated differently. One group may value rapid innovation; another may value reliability and continuity. One institution may prioritize employment; another ecological regeneration; another strategic autonomy; another freedom of inquiry. A relation can therefore be highly generative according to one orientation while appearing destructive according to another. The disagreement concerns both produced outcomes and the standards through which generation is interpreted.

Institutions can respond to plural orientation through several architectures. They can aggregate preferences into a single decision, allocate separate domains of authority, preserve local autonomy, establish rights that constrain aggregation, create deliberative procedures, or maintain experimental diversity across jurisdictions and organizations. Each architecture has generative consequences. Centralization can coordinate large-scale investment but narrow local variation. Decentralization can preserve experimentation but weaken collective capacity. Rights can protect vulnerable subjects while limiting some forms of optimization. GRE treats these trade-offs as empirical and normative objects rather than deriving a universal institutional design.

The distribution of voice matters because heterogeneous values do not enter decision processes with equal force. Wealth, legal status, expertise, organizational ca-

pacity, time, language, and control over infrastructure can affect which orientations become institutionally consequential. A formally plural process can therefore reproduce asymmetry if some actors possess much greater ability to define agendas, supply evidence, or sustain participation. Analysis of orientation must consequently include the conditions of representation and participation.

Plurality also has an epistemic benefit. Different orientations can reveal consequences that a dominant framework misses. Workers, users, local communities, engineers, ecologists, regulators, and investors can perceive different dimensions of the same system. Maintaining structured disagreement can therefore increase the system's capacity to detect emerging harms or opportunities. Diversity of orientation is not automatically valuable, but under some conditions it functions as a distributed sensing and exploration mechanism.

For GRE, the constitutional implication is that economic orientation should remain representationally plural unless a specific analytical or decision context justifies aggregation. Heterogeneous values are not noise to be removed before economic reasoning begins. They are part of the relational field through which generation is directed and evaluated.

3.9.8 Orientation as an Economic and Political Problem

Orientation becomes an economic problem because it influences the allocation and generation of scarce capacities across time. Attention, research effort, capital, infrastructure, education, organizational commitment, and institutional legitimacy cannot be devoted equally to every possibility. Selection therefore shapes which capabilities accumulate, which industries form, which questions receive answers, which risks become visible, and which subjects gain access to future opportunities. Orientation is economically consequential even when no market transaction directly prices it.

It becomes a political problem when the authority to orient generation is unevenly distributed or collectively contested. Governments set research priorities and infrastructure plans. Firms select technologies and business models. Platforms organize visibility. Financial institutions influence investment trajectories. Professional bodies define standards. Universities establish curricula and disciplines. Communities defend or transform local practices. Individuals exercise agency within these fields but do not enter them with equal resources. Orientation is therefore partly a question of who can shape the conditions under which future possibilities become more or less available.

This form of power is upstream from many observable outcomes. Control over a final allocation matters, but control over the categories, infrastructures, questions, and selection procedures through which future allocations will be made can have longer-lived effects. A subject that determines what can be measured, funded, connected, certified, or searched can influence generation without dictating every downstream action. GRE can analyze this as power over generative conditions while still requiring concrete mechanisms rather than inferring power from asymmetry alone.

The political character of orientation also appears in conflicts over temporality. Short electoral cycles, quarterly reporting, long infrastructure lifetimes, ecological regeneration, intergenerational obligations, and scientific research operate on dif-

ferent temporal horizons. Institutions that privilege one horizon can redirect generation away from possibilities whose value emerges later. The question is not simply whether actors discount the future, but how organizational and institutional arrangements determine whose future, which risks, and which forms of value remain actionable in the present.

A generative orientation can also produce foreclosure. Investment in one infrastructure can make alternatives expensive. A dominant technical standard can exclude incompatible innovations. A classification can make some identities administratively invisible. A business model can generate dependency that reduces exit options. Foreclosure is therefore the counterpart of orientation: selecting and reinforcing one trajectory changes the feasibility of others. GRE evaluates orientation partly by tracing these changes in future option sets rather than only immediate outputs.

This does not imply that preserving every option is desirable. Coordination, commitment, specialization, and institution building often require closing alternatives. A society cannot maintain every infrastructure standard simultaneously, and an organization cannot pursue every project. The analytical question concerns the terms under which closure occurs, its reversibility, who bears the resulting constraints, and whether institutions retain capacities for revision when conditions change.

Orientation also connects economic analysis to governance. A governance system can attempt to specify desired outcomes directly, or it can shape fields in which desirable forms of generation are more likely to emerge. The latter approach may involve public infrastructure, open standards, rights, research capacity, plural participation, safety constraints, or mechanisms for feedback and revision. Such field-oriented governance does not eliminate political choice; it relocates part of that choice to the design of enabling and constraining conditions.

The constitutional position of GRE is therefore neither that generation should be maximized nor that orientation should be centralized. GRE makes orientation visible as an object of economic inquiry. It asks how attention, curiosity, aesthetic judgment, epistemic practices, institutions, and heterogeneous values combine to direct generative processes; how orientation distributes future capacities and risks; how power enters selection; and how orientations themselves change through history.

This completes the present chapter's account of one major dimension of GRE's problem-space. Economic generation is mediated by subjects, but subjects themselves are formed through relations; generation is directional, but direction arises through multiple cognitive, institutional, symbolic, and political mechanisms. The next constitutional task is methodological. The following section therefore distinguishes the principal modes through which GRE can describe, explain, reconstruct, compare, interpret, formalize, evaluate, and intervene in the economic processes identified here.

3.10 Modes of GRE Inquiry

Generative Relational Economics requires methodological breadth because its objects are heterogeneous and its questions concern several different kinds of claim. A study may need to describe a relational configuration, explain how it is reproduced, recon-

struct how it emerged historically, compare it with alternative configurations, interpret the meanings through which subjects act, identify causal effects, formalize a mechanism, simulate possible trajectories, evaluate consequences normatively, or design an intervention. These tasks are related, but they are not interchangeable. The role of this section is to distinguish the principal modes through which GRE can conduct inquiry while preserving their mutual compatibility. Its objective is methodological clarification rather than the prescription of a single research design. The discussion proceeds from descriptive and explanatory inquiry through historical, comparative, interpretive, causal, formal, computational, normative, and intervention-oriented modes. Across them, the governing principle is that each mode must make explicit what kind of claim it is entitled to support, which evidence or representation bears that claim, and where its warrant ends.

The distinction among modes concerns the epistemic work being performed rather than a rigid classification of disciplines or techniques. An interview can contribute to descriptive, interpretive, historical, causal, or normative inquiry depending on how it is used. A regression can support description, comparison, or causal inference under different designs. Archival material can reconstruct a historical sequence while also revealing institutional meanings and mechanisms. A simulation can clarify the consequences of specified assumptions without establishing that the modeled mechanism exists empirically. GRE therefore classifies inquiry by the relation between question, evidence, representation, and warranted conclusion rather than by the surface form of the method alone.

The modes also differ from the objects and scales identified earlier in this chapter. The same object can be approached through several modes. A platform can be described as an organization and infrastructure, interpreted through the classifications embedded in its interface, studied causally through changes in ranking rules, reconstructed historically through its institutional development, represented formally as a multilayer network, evaluated normatively through the distribution of generated capacities and harms, and examined interventionally through alternative governance designs. Methodological plurality becomes useful precisely because the object does not determine a unique mode of inquiry.

GRE does not require every project to use every mode. A narrowly designed causal study can be valuable if its boundaries are clear. A historical reconstruction can illuminate the emergence of a generative structure without formalization. An interpretive study can reveal categories that would otherwise be mismeasured. A formal model can clarify possible mechanisms before adequate data exist. The methodological demand is therefore fit rather than comprehensiveness: the mode or combination of modes should match the question and should remain corrigible by evidence or arguments arising from other modes when their domains overlap.

3.10.1 Descriptive Inquiry

Descriptive inquiry establishes what is present, how it is distributed, how it is related, and how it changes over a specified observational domain. In GRE, description can concern entities, subjects, relations, resources, capacities, forms of value, constraints, institutional rules, symbolic representations, trajectories, or fields. Its importance

is easily underestimated because description is sometimes treated as a preliminary stage before "real" explanation. Yet a relational research programme depends heavily on careful description: a mistaken boundary, omitted relation, inappropriate unit, or unstable category can distort every later explanatory or normative claim.

A GRE description is therefore more than an inventory of isolated attributes. It can map relational incidence: who is connected to whom, through which mechanism, under what terms, and with what asymmetries. It can characterize distributions of access, exposure, recognition, risk, or capability. It can identify temporal patterns such as persistence, turnover, accumulation, or decay. It can distinguish administrative recipients from affected subjects and can trace where value, constraints, or opportunities appear outside the nominal boundary of a programme or transaction. Description thereby makes the relational field empirically available before deeper attribution is attempted.

The construction of descriptive categories requires explicit judgment. Terms such as worker, household, platform, community, firm, beneficiary, asset, skill, trust, or harm are not self-interpreting. Their operationalization can depend on legal definitions, institutional records, self-identification, measurement conventions, or analytical reconstruction. GRE therefore treats descriptive categories as representations whose adequacy must be justified relative to the question and scale. A category can be useful without being ontologically final, and a stable administrative classification can remain inadequate for a relational question if it suppresses relevant interactions or affected subjects.

Description also has a temporal dimension. Cross-sectional description captures a configuration at a moment or interval, while longitudinal description tracks changes in states, relations, or distributions. The latter becomes especially important when generation concerns future capacities. A programme that appears distributively modest at one date may substantially change later educational, technological, organizational, or relational possibilities. Conversely, an apparent short-term gain may dissipate or convert into dependence. Descriptive inquiry can reveal these trajectories without yet claiming a mechanism for them.

Rich description can combine quantitative and qualitative evidence. Administrative records may establish scale and distribution; interviews may reveal unrecorded relations; ethnographic observation may show how formal rules are enacted; network data may identify patterns of connectivity; documents may clarify institutional categories; spatial data may reveal infrastructural concentration. GRE has no reason to privilege one evidence type in advance. The relevant standard is whether the descriptive representation captures the features required by the question while making omissions and uncertainty visible.

Descriptive adequacy also depends on boundaries. A study of a firm's wage policy can stop at employees, extend to households, include subcontractors, or incorporate local labor markets and public services. Each boundary produces a different descriptive object. GRE does not assume that the widest boundary is always best; wider boundaries increase complexity and can reduce tractability. The researcher instead states why a boundary is appropriate and tests whether excluded relations materially alter the description.

The output of descriptive inquiry is therefore a warranted account of configuration rather than a claim about why the configuration exists. It establishes patterns that explanatory, historical, causal, interpretive, or normative inquiry may subsequently address. In GRE, this mode is foundational because relational and generative claims become meaningful only after the relevant configurations, transitions, and affected subjects have been specified with sufficient empirical discipline.

3.10.2 Explanatory Inquiry

Explanatory inquiry asks how and why an observed configuration, transition, or regularity occurs. GRE gives particular attention to mechanisms through which relations produce, reproduce, transform, amplify, or constrain later possibilities. Explanation can therefore address immediate effects, recursive feedback, institutional reproduction, conversion among forms of value, subject formation, cross-scale propagation, or changes in the conditions under which subsequent generation occurs.

Explanation requires more than naming a correlation or attaching a familiar concept to an outcome. To say that an outcome results from power, incentives, norms, networks, institutions, culture, or path dependence is incomplete unless the operative process is specified sufficiently to connect conditions to consequences. A GRE explanation should identify the relevant actors or configurations, the relations through which effects travel, the enabling and constraining conditions, the temporal sequence where it matters, and the observations that would distinguish the proposed mechanism from plausible alternatives.

Mechanistic explanation can operate at different levels. A change in organizational behavior may be explained through individual incentives, professional norms, governance rules, technological affordances, inter-organizational dependence, or combinations among them. These explanations need not compete if they address different parts of the process. GRE is particularly interested in explanations that connect levels without treating one as automatically fundamental. A legal rule can alter organizational incentives; organizational practices can reshape individual capabilities; repeated individual actions can stabilize a convention; a convention can later become codified. The explanatory task is to show how these relations connect rather than to reduce them to a single privileged scale.

Generative explanation extends the temporal horizon beyond the immediate outcome. A scholarship programme may explain increased enrollment through reduced cost, but GRE may also ask how participation generates networks, expectations, credentials, institutional capacities, or new constraints that alter later educational and labor-market trajectories. This does not mean every explanation must trace indefinitely downstream. It means that when later capacities are central to the research question, the explanatory account should not stop at the first measurable output merely because it is administratively convenient.

Explanatory inquiry can draw on several other modes. Historical evidence can reveal how a mechanism became possible. Interpretive evidence can show how subjects understand and respond to classifications. Causal designs can estimate whether an intervention changes an outcome. Formal models can clarify whether a proposed mechanism is internally coherent. Comparative cases can test whether the explana-

tion travels across configurations. Computational models can explore implications that are difficult to derive analytically. Explanation is therefore often integrative, but the contributions of these components should remain distinguishable.

The standard of explanatory sufficiency depends on the claim. A local explanation of a policy effect requires less than a theory of institutional transformation. Claims about altered generative conditions require evidence that the later opportunity structure, rule environment, capacities, or relations changed in a way relevant to subsequent processes. Claims about transformation of the effective rule of change require still stronger evidence that the mechanism governing later transitions itself changed. GRE therefore scales explanatory ambition to evidential support.

Explanatory inquiry is central to GRE because the framework is concerned with more than relational association. It seeks to understand how relations become consequential through identifiable processes. At the same time, explanation remains compatible with ontological suspension: a useful mechanism model can explain an empirical pattern without establishing that its analytical categories constitute the ultimate ontology of the economic system.

3.10.3 Historical Inquiry

Historical inquiry reconstructs how economic configurations, categories, subjects, institutions, and generative conditions emerge and transform through time. Its role in GRE is constitutive rather than supplementary. If entities and relations can be historically generated, then their present form cannot always be understood by treating them as fixed inputs to analysis. Historical inquiry asks how the objects that later appear stable became available, how alternative possibilities were closed or retained, and how prior trajectories condition present generative capacity.

A historical GRE study can begin with an institution, technology, classification, market, profession, infrastructure, or relation and reconstruct the sequences through which it acquired its current form. The relevant history may include legislation, organizational decisions, conflict, technical development, demographic change, cultural interpretation, investment, crises, accidents, or encounters with other systems. The aim is not to produce chronology for its own sake. The analytical objective is to identify transformations that changed what later actors could perceive, do, coordinate, own, exchange, contest, or generate.

Historical inquiry is especially important for categories that appear natural after stabilization. The distinction between employee and contractor, the legal form of a corporation, a standardized credential, a property right, a data category, a currency regime, or a professional jurisdiction can become embedded in administrative systems and everyday expectations. Once stabilized, these categories structure evidence and action. Historical reconstruction can reveal their contingency, the relations that produced them, and the alternatives that were once viable. Such reconstruction supports ontological suspension by showing that analytical objects may have histories of constitution.

Temporal ordering can also bear explanatory weight. The same set of conditions can produce different outcomes when encountered in different sequences. Early infrastructure can create increasing returns; a legal designation can precede and en-

able market formation; a crisis can accelerate an institution that had previously remained marginal; a technical standard can become difficult to displace after complementary investments accumulate. Historical inquiry can therefore identify path-dependent mechanisms while avoiding the loose use of "history matters" as an explanation.

GRE also treats methods and evaluative categories as historical. What counts as reliable evidence, recognized value, legitimate participation, acceptable risk, or relevant harm can change. A historical study may therefore examine not only the object of evaluation but the evolution of the evaluative and epistemic apparatus itself. This becomes particularly important when contemporary assessment applies categories that did not exist, had different meanings, or excluded relevant subjects in earlier periods.

Historical evidence is heterogeneous. Archives, legal documents, organizational records, correspondence, material artifacts, statistical series, oral histories, media, technical standards, and retrospective testimony can each illuminate different aspects of a process. Their survival is itself selective. GRE therefore treats the archive as part of the historical relational field: who could record, whose records were preserved, which categories were administratively legible, and which forms of experience remained unrecorded can shape what later researchers are able to reconstruct.

Historical inquiry does not imply that every present problem requires a complete genealogy. The relevant temporal horizon depends on the process. Some mechanisms can be understood through recent organizational history; others depend on decades of institutional accumulation or longer histories of law, infrastructure, or social classification. The methodological requirement is to extend the historical frame far enough that the object and its operative conditions are not mistakenly treated as timeless when their formation is relevant to the explanation.

3.10.4 Comparative Inquiry

Comparative inquiry examines similarities and differences across cases, configurations, periods, scales, or institutional arrangements. In GRE, comparison is valuable because relational and generative mechanisms are often conditional. A relation that generates capability in one institutional environment may generate dependence in another; a governance arrangement that supports participation at one scale may produce exclusion at another; the same technology can reorganize value differently under different property, labor, or regulatory structures.

Comparison can therefore reveal which features are specific to a configuration and which travel across contexts. Cases may be organizations, regions, legal systems, historical episodes, technologies, communities, markets, or interventions. A comparison can hold some features relatively stable while examining variation in others, or it can compare broader configurations whose differences are themselves analytically meaningful. GRE does not require all comparisons to approximate experiments. Configurational comparison can be valuable when the research question concerns how combinations of relations produce different generative trajectories.

The major methodological problem is commensurability. Cases become comparable only through selected dimensions, and the choice of dimensions can obscure

differences in meaning or institutional constitution. "Employment," "household income," "community participation," or "innovation" may be measured similarly across jurisdictions while referring to materially different social arrangements. Comparative inquiry must therefore justify both the common dimension and the retained differences. Translation among categories can be part of the research rather than a preliminary technical step.

Comparison across time presents a related problem. A variable can retain its label while the institutional relations that constitute it change. Longitudinal comparisons of occupations, assets, industries, educational attainment, or household forms may therefore require attention to changing definitions and social significance. GRE treats historical comparability as an empirical and interpretive achievement, not an automatic consequence of having a numerical series.

Comparative inquiry is also useful for mechanism assessment. If a proposed explanation depends on a particular relation, cases in which that relation differs can help evaluate the claim. A platform governance mechanism can be compared across ownership models; a welfare intervention across administrative designs; a cooperative across legal environments; a knowledge commons across licensing regimes. The objective is not necessarily to identify a single universally best arrangement. Comparison can instead map how different relational configurations generate different distributions of capacity, value, risk, or closure.

Negative and deviant cases can be especially informative. A case in which an expected self-reinforcing process fails may reveal a missing enabling condition. A community that resists a dominant institutional trajectory can disclose alternative relations that preserve options. A technological diffusion that remains limited despite strong incentives may reveal interpretive, infrastructural, or legal constraints. GRE can use such cases to refine mechanisms rather than treating them as noise around an average effect.

Comparative inquiry thus provides a disciplined way to study plurality. It can test portability without assuming invariance, and it can illuminate alternative economic arrangements without reducing them to a single ranking dimension. Its contribution is strongest when the basis of comparison, the boundaries of each case, and the limits of generalization are stated explicitly.

3.10.5 Interpretive Inquiry

Interpretive inquiry examines the meanings, classifications, narratives, symbols, expectations, and practical understandings through which economic subjects perceive and act within relational configurations. GRE requires this mode because many economic objects are symbolically mediated. Prices, contracts, credentials, reputations, categories, metrics, risk scores, organizational roles, and legal statuses acquire consequences partly through shared or contested interpretations.

Interpretation enters economic processes in several ways. Subjects respond to what they believe a rule requires, what they expect others to do, what a category signifies, or what an action communicates. An institutional classification can alter behavior because it changes eligibility or sanctions, but also because subjects understand themselves and others through it. A market signal can influence investment be-

cause actors interpret its informational content. A policy can fail because its official category does not correspond to the categories through which affected communities organize practice. Meaning is therefore neither an ornamental layer nor a universal substitute for material explanation. It is one mechanism through which relations become actionable.

Interpretive inquiry can focus on language, documents, interviews, practices, rituals, interfaces, images, classifications, or institutional procedures. The researcher asks how a representation is produced, which distinctions it makes salient, how subjects use or contest it, and what practical consequences follow. Interpretive evidence can reveal why formally identical incentives generate different responses, why some risks remain unrecognized, or why an institutional reform changes subject positions even when resource distributions move little.

GRE distinguishes the meaning attributed by subjects from the analyst's representation. Researchers can misdescribe a relation if they impose categories that erase locally consequential distinctions. Conversely, subjects' interpretations do not exhaust causal explanation. An institution can have effects that participants neither intend nor perceive. Interpretive inquiry therefore contributes one layer of evidence within a plural methodology: it reconstructs situated meaning while remaining open to material, institutional, statistical, and historical evidence about effects beyond conscious understanding.

Symbolic mediation becomes particularly important under conditions of representational abundance. Rankings, dashboards, automated classifications, recommendation systems, financial models, and AI-generated representations can shape what becomes visible and credible. Interpretive inquiry can examine how these representations acquire authority and how subjects orient action around them. It can also ask how categories designed for one purpose migrate into other domains and begin to organize allocation, recognition, or exclusion.

Interpretive disagreement is itself an economic phenomenon. Different actors may attach incompatible meanings to the same resource, relation, technology, or institutional change. A redevelopment project can signify investment to one group and displacement to another; data sharing can signify innovation, surveillance, or public infrastructure depending on the relation. GRE does not require these meanings to be collapsed into a single utility metric before analysis begins. Their coexistence can shape conflict, coalition, legitimacy, and future generative possibilities.

Interpretive inquiry thus expands what counts as economically relevant evidence while remaining disciplined by context and consequence. Its aim is not to replace causal or material analysis with discourse, but to identify when meaning and representation form part of the mechanism through which economic relations are generated, sustained, or transformed.

3.10.6 Causal Inquiry

Causal inquiry asks whether and through what conditions a change in one factor contributes to a change in another. GRE requires causal discipline because relational language can otherwise encourage unwarranted attribution. The presence of a relation, asymmetry, institution, or field does not by itself establish that it caused an

observed outcome. Causal inquiry therefore provides tools for distinguishing association, sequence, mechanism, and intervention-relevant effect.

Causal questions can be narrow or generative. A narrow question may ask whether a transfer increases school attendance. A broader question may ask whether the transfer changes household bargaining, peer networks, expectations, credential accumulation, or later labor-market options. These questions operate on different outcomes and time horizons, and they may require different designs. GRE's contribution is not to replace established causal inference but to broaden the set of causally relevant downstream and relational outcomes when theory gives reason to expect them.

Counterfactual reasoning remains central. To claim that an intervention caused an outcome requires some account of what would have occurred under a relevant alternative. Randomization, natural experiments, quasi-experimental designs, matching, synthetic controls, longitudinal models, process tracing, comparative case analysis, and mechanistic evidence can support counterfactual claims under different assumptions. GRE is methodologically plural about these tools but not indifferent to identification. The choice of design must match the causal claim.

Relational settings create additional challenges. Interference can violate assumptions that one unit's treatment does not affect another. Network spillovers can make the administrative recipient a poor unit for causal analysis. Institutional reforms can change the categories through which outcomes are measured. Feedback can make causes and effects mutually reinforcing across time. Selection into relationships can confound observed associations. GRE therefore treats relational structure as part of causal design rather than as a reason to abandon causal inference.

Causal attribution can also be distributed. A harmful outcome may depend on a sequence of financing rules, organizational incentives, technical standards, local decisions, and infrastructural constraints. No single element is sufficient on its own, yet the configuration can reliably generate the outcome. GRE can analyze such conjunctural causation while distinguishing it from claims that every contributing condition bears equal explanatory or normative weight.

Generative causal inquiry may ask whether an intervention changes later capacities to produce further effects. This creates nested causal questions. A training programme can directly change skill, which changes network access, which changes employment opportunities, which changes household investment. The causal chain can branch and feed back. Researchers need not estimate every link simultaneously, but they should distinguish measured effects from hypothesized downstream mechanisms and avoid presenting an observed endpoint as evidence for the entire generative story.

Causal inquiry therefore disciplines GRE's ambition. It permits strong claims where design and evidence support them and encourages restraint where mechanisms remain plausible but unverified. Relational complexity expands the causal questions worth asking; it does not lower the evidential burden for answering them.

3.10.7 Formal Inquiry

Formal inquiry constructs explicit representations of economic structures or processes in mathematical, logical, graphical, or computationally specified form. Its role in GRE is clarification. Formalization can make assumptions visible, expose inconsistencies, distinguish mechanisms that natural language leaves conflated, derive consequences, and reveal which empirical observations would discriminate among alternative accounts.

The appropriate formalism depends on the problem. Dynamical systems can represent trajectories, stability, and regime change. Networks and hypergraphs can represent relational topology and higher-order interaction. Multilayer structures can distinguish relation types. Optimization and game-theoretic models can clarify strategic constraints and incentive compatibility. Probabilistic models can represent uncertainty and conditional dependence. Field-like representations can describe distributed conditions when locality or spatial organization matters. Logical or categorical formalisms can clarify compositional structure. GRE does not designate one of these as its universal mathematics.

Formal inquiry begins by specifying what the symbols represent. A node may stand for a person, organization, legal entity, document, or technical component; an edge may encode communication, ownership, exchange, dependency, recognition, or another relation. A state variable can summarize a capacity, stock, classification, or measured condition. The model becomes meaningful only through the mapping between formal object and empirical interpretation. Two models with identical mathematics can therefore represent substantively different economic mechanisms.

Formalization also requires ontological restraint. A network representation does not prove that the economy is fundamentally a network, and a state-space model does not establish that the selected variables constitute a complete economic state. The formal representation is an analytical instrument whose adequacy depends on the question, assumptions, and empirical correspondence. GRE's ontological suspension is compatible with strong formal work precisely because it separates representational usefulness from metaphysical commitment.

One important use of formal inquiry is to distinguish levels of transformation. A model can represent change in state under fixed rules, changes in parameters, changes in topology, or transformations in the effective rule itself. These are different formal problems. GRE's concern with changing generative conditions becomes clearer when the model states which elements are permitted to vary and which remain fixed. A formalism that endogenizes network ties while fixing node identities captures one form of relational change but leaves other forms outside the model.

Formal inquiry can also produce impossibility or boundary results. Under specified assumptions, certain combinations of objectives may be incompatible; some allocation rules may generate unavoidable trade-offs; some dynamics may be unstable; some information may be insufficient for identification. Such results can be valuable even when the assumptions are idealized because they clarify where a proposed intervention requires additional structure or information.

The evidential status of a formal result must nevertheless remain explicit. A theorem establishes a consequence of assumptions. A numerical model shows behavior

of a specified representation. Neither alone establishes that the assumptions hold empirically. Formal inquiry becomes empirically explanatory when the mapping, assumptions, and relevant predictions or mechanisms are supported by evidence. GRE therefore treats formalization as one rigorous mode among several, especially powerful when combined with descriptive, historical, causal, or interpretive work.

3.10.8 Computational Inquiry

Computational inquiry uses algorithmic procedures to analyze data, simulate specified systems, explore high-dimensional models, search large possibility spaces, or construct representations that would be difficult to handle analytically. It overlaps with formal inquiry but is not identical to it. A formal model can be studied without computation, while computational analysis can involve empirical pattern detection whose theoretical structure remains comparatively weak. GRE distinguishes these uses so that computational power is not mistaken for explanatory completeness.

Simulation is one major application. Agent-based models can explore how heterogeneous local rules generate aggregate patterns; network simulations can study diffusion, contagion, coordination, or rewiring; dynamical models can examine sensitivity and regime change; Monte Carlo methods can characterize uncertainty; optimization algorithms can explore feasible designs under constraints. Simulation is particularly useful when feedback, heterogeneity, or combinatorial complexity makes closed-form analysis difficult.

The epistemic status of simulation remains conditional. A simulated trajectory is evidence about the behavior of the model under specified assumptions. It becomes evidence about a target economic system only through an additional argument that the model represents relevant features adequately. Calibration, validation, sensitivity analysis, out-of-sample comparison, qualitative mechanism matching, and robustness checks can strengthen this bridge. The visual plausibility of a simulated pattern is insufficient on its own.

Computational inquiry also includes data-intensive empirical methods. Machine learning can classify, predict, embed, cluster, or detect patterns in large datasets. Natural-language processing can analyze documents and discourse. Network algorithms can identify structural positions or communities. Spatial computation can reveal geographical concentration and accessibility. These methods can extend observational capacity, but the resulting representations inherit the categories, sampling processes, missingness, labels, and objectives of the data-generating system.

For GRE, computational representation can itself become an object of inquiry. A credit score, recommendation model, allocation algorithm, or generative AI system does not merely describe an economic field; once used operationally, it can alter access, visibility, bargaining power, subject classification, and future data. The computational model can therefore enter the generative relation it represents. Researchers may need to study both model performance and the feedback through which deployment changes the target system.

Computation can further support exploratory work under ontological uncertainty. Researchers can test several network boundaries, alternative state representations, or competing mechanisms and examine which are robust to changes in specification.

Such exploration is valuable if it is reported transparently and distinguished from confirmatory inference. Computational flexibility increases the importance of documenting choices because many plausible pipelines can yield different apparent structures.

GRE therefore welcomes computational inquiry without treating computation as a substitute for theory, meaning, causality, or normative judgment. Its contribution lies in extending what can be represented and explored while maintaining explicit links among algorithm, data, modeled object, and warranted conclusion.

3.10.9 Normative Inquiry

Normative inquiry evaluates economic arrangements, relations, processes, or interventions according to articulated standards of value, justice, participation, capability, harm, responsibility, freedom, sustainability, or other justified criteria. GRE requires this mode because generativity is not intrinsically beneficial. A relation can generate wealth and dependency, knowledge and exclusion, capability and ecological damage, trust and vulnerability, innovation and concentration. Description of generation therefore cannot settle whether the generated configuration is desirable.

Normative inquiry begins by making the evaluative standard visible. A study may evaluate distribution, procedure, recognition, participation, capability, rights, ecological integrity, intergenerational effects, or the preservation of future options. These standards can converge in some cases and conflict in others. GRE does not resolve such conflict by assuming that all values can be converted into a common metric. Monetary valuation, utility, capability, rights, and relational goods can each illuminate different dimensions while leaving remainders that resist equivalence.

The distinction between generated value and generated harm is central. An intervention that expands productive capacity can simultaneously concentrate decision authority. Infrastructure can increase mobility while displacing communities. A platform can create new forms of participation while producing surveillance or dependency. Normative inquiry therefore follows the distribution and conversion of effects across subjects, scales, and time rather than assigning the entire process a single positive or negative label from one immediate outcome.

Participation matters both instrumentally and intrinsically. Subjects affected by an intervention may hold knowledge unavailable to designers, making participation epistemically valuable. Participation can also constitute recognition and agency rather than merely improve technical outcomes. Yet participation itself varies in form and power. Consultation, veto authority, co-design, ownership, and self-governance are not equivalent. GRE can therefore examine the relational structure of participation rather than treating its nominal presence as sufficient.

Normative inquiry also addresses capability and future generativity. An arrangement can be evaluated partly by how it changes subjects' capacities to act, learn, cooperate, exit, contest, or generate further value. This future-oriented criterion does not imply that more capability is always better or that every option must be preserved. Some capabilities are harmful, and institutional commitments often require selective closure. The normative problem concerns which capacities are expanded or foreclosed, for whom, under what justification, and with what possibilities for revision.

Evaluation must remain historically and contextually responsive. Normative concepts can have general aspirations while their application depends on institutions, technologies, ecological conditions, and available alternatives. Standards themselves can also be criticized and revised through new knowledge or previously excluded perspectives. GRE therefore treats normative inquiry as reasoned and contestable rather than as a final scoring procedure appended after positive analysis.

The mode remains analytically distinct from empirical explanation even when the two interact. Evidence can show who is harmed, which capacities change, or how participation is distributed. It cannot by itself determine how conflicting claims should be weighted. Conversely, normative arguments that ignore empirical mechanisms can recommend interventions that reproduce the very harms they seek to address. GRE joins the modes through mutual constraint while preserving the distinction between what occurs and how it ought to be evaluated.

3.10.10 Intervention-Oriented Inquiry

Intervention-oriented inquiry asks how knowledge can inform deliberate attempts to alter a relational configuration, its generative conditions, or the processes through which future outcomes are produced. It is distinct from normative inquiry because deciding that a condition is undesirable does not establish how it can be changed. It is also distinct from causal inquiry because estimating the effect of one intervention does not by itself provide a complete strategy for governance under changing conditions.

A GRE intervention begins with diagnosis. The researcher or practitioner identifies the relevant relations, subjects, constraints, capacities, value flows, representations, and scales. The intervention target may be an allocation, a rule, an infrastructure, a relation among organizations, an information environment, a participation mechanism, or a field condition that makes certain actions easier or harder. This breadth allows GRE to consider interventions that modify generative conditions rather than only redistribute final outputs.

Intervention design then requires an explicit theory of change. Which relation is expected to change? Through what mechanism? Which subjects can respond? Which enabling conditions are required? What downstream pathways are anticipated? Which unintended effects are plausible? At what time horizon should evaluation occur? These questions prevent “relational intervention” from becoming a vague label for any complex policy.

Field-oriented intervention is one important possibility. Instead of specifying a single terminal outcome, governance can alter conditions under which desirable forms of generation become more feasible. Open standards can lower barriers to entry; public infrastructure can expand capability; rights can protect participation; information systems can make harms visible; funding structures can diversify inquiry; modular regulation can preserve reversibility. Such approaches remain interventions with distributive and political consequences even when they do not centrally prescribe final behavior.

Intervention-oriented inquiry also requires feedback. Economic systems respond to policy, and subjects can adapt strategically or creatively. An initially effective rule

can become ineffective after behavior changes. A subsidy can create dependence; a measurement target can be gamed; a new right can generate institutional innovation; an infrastructure can enable uses that designers did not anticipate. GRE therefore treats monitoring and revision as part of intervention rather than as post hoc maintenance.

Reversibility and repair deserve explicit attention. Some interventions are easy to modify, while others create sunk costs, legal entitlements, ecological damage, technical lock-in, or institutional dependencies. An intervention that transforms generative conditions can make later reversal difficult even if the original allocation was modest. Design can therefore consider exit, rollback, sunset, compensation, remediation, and mechanisms for affected subjects to challenge or revise the arrangement.

Intervention-oriented inquiry is necessarily ethical and political. Choosing what to change, whose capacities to expand, which risks to accept, and which alternatives to close involves normative judgment and distributions of authority. Technical sophistication cannot remove these questions. What GRE can contribute is a disciplined account of how proposed interventions enter relational fields, how their effects propagate beyond immediate recipients, how they alter future capacities and constraints, and how governance can remain responsive to evidence and contestation.

The ten modes distinguished in this section are therefore complementary ways of making GRE's research programme operational. Descriptive inquiry establishes configurations; explanatory inquiry identifies mechanisms; historical inquiry reconstructs formation; comparative inquiry tests variation and plurality; interpretive inquiry recovers meaning and symbolic mediation; causal inquiry disciplines attribution; formal inquiry clarifies explicit structures; computational inquiry extends representation and exploration; normative inquiry evaluates consequences and arrangements; and intervention-oriented inquiry connects analysis to deliberate change. Their combination is problem-dependent rather than fixed.

Methodological plurality, however, requires epistemic discipline. Combining modes does not automatically produce stronger knowledge if their assumptions, evidential statuses, and inferential limits remain implicit. The next constitutional task is therefore to state the commitments that govern how GRE moves among these modes: ontological suspension, partial observation, distinction between relation and representation, explicit boundary and scale selection, mechanism-sensitive attribution, historical dependence, methodological pluralism, revisability, and epistemic humility.

3.11 Epistemic Commitments of GRE

The methodological plurality established in the preceding section creates a further constitutional requirement. If Generative Relational Economics permits descriptive, historical, interpretive, causal, formal, computational, normative, and intervention-oriented inquiry, it also requires standards governing how claims move across those modes and how uncertainty is represented. Methodological plurality without epistemic discipline can produce a collection of incompatible assertions whose evidential status remains unclear. The role of this section is therefore to state the principal

epistemic commitments that constrain GRE inquiry across methods and domains. Its objective is neither to supply a complete philosophy of science nor to impose a single theory of knowledge. It instead specifies a working discipline for research conducted under relational complexity, historical change, partial observability, heterogeneous forms of evidence, and revisable analytical categories.

The commitments are organized around nine requirements: ontological suspension, acknowledgment of partial observation, separation of relation from representation, explicit boundary and scale selection, mechanism before unwarranted attribution, historical and contextual dependence, methodological pluralism, revisability of analytical categories, and epistemic humility. They are mutually reinforcing. Ontological suspension restrains the conversion of useful models into premature metaphysical claims. Partial observation prevents the observed record from being equated with the whole relational configuration. Distinguishing relation from representation keeps measurements, categories, graphs, narratives, and models analytically separate from the processes they represent. Explicit boundary and scale selection makes exclusions visible. Mechanism disciplines attribution. Historical dependence limits the portability of claims across contexts and periods. Methodological pluralism allows different forms of evidence to correct one another. Revisability makes the analytical vocabulary responsive to changing objects and evidence. Epistemic humility calibrates the strength of conclusions to the scope of their warrant.

These commitments do not require a researcher to remain permanently agnostic about every substantive question. GRE can make strong empirical or theoretical claims when evidence, design, and argument justify them. The commitments instead determine what must be shown before such strength is warranted. A causal estimate obtained from a credible design can support a bounded causal claim. A historically reconstructed mechanism can support an explanation when the documentary and comparative record is sufficiently strong. A formal theorem can establish consequences within a defined model. A normative argument can defend criteria under stated premises. Epistemic restraint does not weaken inquiry; it clarifies where the force of a conclusion comes from and which transformations of the claim would exceed the evidence that supports it.

The same discipline is particularly important because GRE studies processes that may alter the categories through which they are observed. A platform can reorganize what counts as work, a legal reform can alter the recognized economic subject, an accounting standard can change what becomes economically visible, an artificial system can redistribute capacities among human and organizational actors, and a governance intervention can transform the relations that later measurements attempt to describe. In such settings, the research object and the research representation can co-evolve. GRE therefore requires epistemic commitments that are compatible with historical transformation rather than assuming a permanently fixed ontology, vocabulary, or observation regime.

3.11.1 Ontological Suspension

Ontological suspension is the first epistemic commitment because GRE deliberately works with heterogeneous representations of economic reality. An inquiry may describe persons, organizations, institutions, flows, relations, fields, trajectories, networks, states, constraints, events, capacities, or symbolic objects. Each representation can disclose features that another suppresses. GRE therefore withholds claims about the ultimate ontological status of these objects unless the local inquiry requires such a claim and adequate argument is available.

Ontological suspension does not imply that nothing exists independently of description, nor does it reduce inquiry to arbitrary perspectivism. It is a methodological restraint concerning the relation between analytical usefulness and metaphysical conclusion. Treating a firm as an entity can be economically useful because the firm has relatively stable legal, organizational, accounting, and decision-making properties. Treating the same firm as a nexus of contracts, a field of authority, a network of relations, a bundle of productive capacities, or a historical process can also be useful for other questions. The availability of several productive representations does not by itself decide which description identifies the firm's final or most fundamental mode of being.

This suspension is especially important when scientific formalisms are transferred into economic analysis. A state space can organize possible configurations without proving that the economy literally consists of points in a pre-given mathematical space. A network model can represent relations without proving that node and edge ontology is fundamental. A field representation can model distributed conditions without establishing a physical field ontology for social life. An agent-based model can operationalize actors without settling the philosophical status of agency. GRE treats such formalisms as analytical constructions whose adequacy depends on the question, assumptions, empirical correspondence, and explanatory gain.

The commitment also protects inquiry against premature reduction. Economic value need not be reduced to price because price is measurable. Institutional recognition need not be reduced to individual preference because choice data are available. Collective capacities need not be reduced to the sum of personal attributes when organizational relations contribute to what can be done. Conversely, relational language does not license the reduction of entities to relations in every context. Relational constitution and relative entityhood can coexist at different scales and for different purposes.

Ontological suspension therefore supports a layered practice of commitment. GRE can commit locally to an operational ontology for a study: it may define firms, households, algorithms, jurisdictions, or communities as analytical units and proceed rigorously within that specification. The suspension concerns the elevation of that local choice into a universal claim. A representation is adequate when it supports warranted inquiry into the relevant mechanism or phenomenon; it becomes ontologically overextended when its convenience is treated as proof that excluded dimensions are unreal or insignificant.

This commitment also preserves the possibility of theoretical correction. New evidence can reveal that an apparently stable entity is internally heterogeneous, that a

presumed relation is mediated by an unobserved institution, or that a category formerly treated as natural is historically contingent. GRE should permit the analytical ontology to change with the inquiry rather than defend the initial representation merely because it was useful at an earlier stage. Ontological suspension is thus not indecision. It is a discipline of keeping the strength of ontological claims proportionate to the work they actually perform.

3.11.2 Partial Observation

GRE assumes that economic observation is structurally partial. Researchers encounter traces, measurements, classifications, documents, transactions, interviews, images, records, behavioral outputs, and other manifestations of processes rather than an exhaustive presentation of the processes themselves. This partiality is not a temporary defect that disappears once sufficiently large datasets are obtained. Even abundant observation remains conditioned by what can be recorded, which categories are used, which events become legible, which populations are included, and which temporal or relational scales are accessible.

Partial observation has several forms. Some variables are simply unobserved. Others are observed through proxies whose validity depends on context. Some relations leave weak administrative traces. Informal activity may be systematically missing from official records. Household labor can remain economically consequential while being absent from market transactions. Platform data can be highly granular while revealing little about off-platform constraints. Historical archives can preserve institutional voices more consistently than marginalized ones. A sensor system can continuously observe behavior while remaining unable to identify meaning or motive. The volume of evidence therefore does not determine its completeness.

The relational character of GRE makes this issue especially consequential. Observing an individual without observing relevant relations can produce a misleading description of capacity, constraint, or choice. A worker's income does not fully disclose bargaining power, household obligations, visa dependence, care responsibilities, access to infrastructure, or exposure to algorithmic evaluation. A firm's balance sheet can omit the public infrastructures, ecological dependencies, cultural resources, or community relations that condition production. A policy's administrative beneficiary list can omit subjects affected through prices, labor markets, household relations, ecological effects, or institutional precedents.

Partial observation also has a temporal dimension. Data may capture a process after important generative events have already occurred. Current inequality can reflect earlier institutional selections that are no longer directly visible. An observed preference can be the result of prior adaptation, exclusion, learning, or habituation. A stable relation may have emerged from a sequence of contingencies that cross-sectional evidence cannot recover. GRE therefore distinguishes observing a current configuration from knowing the history that generated it.

The commitment to partial observation changes how evidence is reported. Missingness, measurement error, selection, proxy construction, archival survival, model dependence, and unobserved mediation should be treated as substantive features of the epistemic situation rather than technical footnotes. A study need not solve every

limitation, but it should identify those that materially affect interpretation. When evidence supports only a restricted claim, the claim should remain restricted.

Partiality also motivates triangulation without turning triangulation into automatic confirmation. Different evidence sources can compensate for different blind spots. Administrative data may establish distributional patterns; interviews can identify mechanisms or meanings absent from records; archival sources can reconstruct institutional change; ethnography can reveal enactment; experiments can isolate effects under constrained conditions; computational traces can show large-scale patterns. Agreement among these sources can strengthen confidence, while disagreement can reveal that they are observing different layers of the process.

GRE therefore treats observability as part of the economic and institutional environment. What becomes observable can itself be shaped by law, technology, organizational incentives, classification systems, and power. Some actors can make their activities legible while others remain invisible; some institutions can require reporting; some platforms can monopolize data; some harms appear only after measurement categories are created. Observation is consequently both an epistemic relation and, in many settings, an object of economic analysis.

3.11.3 Distinction between Relation and Representation

GRE distinguishes the relations under study from the representations through which those relations become analytically accessible. A representation can be a variable, category, graph, matrix, equation, narrative, map, model, legal classification, accounting entry, database schema, or visual diagram. Each representation selects and organizes features of a target domain. None should be treated as identical to the relation merely because it is useful for describing it.

This distinction is fundamental to relational inquiry because representations can create an appearance of precision that exceeds their empirical warrant. A network edge can encode communication, ownership, authority, trust, exchange, co-membership, or inferred association. Two edges of identical graphical form can represent substantively different relations. A weight attached to an edge may record frequency, monetary value, probability, distance, or a model-derived score. The mathematical object is therefore interpretable only through the measurement and theoretical decisions that produced it.

The same issue appears in categorical and institutional representations. A legal category can stabilize a relation for governance without exhausting its social meaning. An accounting classification can make a form of value visible while excluding others. A survey category can facilitate comparison while compressing heterogeneous experiences. An algorithmic score can summarize observed correlates while becoming institutionally consequential through decisions made on its basis. Representation can therefore both describe relations and participate in their transformation.

GRE consequently requires researchers to specify the mapping between representation and target. If “trust” is represented by repeated cooperation, the inferential gap should be stated. If “power” is represented by network centrality, the mechanism connecting centrality to power must be argued rather than assumed. If a latent variable is used to summarize capability, the construction and interpretation of that

variable should remain visible. If text embeddings represent semantic similarity, similarity in the model space should not automatically be equated with shared meaning among subjects.

This distinction also protects formal analysis from reification. A model can derive properties of a representation with complete mathematical rigor while leaving open whether the represented mechanism is empirically operative. Computational sophistication cannot bridge that gap by itself. A simulation result is a consequence of a model and its parameterization. It becomes evidence about an empirical target only through validation, calibration, comparison, and argument connecting the representation to observed processes.

Representations can nevertheless become economically real in a second sense: actors may respond to them. Credit scores, rankings, performance indicators, ratings, risk categories, forecasts, and accounting metrics can alter behavior and resource allocation. The fact that a representation becomes causally consequential does not erase the distinction between representation and relation; it creates an additional relation in which the representation enters the system it describes. GRE should then study both its descriptive adequacy and its performative effects.

Maintaining this distinction enables stronger rather than weaker modeling. It allows researchers to use abstraction aggressively while keeping track of what has been abstracted. A representation can be deliberately narrow if the local question is narrow. The epistemic requirement is transparency concerning what the representation contains, what it excludes, how it was constructed, and which claims can legitimately be inferred from it.

3.11.4 Explicit Boundary and Scale Selection

Every GRE inquiry selects a boundary and scale. The selection determines which entities, relations, periods, jurisdictions, infrastructures, ecological conditions, and forms of value enter the analysis. Because GRE often studies effects that propagate beyond administrative recipients or immediate transactions, boundary selection is an epistemic decision with direct consequences for what can be observed and explained.

A boundary is never justified merely by being available in the data. Firm-level data encourage a firm boundary; household surveys encourage a household boundary; national statistics encourage a national boundary. These sources can be appropriate, but the research question may require a different relational domain. A wage change can affect households, local demand, public revenue, migration, or subcontracting. A technological intervention can change organizational workflows, professional identities, educational demand, and infrastructural dependence. An ecological extraction can produce effects beyond the jurisdiction in which economic value is recorded. The boundary should therefore be selected in relation to the mechanism under investigation.

Scale selection poses a related problem. The individual, organization, community, institution, ecosystem, and transnational system are not simply nested containers with fixed causal priority. A process that appears exogenous at one scale can become endogenous at another. An organizational rule can constrain an individual while being generated by industry regulation, professional norms, or platform infrastructure.

A national policy can appear autonomous until cross-border capital, legal regimes, or supply chains are included. GRE requires the researcher to state which scale is analytically primary and which cross-scale effects are being omitted or modeled.

Explicit selection does not require maximal expansion. The widest possible system boundary is rarely the most useful. Expanding a model can reduce identification, tractability, interpretability, or evidential quality. A bounded inquiry can be superior when the excluded relations are unlikely to alter the conclusion materially. GRE therefore favors justified boundaries rather than maximal boundaries. The researcher should explain why the chosen domain is sufficient for the claim and identify plausible pathways through which excluded relations could matter.

Temporal boundaries require equal attention. A programme evaluated after six months may appear successful while longer-term dependency, capability formation, institutional learning, or ecological cost remains unobserved. Conversely, a long historical window can obscure short-run mechanisms by aggregating distinct institutional regimes. The relevant temporal scale depends on the generation process being studied. Some effects are immediate; others emerge through accumulation, threshold crossing, learning, reproduction, or delayed conversion.

Boundary and scale choices can themselves be politically consequential. Administrative categories define who counts as a beneficiary, employee, resident, household member, owner, victim, or stakeholder. Jurisdictional boundaries determine which costs enter public accounting. Corporate boundaries can externalize labor or ecological relations into subcontracting and supply chains. GRE therefore examines not only the researcher's boundary but also the boundaries through which economic actors and institutions organize responsibility and visibility.

The epistemic commitment is straightforward: boundary and scale should be stated, defended, and revisable. Where conclusions are sensitive to alternative boundaries, that sensitivity is part of the result. A claim that survives reasonable changes in scale has different epistemic status from one that depends on a narrow administrative frame. GRE treats this sensitivity as informative rather than embarrassing because it reveals where economic descriptions are relationally contingent.

3.11.5 Mechanism before Unwarranted Attribution

GRE is interested in generation, propagation, conversion, subject formation, power, orientation, and structural transformation. These concepts can become excessively expansive if they are used to attribute every downstream difference to an initial relation. The fifth epistemic commitment therefore requires mechanism before unwarranted attribution. A relational association or temporal sequence becomes a generative claim only when the study provides a defensible account of how the earlier configuration contributed to the later one.

Mechanism can take different forms. It may involve incentives, authority, learning, information, legal recognition, technological affordances, resource transfer, network diffusion, social interpretation, institutional reproduction, ecological feedback, or strategic adaptation. The relevant mechanism can be probabilistic rather than deterministic and can operate jointly with other causes. GRE does not require a single universal mechanism of generation. It requires the mechanism invoked in a partic-

ular explanation to be specified sufficiently that evidence could distinguish it from plausible alternatives.

This standard is especially important for relational language. A relation between two actors does not automatically explain an outcome merely because the actors are connected. Network position, for example, can matter through access to information, bargaining leverage, reputational visibility, control of brokerage, exposure to contagion, or institutional authority. Different mechanisms can produce similar network patterns. A claim about the economic significance of structure therefore requires more than descriptive topology.

The same discipline applies to power. Persistent asymmetry is relevant to power, but asymmetry alone does not establish the mechanism through which one actor constrains another's options, shapes rules, controls resources, determines classifications, or alters future generative conditions. GRE should identify how asymmetry becomes actionable. Ownership rights, legal authority, infrastructure dependence, agenda control, data access, financial leverage, or control over recognition may provide such mechanisms. Where the pathway remains uncertain, the claim should be framed as a hypothesis rather than a conclusion.

Mechanism also disciplines claims about value conversion. If educational participation is said to generate social capital, which interactions produce continuing relations? If trust is said to generate economic cooperation, what institutional or experiential processes stabilize expectations? If cultural recognition is said to improve economic capability, through which access, motivation, legitimacy, or network pathways does the conversion occur? Naming the initial and final categories is insufficient; the transformation between them is the object that requires explanation.

This commitment does not imply that every GRE study must identify a complete micro-mechanism. Some phenomena are best explained at organizational, institutional, or ecological scales. A legal rule can have a causal effect without being reduced to individual psychology. A market design can alter incentives without reconstructing every subjective deliberation. Mechanistic adequacy is scale-relative. The requirement is that the explanatory link be more specific than a retrospective association and that the proposed pathway fit the level at which the claim is made.

Mechanism before attribution also protects normative analysis. Harm should not be assigned to a particular actor or intervention merely because the harm occurred within a broader relational system. Responsibility can be distributed, mediated, historically inherited, or structurally reproduced. Normative attribution may therefore require a separate analysis of control, foreseeability, benefit, capacity, institutional role, and available alternatives. GRE's relational orientation expands the field of possible responsibility while simultaneously requiring greater care in attributing it.

3.11.6 Historical and Contextual Dependence

GRE treats economic categories, mechanisms, and regularities as potentially dependent on historical and institutional context. This commitment follows from the earlier chapters' emphasis on changing productive relations, subject forms, technologies, norms, legal categories, and value structures. A relation that operates in one institutional environment may change meaning or effect in another. Historical and

contextual dependence therefore constrains generalization without eliminating the possibility of general knowledge.

Context dependence can enter through mechanisms. Credit can expand productive capacity in one institutional setting and reinforce dependence in another. Informal networks can provide resilience where formal systems are weak while reproducing exclusion where membership is restrictive. Algorithmic evaluation can reduce some forms of discretion while creating new informational asymmetries and dependencies. A cooperative structure can enable collective control under supportive legal and financial conditions yet remain marginal under a regime that withholds access to capital or procurement. The nominal form of a relation therefore does not uniquely determine its generative effects.

Historical dependence also affects categories. The economic meaning of "worker," "firm," "household," "property," "skill," "platform," or "currency" is shaped by institutional arrangements that change over time. A category can retain its name while the relations that constitute it transform. GRE should therefore avoid treating administrative continuity as proof of substantive continuity. Historical reconstruction can be necessary even when contemporary data appear precise.

The commitment does not require every proposition to be historically unique. Recurrent mechanisms can be identified across cases, and comparative analysis can reveal robust patterns. The epistemic task is to specify the domain of portability. A mechanism may generalize across institutional settings under identifiable conditions; a formal model may describe a family of processes; a causal effect may transport when relevant effect modifiers are sufficiently similar. GRE therefore distinguishes universalizing language from conditional generalization.

Context dependence also concerns meaning. Economic actors interpret rules, resources, risks, and opportunities through historically situated symbolic and normative frameworks. The same monetary transfer can signify compensation, obligation, charity, recognition, debt, or entitlement in different settings, with different relational consequences. Interpretive evidence can therefore be necessary when the mechanism depends on how actors understand the relation.

The historical commitment extends to the researcher's categories and methods. Measures calibrated in one period can lose validity as institutions change. A proxy for employment stability can fail when contractual forms transform. A model of media attention can become obsolete after a platform redesign. A measure of technological capability can change meaning as complementary infrastructures diffuse. GRE should treat measurement regimes as historically situated rather than assume that a stable variable label guarantees stable construct validity.

This commitment encourages temporal comparison and repeated evaluation. A finding can be valid for the period studied and later require revision because the object changed. Such revision does not necessarily invalidate the earlier research; it can reveal the historical conditions under which the earlier claim held. GRE therefore regards the temporal domain of a claim as part of its specification.

3.11.7 Methodological Pluralism

Methodological pluralism is an epistemic commitment because no single method has privileged access to every aspect of a generative relational process. Quantitative estimation, qualitative interpretation, historical reconstruction, formal modeling, computational simulation, comparative analysis, experiments, ethnography, archival work, network analysis, and participatory methods each make some features more visible and others less so. GRE therefore treats methods as differentiated instruments of inquiry whose adequacy depends on the claim being made.

Pluralism differs from methodological eclecticism without standards. The presence of several methods does not strengthen a study automatically. Each method must contribute an identifiable epistemic function. A qualitative study can identify mechanisms and meanings that guide quantitative measurement. A quantitative design can estimate the distribution or magnitude of an effect suggested by qualitative evidence. Historical analysis can reveal institutional transitions that make a cross-sectional association intelligible. Formal modeling can clarify whether a proposed mechanism is internally coherent. Simulation can explore trajectories under specified assumptions. Their combination is valuable when the outputs constrain or inform one another.

Pluralism also means that methodological disagreement can be productive. If administrative data indicate improved employment while interviews reveal increased insecurity, the discrepancy may reflect different populations, time horizons, definitions, or dimensions of the outcome. GRE should investigate the divergence rather than force immediate convergence. Different methods can reveal multiple aspects of a heterogeneous value structure or relational configuration.

No hierarchy follows automatically from formal precision. Mathematical and computational methods can make assumptions explicit, derive implications, and handle complexity that prose alone cannot. Their precision concerns the representation once specified. Empirical relevance still depends on the quality of the mapping between model and target. Conversely, qualitative richness does not eliminate the need for disciplined inference. Interpretive accounts require transparent evidence, plausible alternatives, and attention to scope. Historical narratives require source criticism. Normative arguments require defensible premises. Methodological pluralism therefore expands the repertoire of rigor rather than relaxing it.

The commitment also preserves compatibility with established economics. GRE does not require replacing econometrics, experiments, equilibrium analysis, mechanism design, industrial organization, public economics, labor economics, or other established approaches when they answer the relevant question well. A GRE inquiry can incorporate these methods and add relational or generative analysis where it materially changes explanation. Pluralism includes the possibility that the best answer to a bounded question is supplied by an existing method without specifically GRE additions.

Pluralism has institutional implications for research design. Data infrastructures, publication norms, disciplinary training, and funding systems often privilege some evidence types over others. A research programme that studies heterogeneous relational processes must resist converting institutional convenience into epistemic hi-

erarchy. This does not mean every project must be interdisciplinary. It means that exclusions among methods should be justified by the question rather than inherited uncritically from disciplinary boundaries.

The strongest form of methodological pluralism in GRE is mutual corrigibility. Formal models can expose ambiguity in conceptual claims. Historical evidence can show that apparently universal categories are contingent. Qualitative evidence can reveal omitted mechanisms. Causal designs can challenge compelling narratives. Computational models can test whether proposed local rules produce the claimed system-level pattern. Normative analysis can reveal that an empirically efficient intervention depends on contested evaluative premises. Methods become part of a common research programme when they can correct one another without being forced into a single epistemology.

3.11.8 Revisability of Analytical Categories

GRE treats its analytical categories as revisable. Relation, subject, value, capacity, institution, field, constraint, trajectory, generativity, and power are working concepts whose definitions should become more precise through research. The commitment to revisability follows from ontological suspension and historical dependence: if the objects of inquiry can change and if different representations disclose different aspects of them, then the vocabulary of the research programme cannot be permanently fixed at its founding stage.

Revisability does not imply conceptual looseness. A study should define its categories precisely enough to support inference. The revision occurs when evidence, theoretical contradiction, cross-case comparison, or improved formalization shows that the existing category fails. The relevant distinction is between local precision and global finality. GRE can use a precise operational definition while remaining open to revising that definition in later research.

Category revision can take several forms. A category can be subdivided when previously hidden heterogeneity becomes important. Several categories can be combined when distinctions prove analytically unproductive. Boundaries can change when new relations become visible. A category can move from exogenous condition to endogenous object of inquiry. A variable treated as an attribute can be reconceptualized as relationally generated. A representation can be abandoned if it systematically misclassifies the phenomenon.

Economic subjecthood provides one example. A research programme built exclusively around human individuals would be strained by organizations, automated systems, collective entities, or hybrid arrangements that make economically consequential selections. Expanding the category of operational economic subject can improve analysis, but that revision need not erase distinctions concerning consciousness, personhood, legal standing, or moral status. Revisability allows the category to change while preserving distinctions that remain normatively or empirically necessary.

Value provides another example. Price can remain a central economic representation of value without exhausting the relevant evaluative or relational phenomena. Research can discover forms of value whose realization depends on access, recognition, participation, ecological capacity, institutional continuity, or future capability.

Revising the analytical vocabulary to capture these forms does not require treating them as commensurable or collapsing them into a single metric.

Revisability also applies to GRE itself. Concepts introduced in this book are provisional elements of a research programme rather than protected doctrine. Later empirical work may show that some distinctions are unproductive, that other concepts are missing, or that the framework overstates the usefulness of generative analysis in particular domains. A research programme becomes cumulative not by preserving every founding category but by creating procedures through which categories can be criticized, compared, refined, and replaced.

This commitment places a burden on documentation. When categories change across studies or over time, researchers should record how definitions differ and why. Conceptual drift can otherwise appear as empirical change. GRE therefore favors transparent conceptual provenance: the history of a category's operationalization is part of the knowledge needed to compare results.

3.11.9 Epistemic Humility

Epistemic humility is the concluding commitment because it governs the relation among all the preceding ones. It requires the strength, scope, and precision of a claim to remain proportionate to the evidence and argument that support it. Humility does not require weak conclusions where strong conclusions are justified. It requires researchers to distinguish what has been observed from what has been inferred, what has been modeled from what has been validated, what is locally supported from what is generalized, and what is normatively defended from what is empirically established.

In relational economic inquiry, overstatement can arise easily because the studied systems are interconnected. Once a downstream effect is observed, it is tempting to narrate a complete chain of generation. Once a network pattern appears, it is tempting to attribute power or influence. Once a simulation reproduces a stylized fact, it is tempting to treat the mechanism as confirmed. Once an intervention succeeds locally, it is tempting to generalize it across contexts. Epistemic humility interrupts these moves by requiring an explicit account of the inferential bridge.

Humility also concerns uncertainty that cannot be reduced to a probability estimate. Researchers can face model uncertainty, category uncertainty, boundary uncertainty, interpretive disagreement, historical incompleteness, unknown unknowns, or normative pluralism. Quantification is valuable when a defensible probability model exists, but not every epistemic limitation is probabilistic. GRE therefore permits qualitative statements of uncertainty where numerical precision would be misleading.

The commitment is especially important for intervention. Application-dominant praxis often requires action before knowledge is complete. Epistemic humility does not imply inaction under uncertainty. It changes how intervention is designed: assumptions are made explicit, monitoring is built in, reversible steps are preferred where feasible, affected subjects retain opportunities for contestation, and the intervention is treated as a source of new evidence rather than the execution of a final truth. Learning and governance become coupled.

Humility also requires attention to the distribution of epistemic authority. Researchers, administrators, firms, communities, workers, users, and affected populations can possess different forms of knowledge. Expertise can be real without being total. Local experience can identify mechanisms invisible to aggregate data while remaining limited in scope. Institutional actors can possess operational information while having incentives to frame it selectively. GRE therefore treats disagreement among knowledge holders as an object for analysis rather than assuming that one standpoint has automatic priority across all questions.

This commitment extends to artificial and computational systems. Large models, automated inference, and high-dimensional data can increase the scale and speed of analysis, but they do not eliminate uncertainty concerning data generation, representation, causal identification, normative criteria, or institutional effects. Computational confidence can be numerically precise while remaining epistemically narrow. GRE should therefore distinguish predictive performance from explanatory adequacy, statistical calibration from normative legitimacy, and representational capacity from knowledge of the target process.

Epistemic humility finally concerns the research programme's own historical position. GRE is being constituted under particular contemporary conditions: changing productive relations, computational abundance, new forms of artificial capability, ecological constraints, institutional complexity, and increasing visibility of relational and generative processes. These conditions make the programme plausible and potentially useful; they do not guarantee its enduring adequacy. Future economic forms may require different concepts. Existing theories may explain domains where GRE adds little. Evidence may contradict central hypotheses. The programme should be organized so that such correction is possible without treating revision as failure.

Taken together, the commitments of this section define a disciplined epistemic posture for Generative Relational Economics. GRE can make strong claims, employ sophisticated formalisms, combine diverse evidence, and participate in intervention, but it should do so while suspending unnecessary ontological conclusions, acknowledging partial observation, separating relations from their representations, making boundaries and scales explicit, demanding mechanisms for attribution, locating claims historically, preserving methodological pluralism, revising categories when required, and calibrating confidence to warrant. These commitments prepare the transition from inquiry to praxis. The following section turns to how GRE moves from explanation and evaluation toward relational diagnosis, generative diagnosis, and intervention under conditions where knowledge remains necessarily incomplete.

3.12 Praxis in Generative Relational Economics

The preceding sections established the objects, scales, questions, analytical perspective, modes of inquiry, and epistemic commitments of Generative Relational Economics. Those elements define how GRE can study economic relations, but a research programme concerned with generative conditions also requires an account of how inquiry can enter practice. The role of this section is to specify a preliminary praxis architecture for GRE: a disciplined way of moving from explanation toward interven-

tion while preserving the epistemic restraints developed above. Its objective is not to provide a universal policy cycle or a general theory of governance. It identifies a recurrent sequence of practical operations through which relational and generative knowledge can inform action under conditions of incomplete knowledge, heterogeneous values, changing environments, and effects that propagate beyond the administratively designated recipient.

GRE praxis begins from a distinction between understanding a system and acting within it. Explanation can identify mechanisms, constraints, distributions, histories, and relational structures, yet intervention changes the very configuration that explanation describes. An intervention can redistribute resources, alter expectations, create or dissolve relations, redefine institutional categories, shift bargaining positions, generate new dependencies, reorganize attention, and modify later capacities for action. Praxis therefore cannot be represented as the simple application of a finished model to a passive target. It is an entry into an evolving relational domain in which the intervention, the affected subjects, the environment, and the relevant knowledge can all change through their interaction.

For that reason, the praxis architecture developed here is iterative. It moves through relational diagnosis, generative diagnosis, identification of constraints and enabling conditions, intervention design, allocation understood as relational intervention, tracing of downstream effects, feedback and revision, adaptive governance, and, where required, withdrawal, reversal, or repair. These operations can overlap, recur, or be entered from different points. They are not a mandatory sequence imposed on every practical problem. Their function is to prevent a narrow intervention logic in which resources are allocated, an immediate output is measured, and wider changes are treated as externalities unless they happen to fit the original administrative frame.

The praxis perspective also preserves the distinction between research-dominant and application-dominant activity. Research-dominant praxis principally seeks improved understanding, even when research design itself changes the studied field. Application-dominant praxis principally seeks to alter an economic or institutional situation under practical constraints. The difference concerns orientation rather than an absolute separation between knowledge and action. Research can generate interventions, and interventions can generate knowledge. GRE therefore treats praxis as a domain in which explanation, evaluation, experimentation, governance, and learning become coupled while remaining analytically distinguishable.

A further constraint is normative. Generativity is not itself a sufficient criterion of success. An intervention can generate economic activity while deepening dependence, produce capabilities for one group while foreclosing possibilities for another, increase circulation while accelerating extraction, or create institutional stability by suppressing exit and contestation. Section 3.12 therefore develops the architecture of intervention without resolving the normative standards by which generated consequences should be judged. Those standards are taken up in the following section. Here the central concern is more basic: how GRE can intervene without treating either the target of intervention or the intervention's own consequences as fixed in advance.

3.12.1 From Explanation to Intervention

The movement from explanation to intervention is a change in epistemic and practical burden. Explanatory inquiry asks what relations, mechanisms, histories, and conditions contributed to an observed pattern. Intervention asks what may happen if some part of that configuration is deliberately altered. The second question contains the first but adds counterfactual, organizational, ethical, and temporal demands. A mechanism that explains a past outcome may not remain invariant after actors learn about the intervention, institutions adapt, or the distribution of resources changes. GRE therefore resists the assumption that an explanatory model can be converted directly into a policy instrument without re-examining the relations through which the intervention will operate.

A practical intervention enters a field already structured by prior relations. Subsidizing a household, financing a firm, redesigning a public service, opening access to data, changing a legal entitlement, or introducing an artificial system does more than modify one variable. It can alter who interacts with whom, which claims become enforceable, which actions become feasible, whose knowledge becomes authoritative, and which future trajectories become easier to sustain. The intervention should therefore be represented not only by its administrative action but also by the relational changes through which its consequences may be mediated.

This perspective changes the meaning of implementation. Implementation is often treated as the stage in which a previously selected intervention is executed with fidelity. GRE instead treats implementation as an epistemically productive period in which assumptions about relations, mechanisms, and capacities encounter an evolving empirical configuration. Deviations from the original design can indicate administrative failure, but they can also reveal that the initial model omitted relevant actors, constraints, interpretations, or feedback mechanisms. Praxis requires distinguishing avoidable execution error from informative evidence that the intervention theory requires revision.

The transition from explanation to intervention also introduces strategic interaction. Subjects can anticipate policy, resist classification, exploit new opportunities, reorganize coalitions, change reporting behavior, or redirect resources. Organizations can internalize an intervention into routines that differ from its stated purpose. Platforms can redesign interfaces in response to regulation. Beneficiaries can combine an allocation with household, community, or informal resources in ways that produce unanticipated effects. These responses are part of the relational system rather than noise surrounding an otherwise fixed treatment.

GRE therefore favors interventions whose theory of change states at least four elements. First, it identifies the relevant relations through which the intervention is expected to operate. Second, it specifies the generative claim: what capacities, structures, opportunities, constraints, or forms of value are expected to emerge or transform. Third, it states the anticipated temporal and scalar pathways through which effects may propagate. Fourth, it identifies observations that would count against the intervention theory. The resulting design remains provisional, but its provisionality is disciplined rather than vague.

Intervention under uncertainty does not imply paralysis. Many economic and gov-

ernance problems require action before the relational system is fully known. The practical question is how to make action compatible with learning. GRE therefore gives special weight to staged implementation, monitoring, contestability, modularity, reversible components, and explicit review points where feasible. These features do not eliminate uncertainty. They reduce the cost of discovering that the intervention has altered the field in ways the initial explanation did not anticipate.

3.12.2 Relational Diagnosis

Relational diagnosis identifies the configuration within which the practical problem is constituted. Its purpose is not to produce an exhaustive map of all social relations. It asks which relations are materially relevant to the problem, how they are organized, which boundaries have been selected, and where the apparent administrative object depends on actors or conditions outside that boundary. Diagnosis therefore precedes intervention design because the same nominal problem can require different action when its relational constitution differs.

A relational diagnosis begins by identifying the subjects, organizations, institutions, infrastructures, symbolic systems, and ecological conditions that participate in the relevant economic situation. It then asks how access, authority, recognition, information, resources, obligations, and opportunities are distributed among them. The resulting map may be qualitative, quantitative, historical, network-based, institutional, or mixed. Its adequacy depends on whether it reveals relations that are necessary to understand the practical problem rather than on whether it maximizes representational complexity.

Consider a programme intended to improve employment access. An administrative diagnosis might begin with unemployed individuals and available jobs. A relational diagnosis can reveal additional mechanisms: transportation, childcare, credential recognition, social networks, disability access, hiring intermediaries, platform ranking, visa status, household obligations, employer risk practices, or regional housing costs. These are not automatically the correct variables in every case. Their relevance depends on whether they mediate the conversion of an employment opportunity into an actual capability to obtain and sustain work.

Relational diagnosis also identifies asymmetry. The relevant question is not only who possesses more resources, but which actors can define categories, set terms of exchange, control infrastructures, impose switching costs, delay decisions, externalize risk, or withdraw without comparable loss. Two actors may exchange voluntarily while facing highly unequal exit conditions. A platform and a small supplier may both be organizations, yet their capacity to redesign the interaction can differ drastically. Diagnosing these asymmetries matters because an intervention that treats formally similar actors as substantively equivalent can reproduce the mechanism that generated the problem.

The diagnosis should also be historical. Present relations can depend on prior institutional settlements, accumulated debts, inherited infrastructures, past exclusions, or sequences of investment that make current alternatives unequally costly. A cross-sectional map can show who is connected to whom while missing why the relation has its present form or why some apparently available alternatives are prac-

tically inaccessible. Historical reconstruction helps distinguish a relation that is contingent and readily modifiable from one stabilized by layered commitments and path-dependent investments.

The output of relational diagnosis is therefore a bounded working representation of the practical field. It should make its exclusions visible. No map captures every relation, and an attempt to include everything can make intervention impossible. GRE instead requires an explicit statement of which relations are treated as inside the diagnostic boundary, which are treated as environmental conditions, and which remain uncertain. The map is revisable as intervention reveals previously hidden dependencies.

3.12.3 Generative Diagnosis

Relational diagnosis identifies the configuration; generative diagnosis asks what that configuration tends to produce. The distinction matters because the same relational structure can be significant for different reasons depending on the processes it sustains. A credit relation can generate productive capacity, dependency, reputational effects, data, bargaining power, future borrowing opportunities, or combinations of these. A school can distribute instruction while also generating networks, credentials, expectations, classifications, and future access. A platform can facilitate exchange while generating information asymmetries, behavioral dependence, market visibility, or new organizational capabilities.

Generative diagnosis therefore focuses on transformations rather than only states. It asks what changes because a relation persists, intensifies, weakens, or is removed. The relevant outcomes can include resources, capacities, identities, institutional routines, legal positions, expectations, symbolic categories, ecological conditions, or the ability to enter later relations. This focus is particularly important when immediate outputs are poor proxies for longer-horizon consequences. A grant may be fully disbursed while failing to produce the organizational capacity it was intended to support. A training programme may improve measured skills while weakening participation because the credential is not institutionally recognized. A subsidy may increase adoption while entrenching dependence on a proprietary infrastructure.

The generative diagnosis should distinguish several pathways. Some effects arise directly from the intervention target. Others are mediated through relations with third parties. Some emerge from feedback: an initial change alters behavior, which changes the environment faced by later participants. Some effects accumulate only after repeated interactions. Others occur through symbolic or classificatory change, where being recognized as eligible, risky, employable, innovative, or compliant modifies later treatment by institutions.

Generative diagnosis also asks what is reproduced. A relational configuration may produce no dramatic new outcome while continually regenerating a distribution of advantage, vulnerability, or access. Stable inequality can be generative in this sense because institutions repeatedly convert initial asymmetries into later opportunities. Conversely, a relation can sustain capabilities that would deteriorate if the relation disappeared. Maintenance, reproduction, and repair are therefore forms of generation when they preserve conditions that require continuing relational work.

A further question concerns foreclosure. Generation can expand possibilities for some actors while reducing the future option set for others or for the same actors at a later time. Infrastructure investment can enable activity while creating technological lock-in. Debt can finance capacity while narrowing future discretion. Standardization can reduce coordination costs while suppressing alternative forms of practice. Generative diagnosis therefore traces both enabling and constraining transformations without assuming that generation is uniformly expansive.

The practical output of generative diagnosis is a set of plausible mechanism pathways linking the relational configuration to changes that matter for the intervention. These pathways can be compared, tested, revised, or ranked by evidential support. GRE does not require every pathway to be fully identified before action. It requires the intervention to state what it expects to generate and why, so that later observations can update rather than merely decorate the original theory.

3.12.4 Identification of Constraints and Enabling Conditions

Diagnosis becomes actionable when it identifies conditions that limit or enable transformation. GRE uses constraint in a broad but disciplined sense: a constraint changes the set, cost, probability, or viability of available transformations without necessarily making an action logically impossible. Enabling conditions operate in the opposite direction by making some transformations more feasible, durable, or accessible. The same condition can constrain one pathway while enabling another.

Constraints can be material, institutional, relational, informational, temporal, symbolic, ecological, or cognitive. A lack of capital is a material constraint, but the ability to use capital may depend on licenses, trusted partners, language access, data, infrastructure, or the timing of payments. A legal entitlement can exist while remaining practically inaccessible because procedural complexity, documentation requirements, or fear of institutional contact limits its use. An organization can possess technical capacity while lacking the authority to deploy it. A community can possess knowledge while lacking channels through which institutions recognize that knowledge as actionable.

The distinction between constraint and symptom is central. Low participation can be treated as a behavioral problem and addressed through incentives, yet the underlying constraint may be timing, distrust, inaccessible procedures, reputational risk, or exclusion from the networks through which information circulates. Raising an incentive can improve participation while leaving the deeper constraint unchanged, or it can worsen inequality if only already advantaged actors can respond. Constraint identification therefore asks which conditions actually regulate the transformation pathway relevant to the intervention.

Enabling conditions deserve equal analytical attention. Praxis often becomes overly problem-centered and maps only deficits. Existing trust relations, local organizations, informal knowledge, public infrastructure, legal protections, professional norms, ecological capacities, and mutual-aid practices can already support generation. An intervention that ignores these conditions can displace them with a formal system that appears more legible while being less generatively capable. GRE therefore asks which existing relations should be preserved, strengthened, connected, or

left undisturbed.

Constraints and enabling conditions are also scale-relative. A national regulation can constrain an organization while enabling fairer competition across a sector. A household norm can constrain an individual's labor-market participation while enabling care provision that sustains other members. A standardized protocol can constrain local discretion while enabling interoperability. Praxis requires representing these tensions rather than declaring a condition simply enabling or constraining in the abstract.

The identification process should therefore produce intervention points rather than a flat inventory. Some constraints are proximal and modifiable; others are structural conditions that cannot be changed within the intervention horizon. Some enabling conditions can be activated with modest resources; others require institutional reform. Distinguishing these categories helps prevent designs that target visible but weakly generative variables while leaving the mechanisms of exclusion or capacity formation intact.

3.12.5 Intervention Design

Intervention design translates diagnosis into a provisional configuration of actions, resources, institutions, and learning procedures. GRE does not require a distinctive policy instrument. Taxes, transfers, public investment, regulation, organizational redesign, information provision, infrastructure, standards, cooperative arrangements, educational programmes, platform rules, procurement, or combinations of these can all be compatible with GRE. What distinguishes the praxis perspective is how the intervention is specified: in relation to mechanisms, downstream generation, scale, feedback, and revisability.

A GRE intervention should first identify its operative target. The target can be a resource constraint, a relation, a conversion mechanism, an institutional rule, a boundary, a feedback loop, an information structure, or an enabling condition. Target clarity matters because interventions with the same administrative recipient can act through different mechanisms. A cash transfer and a childcare service may both support household economic participation, but they alter different constraints and relational structures. Their effects should not be inferred from the shared identity of the recipient.

Second, intervention design should distinguish the intended immediate change from the intended generative effect. Providing equipment is an immediate allocation. Developing a durable productive capacity may be the generative objective. Changing a regulation is an immediate institutional act. Increasing entry, reducing dependency, or enabling new organizational forms may be the intended downstream effect. This distinction makes it possible to observe successful implementation together with failed generation, or imperfect implementation together with unexpected generative benefits.

Third, design should state relevant temporal horizons. Some interventions seek rapid stabilization; others seek capacity formation whose effects appear slowly. A short evaluation window can misclassify a long-horizon intervention as ineffective or reward interventions that produce immediate outputs by drawing down future re-

sources. GRE therefore encourages explicit differentiation among immediate, intermediate, and longer-horizon effects without assuming that longer is always better.

Fourth, intervention design should anticipate heterogeneity. Subjects differ in resources, vulnerabilities, interpretation, institutional status, and ability to convert an allocation into later capacity. Uniform provision can therefore generate unequal outcomes. The design question is not necessarily to individualize every intervention, which can become administratively costly or intrusive. It is to identify forms of heterogeneity that are mechanism-relevant and to determine whether adaptive, tiered, or plural pathways are needed.

Fifth, design should include learning architecture. Monitoring variables, qualitative feedback, review intervals, stop conditions, and procedures for incorporating affected participants should be established before implementation where possible. This prevents evaluation from becoming an after-the-fact search for favorable indicators. It also recognizes that some of the most important effects may be discovered only after the intervention enters the field.

Intervention design in GRE is therefore closer to constructing a revisable relational hypothesis than to selecting a fixed treatment. The design states what is being changed, through which relations, toward which generative effects, under which assumptions, across which scales and time horizons, and with what procedures for detecting error. The resulting intervention can still be administratively simple. Analytical sophistication does not require operational complexity when the mechanism is clear.

3.12.6 Allocation as Relational Intervention

Allocation is a central economic operation, but GRE treats allocation as the beginning of a relational process rather than its endpoint. Money, time, attention, infrastructure, rights, data access, institutional recognition, expertise, or productive assets enter existing relations when allocated. Their consequences depend on conversion conditions, obligations, expectations, complementary resources, and the position of the recipient within wider structures.

This perspective changes the unit of practical analysis. A transfer to an individual may affect a household, landlord, creditor, employer, local market, or platform through expenditure, bargaining, debt repayment, mobility, or information. Funding an organization can change its internal authority, external partnerships, reputational standing, and future ability to attract resources. Granting data access can create research capacity while redistributing informational advantage. Allocation therefore changes relations even when the formal instrument is directed to a discrete recipient.

Relational allocation does not mean that every allocation must be socially conditioned or collectively administered. Direct individual transfers can be valuable precisely because they reduce dependence on gatekeepers. The analytical point is that the intervention should ask what relations the allocation enters or transforms. An unconditional transfer can weaken a coercive relation by increasing exit capacity. A conditional transfer can create a new monitoring relation. A loan can expand productive capacity while strengthening a creditor's claims. The relational effects depend on design and context rather than on the category of instrument alone.

Allocation also has temporal structure. Resources can be consumed, invested, circulated, pooled, converted, or used to maintain existing capacities. Timing can determine which pathway becomes viable. A delayed payment can destroy a fragile organization even if the total allocation is adequate. A predictable stream can generate planning capacity beyond its nominal monetary value. A one-time grant can enable experimentation but fail to sustain maintenance. GRE therefore treats schedule, predictability, reversibility, and duration as properties of the allocation relation.

The recipient itself may be generated through allocation. Programmes define eligibility categories, create beneficiary identities, establish reporting obligations, and sometimes produce organizations capable of receiving funds. Public procurement can constitute firms as qualified suppliers. Credit scoring can define economically consequential categories of risk. Allocation systems therefore participate in the production of subjects and classifications, not merely in the distribution of pre-existing resources among them.

For praxis, the implication is that allocation should be evaluated through both direct transfer and relational transformation. The relevant questions include what capacity the resource creates, what dependencies accompany it, what complementary conditions are required, which actors gain authority, how value is recirculated or extracted, and what happens when the allocation stops. These questions extend ordinary allocation analysis rather than replacing it.

3.12.7 Tracing Downstream Effects

Once an intervention enters a relational field, praxis requires tracing effects beyond its immediate output. Downstream tracing follows the propagation, conversion, recirculation, dissipation, extraction, and stabilization of changes generated by the intervention. The purpose is not to attribute every later event to the intervention. It is to identify plausible pathways through which initially local changes become economically consequential elsewhere or later.

Downstream effects can be direct, mediated, recursive, or displaced. A subsidy can increase demand directly, alter supplier investment through expectation, change local prices through market response, and affect future policy through political interpretation. A new infrastructure can reduce transport costs, reorganize land values, change settlement patterns, and later alter fiscal capacity. A platform rule can affect user behavior, which changes the data used by the platform, which then changes ranking or recommendation, producing a recursive effect.

Tracing requires temporal discipline. Early indicators can differ from later effects because actors adapt and complementary investments emerge. Some harms are delayed. Some benefits require repeated interaction before they become visible. GRE therefore distinguishes outcome timing from causal distance. An effect that occurs quickly can still be relationally distant if it is mediated through several actors, while a delayed effect can arise from a simple accumulation mechanism.

Tracing also requires counterfactual restraint. Observing a later change in a connected actor does not prove that the intervention generated it. Evidence can come from experimental or quasi-experimental designs, process tracing, comparative cases, administrative sequences, qualitative testimony, network change, simulation,

or combinations of these. The method should match the claim. The broader the asserted downstream attribution, the greater the burden of distinguishing intervention effects from concurrent change.

Some downstream effects concern value conversion rather than magnitude. An allocation can be converted into political influence, social recognition, technical capacity, ecological pressure, or future access. These forms may not be commensurable with the original resource. Tracing therefore cannot always be reduced to adding monetary benefits and costs. GRE can use monetary valuation where appropriate while preserving additional dimensions when conversion into a scalar measure would erase mechanism-relevant differences.

The practical function of downstream tracing is to maintain contact between intervention and evolving reality. It provides evidence for revision, identifies beneficiaries or harmed parties omitted from the original frame, and detects when an intervention's generative pathway has changed. It also prevents a programme from declaring success solely because the administratively proximate output was delivered as planned.

3.12.8 Feedback and Revision

Feedback converts intervention into learning when observations are allowed to alter the intervention theory and design. GRE distinguishes feedback from mere monitoring. Monitoring records whether specified indicators change. Feedback becomes analytically consequential when those observations can revise assumptions about relations, mechanisms, boundaries, timing, subject heterogeneity, or normative effects.

A useful feedback architecture separates implementation evidence from generative evidence. Implementation evidence asks whether the intervention occurred as intended: funds reached recipients, infrastructure was built, a rule was applied, or a service became available. Generative evidence asks whether the intended transformations followed and what additional transformations occurred. Maintaining this distinction prevents implementation fidelity from being mistaken for substantive success.

Revision can occur at several levels. Parameters can be adjusted while the intervention theory remains intact. Delivery can change because conversion conditions differ across groups. The relational target can change when a hidden intermediary becomes visible. The generative objective itself can be revised when the original aim proves infeasible, harmful, or normatively contested. In more substantial cases, the intervention can reveal that the original problem representation was wrong and requires reconstruction.

Feedback should include affected subjects where their experience provides access to mechanisms or harms not visible in aggregate indicators. Participation is not automatically epistemically superior; local actors can disagree, possess partial information, or face incentives that shape reporting. Their knowledge nevertheless belongs to the evidential field. A feedback system that listens only to administrative data can systematically miss changes in trust, dignity, informal burden, strategic adaptation, or hidden exclusion.

Revision also requires institutional capacity. An organization can collect excellent evidence yet be unable to change because budgets, legal mandates, procurement contracts, professional incentives, or political commitments lock the intervention into its original form. GRE therefore treats the ability to revise as part of intervention design. Review authority, modular contracts, contingency funds, sunset clauses, and explicit decision rules can create practical room for learning, where appropriate.

Feedback is thus not a final stage after implementation. It is a continuing relation between action and evidence. Praxis becomes adaptive when the intervention is organized so that new information can change subsequent action without abandoning accountability or making goals infinitely movable.

3.12.9 Adaptive Governance

Adaptive governance is the institutionalization of revision under changing conditions. It becomes relevant when the intervention affects a system whose relations, actors, or environment evolve on a time scale comparable to the governance process. In such settings, a one-time optimal design can become obsolete even if it was well justified when adopted. GRE therefore treats governance as an ongoing arrangement for observing, deciding, revising, coordinating, and contesting changes in a relational field.

Adaptation does not mean continuous discretionary change. Constant revision can destroy predictability, undermine investment, and make rights dependent on administrative mood. Stable rules can themselves be enabling conditions. Adaptive governance therefore requires deciding which elements should remain stable and which should be revisable. Constitutional protections, procedural rights, or long-horizon commitments may provide a stable frame within which parameters, implementation mechanisms, or experimental components can change.

The architecture of adaptation should match the distribution of knowledge and consequence. Centralized revision can coordinate across regions and prevent local capture, while decentralized adaptation can respond to context and reveal heterogeneous mechanisms. Multi-level governance can combine these functions when authority, information, and accountability are allocated explicitly. GRE does not presume decentralization to be intrinsically more relational or generative. The relevant question is which governance structure can perceive and respond to the mechanisms that matter while preserving legitimate constraints on power.

Adaptive governance also involves threshold decisions. Some observed variation is noise; some indicates a changing mechanism. Revising too quickly can chase temporary fluctuations, while revising too slowly can entrench harm. Governance therefore needs criteria for escalation, experimentation, suspension, and review. These criteria can be quantitative, qualitative, procedural, or mixed depending on the domain.

Learning across cases is another component. Local adaptation can generate knowledge that becomes useful elsewhere, but portability requires comparison of mechanisms and boundary conditions. A successful intervention in one institutional environment may fail where trust, infrastructure, legal authority, or subject composition differs. Adaptive governance therefore builds cumulative knowledge by documenting not only whether an intervention worked, but under which relational conditions

and through which pathway.

At its strongest, adaptive governance alters its own learning capacities. Monitoring systems improve, categories are revised, participation channels change, and institutional memory accumulates. Governance thereby becomes a generative process whose output includes future ability to govern. This recursive feature is central to GRE praxis: the intervention should be evaluated partly by whether it leaves the system more capable of perceiving, contesting, and responding to later problems.

3.12.10 Withdrawal, Reversal, and Repair

A praxis architecture is incomplete if it specifies how to begin and revise interventions but not how to stop them. Withdrawal, reversal, and repair are distinct practical operations. Withdrawal ends or reduces an intervention. Reversal seeks to restore a prior condition or undo a change where feasible. Repair addresses harms, dependencies, damaged relations, or lost capacities that persist after withdrawal. GRE treats these operations as part of intervention design rather than exceptional responses to obvious failure.

Withdrawal can be required for several reasons. An intervention may fail to generate its intended effect, produce unacceptable harm, become obsolete as conditions change, or create costs that exceed its continuing value. It can also succeed so thoroughly that the intervention is no longer required. A temporary guarantee, emergency subsidy, or transitional institution should not become permanent merely because its removal was never designed.

Stopping an intervention can itself be generatively consequential. Organizations may have invested around a subsidy, households may depend on a service, communities may have reorganized around infrastructure, or markets may have adapted to a regulatory regime. Abrupt withdrawal can therefore destroy capacities that the intervention helped create. Exit design should consider notice, transition periods, transfer of responsibilities, preservation of useful infrastructure, and the distribution of adjustment costs.

Reversal is more demanding because relational change is often path dependent. Restoring a prior rule does not necessarily restore the prior system. Actors have learned, investments have shifted, expectations have changed, and some capacities may have disappeared. A policy reversal can therefore create a third configuration rather than return to the first. GRE treats reversibility as a graded property: some components can be reversed mechanically, others only approximately, and some transformations are effectively irreversible within the relevant horizon.

Repair addresses the residual consequences of intervention. It can involve compensation, restoration of access, institutional reform, rebuilding trust, data deletion or correction, ecological remediation, debt restructuring, reinstatement of rights, or support for capacities weakened by the intervention. Repair is not equivalent to monetary compensation because the harmed object may be relational, institutional, ecological, symbolic, or temporal. A payment can acknowledge loss while leaving the mechanism that produced the loss intact.

The possibility of repair also changes how interventions should be designed. Sys-

tems that preserve audit trails, appeals, modularity, data provenance, and institutional responsibility are easier to correct. Interventions that diffuse responsibility across opaque chains can make harm difficult to attribute and repair. GRE therefore treats repairability as a practical design consideration alongside effectiveness and adaptability.

Withdrawal, reversal, and repair complete the preliminary praxis cycle developed in this section. GRE moves from explanation toward intervention by diagnosing the relational field, identifying what the field generates, locating constraints and enabling conditions, designing a provisional intervention, treating allocation as a relational act, tracing downstream effects, learning through feedback, adapting governance, and retaining the capacity to stop or repair what has been created. The sequence remains heuristic rather than universal. Its purpose is to organize intervention under incomplete knowledge without reducing practice to either static optimization or unconstrained experimentation.

This praxis architecture also clarifies why evaluation cannot be postponed to a single terminal outcome. Each stage creates questions about value, harm, participation, capability, dependency, future possibility, and domination. An intervention may be operationally adaptive while normatively unacceptable, or normatively attractive in intention while generatively destructive in practice. The following section therefore turns from the architecture of action to the standards by which generated consequences can be evaluated under plural and sometimes incommensurable values.

3.13 Evaluation and Normative Orientation

Generative Relational Economics requires a normative vocabulary because the processes it studies can enlarge possibility, redistribute capacity, stabilize cooperation, create dependency, intensify domination, or foreclose alternative futures. The role of this section is to specify the evaluative dimensions through which such consequences can be examined without converting generativity itself into a moral criterion. Its objective is to distinguish descriptive claims about what an economic relation generates from normative judgments about whether the generated configuration should be sustained, revised, constrained, or repaired. The discussion proceeds through ten connected dimensions: the normative status of generativity; generated value and harm; participation; capability; relational quality; future possibility; dependency and domination; generative foreclosure; plural and incommensurable values; and the division of labor between GRE and GREthic. The method is constitutive and normative. It does not attempt to derive one complete moral theory from GRE. It identifies evaluative objects and inferential disciplines that allow GRE to remain normatively explicit while preserving plurality among competing theories of justice and ethical judgment.

The need for this distinction follows directly from the analytical architecture developed above. A relation can be highly generative in the descriptive sense because it produces new organizations, knowledge, technologies, markets, habits, classifications, capabilities, and forms of value. The same relation can distribute those consequences asymmetrically, externalize harms, narrow exit options, or reorganize the

field so that some future possibilities become inaccessible. An intervention can therefore succeed according to one generative objective while producing losses elsewhere in the relational domain. GRE evaluation must trace both kinds of consequence rather than allowing the presence of generation to function as evidence of desirability.

Normative evaluation also requires attention to temporal depth. Immediate welfare gains can be accompanied by long-run dependency. Short-term loss can sometimes create later capability. A stable relation can protect vulnerable participants while also becoming difficult to contest. An institution can increase aggregate opportunity while decreasing the range of trajectories available to a particular group. GRE therefore treats present outcome, relational position, future capacity, and transformation of possibility as analytically separable evaluative objects. Their relative importance cannot be fixed once for every inquiry.

Evaluation is also complicated by heterogeneous value. Economic decisions can affect income, security, care, recognition, ecological integrity, autonomy, knowledge, belonging, trust, aesthetic experience, institutional legitimacy, and many other forms of value whose relations are only partially commensurable. Monetary valuation can be useful within a defined problem while leaving significant evaluative remainders. GRE consequently distinguishes commensuration as an analytical or institutional operation from the stronger claim that the values being compared possess a common natural metric.

The resulting normative stance is neither value-neutrality nor normative closure. GRE accepts that economic inquiry frequently contains evaluative choices in the selection of outcomes, boundaries, scales, and affected subjects. It therefore seeks to make those choices explicit and contestable. At the same time, GRE does not treat its own analytical categories as sufficient to decide every ethical conflict. Participation, capability, relational quality, future possibility, dependency, domination, and foreclosure provide a multidimensional evaluative field. Normative judgment still requires specification of who is affected, which values are at stake, how conflicts among values are handled, and which ethical or political principles justify intervention.

This distinction creates an interface with GREthic. GRE supplies economic analysis of generative structures, distributions, dependencies, conversion pathways, and changes in future possibility. GREthic addresses the broader ethical problem of how such findings should enter judgment, justification, institutional design, and the evolution of normative criteria. Their relation is therefore collaborative without being identical. The present section establishes that interface while keeping GRE's disciplinary center within economics.

3.13.1 Normative Status of Generativity

Generativity describes a capacity of a relation, process, institution, or configuration to produce further states, capacities, relations, values, or possibilities. That descriptive property has no fixed normative sign. Productive networks, monopolistic infrastructures, extractive regimes, scientific communities, predatory markets, mutual-aid institutions, and systems of surveillance can all generate durable consequences. The fact that a configuration generates more than its immediate output identifies an important economic property; it does not establish that the resulting trajectory should

be preferred.

This distinction is foundational because GRE gives generativity an unusually prominent analytical role. Without an explicit normative separation, the vocabulary of generation could encourage a subtle bias toward expansion, novelty, proliferation, or self-reproduction. Economic history supplies many cases in which highly generative arrangements produced wealth together with coercion, ecological depletion, exclusion, or durable hierarchy. A relation can reproduce itself efficiently because the costs of exit are high. An institution can generate rapid innovation because risks are shifted toward actors with weak bargaining power. A platform can generate dense interaction while concentrating control over the infrastructure through which that interaction occurs. Descriptive generativity therefore requires an additional evaluative step.

The relevant question is not whether generation occurs, but what is generated, for whom, through which relations, under which constraints, and with what effects on later possibility. These questions prevent GRE from treating generativity as a scalar objective that can be maximized independently of content. More generation can be desirable in one dimension and damaging in another. A research system can generate knowledge while degrading working conditions. A credit system can generate entrepreneurial capacity while expanding vulnerability to debt. A welfare programme can generate security while also creating administrative classifications that constrain mobility. Evaluation therefore concerns the structure and distribution of generation.

Normative analysis must also distinguish generativity from regeneration. A system can generate novelty while eroding the material or social conditions required for continuation. Another system can maintain those conditions without producing substantial novelty. A third can restore damaged capacities while limiting some current activities. These trajectories involve different evaluative questions. GRE therefore avoids equating novelty, persistence, resilience, growth, and regeneration with one another. Each describes a different relation between current activity and future conditions.

A similar distinction applies to self-reinforcement. Some beneficial institutions require positive feedback to remain viable. Some harmful institutions also acquire self-reproducing capacities. The presence of a stable attractor-like pattern, increasing returns, or institutional persistence does not imply normative legitimacy. Evaluation must examine whether the mechanisms of reproduction preserve contestability, participation, and the possibility of revision or whether they make domination and exclusion increasingly difficult to reverse.

The normative status of generativity is consequently conditional and relational. GRE can identify generative mechanisms and compare their consequences without assigning a universal value to generation itself. Normative evaluation begins when the analysis asks how generated consequences affect subjects, relations, capacities, values, dependencies, and future possibility. The remaining subsections specify those dimensions in greater detail.

3.13.2 Generated Value and Generated Harm

Generated value and generated harm are parallel analytical objects. Both can emerge downstream from an economic relation, both can propagate beyond the administrative recipient, and both can change form as they circulate. The evaluative task is therefore broader than measuring the immediate benefit and subtracting a directly observed cost. GRE asks how value and harm are produced, distributed, converted, accumulated, displaced, and transmitted across scales and time.

Generated value can include income, capability, knowledge, security, trust, coordination, infrastructure, recognition, institutional capacity, ecological restoration, or access to future opportunities. Some forms of value are directly appropriable by a subject; others exist only through a relation or shared condition. A public standard, a trusted institution, a functioning ecosystem, or a community of practice can generate benefits whose value cannot be represented adequately as the possession of one individual. GRE therefore evaluates value at the level at which it is generated and realized.

Generated harm has equally varied forms. An intervention can increase surveillance, dependency, stigma, ecological burden, exclusion, precarity, misinformation, or concentration of bargaining power even when the designated recipient receives a material benefit. Harm can also be displaced. A low consumer price can be sustained through labor conditions elsewhere in the supply chain. Local ecological improvement can depend on transferring waste or extraction to another region. An automated system can reduce transaction costs while increasing the exposure of a minority of users to unreviewable classification errors. Evaluation must therefore examine relational incidence rather than only administrative incidence.

Value and harm can coexist within the same generative pathway. Education can expand capability while imposing debt. Infrastructure can improve access while displacing residents. Intellectual-property protection can support some forms of investment while constraining downstream experimentation. Social protection can reduce insecurity while creating reporting burdens or intrusive eligibility regimes. Such configurations should not be forced into a premature net-value judgment when the affected values are heterogeneous and differently distributed.

Temporal ordering further complicates evaluation. Harm can be immediate while value is delayed, or the reverse. Some effects are reversible; others create durable path dependence. A temporary subsidy may generate a lasting market or a lasting dependency. A short-lived exclusion can alter educational or professional trajectories for decades. GRE therefore records persistence and reversibility as part of the evaluative description rather than treating all consequences as contemporaneous flows.

This framework also makes attribution important. A downstream harm may be associated with an intervention without being generated by the mechanism under study. Conversely, a benefit may be credited to an intervention even though it depends mainly on pre-existing relations or complementary institutions. Normative evaluation should therefore inherit the epistemic discipline of Section 3.11: claims about generated value and harm require a stated mechanism, boundary, scale, and degree of evidential confidence.

3.13.3 Participation

Participation concerns the capacity of affected subjects to enter, influence, contest, benefit from, and withdraw from the relations through which economic life is organized. It is an evaluative object because economic systems do more than distribute resources. They distribute positions from which subjects can speak, act, create, coordinate, challenge classifications, and contribute to future generation. A configuration can therefore increase material output while narrowing meaningful participation.

Participation has several dimensions. Access concerns whether a subject can enter a relevant institution, market, infrastructure, profession, community, or decision process. Voice concerns whether the subject can make claims that receive institutional attention. Influence concerns whether participation can alter decisions rather than merely register preference. Recognition concerns whether the subject is legible within the categories through which resources and rights are allocated. Contestability concerns whether classifications, decisions, or rules can be challenged. Exit concerns whether participation remains voluntary in a meaningful sense or is sustained by dependence and prohibitive switching costs.

These dimensions need not move together. A platform can provide wide access while retaining centralized control over ranking and rule change. A formal consultation process can permit voice while leaving participants with little influence. A labor market can allow nominal exit from an employer while economic insecurity makes exit practically costly. A public service can grant rights in principle while administrative categories render some users difficult to recognize. GRE therefore avoids reducing participation to formal inclusion.

Participation also has a generative dimension. Being able to participate can develop knowledge, confidence, social ties, institutional literacy, bargaining capacity, and new forms of collective organization. Exclusion can have the opposite effect by reducing opportunities to acquire the capacities later required for participation. Present access can therefore shape future access. Evaluation should examine whether an arrangement generates broader capacities for participation or produces cumulative disadvantages that narrow future entry.

The economic significance of participation becomes especially visible under conditions of technological abundance. If productive tasks can increasingly be performed by artificial or highly automated systems, a framework that ties economic participation exclusively to productive necessity can leave human subjects with reduced access to income, institutions, social recognition, or meaningful collective activity. GRE does not presume a particular technological outcome, but it treats the institutional organization of participation as a distinct problem from the allocation of productive tasks.

Participation should not be romanticized. More participation can impose time costs, reproduce inequalities in voice, or shift responsibility onto subjects with limited resources. Some technical decisions require specialized knowledge; some participants may prefer delegation. The normative question therefore concerns the quality and consequences of participation, including who bears its burdens, what forms of representation are available, and whether nonparticipation is compatible with protection from arbitrary decisions.

3.13.4 Capability

Capability concerns the effective ability of subjects to pursue relevant actions and ways of living within their actual relational and institutional conditions. For GRE, capability is an especially important evaluative object because economic relations can generate or destroy the conditions through which resources become usable. An allocation that appears equal at the level of resources can produce unequal capability when subjects face different conversion conditions.

Capability therefore extends evaluation beyond possession. Access to money, information, technology, or legal rights matters only partly through the quantity received. Its practical significance depends on health, time, knowledge, infrastructure, social recognition, legal status, language, care obligations, physical accessibility, institutional trust, and many other conversion conditions. GRE can analyze these conditions as part of the relational field through which a resource becomes an effective opportunity.

Capabilities can also be cumulative. Education can increase the ability to learn further skills. Secure housing can improve the ability to sustain employment or study. Access to digital infrastructure can expand the capacity to participate in markets, administration, and knowledge production. Conversely, repeated exclusion can reduce the capacities needed to take advantage of later opportunities. Evaluation should therefore trace capability trajectories rather than treating capability as a static stock.

The generative perspective adds a second question: who controls the conditions under which capability can be exercised? A subject may possess technical competence while depending on a platform, license, visa, credential, payment network, data infrastructure, or institutional recognition. Capability is then relationally enabled. If access to the enabling condition can be withdrawn unilaterally, the subject's practical freedom may be more fragile than a simple skill inventory suggests.

Capability evaluation must also preserve normative pluralism. GRE does not need to specify one universal list of valuable capabilities in order to treat capability formation as economically significant. Different inquiries can justify different evaluative sets depending on the affected population, institutional context, and normative framework. The important discipline is to state which capabilities are being evaluated, why they matter, and how their measurement relates to the actual opportunities of subjects.

The distinction between capability and performance is equally important. A subject can possess a genuine opportunity without exercising it. Economic evaluation should not automatically infer deprivation from nonuse or success from observed functioning. Choices can reflect preference, but they can also reflect adaptation to constraint, uncertainty, social expectation, or limited information. GRE therefore treats capability as an evaluative lens that requires contextual interpretation rather than direct inference from observed behavior alone.

3.13.5 Relational Quality

Relational quality concerns the properties of the relations through which economic activity is organized. It directs evaluation toward features that can disappear when

analysis looks only at individual outcomes. Two arrangements can deliver similar material distributions while differing substantially in reciprocity, transparency, recognition, reliability, contestability, vulnerability to arbitrary power, or the burdens required to sustain cooperation.

Relational quality is deliberately a plural category. A high-quality relation in one context can emphasize trust and continuity; another can require independence and easy exit; a third can require procedural transparency or protection from discrimination. GRE therefore does not assume that one relational form is universally superior. It asks which properties are normatively relevant to the local relation and how those properties affect both current experience and later generative possibility.

Trust provides one example. Trust can reduce transaction costs, support cooperation, and enable forms of joint action that formal contracting cannot fully specify. Yet trust can also create vulnerability when one party controls information or enforcement. Dense trust within a group can coexist with exclusion of outsiders. Evaluation therefore concerns the conditions under which trust is generated, whether reliance is reciprocated, and what protections exist when trust is breached.

Recognition provides another example. Economic relations can treat subjects as interchangeable units or as participants whose claims and histories matter. Recognition can affect bargaining, access, dignity, willingness to cooperate, and institutional legitimacy. At the same time, institutional recognition often depends on categories that simplify complex identities. A recognition regime can include some subjects by making others invisible. Relational quality therefore includes the revisability of the categories through which recognition is granted.

Contestability is especially important in relations involving asymmetry. A subject may accept unequal expertise, authority, or capability when decisions remain reviewable and reasons can be challenged. The same asymmetry can become more problematic when rules are opaque, appeals are impossible, or dependence makes disagreement costly. GRE therefore treats relational quality as connected to the governance of asymmetry rather than to equality in every dimension.

Relational quality also has generative consequences. Relations characterized by reliability and fair contestation can support investment, experimentation, and long-term cooperation. Relations characterized by arbitrary sanction or unstable recognition can encourage defensive behavior, information withholding, and short planning horizons. Evaluation should consequently examine both the intrinsic and generative significance of relational quality without assuming that its value can be reduced to later efficiency gains.

3.13.6 Future Possibility

Future possibility concerns the range and quality of trajectories that remain realistically available after an economic relation or intervention has taken effect. It is central to GRE because present arrangements continually reshape the conditions of later action. Evaluation therefore extends beyond current welfare to ask whether subjects and institutions retain meaningful capacity to revise, learn, exit, recombine resources, or pursue alternative forms of life and organization.

Future possibility differs from abstract logical possibility. An option can exist formally while remaining practically inaccessible because of cost, law, infrastructure, knowledge, social position, or path dependence. GRE is concerned with feasible and relationally supported possibility. The relevant question is whether subjects possess the conditions required to convert an apparent option into a credible trajectory.

Economic development can expand future possibility by generating infrastructure, education, savings, institutional competence, public knowledge, and trusted coordination. It can also narrow possibility through debt lock-in, ecological depletion, monopoly, rigid standards, irreversible investment, or loss of local capability. The same intervention can expand options for one group while constraining another. Evaluation must therefore be distributional and multiscale.

Optionality also interacts with commitment. Some valuable projects require long-term coordination, sunk investment, and stable expectations. Preserving every option can prevent the formation of institutions whose value depends on continuity. GRE therefore does not treat maximal reversibility as a universal goal. It asks whether commitments are justified, whether affected subjects understand the resulting constraints, whether revision remains possible under changing conditions, and whether the burdens of irreversibility are distributed fairly.

The temporal horizon of evaluation matters. A policy that preserves short-run choice can undermine long-run ecological or fiscal possibility. A restrictive rule can reduce present options while protecting conditions needed for future generations. GRE therefore requires explicit time horizons and rejects the assumption that present preference alone exhausts normative relevance. Intergenerational effects become part of economic evaluation when current activity alters the capability and action space available later.

Future possibility also provides a bridge between economic and political evaluation. Control over infrastructure, standards, data, property, legal categories, or knowledge systems can determine which later projects become feasible. Power can therefore operate by structuring possibility before any specific decision is made. Evaluation of future possibility helps identify such upstream effects and prepares the analysis of power in the following section.

3.13.7 Dependency and Domination

Dependency is a pervasive feature of economic life. Individuals depend on households, organizations, infrastructures, ecological systems, legal institutions, markets, and other persons. Firms depend on suppliers, finance, standards, workers, customers, and public order. Dependency therefore cannot serve as a simple indicator of injustice. The evaluative problem concerns the structure of dependence: how essential the relation is, whether alternatives exist, how burdens and benefits are distributed, and whether one party can exercise discretionary power over another's conditions of action.

Some dependencies are reciprocal and mutually enabling. Specialization creates interdependence because actors can achieve more through coordinated reliance than through autarky. Care relations can involve deep dependence while also generating security, capability, and belonging. Public infrastructure creates dependence

on collective institutions that may be normatively desirable. GRE therefore distinguishes dependency from domination rather than treating self-sufficiency as the default ideal.

Domination becomes relevant when dependency is combined with power that is difficult to contest, exit, or subject to accountable rules. A worker can depend on an employer, a seller on a platform, a tenant on a landlord, or a state on a creditor. Whether the relation becomes dominating depends on the available alternatives, procedural protections, transparency, collective organization, legal constraints, and the ability to challenge arbitrary decisions. The analysis therefore concerns relational structure rather than the mere presence of unequal capability.

Generative mechanisms can deepen dependency over time. A platform can become more indispensable as participants invest in platform-specific reputation or data. A lender can acquire increasing influence when refinancing becomes necessary. A technology ecosystem can create switching costs through proprietary standards and complementary investments. Such processes transform an initially optional relation into one that shapes the subject's future possibilities. GRE evaluates the trajectory of dependency, not only its initial contractual form.

Dependency can also be hidden by administrative boundaries. An organization may appear autonomous while relying on unpaid care, public infrastructure, ecological services, or precarious subcontracting. A wealthy region can reduce local dependence by externalizing extraction elsewhere. Evaluation should therefore trace dependency across scales and identify whose capacities sustain the apparent independence of others.

The normative task is consequently to distinguish enabling interdependence from dependency that concentrates arbitrary power or systematically transfers risk. This distinction is contextual and requires attention to alternatives, voice, exit, reciprocity, and governance. GRE can map these conditions economically while leaving broader ethical judgment open to explicit normative argument.

3.13.8 Generative Foreclosure

Generative foreclosure occurs when a present economic relation, intervention, or institutional arrangement reduces the capacity to generate relevant future alternatives. Foreclosure is stronger than an ordinary opportunity cost. Every choice excludes some alternatives because resources and time are finite. Generative foreclosure concerns changes to the conditions of future generation themselves: the loss of capabilities, relations, infrastructures, ecological conditions, institutional pluralism, or epistemic resources required to create or recognize later options.

A technological standard can produce generative foreclosure when complementary investment makes alternative architectures prohibitively costly. Concentrated ownership of research infrastructure can narrow which questions can be investigated. Educational exclusion can reduce not only present opportunity but also the later capacity to formulate and pursue new projects. Ecological degradation can remove future productive and cultural possibilities that current actors cannot fully specify. In each case, the loss concerns the generative field rather than one foregone transaction.

Foreclosure can be intentional or emergent. A dominant actor may deliberately raise barriers to entry. An institution may unintentionally create lock-in through cumulative coordination. A society may deplete a resource without any actor intending to eliminate later possibilities. Normative evaluation therefore cannot rely only on motive. It must examine the mechanisms through which possibility is narrowed and the distribution of the resulting loss.

The concept also requires restraint. Stable institutions necessarily reduce some degrees of freedom by creating rules, commitments, standards, and expectations. Such constraint can itself enable generation by lowering uncertainty and coordinating investment. GRE therefore distinguishes productive structuring from foreclosure by asking whether the constraint preserves meaningful routes for learning, contestation, recombination, and revision relative to the values at stake.

Irreversibility is an important but incomplete indicator. Some irreversible changes are desirable; some reversible systems can still reproduce severe domination. The evaluative question concerns which future capabilities and relations are lost, who bears the loss, whether the loss was foreseeable, whether affected subjects had meaningful participation, and whether compensating generative capacities are created elsewhere. Foreclosure is thus a relational and normative concept rather than a synonym for permanence.

Generative foreclosure gives GRE a way to evaluate economic processes whose most important harms are difficult to observe in present output measures. The absence of a future innovation, institution, community, ecological state, or life trajectory cannot be measured in the same way as an existing commodity. Evaluation therefore requires counterfactual and historical reasoning, explicit uncertainty, and humility concerning possibilities that current categories may fail to represent.

3.13.9 Plural and Incommensurable Values

GRE assumes that economic evaluation can involve several forms of value whose relations are partial, contested, or context-dependent. Income, security, autonomy, care, recognition, ecological integrity, knowledge, cultural continuity, trust, and future possibility can matter simultaneously without reducing naturally to one metric. The presence of plural value therefore creates a problem of judgment rather than a technical defect awaiting universal conversion.

Commensuration can still be useful. Budgets require numerical comparison; cost-effectiveness analysis can clarify trade-offs within a defined objective; markets generate prices that coordinate many transactions; legal and administrative systems require thresholds and categories. GRE treats these operations as institutionally situated forms of comparison. The existence of a price or index demonstrates that a conversion rule has been established for a purpose. It does not prove that every ethically relevant dimension has been captured.

Partial comparability is often sufficient for action. One option can dominate another across several relevant dimensions without requiring a common cardinal scale. Thresholds can exclude arrangements that violate minimum conditions of safety, participation, or rights. Deliberative procedures can address remaining conflicts. Scenario analysis can reveal how rankings change under different value weightings.

GRE therefore does not infer decision paralysis from incommensurability.

Plural value also changes the interpretation of conversion. An institution can transform cultural recognition into market demand, social trust into credit access, educational status into employment opportunity, or ecological resources into monetary revenue. Such conversions can create value while also degrading or crowding out the source relation. Evaluation should therefore examine who controls conversion interfaces, which values become legible after conversion, and which remainders disappear from institutional accounting.

Conflicts among values can also be distributional. A policy may maximize aggregate income while concentrating ecological harm in one community. A conservation programme may protect biodiversity while limiting livelihoods or customary access. An automated service may improve average efficiency while weakening procedural recognition for individuals who require exceptions. These conflicts cannot be resolved by naming all values equally important. Normative judgment must specify priority rules, procedural safeguards, compensation, thresholds, or other principles appropriate to the case.

GRE's contribution is to keep the value architecture visible. It can trace where values are generated, converted, captured, dissipated, or rendered institutionally invisible. It can identify the relations through which one value form gains priority over another. It can also expose where apparent commensurability depends on a contested institutional convention. The choice among competing normative resolutions remains an explicit ethical and political task.

3.13.10 Relation between GRE and GREthic

The normative dimensions developed in this section create a direct interface between GRE and GREthic. Their division of labor should remain explicit. GRE is an economic research programme concerned with relational constitution, generation, allocation, value transformation, capability, power, dependency, and changes in future possibility. GREthic addresses the broader ethical problem of how relational and generative consequences should be interpreted, justified, contested, and governed when several values, subjects, and temporal horizons are involved.

This division does not make GRE normatively empty. Economic research already contains evaluative choices in the definition of welfare, harm, efficiency, opportunity, risk, and admissible intervention. GRE adds explicit dimensions such as participation, relational quality, future possibility, dependency, domination, and foreclosure. These dimensions belong legitimately within economic evaluation because they describe economically generated conditions. The ethical question becomes more demanding when the inquiry asks how competing dimensions should be weighted, which constraints should function as side conditions, whose claims have priority, or what constitutes a just relation.

GREthic can therefore operate as a neighboring normative domain rather than as a final module appended after economic analysis. Ethical judgment can alter the research boundary, the choice of evaluative dimensions, the treatment of uncertainty, the design of participation, and the interpretation of evidence. Conversely, economic analysis can revise ethical judgment by revealing hidden dependencies,

indirect harms, conversion mechanisms, or long-run consequences that were absent from the initial normative description. The relation between GRE and GREthic is consequently iterative.

A generative ethical perspective also faces the problem of changing criteria. Institutions learn, social meanings evolve, new subjects become visible, and technologies create forms of action that earlier normative vocabularies did not anticipate. Ethical evaluation therefore cannot assume that a fixed list of criteria will remain sufficient under every historical condition. GREthic must be capable of examining how normative categories themselves emerge, stabilize, exclude, and require revision. This does not imply that every value is historically arbitrary. It means that the institutional expression and interpretation of values require continuing critical examination.

The interface is especially important for application-dominant praxis. An intervention can be technically effective and economically generative while raising unresolved questions of justice. In such cases GRE can provide the relational diagnosis, trace the effects, identify capability changes, map dependency, and evaluate future possibility. GREthic can help articulate the normative standards governing participation, acceptable asymmetry, protection from domination, treatment of irreversible harm, and procedures for revising the intervention when values conflict.

The distinction also protects disciplinary restraint. GRE need not become a complete moral philosophy in order to analyze normatively significant economic processes. GREthic need not replace economic explanation with ethical vocabulary. Their productive relation depends on maintaining both the empirical and normative burdens of argument. Ethical claims require justification; economic claims require evidence and mechanism; interventions require both.

The normative architecture established in Section 3.13 therefore completes an important part of Chapter 3's constitution of GRE. Generativity becomes an object of evaluation rather than a criterion of goodness. Generated value and harm, participation, capability, relational quality, future possibility, dependency, domination, foreclosure, and plural values provide a multidimensional field for judgment. The following section turns to one of the most consequential mechanisms through which these dimensions become unequally distributed: power and asymmetry within the GRE problem-space.

3.14 Power and Asymmetry within the GRE Problem-Space

Generative Relational Economics requires an explicit account of power because economic relations rarely begin from symmetric positions, and the consequences of those asymmetries can accumulate through the very processes that GRE studies. The role of this section is to identify the principal forms of asymmetry that can become economically consequential and to clarify the conditions under which asymmetry is converted into power. Its objective is to avoid two opposite reductions: treating every difference between subjects as domination, and treating power as a property possessed independently of the relations through which it becomes effective. The discussion proceeds through resource, capability, knowledge, institutional, vulnerability, and exit asymmetries; the conversion of asymmetry into power; the limits

of capability equalization and counter-power; and relational governance under persistent asymmetry. The method is constitutive and analytical. It establishes a vocabulary for later empirical, normative, and governance work without presuming that one scalar measure can represent every relevant form of power.

The starting point is a distinction between *asymmetry* and *power*. An asymmetry exists when subjects occupy different positions with respect to resources, capacities, information, institutional authority, vulnerability, or alternatives. Power arises when such differences become usable, durable, or institutionally supported means of shaping another subject's feasible actions, access to resources, interpretive environment, exposure to risk, or future conditions of generation. A highly capable subject can therefore remain weak in a particular relation when its capabilities are irrelevant to the terms of interaction. Conversely, a subject with modest resources can exercise substantial power when it controls a scarce interface, legal authorization, standard, platform, bottleneck, or exit option on which others depend.

Power is consequently relational, domain-specific, and temporally structured. The same pair of subjects can be asymmetric in opposite directions across different domains. A worker can possess knowledge essential to production while remaining institutionally subordinate in wage negotiation. A state can regulate a corporation domestically while depending on that corporation for infrastructure, tax revenue, or technological expertise. A user can choose among digital services while having little capacity to alter the standards through which data are collected and converted into commercial value. The relevant question for GRE is therefore not simply who has more, but how a difference is connected to a mechanism through which one subject can affect another subject's present options or future generative conditions.

This emphasis also distinguishes power from immediate coercion. Power can operate through direct commands, but it can also operate by shaping defaults, eligibility criteria, technical standards, access routes, classifications, expectations, and the cost of refusal. It can be episodic or structurally persistent. It can be consciously exercised or reproduced through institutions whose participants do not individually intend the resulting asymmetry. GRE therefore treats power as a family of relational mechanisms that affect the generation and distribution of possibility. Normative evaluation enters when those mechanisms are assessed in terms of domination, justice, harm, participation, capability, or foreclosure, but descriptive power analysis must first identify how the relation works.

3.14.1 Resource Asymmetry

Resource asymmetry concerns unequal access to economically consequential stocks or flows such as money, land, infrastructure, energy, data, equipment, labor time, organizational slack, credit, logistics, or legally protected assets. It is among the most visible forms of economic difference because many resources are already measured through accounting, ownership, or administrative systems. Yet possession alone does not determine relational power. What matters is the role that a resource plays within a specific relational configuration.

A resource becomes power-relevant when control over it changes another subject's feasible set or bargaining position. The owner of a scarce input can influence down-

stream producers when substitutes are limited and switching is costly. A lender can impose conditions when borrowers face liquidity constraints and alternative finance is unavailable. A landlord's control over housing can become consequential when residence is tied to employment, schooling, legal status, or local social networks. A platform's control over computational infrastructure can matter when users, firms, or public institutions depend on that infrastructure for participation in other economic processes. The same nominal resource can therefore carry very different power consequences depending on substitutability, timing, dependence, and institutional context.

Resource asymmetry also has a generative dimension. Resources can be consumed, but they can also be converted into capacities for producing later resources. Capital can finance research, data collection, legal representation, lobbying, recruitment, or acquisition. Infrastructure can make future coordination cheaper. Land ownership can generate collateral. A large user base can generate additional data and network effects. Resource inequality can therefore reproduce or amplify itself when existing holdings enable access to mechanisms that generate further advantage.

GRE analysis should distinguish this recursive possibility from simple accumulation. A subject can possess more resources without gaining additional structural leverage if the relevant relation remains competitive and alternatives remain accessible. Conversely, a relatively small resource difference can become decisive when it controls a bottleneck or threshold. The analytical task is thus to identify the conversion mechanism: which resource matters, to which relation, over what time horizon, through which institutional or technical structure, and with what downstream effects on future capacity.

This distinction also matters for policy. Redistribution of money can reduce one resource asymmetry while leaving infrastructural, legal, informational, or organizational asymmetries intact. Access subsidies can improve current consumption without altering control over the mechanisms that generate future options. Resource equalization is therefore one possible intervention among several. GRE asks whether the relevant inequality lies in holdings, access, conversion capacity, rule-making position, or the structure through which resources become generative.

3.14.2 Capability Asymmetry

Capability asymmetry concerns differences in what subjects are able to do within a defined economic relation. Capabilities may include technical competence, organizational coordination, computational capacity, mobility, learning, bargaining skill, physical endurance, social connectivity, legal competence, linguistic access, or the ability to mobilize resources under time pressure. Capability differs from resource possession because two subjects with formally similar resources can have very different capacities to convert them into effective action.

This distinction is central in contemporary economies where productive capability can differ sharply across persons, organizations, and artificial systems. A large model can process information at scales unavailable to an individual worker. A multinational firm can coordinate legal, financial, and logistical operations across jurisdictions that a small supplier cannot match. An experienced organization can exploit

a regulatory opportunity that a newly formed association does not yet understand. These differences can affect bargaining positions, speed, error tolerance, and the range of feasible strategies.

Capability asymmetry becomes power-relevant when it changes the terms under which other subjects must participate. Superior prediction can support price discrimination. Superior legal capacity can make contractual complexity costly for weaker parties to contest. Superior computational capacity can enable rapid experimentation over markets, attention, or product design. Superior logistical coordination can make a supplier difficult to replace. In each case the capability matters because it is connected to a relation through which the more capable subject can shape conditions faced by others.

At the same time, capability differences do not by themselves establish domination, moral superiority, or ontological hierarchy. Specialized capabilities are common in cooperative systems. A surgeon and patient, pilot and passenger, engineer and user, or teacher and student occupy asymmetric capability relations that can be socially valuable when authority, accountability, consent, and institutional safeguards are appropriately organized. The relevant GRE question is whether capability asymmetry becomes a mechanism for unilateral control, extraction, dependency, or foreclosure, or whether it is embedded in reciprocal and revisable arrangements that distribute benefits and protect affected subjects.

Capability asymmetry also changes historically. Training, tools, institutional access, automation, collective organization, and technical infrastructure can expand or reduce particular capabilities. The introduction of artificial intelligence makes this especially visible because capability gaps can change quickly and unevenly across tasks. A useful GRE analysis therefore tracks the trajectory of capability differences rather than treating them as fixed attributes. It asks who gains new capabilities, who loses the economic relevance of existing ones, what new dependencies arise, and which institutions govern the conversion of capability differences into economic authority.

3.14.3 Knowledge Asymmetry

Knowledge asymmetry concerns unequal access to information, interpretive resources, expertise, explanatory models, evidence, or the capacity to recognize the significance of available information. It extends beyond the familiar problem of one party knowing more facts than another. Economic power can also arise from asymmetries in classification, prediction, interpretation, and the ability to determine which descriptions become institutionally actionable.

A seller may know more about product quality than a buyer. A financial institution may know more about pricing models and contractual risk than a client. A platform may observe aggregate behavioral patterns invisible to individual users. A government agency may hold administrative records unavailable to the public. A technical community may control specialized vocabularies required to contest a decision. These are distinct knowledge relations, and their power effects depend on how the knowledge is connected to action.

Knowledge becomes especially consequential when one subject can make decisions on the basis of information that another cannot inspect, verify, or meaningfully

interpret. The weaker subject may then depend on assurances, reputation, certification, professional norms, or institutional oversight. Such dependence is not intrinsically pathological; complex economies require extensive reliance on expertise. The power problem emerges when epistemic dependence combines with weak accountability, conflicts of interest, high switching costs, or control over the channels through which claims can be challenged.

Knowledge asymmetry also includes the power to produce or stabilize representations. Economic subjects are frequently acted upon through categories: credit scores, risk classes, performance metrics, eligibility rules, rankings, profiles, diagnoses, forecasts, and algorithmic classifications. The subject who controls the production or interpretation of a category can influence access to employment, credit, insurance, visibility, public benefits, or market participation. In such cases knowledge power does not consist only in possessing hidden information. It also consists in shaping the representational architecture through which institutions perceive other subjects.

GRE therefore distinguishes informational access, interpretive competence, model authority, and representational control. These dimensions can diverge. Data can be publicly available while computational requirements make meaningful analysis inaccessible. A model can be technically transparent while the institutional consequences of its output remain opaque. A subject can understand a classification yet lack any procedure for contesting it. Knowledge governance consequently requires more than disclosure. It may require intelligibility, auditability, contestability, alternative expertise, evidential access, and institutional routes through which interpretations can be revised.

The generative dimension of knowledge asymmetry is equally important. Knowledge can generate later knowledge, and control over data or research infrastructure can compound advantages. Organizations with larger observational fields can train better models, attract more users, and generate still more data. Institutions that define legitimate evidence can also shape which questions receive funding and which phenomena become visible. Knowledge asymmetry can therefore alter the future epistemic field itself, making it a central GRE object rather than merely a background imperfection in exchange.

3.14.4 Institutional Asymmetry

Institutional asymmetry concerns unequal positions within rule-making, authorization, recognition, enforcement, classification, and dispute-resolution structures. It is distinct from resource or capability asymmetry because an institution can grant authority to a subject whose private resources are limited. A regulator, court, standards body, professional association, university, central bank, certification agency, or platform governance unit can exercise substantial influence through the rules it is authorized to establish or interpret.

Institutional position shapes who can define admissible participation, whose claims count, which categories receive legal recognition, and which remedies are available when conflict occurs. Formal authority is one obvious form. Less visible forms include agenda-setting, control over procedure, discretionary interpretation, default-setting, accreditation, and the capacity to delay or accelerate decisions.

Timing itself can become power when one party can tolerate delay and another cannot.

Institutional asymmetry is often self-reinforcing because rules influence the resources and capabilities available to participants. Licensing can protect quality and safety while also raising entry barriers. Intellectual-property rules can reward innovation while concentrating control over subsequent use. Procurement standards can improve accountability while favoring organizations with administrative capacity to comply. Corporate governance rules can distribute formal voting rights while leaving agenda formation concentrated. Institutional analysis therefore asks not only what a rule states but how it reorganizes relational possibilities.

GRE treats institutional asymmetry as especially important because institutions mediate conversion among other forms of asymmetry. Wealth can be translated into lobbying, litigation, or organizational access. Expertise can be converted into recognized professional authority. Formal office can provide privileged information. Institutional status can determine whose vulnerability receives protection and whose losses remain externalized. Institutions are thus conversion structures through which resources, capabilities, knowledge, and recognition become power.

This does not imply that institutional asymmetry should be eliminated. Governance itself requires differentiated roles, mandates, and responsibilities. The relevant question is how authority is bounded, justified, monitored, revisable, and connected to affected subjects. An institution can exercise asymmetric authority while remaining constrained by procedure, transparency, appeal, rotation, representation, or substantive rights. GRE therefore analyzes the architecture of authority rather than treating formal symmetry as the only legitimate institutional form.

3.14.5 Vulnerability Asymmetry

Vulnerability asymmetry concerns differences in exposure to loss and differences in the capacity to absorb, recover from, or adapt to that loss. It introduces a dimension of power that is easy to miss when analysis focuses only on holdings or productive capacities. Two subjects may enter the same formal transaction while facing radically different consequences if the transaction fails.

A worker dependent on one employer can face greater loss from contract termination than the employer faces from replacing one worker. A small supplier can be more vulnerable to delayed payment than a large purchaser is to delayed delivery. A tenant can face relocation costs that exceed the landlord's costs of replacing the tenant. A household with minimal savings can be more affected by a small price shock than a wealthier household is by a larger nominal loss. These differences change bargaining relations even when contractual rights appear formally symmetric.

Vulnerability can arise from biological, social, legal, ecological, financial, or infrastructural conditions. It can also be generated by prior economic relations. Debt can increase sensitivity to income interruption. Loss of public infrastructure can increase dependence on private providers. Concentrated employment can make a region vulnerable to one firm's decisions. Data-driven personalization can expose particular groups to targeted exploitation. Vulnerability is therefore often historically produced rather than merely given.

The conversion of vulnerability into power occurs when another subject can credibly condition access to necessities, impose risks, or shift costs onto those less able to bear them. The stronger party need not intentionally threaten harm. Structural vulnerability can influence behavior because subjects anticipate the consequences of refusal. A worker may accept unfavorable terms because unemployment is costly. A state may offer concessions to a mobile investor because local employment is concentrated. A consumer may accept invasive data practices because essential services have become digitally mediated.

GRE analysis should also distinguish vulnerability from weakness in every domain. A subject can be technologically capable and financially wealthy while highly vulnerable to reputational, legal, ecological, or infrastructural disruption. Conversely, a subject with few resources can be relatively resilient when needs are modest, alternatives are available, and social support is strong. Vulnerability therefore requires explicit specification of the relevant hazard, exposure, recovery capacity, and time horizon.

This perspective has normative implications, but the descriptive analysis comes first. Governance can reduce vulnerability by creating buffers, insurance, redundancy, public options, collective support, or guaranteed access to essentials. Yet such interventions can create new dependencies if they centralize provision without contestability. The GRE question is how vulnerability is generated, distributed, converted into leverage, and transformed by the institutions intended to manage it.

3.14.6 Exit Asymmetry

Exit asymmetry concerns differences in the cost, feasibility, and consequences of leaving a relation. It is one of the clearest mechanisms through which other asymmetries become durable. A relation can appear voluntary at entry while becoming difficult to leave once investments, identities, data, legal obligations, infrastructures, social ties, or specialized capabilities accumulate around it.

Exit costs take many forms. Financial penalties and contractual restrictions are explicit examples. Others include retraining, relocation, loss of reputation, incompatibility of technical systems, loss of accumulated data, social isolation, disruption of care arrangements, immigration consequences, or forfeiture of institution-specific benefits. Exit can also be asymmetric because one party can replace the other more easily. A large platform can lose an individual user with little consequence, while the user may lose access to a network on which professional or social activity depends.

Exit asymmetry matters because it alters the practical meaning of consent. Continued participation can reflect genuine preference, but it can also reflect high switching costs, dependence, fear of retaliation, or lack of viable alternatives. GRE therefore treats observed continuation as evidence that requires interpretation rather than as automatic proof that a relation remains mutually beneficial.

The generative dimension of exit is particularly important. Participation in a relation can produce assets that are specific to that relation: reputation scores, social connections, customized tools, accumulated knowledge, eligibility, or identity. These assets can increase productivity and value while simultaneously making exit more costly. Successful cooperation can therefore deepen dependence even without inten-

tional lock-in. The governance problem is to preserve the benefits of relational investment while preventing accumulated specificity from becoming unilateral leverage.

Exit is also only one response to problematic relations. Voice, contestation, collective bargaining, institutional appeal, and internal reform can be preferable when relationships are valuable and exit would destroy jointly generated capacities. An exclusive focus on exit can therefore privilege subjects already able to move while leaving the most embedded or vulnerable participants unprotected. GRE analyzes exit together with voice, representation, repair, and alternative provision.

Exit asymmetry can be reduced through interoperability, portability, nonretaliation rules, social insurance, public alternatives, transferable credentials, data mobility, and limits on restrictive contracts. Such measures alter the relational field even if few subjects actually leave. The credible possibility of exit can change bargaining power. Exit governance is therefore about the structure of alternatives, not merely the observed frequency of departure.

3.14.7 Conversion of Asymmetry into Power

The preceding forms of asymmetry become analytically significant when they are connected to mechanisms of conversion. GRE treats conversion as the process through which a difference in resources, capability, knowledge, institutional position, vulnerability, or exit becomes effective influence over another subject's options or over the conditions from which future options are generated. This conversion is neither automatic nor uniform.

Several relational conditions commonly affect conversion. Scarcity matters because control over abundant and substitutable resources usually provides less leverage than control over bottlenecks. Dependence matters because the value of an asymmetry rises when other subjects rely on the advantaged subject for essential functions. Replaceability matters because subjects with many alternatives can resist conditions that dependent subjects must accept. Coordination matters because individually weak subjects can aggregate resources or voice. Institutional recognition matters because formal rules can authorize, limit, or redirect the use of an advantage. Information matters because leverage can depend on subjects understanding their alternatives and the likely consequences of refusal. Time matters because a party that can wait often has bargaining advantages over a party facing urgent costs.

Power conversion can also be recursive. A resource advantage can buy expertise; expertise can influence institutional design; institutional design can protect future resource accumulation. Superior knowledge can improve targeting; improved targeting can increase profit; profit can finance further data collection. Control over infrastructure can generate dependence; dependence can support contractual authority; contractual authority can increase exit costs. Such cycles matter to GRE because they transform temporary differences into persistent relational structures.

The concept of conversion also helps distinguish power from inequality. A wealthy subject can lack power over a regulator empowered to impose binding rules. A technically capable firm can remain dependent on a monopolistic supplier. A state with formal sovereignty can be constrained by financial, technological, or security dependencies. Power maps therefore need not reproduce wealth rankings. GRE analysis

should trace conversion pathways rather than infer power from one observable variable.

Power can furthermore operate through the generation of expectations. If subjects anticipate that one party can impose costs, deny access, classify them adversely, or shape future opportunities, they may alter behavior before any explicit exercise occurs. This anticipatory effect can make power difficult to observe through events alone. Stable compliance can coexist with strong asymmetry precisely because overt conflict becomes unnecessary. Empirical inquiry may therefore need to study suppressed alternatives, unrealized options, counterfactual bargaining positions, and institutionalized expectations.

The conversion perspective also clarifies why power is domain-specific. A subject can be powerful in hiring and weak in finance, powerful in data and weak in law, powerful domestically and dependent internationally. GRE should therefore resist the temptation to compress heterogeneous power relations into one universal rank. A multidimensional mapping of asymmetries, conversion mechanisms, and affected generative conditions is often more informative than a single power score.

3.14.8 Limits of Capability Equalization

Capability enhancement is one important response to asymmetry. Education, public infrastructure, assistive technology, access to finance, legal aid, data access, computational tools, collective organization, and social protection can increase the ability of weaker subjects to participate, contest, adapt, and generate alternatives. Yet capability equalization has limits as a general theory of power reduction.

First, some asymmetries arise from differentiated roles rather than remediable deficits. Regulators and regulated entities, doctors and patients, judges and litigants, infrastructure operators and users, or specialized technical teams and general publics occupy different positions because complex systems distribute functions. Governance must then organize accountability across unequal roles rather than assume that every participant should acquire identical capabilities.

Second, capability enhancement can leave institutional conversion mechanisms untouched. Training workers may improve mobility while employers retain unilateral control over scheduling, surveillance, or termination. Financial literacy can improve decisions while contractual complexity and market concentration remain. Digital skills can expand participation while platforms retain control over standards, visibility, and data. Strengthening the weaker subject can therefore be valuable without fully altering the relation that generates the asymmetry.

Third, capabilities can themselves become positional. If all participants acquire a skill that was previously scarce, the advantage associated with that skill can move elsewhere. Credential inflation provides one familiar pattern: expanding qualifications can increase absolute competence while preserving relative competition for scarce positions. In technological domains, widespread adoption of one tool can raise the baseline expected from all participants and create a new asymmetry around access to more advanced infrastructure.

Fourth, equalization can impose burdens. Requiring vulnerable subjects to be-

come expert negotiators, data analysts, legal specialists, or cybersecurity practitioners shifts responsibility onto those already facing structural disadvantage. Some protections are better provided through institutional design, fiduciary duties, public options, default rules, or limits on permissible extraction than through endless demands for individual capability upgrading.

GRE therefore treats capability equalization as one component of relational governance. The relevant question is which asymmetry should be reduced by expanding capability, which should be bounded through institutional rules, which should be made contestable through collective organization, and which should be accepted as functionally necessary but governed through accountability. The objective is not symmetry for its own sake. It is to prevent capability differences from becoming unjustified control over the conditions of participation and future generation.

3.14.9 Limits of Counter-Power

Counter-power refers to capacities that enable subjects to resist, negotiate, constrain, or redirect an existing concentration of power. Collective bargaining, competition, regulatory oversight, courts, professional associations, consumer organization, public alternatives, investigative journalism, open technical standards, mutual aid, and democratic participation can all function as forms of counter-power in different contexts. GRE treats them as relational interventions rather than as automatic restorations of balance.

Counter-power is often necessary because persistent asymmetry cannot be addressed by individual adaptation alone. Workers can negotiate more effectively through collective organization. Small firms can benefit from shared infrastructure or interoperability mandates. Consumers can rely on regulators or courts when individual monitoring is costly. Communities can build institutions that reduce dependence on a single provider. Such arrangements change the structure through which asymmetry is converted into power.

Yet counter-power has limits. It can become concentrated in its own right. A union, regulator, professional body, platform cooperative, or civic organization can develop internal hierarchies and exclusion mechanisms. Institutions created to represent weaker subjects can become difficult for those subjects to contest. Competition can constrain one monopoly while producing instability or shifting concentration to another layer of the system. Transparency can expose misconduct while advantaging actors with superior capacity to process disclosed information. Counter-power therefore requires its own governance.

Counter-power can also reproduce the ontology of the power it contests. If resistance must use the same metrics, platforms, legal categories, or technical infrastructure established by the dominant actor, alternatives may remain confined within the existing field. A community can gain representation without gaining control over the categories through which its interests are recognized. A new market entrant can challenge price while leaving data extraction practices unchanged. GRE therefore asks whether counter-power changes bargaining within a relation or transforms the generative conditions of the relation itself.

Temporal asymmetry further complicates counter-power. Concentrated actors can

sometimes act quickly while collective organizations require deliberation, consent, and coordination. Conversely, public institutions can impose durable constraints that private actors cannot easily evade. The relevant balance is therefore dynamic. Effective governance must consider response speed, persistence, institutional learning, and the capacity of power holders to adapt around controls.

The limit of counter-power does not imply resignation. It indicates that balancing strategies should be evaluated recursively. A mechanism introduced to constrain power should itself be analyzed for new dependencies, exclusions, and conversion pathways. GRE's contribution is to keep that second-order question visible: what does the counter-power generate, whose capacities does it strengthen, which relations does it stabilize, and what new asymmetries emerge from its operation?

3.14.10 Relational Governance under Persistent Asymmetry

Many economic systems will continue to contain substantial asymmetries even under ambitious reforms. Subjects differ in knowledge, scale, specialization, mobility, resources, biological needs, legal mandates, technical capabilities, and exposure to risk. Relational governance therefore cannot depend on the expectation that legitimate order will emerge only after differences have been eliminated. Its task is to organize persistent asymmetry so that necessary differentiation does not become uncontrolled domination or generative foreclosure.

A GRE governance perspective begins by specifying the relevant asymmetries and their conversion mechanisms. It asks which subjects depend on which others, what alternatives exist, which resources or capabilities function as bottlenecks, who defines the institutional categories of participation, how vulnerability is distributed, and what happens if a subject attempts to exit or contest the relation. This diagnosis identifies where safeguards are likely to matter.

Several governance principles follow from the analysis, although their concrete form remains context-dependent. Authority can be bounded by mandate and review. Essential services can be protected by continuity obligations or public alternatives. Exit can be made more credible through portability and interoperability. Knowledge asymmetry can be addressed through independent expertise, audit, contestation, and evidential access. Vulnerability can be reduced through buffers, insurance, redundancy, and guaranteed minimum capacities. Collective organization can strengthen voice. Rule-making can include affected subjects without presuming that participation alone resolves all asymmetry. Institutions can preserve appeal, revision, and sunset mechanisms so that temporary arrangements do not harden into unchallengeable structures.

Relational governance also requires attention to generative conditions. A policy can constrain abusive behavior in the present while leaving the mechanisms that reproduce future dependence untouched. Conversely, an intervention can redistribute immediate resources while weakening the organizational capacities through which a community previously governed itself. GRE therefore evaluates governance at more than one temporal layer: present protection, future capability, relational quality, structural transformation, and preservation of alternative pathways.

The concept of persistent asymmetry also changes the meaning of fairness. For-

mal equality of rules can coexist with radically unequal vulnerability or exit costs. Identical disclosure can be useless when interpretive capacities differ. Equal access to a market can mask unequal control over infrastructure. Governance may therefore require differentiated protections or obligations in order to make participation substantively contestable. Such differentiation must itself remain transparent and revisable because protective categories can reify the subjects they are intended to assist.

Power analysis should also remain separate from final normative judgment. A concentrated authority may sometimes be justified by coordination, safety, fiduciary responsibility, or public purpose. A decentralized arrangement can reproduce severe power through infrastructure, convention, or cumulative advantage. GRE therefore does not infer justice from decentralization, symmetry, or participation alone. It supplies a relational map of how influence is generated and sustained; normative evaluation then asks whether those mechanisms are justified under the relevant ethical, legal, and political standards.

This section therefore places power within the GRE problem-space as a dynamic relation among asymmetries, conversion mechanisms, dependencies, institutional structures, and future generative conditions. Resource, capability, knowledge, institutional position, vulnerability, and exit are analytically distinct sources of asymmetry. Their conversion into power depends on scarcity, substitutability, dependence, coordination, authorization, time, and the structure of alternatives. Capability equalization and counter-power can alter these relations, but each has limits and can generate new asymmetries. Relational governance must consequently remain adaptive, contestable, and attentive to second-order effects.

The analysis also prepares the next constitutive problem. Persistent asymmetry does not occur among identical subjects. Economic relations increasingly connect persons, organizations, states, artificial systems, ecological systems, and other heterogeneous participants whose capacities, temporalities, vulnerabilities, and value structures differ in kind as well as degree. The following section therefore turns from asymmetry within relations to the broader problem of heterogeneity and coexistence.

3.15 Heterogeneity and Coexistence

Generative Relational Economics requires an explicit account of heterogeneity because many economic relations connect subjects, systems, and processes that differ in ways that cannot be reduced to variation along a single scale. The role of this section is to establish coexistence across heterogeneous forms as a constitutive problem of GRE rather than as a residual complication added after a homogeneous model has been constructed. Its objective is to clarify how economic coordination, exchange, dependence, conflict, and joint generation remain possible when participants differ in subject form, intelligence, temporality, vulnerability, value structure, and degree of mutual intelligibility. The discussion proceeds from heterogeneous subjects and forms of intelligence through temporal and vulnerability differences, heterogeneous values, partial mutual intelligibility, economic relation under incomplete commen-

surability, human–AI relations, more-than-human relations, and boundary cases involving radically different subjects. The method is constitutive and analytical. It identifies conditions under which heterogeneous coexistence can be studied without presuming either complete commonality or complete incomparability.

Heterogeneity matters to GRE for a reason deeper than descriptive diversity. Difference can alter the mechanisms through which relations are formed, interpreted, stabilized, and transformed. Subjects that process information at different speeds can experience the same contract differently. Subjects with different vulnerabilities can bear the same nominal risk unequally. Subjects organized around different value structures can participate in the same economic arrangement while understanding its significance in different terms. Human and artificial systems can cooperate productively while differing sharply in embodiment, temporal horizon, memory, responsibility, and normative status. Economic coexistence therefore often depends on interfaces that enable coordination across difference rather than on the elimination of difference itself.

This perspective also changes the analytical meaning of coordination. Coordination need not imply shared ontology, identical preferences, common measures of value, or full mutual comprehension. It can arise through partial translation, rule-governed interfaces, protocols, conventions, negotiated thresholds, legal forms, institutional guarantees, or stable expectations concerning a limited domain of interaction. Such arrangements can be robust even when deeper interpretations remain divergent. They can also be fragile when the interface suppresses differences that later become economically consequential. GRE therefore asks both how heterogeneous subjects manage to relate and which differences remain unresolved beneath an apparently successful relation.

Heterogeneity should consequently be distinguished from disorder. A heterogeneous system can possess highly organized relations, and a homogeneous representation can conceal important differences. Likewise, coexistence should be distinguished from harmony. Subjects can coexist through cooperation, competition, dependency, conflict, indifference, mutual constraint, or asymmetric accommodation. The relevant GRE question is not whether heterogeneity produces agreement, but how different forms remain connected, how the relation distributes benefits and burdens, and how the terms of coexistence shape future generative possibilities.

3.15.1 Heterogeneous Subjects

The first dimension of heterogeneity concerns the kinds of subjects that participate in economic relations. Earlier sections treated economic subjecthood as relationally situated, institutionally recognized, temporally persistent, and historically transformable. The present section extends that argument by emphasizing that an economy can contain multiple subject forms at once. Individual persons, households, firms, states, cooperatives, communities, platforms, algorithmic systems, hybrid organizations, and other collective or artificial arrangements can all occupy economically consequential positions while remaining different in constitution and status.

These differences matter because the capacities through which subjects enter relations are not interchangeable. A natural person may possess legal rights, embodied

needs, lived vulnerability, memory, social identity, and moral standing that differ categorically from the capacities of a corporation or software system. A corporation can persist across changes in personnel, accumulate assets, sign contracts, and coordinate action across large spatial scales. A public institution can exercise legally authorized powers that private actors lack. An artificial system can process or generate representations at speeds and volumes unavailable to human participants while lacking many forms of embodied participation through which human economic life is organized.

GRE therefore resists the temptation to create one abstract subject model and treat every participant as a parameterized instance of it. A unified formal representation can be useful for a local task, but the analyst must identify which dimensions of subjecthood have been suppressed. Treating a household, a company, and an automated trading system as "agents" can clarify interaction structure while obscuring differences in accountability, embodiment, temporal persistence, legal rights, or the capacity to experience harm. The representational convenience of a common agent label does not establish ontological or normative equivalence.

Heterogeneous subjecthood also means that relations can be constitutive in different ways for different participants. Employment may constitute livelihood and social identity for a worker while functioning as a cost and organizational input for a firm. Credit can appear as a portfolio exposure to a lender and as a condition of continued residence or enterprise survival to a borrower. A platform can treat a user interaction as data-generating activity while the user experiences it as communication, work, entertainment, or social participation. The same relation can therefore occupy different places in the reproduction of each subject.

This asymmetry of significance is analytically important. Economic relations cannot always be understood by assigning the same type of variable to each side. The relation may link subjects whose persistence conditions are fundamentally different. One participant can exit with limited consequence while another loses access to income, identity, infrastructure, or social connection. GRE analysis should therefore specify what the relation does for each subject, which capacities it supports, which vulnerabilities it exposes, and how these differences affect bargaining, interpretation, and future generation.

Heterogeneous subjects can nevertheless form stable relations. Stability may arise through law, trust, standards, routines, contracts, technical interfaces, conventions, organizational design, or repeated adaptation. The existence of such stability shows that shared subject form is not a prerequisite for economic relation. What matters is whether the relation contains sufficiently compatible interfaces for action, interpretation, and expectation within the domain that must be coordinated.

3.15.2 Heterogeneous Forms of Intelligence

Economic analysis often speaks of information, knowledge, skill, and rationality as though intelligence were a single capacity that subjects possess in greater or lesser amounts. GRE treats intelligence more cautiously. Different subjects can exhibit different forms of problem solving, inference, adaptation, memory, perception, coordination, judgment, and representation. These forms may be partly comparable for a

defined task without being reducible to one general economic scale.

Human economic intelligence includes dimensions that are difficult to separate cleanly: practical know-how, embodied familiarity, social interpretation, linguistic competence, moral judgment, imagination, aesthetic discrimination, memory, emotional response, and the capacity to act under incomplete and ambiguous conditions. Collective subjects can display organizational intelligence that no member possesses individually, including routines, distributed expertise, institutional memory, and coordinated response. Computational systems can display high performance in search, optimization, prediction, generation, classification, or symbolic transformation while relying on infrastructures, training processes, objectives, interfaces, and external forms of validation that structure what their outputs mean and how they are used.

Task-specific comparison is therefore often more informative than a universal ranking. One system may outperform another at high-dimensional pattern recognition while performing poorly where contextual interpretation, embodied judgment, accountability, or long-horizon institutional memory is decisive. An expert organization may coordinate a complex regulatory process effectively while responding slowly to unfamiliar technological change. A local community may possess detailed ecological knowledge that is poorly represented in standardized datasets. Heterogeneous intelligence appears as differentiated capability profiles rather than as a single ladder.

This matters economically because different forms of intelligence can become complementary. A relation can generate value precisely because participants perceive or process different features of a problem. Human–machine systems can combine computational scale with human contextual judgment. Interdisciplinary teams can connect different epistemic traditions. Firms can coordinate specialized units whose local knowledge would be insufficient in isolation. Markets themselves can sometimes coordinate dispersed information without requiring any participant to possess a complete representation of the system.

Complementarity, however, does not eliminate power. The party that controls the interface among forms of intelligence can shape which outputs count, which errors are visible, which judgments are overridden, and which forms of knowledge become economically legible. Standardization can facilitate coordination while devaluing tacit or local knowledge. Automated decision systems can increase processing capacity while concentrating control over model design, data, thresholds, or appeals. The governance of heterogeneous intelligence is therefore partly a problem of interface design and partly a problem of institutional power.

GRE should accordingly distinguish capability difference from epistemic authority. Superior performance in one domain does not automatically justify decision authority in another. Prediction accuracy does not itself settle normative legitimacy. Computational scale does not settle interpretive authority. Human status does not guarantee technical competence. A mature analysis asks which form of intelligence is relevant to which claim, what evidence supports its reliability, how different forms are combined, and who controls the terms of combination.

3.15.3 Heterogeneous Temporalities

Economic subjects also inhabit different temporal structures. Temporal heterogeneity concerns differences in pace, horizon, persistence, delay, memory, reversibility, and the timing through which consequences become visible. These differences can be as consequential as differences in resources or capability because a relation that is sustainable at one temporal scale can be destructive at another.

Individuals often make decisions under lifetimes measured in decades, daily needs measured in hours, and contractual obligations measured in months or years. Firms may evaluate projects through reporting cycles, investment horizons, product lifecycles, or expectations concerning market entry and exit. Public institutions can operate through electoral, budgetary, legal, and infrastructural timescales. Financial systems can react within milliseconds while housing, education, ecological restoration, demographic change, and institutional trust can unfold over decades. Artificial systems can process and update representations rapidly while the social institutions required to evaluate, regulate, or contest their deployment move more slowly.

Temporal heterogeneity creates coordination problems. A rapidly adjusting actor can repeatedly change strategy before a slower institution completes review. Short-term financial incentives can conflict with long-term maintenance or ecological resilience. A policy may generate immediate benefits while degrading capacities that become visible only years later. Conversely, insisting on very long evaluation horizons can leave urgent present vulnerabilities insufficiently addressed. No single time horizon is automatically privileged across all economic questions.

GRE therefore treats temporal alignment as an analytical problem. Contracts, standards, insurance, reserves, review periods, waiting times, sunset clauses, intergenerational institutions, and adaptive governance can all be understood partly as devices for coordinating subjects whose consequences and capacities unfold at different rates. Such devices do more than schedule action. They distribute whose temporality receives priority. A deadline can privilege the actor able to mobilize quickly. A long approval process can protect against irreversible harm while disadvantaging subjects facing immediate need. A quarterly reporting regime can orient organizations toward measurable near-term outputs at the expense of slower generative effects.

Temporal heterogeneity also complicates attribution. A downstream effect may emerge long after the originating intervention, after intermediate relations have changed and after responsible institutions or personnel have disappeared. Conversely, a long-standing structure can condition present action without appearing in short observational windows. GRE analysis should therefore state the temporal horizon of its claims and examine whether the relevant mechanism operates faster or slower than the data used to identify it.

Coexistence across heterogeneous temporalities requires more than synchronization. Some differences should remain. Ecological regeneration cannot necessarily be accelerated to match financial expectations. Human deliberation may require time that automated processing does not. Institutional due process can be intentionally slower than market reaction. The governance question is therefore which temporal differences should be bridged, which should be protected, and how costs created by temporal mismatch are distributed.

3.15.4 Heterogeneous Vulnerabilities

Subjects differ not only in what they can do but also in what can harm them, how quickly harm occurs, how visible it is, and how readily recovery is possible. Vulnerability heterogeneity concerns these differentiated exposures and recovery conditions. It is especially important because relations that appear symmetric in formal terms can create highly asymmetric consequences when participants have different capacities to absorb loss.

The same monetary loss can be marginal for one subject and existential for another. A temporary service interruption can inconvenience a large organization while eliminating a small firm's only route to customers. Delayed payment can be a minor accounting issue for a well-capitalized buyer and a liquidity crisis for a supplier. Exposure of personal information can create embodied or social risks for an individual that have no equivalent in the experience of an automated system. Environmental degradation can affect communities whose livelihoods depend directly on local ecosystems while remaining abstract in the accounting of distant investors.

Vulnerability is therefore relational and domain-specific. A subject can be highly capable in one domain and vulnerable in another. Large firms can possess extensive resources while depending critically on specific infrastructure or regulatory permissions. States can exercise coercive authority while remaining technologically dependent. Artificial systems can be operationally powerful yet dependent on electricity, hardware, data centers, network access, maintenance, and human authorization. Vulnerability analysis should identify the failure conditions that matter for the particular relation rather than infer resilience from general size or capacity.

Recovery is as important as exposure. Two subjects exposed to the same disturbance can differ in reserves, insurance, social support, legal recourse, substitutability, repair knowledge, or access to alternative relations. These differences affect bargaining because the subject that can survive delay or failure usually possesses greater strategic freedom. Exit asymmetry, discussed in the previous section, is one expression of this wider vulnerability structure.

GRE also asks how relations generate vulnerability over time. Specialization can increase efficiency while producing dependence on narrow supply chains. Platform participation can expand market access while making future income dependent on ranking systems or account continuity. Debt can finance productive capacity while increasing sensitivity to interest rates or income interruption. An ecological intervention can raise present output while reducing resilience to later shocks. Vulnerability is therefore often produced jointly with value.

Governance under heterogeneous vulnerability should not assume that formally equal treatment produces equivalent protection. Uniform rules can distribute risk unequally when participants have different failure thresholds. At the same time, vulnerability should not be used as a permanent identity that freezes subjects into protected categories. The analytical task is to identify specific exposure, consequence, recovery capacity, and the mechanisms through which the relation modifies them.

3.15.5 Heterogeneous Value Structures

Economic coexistence frequently connects subjects that organize value differently. Value heterogeneity includes differences in what is valued, how value is recognized, which trade-offs are acceptable, what temporal horizon matters, what forms of loss are considered substitutable, and which goods are treated as inappropriate for exchange. GRE therefore treats value structure as plural rather than assuming that all relevant evaluation can be represented through a single utility, price, welfare index, or scalar measure.

Some values are readily expressed through monetary exchange because institutions already provide stable units, markets, contracts, and accounting conventions. Others are represented through rights, duties, thresholds, rankings, narratives, professional norms, ecological indicators, cultural meanings, or qualitative judgments. A community may value continuity of place in ways poorly represented by compensation for relocation. A worker may value autonomy, recognition, security, or meaningful participation alongside income. A public institution may be bound by legality and equal treatment even where another arrangement would reduce cost. Ecological relations can involve irreversibility, species loss, or system resilience that resists straightforward substitution.

Heterogeneous value structures do not imply that coordinated decision is impossible. Institutions routinely make decisions under plural values. They use budgets together with rights constraints, technical standards, minimum thresholds, deliberation, priority rules, side constraints, multicriteria evaluation, and negotiated settlements. These devices are forms of practical ordering rather than proof that all underlying values have become commensurable.

This distinction between ordering and commensurability is central. A decision can select one option without establishing a universal measure that converts every relevant value into a common unit. A legal prohibition can exclude some options before cost comparison begins. A safety threshold can structure a feasible set without pricing every possible injury. Negotiation can produce agreement acceptable to different parties for different reasons. GRE can analyze these arrangements as relational mechanisms for coordinating value heterogeneity.

Value heterogeneity also creates power questions. The institution that chooses the metric can privilege values that fit that metric. Monetary valuation can make some losses legible while rendering others peripheral. Quantitative indicators can improve transparency while narrowing attention to what is measurable. Expert vocabularies can facilitate comparison while excluding affected participants whose reasons are expressed differently. The politics of value therefore includes the design of representation and conversion rules.

GRE evaluation should preserve this plurality where it is substantively real. Scalar measures remain useful where a common measure is justified, but they should not acquire authority merely because they simplify optimization. When values are only partially commensurable, the analysis should record the remaining plurality rather than treating it as noise around a preferred metric.

3.15.6 Partial Mutual Intelligibility

Heterogeneous subjects rarely understand one another completely. Their categories, temporal horizons, sensory access, institutional roles, languages, models, and value structures can differ. Yet complete mutual understanding is not required for economic relation. Partial mutual intelligibility refers to the degree of shared interpretation sufficient for a defined form of coordination while leaving other aspects of the participants' worlds untranslated.

A buyer and seller can agree on quantity, quality, price, and delivery without sharing the same reasons for valuing the transaction. Organizations from different legal cultures can cooperate through contracts and technical standards while retaining different institutional assumptions. Humans can use computational systems whose internal representations they do not fully reconstruct, provided interfaces, validation procedures, and accountability arrangements make the relevant outputs sufficiently interpretable for the task. Scientific and local knowledge systems can sometimes coordinate around observable indicators while interpreting causal significance differently.

Partial intelligibility is therefore often produced by interfaces. A contract translates complex intentions into enforceable obligations. A standard reduces heterogeneous production processes to specified performance criteria. An API enables computational systems built on different internal architectures to exchange defined messages. A price compresses information relevant to exchange while leaving many reasons and consequences outside the transaction. A legal category makes different cases administratively comparable while suppressing detail. These interfaces enable relation precisely by limiting what must be mutually understood.

The reduction involved in an interface can be productive, but it can also generate misrecognition. When the interface omits a difference that later becomes consequential, coordination can fail. A metric can appear shared while participants interpret it differently. A model output can be operationally accepted without agreement on its epistemic status. A standardized category can group subjects whose vulnerabilities diverge sharply. The existence of a functioning interface therefore does not establish deep mutual understanding.

GRE analysis should ask what must be intelligible for the relation to function and what remains opaque. It should also ask who bears the risk created by opacity. If one party can demand explanation while the other cannot, interpretive asymmetry can become power. If a computational system influences access to credit, employment, or public services, the intelligibility required for legitimate use can be greater than the intelligibility required merely for technical operation.

Partial mutual intelligibility offers a middle position between two unrealistic assumptions: complete transparency and complete incommensurability. Economic life often proceeds through workable but incomplete translations. The quality of coexistence depends on whether these translations are sufficient for the stakes involved, revisable when they fail, and governed in ways that distribute interpretive risk fairly.

3.15.7 Economic Relations without Full Commensurability

Economic relation does not require every relevant object, value, subject, or consequence to be representable on one common scale. Exchange itself can involve commensuration for a limited purpose while broader aspects of the relation remain incommensurable. GRE therefore distinguishes local comparability from full commensurability.

A wage places a monetary value on labor time for the purpose of employment, but it does not establish that income exhausts the value of work, identity, health, autonomy, or social recognition. Insurance can assign compensation schedules to losses without implying that the compensated state is equivalent to the pre-loss state. Environmental markets can price particular emissions or ecosystem services while leaving cultural, ecological, and intergenerational values only partially represented. Cost-benefit analysis can support a decision under specified assumptions without becoming a complete theory of value.

Relations under incomplete commensurability often rely on layered decision rules. Some dimensions are priced. Others are protected through rights or prohibitions. Some are represented through minimum standards, negotiated conditions, or procedural safeguards. Others remain open to qualitative judgment. Such layered arrangements can be analytically messy, but the mess may reflect genuine plurality rather than methodological failure.

GRE can therefore study conversion without assuming equivalence. A value can be converted into another form through an institution even when the conversion is contested or incomplete. Time can be converted into wages; attention into advertising revenue; reputation into credit access; ecological damage into compensation obligations; research prestige into funding opportunity. The existence of a conversion mechanism shows that a relation connects the forms. It does not prove that the forms are intrinsically equivalent.

This distinction helps analyze exploitation and loss. When an institution repeatedly converts one form of value into another under asymmetric terms, the question is not only how much is transferred but which dimensions disappear during conversion. A platform can monetize social interaction while leaving users with limited claims on the resulting economic value. A development project can compensate property loss while failing to restore community networks. A labor contract can pay for output while externalizing health or care burdens. In each case, commensuration can enable exchange while concealing residual effects.

Coexistence under plural values therefore requires institutional creativity. Markets are one mechanism among several. Deliberation, commons governance, public provision, professional standards, rights, mutual aid, licensing, quotas, thresholds, and hybrid arrangements can coordinate heterogeneous values in different ways. GRE does not presume in advance which mechanism is appropriate. It asks how the chosen mechanism makes some values comparable, leaves others outside comparison, distributes authority over conversion, and alters future possibilities.

3.15.8 Human–AI Relations as a Contemporary Case

Human–AI relations provide a contemporary case in which heterogeneity of subject form, intelligence, temporality, vulnerability, and value can appear simultaneously. GRE can analyze these relations without first resolving philosophical questions about machine consciousness or personhood. The immediate economic question is how human and artificial operational subjects become connected through production, decision, communication, ownership, infrastructure, and institutional authority.

The asymmetry is multidimensional. Artificial systems can process or generate large volumes of symbolic material rapidly, replicate outputs at low marginal cost, and operate continuously within suitable infrastructure. Humans retain forms of embodiment, lived vulnerability, social membership, legal standing, moral responsibility, contextual experience, and value formation that are not established by computational performance. Organizations often mediate between the two, determining data access, deployment goals, review procedures, liability, and the distribution of gains.

This heterogeneity creates complementary possibilities. Artificial systems can extend search, translation, drafting, prediction, pattern recognition, or simulation. Human participants can contribute contextual interpretation, problem selection, normative judgment, embodied knowledge, accountability, and decisions concerning what purposes should be pursued. The generative question is how the relation changes the capabilities of both the immediate participants and the surrounding institutions.

It also creates new dependencies. Workers can become dependent on tools they do not control. Organizations can become dependent on model providers, computational infrastructure, or proprietary interfaces. Users can rely on systems whose update cycles alter behavior faster than institutional procedures adapt. Expertise can shift from producing outputs directly to evaluating, directing, integrating, or contesting machine-generated outputs. These changes can redistribute bargaining power even when aggregate productivity rises.

Human–AI coexistence therefore should not be analyzed through replacement alone. Substitution is one possible relation. Others include complementarity, supervision, delegation, contestation, infrastructural dependence, mutual adaptation, and reorganization of occupational or institutional roles. The relevant GRE object is the evolving relational configuration: who controls the system, who defines objectives, who bears error, who receives generated value, which human capacities are strengthened or weakened, and how future alternatives are shaped.

The case also clarifies partial mutual intelligibility. Humans may use outputs without understanding every internal computational process, while artificial systems operate on representations that do not amount to human understanding in any straightforward sense. Economic coordination can nevertheless occur through interfaces, tests, standards, feedback, and institutional review. The adequacy of that partial intelligibility should depend on stakes. A low-risk drafting aid and a system affecting liberty, livelihood, healthcare, or public authority require different evidential and governance conditions.

GRE therefore treats human–AI relations as an important contemporary domain of heterogeneous coexistence, while maintaining ontological and normative caution.

Operational capability does not settle personhood. Performance difference does not settle moral status. Economic usefulness does not settle legitimacy. These questions remain connected but analytically distinct.

3.15.9 More-than-Human and Ecological Relations

Economic systems also coexist with organisms, ecosystems, climatic processes, material cycles, and other more-than-human structures whose dynamics are constitutive of production and life. GRE includes these relations because economic generation depends on ecological and material conditions even when those conditions are poorly represented by conventional economic subjects.

More-than-human analysis requires ontological care. A forest, river, species, or ecosystem need not be treated as a subject in exactly the same sense as a human person or organization for its relational role to be economically consequential. Ecological systems can impose constraints, provide capacities, absorb waste, regenerate resources, transmit disturbances, and respond to interventions through dynamics that exceed the intentions of economic actors. Some legal or cultural traditions may also recognize nonhuman entities through forms of representation or standing. GRE can study these arrangements without requiring one universal theory of nonhuman subjecthood.

Ecological heterogeneity is strongly temporal. Soil formation, forest succession, hydrological cycles, species recovery, and climate processes can unfold at rates that differ from market, budgetary, and political cycles. An economic system can therefore appear productive within a short window while drawing down slower regenerative capacities. Conversely, ecological protection can impose immediate costs while preserving long-horizon generative conditions. The choice of temporal scale becomes part of evaluation rather than a neutral technical setting.

Vulnerability is likewise heterogeneous. An industrial actor may be able to relocate while a local ecosystem cannot. A community may depend on a specific river or coastal system whose loss is not replaceable by monetary compensation. Species and ecological processes can cross thresholds beyond which recovery becomes difficult or impossible on humanly relevant timescales. These differences complicate models that assume reversible substitution among resources.

Partial intelligibility appears here as well. Human institutions do not fully observe ecological systems. Models, indicators, monitoring networks, local knowledge, and scientific interpretation provide partial representations. Intervention therefore occurs under uncertainty about feedback, thresholds, and delayed effects. GRE's epistemic commitments require the distinction between ecological reality and its representation to remain explicit, especially where uncertainty interacts with potentially irreversible change.

The economic question is how relations with more-than-human systems affect present and future capacities. Extraction, cultivation, conservation, restoration, pollution control, infrastructure, and land-use rules all modify ecological conditions from which later economic possibilities emerge. More-than-human coexistence is thus central to generative analysis because the future economy is partly generated through relations with systems that exceed the boundaries of human institutions.

3.15.10 Boundary Cases of Radically Different Subjects

The most demanding cases for GRE arise when participants differ so substantially that ordinary assumptions of shared preference, common language, reciprocal recognition, or comparable vulnerability become unreliable. These boundary cases may involve relations among human communities with sharply different ontologies, future artificial systems with unfamiliar forms of agency, interspecies relations, intergenerational relations in which one party is not yet present, or institutional interactions with ecological systems that cannot participate in negotiation in conventional terms. The purpose of considering such cases is not to classify every entity as a subject. It is to test which parts of GRE remain usable when mutual similarity is minimal.

The first requirement is to separate relation from reciprocity. A subject or system can be economically affected by another without being able to respond in the same channel. Future generations can bear consequences of present debt, infrastructure, ecological damage, and knowledge preservation without participating in present bargaining. Nonhuman systems can constrain or respond to economic activity without expressing preferences through markets or language. An artificial system can alter human opportunities while its own status as a bearer of interests remains unsettled. Economic relation can therefore exist under asymmetric capacities for representation and response.

The second requirement is representational humility. When one side cannot articulate its interests through the dominant institutional interface, another actor often speaks on its behalf. Guardians, regulators, scientific experts, community representatives, trustees, legal advocates, or technical proxies can perform this role. Representation may be necessary, but it creates a second-order relation in which the representative's categories can shape what becomes visible. GRE analysis should therefore examine not only the represented subject or system but also the institutions that authorize, translate, and contest representation.

The third requirement is to distinguish coordination from assimilation. Radically different subjects need not become similar in order to coexist. Governance can instead create protected distances, limited interfaces, non-interference rules, thresholds, buffer zones, rights, or protocols that make coexistence possible while preserving difference. In some cases the appropriate relation is closer integration; in others it may be separation or restriction of contact. GRE does not prescribe one universal form of coexistence because the relevant vulnerabilities, values, and generative effects differ.

Boundary cases also expose the limits of commensuration. Where interests or values cannot be credibly translated into one metric, decision may require procedural legitimacy, precaution, rights, representation, plural evaluation, or explicit acknowledgment of unresolved disagreement. A decision can still be made, but the residual disagreement remains part of the record rather than disappearing into a scalar result. This is especially important where the affected party cannot later recover from the imposed decision.

The broader constitutional implication is that GRE should be able to study economies composed of heterogeneous forms without making homogeneity a hidden precondition of analysis. Economic relation can persist through partial intelligibility,

bounded interfaces, heterogeneous values, differentiated temporalities, unequal vulnerabilities, and incomplete commensurability. The task is to identify which differences matter to the relation, which interfaces make coordination possible, which conversions obscure residual losses, and how the terms of coexistence alter future generative possibilities.

Heterogeneity therefore belongs inside the GRE problem-space rather than at its margins. It prevents the economic subject from being silently standardized, prevents intelligence from being reduced to one ranking, prevents temporality from being treated as uniform, prevents vulnerability from being inferred from formal equality, and prevents value from being collapsed into a single measure. It also provides a bridge to the next constitutional problem. Once GRE accepts heterogeneous forms as legitimate participants and objects of inquiry, it must state more precisely where its own disciplinary boundaries lie and how it relates to neighboring economic and social-scientific traditions. The following section therefore turns to the boundaries of Generative Relational Economics.

3.16 Boundaries of Generative Relational Economics

Generative Relational Economics is intended to remain intellectually permeable without becoming disciplinarily indeterminate. The role of this section is to specify the principal boundaries through which GRE relates to neighboring economic and social-scientific traditions while preserving a recognizable problem-space of its own. Its objective is neither to rank adjacent approaches nor to absorb them into a single synthesis. Instead, the section clarifies where GRE can borrow concepts, methods, evidence, and explanatory mechanisms; where genuine overlap exists; and where a distinction should be maintained because the neighboring tradition asks a different primary question, uses a different evaluative register, or makes commitments that GRE does not need to adopt. The discussion proceeds through mainstream economics, political economy, relational economics, economic sociology, complexity economics, evolutionary economics, capability approaches, ecological and regenerative economics, generative justice, and general Generative Relational Theory. The method is boundary-setting rather than genealogical. Chapter 2 reconstructed intellectual lineages; the present task is to define interfaces for an emerging research programme.

A disciplinary boundary in this sense is not a wall. GRE can use optimization, causal inference, institutional analysis, network models, historical interpretation, capability concepts, ecological accounting, or justice-oriented evaluation whenever those tools are appropriate to the claim under investigation. The boundary concerns the conditions under which such borrowing remains intelligible. A borrowed method does not make a study identical with the field from which that method came, and a shared object does not erase differences in analytical emphasis. Firms, households, technologies, institutions, ecosystems, capabilities, and power can all be studied by several traditions at once while being rendered differently by each.

This openness is necessary because many GRE questions are intrinsically composite. A study of platform labor may require conventional price and labor-market analysis, institutional and legal interpretation, network structure, computational measure-

ment, political-economic analysis of control, and normative evaluation of capability or dependency. A study of agricultural transition may require cost and productivity analysis, ecological constraints, household reproduction, institutional history, technological coevolution, and long-horizon generative effects. GRE contributes when the inquiry asks how relations among these elements generate, distribute, stabilize, transform, or foreclose later capacities and possibilities. It does not require every neighboring perspective to be translated into GRE terminology.

Boundary maintenance therefore serves two purposes. First, it protects GRE from conceptual inflation. If every relational, dynamic, institutional, or justice-oriented economic study were automatically classified as GRE, the programme would lose analytical content. Second, it protects neighboring fields from retrospective appropriation. GRE can inherit and recombine resources while acknowledging that those resources have their own histories, standards, and unresolved debates. The disciplinary identity developed in this chapter depends on dialogue without theoretical identity.

3.16.1 GRE and Mainstream Economics

GRE has no constitutive need to define itself through opposition to mainstream economics. Standard economic analysis contains powerful tools for studying prices, incentives, choice under constraints, equilibrium, strategic interaction, causal effects, welfare consequences, production, and allocation. Where a research problem is adequately specified by those objects, GRE gains little by redescribing the same analysis in relational vocabulary. The boundary is therefore positive: GRE becomes useful when the research question concerns how the relevant preferences, capacities, constraints, institutional positions, relations, or future opportunity sets are themselves generated and transformed through economic processes.

This distinction can be stated through analytical depth rather than disciplinary hierarchy. A conventional model may treat preferences as given over the horizon of analysis. GRE can accept that local simplification when preference formation is irrelevant to the question. A different study may need to explain how advertising, institutions, peer relations, platform design, education, or repeated participation reshape preferences or salience. In that setting, what was reasonably exogenous in the first model becomes an object of inquiry. The same logic applies to technology, endowments, legal categories, information structures, capabilities, and market boundaries.

Equilibrium analysis provides another example. GRE does not reject equilibrium as a mathematical or empirical concept. A stable or approximately stable configuration can be analytically important. The additional GRE question concerns what relations sustain the configuration, how the stability distributes capacities and vulnerabilities, whether the configuration generates new conditions that alter its own persistence, and what happens when the relevant state space or institutional rules change. Equilibrium can therefore appear within GRE without defining the whole research programme.

The relation is similarly complementary in empirical work. Econometric identification, experimental design, structural estimation, administrative data analysis, and causal inference can provide strong evidence for particular mechanisms or effects.

GRE should use such evidence where available and should not substitute relational prose for identification. At the same time, an estimated local causal effect does not automatically reveal downstream institutional transformation, changing subject positions, altered exit conditions, or long-run generative consequences. Those further claims require further evidence.

The boundary can thus be summarized in terms of problem selection. Mainstream economics often provides the strongest available analysis when the relevant agents, constraints, preferences, technologies, and institutional rules can be treated as sufficiently stable. GRE becomes especially relevant when those conditions are part of what must be explained. The relationship is therefore one of selective extension and mutual correction rather than displacement.

3.16.2 GRE and Political Economy

GRE overlaps substantially with political economy because both can treat economic outcomes as inseparable from institutions, power, historical formation, distribution, and collective organization. Questions concerning ownership, labor, state capacity, financial structure, class, technological control, colonial legacies, regulation, and asymmetric dependence are naturally shared terrain. GRE does not need a separate vocabulary when political economy already provides an adequate account of the relevant mechanism.

The principal difference lies in analytical center of gravity. Political economy frequently organizes inquiry around the distribution and exercise of power among classes, states, firms, institutions, or social groups. GRE includes these objects but asks an additional family of questions concerning what those relations generate over time: capacities, subject positions, dependencies, values, institutional pathways, representational structures, ecological conditions, and the possibility of later action. Power remains central, yet GRE does not make every economic relation reducible to power.

This distinction matters because a relation can be generatively important even when domination is weak or absent. Cooperative institutions can generate capabilities and norms. Public infrastructure can create new spaces of participation. Educational systems can alter the subjects capable of entering later markets or political processes. Technological standards can coordinate activity without being explainable primarily through coercion. Political-economic analysis may already address these effects; GRE emphasizes their generative structure as a recurring cross-domain problem.

Conversely, GRE should not dilute political-economic mechanisms by translating them into neutral language of relation. Ownership, coercion, exclusion, dispossession, monopoly, dependency, and state authority possess specific institutional and historical content. When such mechanisms explain an outcome, they should be named directly. Relational vocabulary is not a substitute for analyzing who controls resources, who bears risk, who sets rules, or who can credibly exit.

GRE therefore sits near political economy while preserving a broader generative question. It can investigate how power structures generate future inequalities and institutional lock-in, but it can also study relations of learning, cooperation, care, eco-

logical reproduction, or symbolic orientation whose economic importance is not exhausted by power. The boundary allows GRE to inherit political economy's seriousness about history and asymmetry without treating political-economic conflict as the sole grammar of economic generation.

3.16.3 GRE and Relational Economics

The strongest conceptual overlap may appear between GRE and approaches that explicitly place relations at the center of economic analysis. Relational economics, relational goods, network-based economic analysis, and other relation-sensitive traditions already challenge the assumption that economic value and behavior can always be understood through isolated individuals and possessed objects. GRE shares the view that access, interaction, recognition, coordination, dependency, and participation can be economically constitutive.

The boundary arises from the second term in the name: generative. GRE is interested not only in the existence or quality of relations but also in what relations bring into being, reproduce, transform, or foreclose. A relation can connect already-defined actors, but it can also alter their capabilities, identities, institutional positions, preferences, expectations, and future relations. The analytical question moves from the structure of a relation to the consequences of participating in and reproducing that relation.

This distinction prevents a relation-first approach from becoming static. Two networks can share similar topology while differing in what their ties generate. Two contractual arrangements can appear similar at one moment while producing different long-term capabilities or dependencies. A cooperative relation can initially create shared capacity and later become exclusionary. A market relation can transmit value while also changing the conditions under which future exchange occurs. GRE therefore requires temporal and generative specification beyond identifying relational structure.

At the same time, GRE does not claim that every relation generates deep transformation. Many relations may be transient, weak, or analytically negligible for the research question. The researcher must establish which relations matter, through which mechanisms, and over what horizon. Relation itself is not an explanatory endpoint.

The boundary with relational economics is thus narrow but meaningful. GRE belongs naturally within a wider family of relational economic approaches, while adding a systematic focus on downstream generation, recursive transformation, heterogeneous forms of value, changing subjects, and future possibility. That addition should be treated as a research orientation rather than as a claim that earlier relational work failed to recognize change or emergence.

3.16.4 GRE and Economic Sociology

Economic sociology provides many of the concepts required for GRE to avoid an overly thin account of economic action. Institutions, social networks, conventions, organizations, classifications, trust, status, embeddedness, cultural interpretation, and

collective identity can all shape what economic relations are possible and how they are understood. GRE therefore shares a substantial empirical and conceptual domain with economic sociology.

The boundary is not based on a sharp separation between "economic" and "social" facts. GRE rejects such a simple partition. The distinction is better located in the organizing research problem. Economic sociology can ask how markets, firms, money, organizations, or valuation are socially constituted. GRE can use those analyses and then ask how the resulting economic relations transform later capacities, values, constraints, subject positions, and structures of possibility. The two directions can be mutually reinforcing.

GRE also retains an explicitly economic concern with allocation, production, circulation, extraction, capability, scarcity, and the organization of resources. These objects prevent the programme from dissolving into a general sociology of relations. A sociological account of trust may explain why exchange becomes possible; GRE may further analyze how the exchange redistributes capacity, creates dependency, alters future bargaining positions, or changes the institutions that sustain trust. A sociological account of classification may explain category formation; GRE may examine how that classification changes access to credit, work, insurance, mobility, or recognition.

This interface is especially important for symbolic and representational objects. Prices, ratings, credentials, risk scores, categories, and rankings can be both social facts and economic mechanisms. GRE can study their generative effects without claiming that economic sociology is merely a precursor to GRE. The traditions differ in disciplinary history and in the questions they prioritize.

The boundary therefore remains porous. GRE depends on sociological evidence whenever economic relations are constituted by social meaning, institutional recognition, or organizational form. It remains recognizably economic when the inquiry centers on how such relations organize resources, capacities, value, scarcity, exchange, production, and future economic possibility.

3.16.5 GRE and Complexity Economics

Complexity economics and GRE share an interest in heterogeneous agents, nonlinearity, adaptation, path dependence, interaction effects, emergent macro-patterns, and systems that change outside simple equilibrium descriptions. Complexity methods can be especially valuable when aggregate outcomes arise from distributed interactions and when feedback alters the trajectory of the system.

The overlap is methodological as well as conceptual. Agent-based models, network models, simulation, nonlinear dynamics, and computational experiments can all contribute to GRE where the research problem is compatible with their assumptions. These tools allow researchers to study distributed generation, threshold effects, coordination, cascading change, and multiple possible trajectories.

GRE nevertheless remains broader than a complexity methodology. A GRE contribution need not contain a simulation, a network model, or a nonlinear formal system. Historical interpretation, institutional analysis, qualitative research, comparative case studies, legal analysis, causal inference, and participatory inquiry can all

be appropriate. Complexity is one representational and explanatory family among several.

A second boundary concerns the representation of emergence. A computational model can demonstrate how a macro-pattern emerges from specified micro-rules. That result is important, but it establishes emergence within the model. GRE must still ask whether the selected agents, rules, state variables, and interactions adequately represent the empirical process. It may also need to explain how the rules themselves were historically generated, interpreted, contested, or transformed.

A third boundary concerns normativity and meaning. Complex adaptive behavior can persist without being desirable. A resilient system can stabilize exclusion, ecological harm, or domination. Actors can interpret the same rule differently, and those interpretations can alter later action. GRE therefore combines complexity-sensitive analysis with explicit attention to historical meaning, institutional authority, heterogeneous value, and normative evaluation.

The relationship is consequently close but non-identical. Complexity economics supplies powerful tools for distributed and nonlinear generation; GRE adds a wider methodological repertoire and makes the generation of rules, subjects, meanings, and evaluative conditions available as research objects where evidence permits.

3.16.6 GRE and Evolutionary Economics

Evolutionary economics offers another close interface because it treats economic systems as historically changing populations of technologies, routines, organizations, practices, and institutions. Innovation, variation, selection, retention, path dependence, learning, and coevolution provide important resources for analyzing processes that cannot be reduced to static optimization.

GRE shares the historical and processual orientation while avoiding an automatic translation of every generative process into evolutionary terms. Generation can occur through variation and selection, but it can also arise through deliberate institutional design, legal reclassification, collective interpretation, negotiated coordination, education, care, public investment, conflict, or sudden technological recombination. Evolutionary mechanisms are therefore important members of a broader generative repertoire.

The distinction is also useful for normative analysis. Persistence or selection does not demonstrate efficiency, justice, desirability, or superior adaptive value in every relevant sense. Institutions can survive because alternatives are suppressed, switching costs are high, incumbents control infrastructure, or vulnerable groups bear the costs of persistence. GRE therefore treats selection outcomes as explanatory objects that may require separate normative evaluation.

Coevolution provides particularly fertile common ground. Firms and technologies, institutions and practices, infrastructures and habits, or policies and expectations can change in mutually conditioning ways. GRE extends the question when the process changes the kinds of subjects, capacities, value forms, or relations that can exist in the next period. The interest lies not only in reciprocal adaptation but in transformation of the conditions under which later adaptation occurs.

GRE can thus use evolutionary models and concepts whenever variation, selection, retention, innovation, and coevolution explain the empirical process. Its boundary lies in refusing to make those mechanisms exhaustive. The programme remains open to generative processes whose historical logic is interpretive, institutional, juridical, ecological, political, or deliberately designed rather than primarily evolutionary.

3.16.7 GRE and Capability Approaches

Capability approaches and GRE share a concern with what people and other relevant subjects are substantively able to do and to become. This creates a natural interface between the evaluation of resources and the analysis of conversion conditions. Equal resources can produce unequal capabilities when subjects face different institutions, environments, social relations, embodied conditions, or access structures.

GRE adopts this insight without treating capability as its sole evaluative language. Capability is one dimension of generative consequence. Economic relations can generate or erode capabilities, but they can also transform dependency, recognition, institutional participation, relational quality, ecological conditions, symbolic orientation, and the possibility of collective action. Some of these effects can be translated into capability terms; others may be better preserved as distinct analytical objects.

The temporal orientation also differs in emphasis. Capability analysis can evaluate the substantive opportunities available at a given time. GRE places particular attention on how those opportunities were generated, how they are maintained, and how present relations alter the capability-generating conditions of the future. This makes capability formation, reproduction, concentration, and erosion central dynamic questions.

Capability asymmetry further enters the analysis of power. A difference in capability does not automatically create domination, but it can become leverage when one subject controls an infrastructure, knowledge resource, legal permission, computational system, or exit option required by another. GRE therefore connects capability analysis to relational conversion mechanisms without reducing capability to power.

The boundary is normative as well as analytical. GRE can use capability-oriented evaluation without claiming to settle the philosophical questions that capability theories address concerning freedom, human flourishing, lists of central capabilities, or the justification of public priorities. Those debates remain neighboring normative resources. GRE's contribution is to investigate how economic relations generate and distribute the conditions under which capabilities become possible, durable, or foreclosed.

3.16.8 GRE and Ecological and Regenerative Economics

Ecological and regenerative economics provide essential resources for any GRE analysis in which economic generation depends on material, energetic, ecological, or more-than-human conditions. Production cannot be understood solely through monetary circulation when it depletes soils, water, biodiversity, climate stability, or other conditions required for future activity. Conversely, economic relations can sustain and regenerate ecological capacities under some institutional arrangements.

GRE shares the emphasis on stocks, flows, throughput, ecological limits, interdependence, and long-horizon reproduction. It also shares the concern that apparent short-term gain can undermine the conditions of later possibility. Generative foreclosure has a direct ecological meaning when present extraction damages the ecological capacities through which future livelihoods or social systems could otherwise be sustained.

The boundary again concerns scope and normativity. GRE uses "generative" in a broader sense than ecological regeneration. A process can generate institutions, subject positions, knowledge, technological capacities, dependencies, or symbolic values while degrading ecological conditions. Conversely, ecological regeneration can occur within social arrangements that distribute benefits or burdens unjustly. The descriptive fact of regeneration therefore requires separate social and normative evaluation.

GRE also avoids treating circularity, resilience, regeneration, and generativity as synonyms. A circular material flow can preserve an unjust labor relation. A resilient system can stabilize harmful dependence. A regenerative ecological practice can impose burdens on communities whose knowledge or land is appropriated. The relevant analysis must specify what is being regenerated, for whom, through which relations, and with what consequences elsewhere.

The relationship is therefore strongly complementary. Ecological and regenerative economics prevent GRE from treating future possibility as socially generated in isolation from biophysical conditions. GRE contributes a wider account of how ecological and economic processes interact with institutions, power, subjects, value forms, and the distribution of future generative capacity.

3.16.9 GRE and Generative Justice

Generative justice is one of the closest normative neighbors of GRE because it directs attention to the circulation and return of generative value and to the conditions under which communities retain control over the processes that produce value. Earlier in the book, this lineage was treated as an established theoretical resource rather than as a retrospective expression of GRE. That distinction remains important at the disciplinary boundary.

GRE shares the concern that evaluation should extend beyond the immediate allocation of outputs. A relation can appear distributively acceptable at one moment while extracting the capacities, knowledge, infrastructures, or ecological conditions that enable future generation. Conversely, an arrangement can strengthen future capability by returning value, knowledge, authority, or productive infrastructure to the subjects and communities involved.

The two programmes nevertheless have different scope. Generative justice is explicitly normative. GRE combines descriptive, explanatory, causal, historical, formal, computational, normative, and intervention-oriented modes. A GRE study can analyze how value recirculates or is extracted without concluding that a particular pattern is just. Normative judgment requires additional premises concerning participation, domination, capability, harm, ecological sustainability, procedural legitimacy, plural values, and future possibility.

GRE also uses a wider conception of what may be generated. Material wealth and productive capacity are central, but economic relations can also generate subject positions, representations, institutional authority, dependencies, expectations, knowledge, ecological conditions, and future option structures. Return of value is therefore one important pattern among several possible generative trajectories.

The boundary preserves attribution and conceptual clarity. GRE can learn directly from generative justice while maintaining a broader economic research programme whose normative analysis remains open to several theories of justice and to the neighboring work of GREthic. The overlap is substantive, but theoretical identity would obscure differences in purpose and scope.

3.16.10 GRE and General Generative Relational Theory

The final boundary is internal to the wider research programme. General Generative Relational Theory provides the broader conceptual space in which relations, generation, ontological emergence, epistemic mediation, historical transformation, power, normativity, and praxis can be studied across domains. GRE is the economic instantiation of that wider framework. The distinction is necessary because not every generative-relational problem is an economic problem.

GRE therefore adopts only the amount of general GR required to investigate economic objects. It studies production, allocation, circulation, exchange, extraction, capability, scarcity, institutions, economic subjecthood, value, power, ecological dependence, and the transformation of future economic possibility. General GR may address analogous structures in law, politics, education, science, aesthetics, knowledge, culture, or other domains where the primary research problem is not economic.

This distinction prevents disciplinary expansion by analogy. A relational pattern discovered in economic analysis should not automatically be generalized to every social domain. Conversely, a concept developed in another GR domain may require translation before it becomes economically meaningful. The relevant mechanisms, evidence, units of analysis, institutions, and normative stakes can differ substantially across domains.

The relation is nevertheless recursive. GRE can contribute concepts and findings back to general GR. Economic studies may reveal new mechanisms of generative foreclosure, recursive power, value conversion, subject formation, or cross-scale transformation that later become useful outside economics. Other GR domains can likewise correct GRE by showing that an apparently economic process depends on legal, political, epistemic, cultural, or ecological structures that GRE alone cannot adequately explain.

General GR should therefore function neither as a doctrinal authority over GRE nor as a collection of metaphysical propositions that economic research is expected to confirm. It is a broader, revisable framework that can coordinate comparison among domains while remaining open to correction from domain-specific work. GRE retains disciplinary responsibility for the quality of its economic evidence and explanation.

The boundaries established across this section give GRE a position that is open without being unlimited. The programme can use mainstream economic models, political-

economic accounts of power, relational and sociological analyses, complexity and evolutionary methods, capability concepts, ecological and regenerative analysis, and generative-justice insights. None of these interfaces requires GRE to become identical with the neighboring field. The criterion is whether the borrowed resource helps explain how economic relations generate, reproduce, distribute, transform, or foreclose later capacities and possibilities.

This boundary-setting also prepares the next task of disciplinary constitution. Once GRE's neighboring interfaces have been identified, a further question becomes unavoidable: what would make a particular study count as a contribution to GRE rather than merely a study that uses relational language? The following section therefore turns from external boundaries to internal research standards, specifying the criteria by which a GRE contribution can state its relational problem, generative claim, evidence, boundary conditions, normative commitments, and cumulative contribution with sufficient clarity to be evaluated and revised.

3.17 Criteria for a GRE Research Contribution

The preceding sections have defined the problem-space, analytical objects, scales, modes of inquiry, epistemic commitments, praxis orientation, normative concerns, and disciplinary boundaries of Generative Relational Economics. A research programme, however, also requires internal standards by which particular studies can be recognized, criticized, compared, and accumulated. The role of this section is to state those standards. Its objective is neither to create a rigid checklist nor to police disciplinary membership through terminology. It is to specify the minimum analytical work required for a contribution to make a recognizably GRE claim. The discussion proceeds through ten criteria: specification of the relational problem; explicit scale and boundary conditions; identification of the generative claim; evidence appropriate to that claim; distinction between representation and relational reality; attention to downstream effects; consideration of alternative generative mechanisms; normative transparency; reproducibility and interpretive traceability; and contribution to cumulative knowledge. The method is constitutional and methodological. These criteria are intended to make GRE research more contestable, revisable, and cumulative rather than more doctrinal.

A study need not satisfy every criterion with the same intensity. A conceptual paper may contribute primarily through category formation and theoretical clarification. A historical study may establish a generative mechanism through archival reconstruction. An econometric study may identify a restricted causal relation while leaving wider ontological questions open. A simulation may explore the consequences of a specified generative mechanism without claiming empirical completeness. An intervention study may generate evidence about relational change that could not be obtained through detached observation alone. The relevant standard is proportionality: the claims made should be supported by an appropriate combination of analytical specification, evidence, and methodological transparency.

GRE therefore treats disciplinary contribution as a relation between a problem, a claim, a representation, evidence, and a cumulative research context. Relational vo-

cabulary alone does not establish that relation. A paper that describes a network, invokes emergence, or discusses downstream effects is not thereby a GRE contribution. The GRE character becomes substantive when the research shows how a specified economic relation contributes to the generation, reproduction, transformation, distribution, or foreclosure of later capacities, values, subjects, constraints, structures, or conditions of possibility, and when that claim is made in a form that other researchers can examine and revise.

3.17.1 Specification of the Relational Problem

A GRE contribution begins by specifying the relational problem under investigation. This requirement is stronger than stating that the topic is "relational." The study should identify which subjects, entities, institutions, infrastructures, representations, ecological conditions, or other analytically relevant configurations are connected, what kind of relation is at issue, and why that relation matters to the economic problem being studied.

The relation may involve exchange, production, financing, employment, ownership, access, dependence, coordination, classification, care, information, legal recognition, infrastructure use, platform participation, resource extraction, ecological dependence, or another economically consequential connection. Its empirical form may be contractual, informal, symbolic, technical, organizational, institutional, spatial, ecological, or distributed across several of these forms. GRE does not require a single taxonomy of relations. It requires enough specification for the researcher and reader to know what is being claimed to connect what.

Relational specification should also identify the economically relevant incidence of the relation. The administrative recipient of a resource, policy, payment, model, or intervention may be only one locus within a wider relational field. A subsidy to a firm can affect workers, suppliers, competitors, financial institutions, local communities, infrastructure demand, and future investment. A credit decision can affect households, landlords, employers, insurers, and later access to other services. A platform rule can alter users, complementors, advertisers, content producers, and labor conditions. The research problem becomes relational when these connections are treated as analytically constitutive rather than as residual externalities added after the main analysis.

The study should further clarify whether the relation is itself the principal object or whether it mediates another object of interest. A paper may examine the formation of a labor relation, the consequences generated through that relation, or the way the relation transforms its own future conditions. These are different research problems. Stating the relation precisely prevents a general language of interdependence from substituting for explanation.

Relational specification does not require exhaustive mapping. Every inquiry selects some relations and leaves others outside the active representation. The contribution lies partly in justifying why the selected relations are sufficient for the local question and in making visible which important relations have been bracketed. A study that names its relational problem clearly can later be extended, challenged, or re-scaled. A study that leaves the relation implicit is harder to evaluate because dis-

agreement about evidence can conceal disagreement about what the object actually is.

3.17.2 Explicit Scale and Boundary Conditions

Every GRE contribution should state the scale and boundary conditions within which its claims are intended to hold. Economic relations change character across temporal, organizational, spatial, institutional, ecological, and analytical scales. An apparent entity at one scale can decompose into heterogeneous relations at another. A mechanism visible in a household, firm, or platform may operate differently at sectoral, juridical, ecological, or transnational scales. Explicit scale selection therefore belongs to the substance of the analysis rather than to a technical appendix.

Boundary conditions specify what is treated as inside the active system of analysis, what is treated as an environment or background condition, and what is excluded. These boundaries can be geographical, institutional, temporal, jurisdictional, organizational, technological, ecological, or representational. They can also be nested. A study of a labor platform may define the platform ecosystem as the primary boundary while treating labor law, payment infrastructure, and macroeconomic conditions as surrounding systems that enter through specified interfaces.

Temporal boundaries require particular care because generative effects can be delayed. An intervention that raises income over six months may reduce a productive or ecological capacity over five years. A technology that expands access in one period can create dependence on proprietary infrastructure later. A relational configuration that appears stable during one institutional regime may dissolve when law, prices, expectations, or political authority change. A GRE contribution should therefore identify the temporal horizon of the claim and, when appropriate, distinguish immediate effects from slower structural or generative transformations.

Explicit boundary conditions also constrain generalization. Evidence from one sector, jurisdiction, historical period, or technological architecture does not automatically establish the same mechanism elsewhere. A GRE study can make a narrow claim and still be theoretically important if it states the conditions under which the mechanism is expected to operate. Conversely, broad claims require correspondingly broad evidence or a carefully justified theoretical argument.

Scale and boundary transparency creates a path for cumulative research. Later studies can test whether a mechanism persists under different institutional arrangements, whether a relation changes when the scale is expanded, or whether a boundary previously treated as external should become endogenous to the analysis. Boundary choice is therefore both a limitation and a research instrument.

3.17.3 Identification of the Generative Claim

A GRE contribution should identify its generative claim explicitly. The generative claim states what the specified relation is proposed to generate, reproduce, transform, distribute, or foreclose, through which mechanism, and over what temporal horizon. This is the criterion that most clearly distinguishes a GRE contribution from a study that merely uses relational language.

The generated object can take many forms. It may be a capability, resource, institutional position, subject identity, expectation, dependency, value form, knowledge structure, ecological condition, network topology, bargaining position, classification, infrastructure, norm, or future option. It may also be a change in the conditions under which further generation occurs. The generative claim should therefore name the analytical object rather than relying on the generic statement that a relation "creates value" or "produces effects."

The mechanism also matters. A relation may generate later capacity through learning, investment, access, network reinforcement, institutional recognition, technological complementarity, legal stabilization, reputational accumulation, ecological regeneration, coordination, or another process. It may generate foreclosure through extraction, depletion, lock-in, exclusion, deskilling, dependency, displacement, institutional erosion, or destruction of alternatives. Different mechanisms can produce similar observed outcomes, and the same mechanism can have different consequences under different conditions.

Generative claims can vary in strength. A descriptive contribution may show that a relational configuration is systematically associated with later capacity formation. A historical contribution may reconstruct a plausible mechanism across a sequence of institutional changes. A causal contribution may identify the effect of a specified relation on a downstream outcome under defined assumptions. A formal contribution may demonstrate that a mechanism can generate a class of patterns within a model. A simulation may explore the conditions under which a proposed mechanism becomes sufficient or insufficient. These claims should be distinguished rather than compressed into one category of proof.

A strong GRE contribution also clarifies whether the mechanism concerns generation within an existing structure or transformation of the structure itself. Creating additional productive capacity under stable rules differs from changing ownership, classification, institutional authority, or the effective rules by which future capacities are generated. The distinction helps prevent ordinary output expansion from being mislabeled as deep generative transformation.

The purpose of requiring an explicit generative claim is therefore diagnostic as well as disciplinary. It enables readers to ask whether the claimed generated object actually changes, whether the proposed mechanism is observed or inferred, whether alternative mechanisms fit the evidence, and whether the effect persists beyond the immediate horizon. Generativity becomes a researchable proposition rather than an honorific description.

3.17.4 Evidence Appropriate to the Claim

Evidence in GRE should be appropriate to the epistemic form and strength of the claim. No single evidential hierarchy governs every generative question. Historical reconstruction, ethnography, interviews, administrative records, experiments, quasi-experiments, surveys, network data, financial records, ecological measurements, computational traces, legal documents, formal proofs, and simulations can each support different kinds of inference. Methodological pluralism therefore requires disciplined matching between claim and evidence.

A claim about lived dependency may require qualitative or interpretive evidence that cannot be replaced by aggregate transaction data. A claim about population-level incidence may require quantitative evidence that interviews alone cannot establish. A claim about historical institutional transformation may require archival evidence and temporal reconstruction. A causal claim about an intervention may require an identification strategy capable of distinguishing the effect from confounding processes. A formal claim requires internally valid derivation under stated assumptions. A simulation establishes consequences of modeled rules and parameters rather than direct observation of the empirical target.

The evidence should also correspond to the downstream object named in the generative claim. If a paper claims that a financing relation generates capability, it should observe or defensibly proxy the relevant capability rather than infer it solely from the initial allocation of finance. If a platform intervention is claimed to increase autonomy, measures of throughput or usage alone are insufficient unless the relation between those measures and autonomy is theoretically and empirically justified. If an ecological practice is claimed to regenerate future production conditions, evidence should reach beyond current output toward the ecological capacities that support future activity.

Mixed evidence can be especially valuable when the generative mechanism crosses representational levels. Quantitative data may reveal a distributional pattern while interviews clarify how the relation operates. Institutional documents can establish formal authority while observed practice reveals its implementation. Simulation can explore whether a proposed mechanism is sufficient to produce an observed macro-pattern while empirical data constrain the plausible parameter range. Such combinations should be integrated through a stated inferential logic rather than accumulated as decorative methodological diversity.

Evidence appropriateness also includes negative evidence and failed expectations. When a proposed generative mechanism predicts downstream change that does not occur, the absence can narrow the mechanism, reveal a missing condition, or indicate that the representation is wrong. GRE should therefore retain evidential structures that permit a generative claim to be weakened or rejected. A programme that can only reinterpret every outcome as evidence of hidden generativity would cease to be empirically corrigible.

3.17.5 Distinction between Representation and Relational Reality

A GRE contribution should distinguish the representation used in analysis from the relational reality the representation is intended to illuminate. Networks, graphs, categories, state spaces, fields, equations, indicators, taxonomies, maps, legal classifications, interview codes, and computational models are analytical constructions. They can disclose important structure while also suppressing, aggregating, or transforming aspects of the target.

The distinction is particularly important because relational analysis often makes structure visually or mathematically compelling. A network diagram can make nodes and edges appear ontologically given even when node identities, tie definitions, missing relations, and temporal aggregation are products of the data-generating process.

A scalar indicator can make heterogeneous value appear commensurable. A field representation can suggest continuity where the empirical system contains discontinuities or institutionally discrete categories. A model can hold agents or rules fixed even when historical change in those objects is part of the substantive problem.

GRE does not therefore require researchers to distrust representation. Representation is unavoidable and productive. The requirement is reflexive specification. A contribution should explain what the representation makes visible, what it treats as stable, what it aggregates, what it excludes, and how those choices affect the claim. The more strongly the conclusion depends on a representational choice, the more important sensitivity to alternative representations becomes.

This criterion also applies to institutional representations. Legal categories, accounting classifications, platform metrics, credit scores, productivity measures, and administrative identities can become economically operative representations. They are not merely researcher-created descriptions. Their use can shape access, recognition, risk, resource allocation, and subject positions. A GRE study may therefore analyze a representation both as an epistemic device and as an economic mechanism.

Maintaining the distinction between representation and relational reality supports ontological suspension. Researchers can use network, field, dynamical, or computational language without claiming that the empirical economy literally possesses the complete ontology of the formalism. The analytical question is whether the representation is adequate to the local problem and generative claim. Competing representations can remain simultaneously useful when they disclose different aspects of the same economic configuration.

3.17.6 Attention to Downstream Effects

A GRE contribution should examine downstream effects far enough to evaluate the stated generative claim. This requirement does not demand infinite causal tracing. It requires the researcher to look beyond the immediate administrative output when the theoretical claim concerns later capacities, relations, values, constraints, or possibilities.

Downstream analysis begins by identifying plausible channels of propagation. A transfer to one organization may alter wages, procurement, investment, debt, market entry, local prices, or political influence. A new classification system may affect eligibility, insurance, credit, employment, or legal recognition. An AI system deployed to increase productivity may alter skill formation, supervision, bargaining power, organizational knowledge, and dependency on technical infrastructure. A conservation intervention may change ecological capacity, land access, community authority, and future livelihood options.

GRE should distinguish propagation from attribution. Observing a downstream change after an intervention does not establish that the focal relation generated it. The contribution should specify the pathway through which the effect is expected to travel and identify evidence consistent with that pathway. Where causal identification is unavailable, the claim should remain calibrated accordingly.

Downstream attention should also include distribution. The same relation can gen-

erate gains for one subject while shifting risk, depletion, dependency, or opportunity loss to another. Aggregate improvement can therefore coexist with localized generative foreclosure. A GRE contribution should identify who receives immediate outputs, who gains later capacity, who bears costs, and whose future options become more or less available when these differences are material to the research question.

Temporal depth matters as well. Some generated effects decay quickly; others accumulate or become self-reinforcing. A short evaluation horizon can misclassify a process whose main economic significance lies in later lock-in, learning, institutionalization, ecological regeneration, or erosion. Researchers should therefore justify the chosen horizon in relation to the mechanism rather than treating the observation window as analytically neutral.

The downstream criterion ultimately protects the concept of generativity from collapsing into ordinary output measurement. GRE asks what a relation leaves behind in the capacities and conditions from which later economic processes proceed. The appropriate downstream horizon is the one required to make that question empirically meaningful.

3.17.7 Attention to Alternative Generative Mechanisms

A GRE contribution should consider plausible alternative mechanisms capable of generating the observed pattern. This criterion follows directly from epistemic humility and from the fact that similar outcomes can emerge from different relational configurations. Mechanism identification becomes stronger when the researcher explains why the preferred account fits the evidence better than important alternatives.

Alternative mechanisms can operate at the same scale or at different scales. Increased productivity within a firm may result from worker learning, capital deepening, selection of more productive workers, changes in task allocation, demand expansion, or measurement artifacts. Increased community income after an intervention may reflect genuine local capability generation, temporary transfers, migration, price effects, or extraction from another location. Institutional persistence may arise from legitimacy, coordination benefits, legal coercion, network lock-in, sunk costs, or the absence of viable alternatives.

GRE should also remain attentive to equifinality: different histories can produce similar configurations. The existence of a stable relation does not uniquely reveal how it was generated. Comparative, historical, and process evidence can help distinguish pathways. In formal or computational research, sensitivity analysis can show whether the result depends on a narrow mechanism or emerges across several model structures.

Alternative mechanisms include representational alternatives. An apparent relation can arise because of measurement, classification, selection, aggregation, or omitted variables. A network pattern can change when edge definitions change. A capability indicator can move because the proxy changes while the underlying capability does not. A historical discontinuity can reflect an archival or institutional change in what was recorded. These possibilities do not invalidate the analysis; they specify additional hypotheses that should be considered where material.

The purpose of this criterion is not to require exhaustive refutation of every imaginable mechanism. It is to prevent a favored generative narrative from becoming insulated from competition. A GRE contribution should identify the most consequential alternatives given the domain, evidence, and claim strength, and state what additional evidence could discriminate among them. Competing mechanisms are part of cumulative research rather than threats to disciplinary coherence.

3.17.8 Normative Transparency

A GRE contribution should make its normative premises transparent whenever evaluative language enters the argument. Terms such as improvement, harm, empowerment, exclusion, justice, sustainability, resilience, capability, autonomy, participation, regeneration, and desirable generation carry normative content that should not be smuggled into a descriptive mechanism claim.

Normative transparency begins by distinguishing what the study observes from how it evaluates what is observed. A relation may generate new productive capacity while also increasing domination. A technology may expand access while weakening privacy or exit. A policy may preserve an institution while reducing the possibility of alternative forms of organization. A regenerative ecological intervention may improve biophysical conditions while distributing burdens inequitably. These cases cannot be evaluated solely by establishing that generation occurred.

The relevant evaluative principles should therefore be stated at the level needed for the claim. A study may adopt a capability perspective, a rights-based standard, a distributive criterion, a relational account of domination, a procedural standard, an ecological constraint, a plural-value framework, or another justified normative basis. GRE does not require one universal normative theory at the level of research contribution. It requires researchers to distinguish the empirical and generative analysis from the premises through which consequences are judged.

Normative transparency is equally important when a study refrains from full evaluation. Researchers may state that a mechanism increases a capability, concentrates control, or changes future options while leaving the overall justice of the arrangement unresolved. Such restraint can be more informative than forcing heterogeneous effects into a single welfare ranking.

Value plurality further requires explicit treatment of commensuration. If a study aggregates several forms of value into one index, score, monetary measure, or optimization objective, it should explain the justification and consequences of that aggregation. Practical commensuration may be necessary for decision-making without establishing that the underlying values are genuinely commensurable. A GRE contribution should preserve this distinction when it matters.

Normative transparency thus protects both positive and normative inquiry. It prevents descriptive evidence from carrying more evaluative force than it can support, while allowing ethical and political judgments to enter economic analysis openly rather than being hidden in model structure, metric selection, or outcome definition.

3.17.9 Reproducibility and Interpretive Traceability

A cumulative research programme requires other researchers to be able to reconstruct how a conclusion was produced. GRE therefore treats reproducibility and interpretive traceability as complementary standards. Their concrete form varies by method, but the underlying requirement is that the pathway from material or data to claim should remain inspectable.

For quantitative and computational work, reproducibility may involve accessible data where ethically and legally possible, documented preprocessing, variable definitions, code, model specifications, parameter choices, random seeds, robustness checks, and version information. Where data cannot be shared, the study should provide enough procedural detail to clarify what another researcher would need to reproduce the analysis under authorized access.

For qualitative, historical, and interpretive research, exact replication may be impossible or conceptually inappropriate. Interpretive traceability becomes the more suitable standard. The researcher should document source selection, coding or interpretive procedures, archival boundaries, translation choices, interview protocols, contextual assumptions, and the evidential basis for major interpretive moves. Readers should be able to distinguish the source material from the interpretation built upon it.

Formal research requires a related form of traceability. Definitions, assumptions, derivations, propositions, and the relation between formal objects and empirical interpretation should be explicit. A proof can be reproducible while its empirical meaning remains ambiguous; both layers therefore need documentation. Simulation requires the same separation between reproducibility of the computational experiment and validity of the modeled representation.

Traceability also applies to boundary and category revision. If a study changes the definition of a subject, relation, value form, or relevant system during analysis, the change should be visible. Such revision can be intellectually productive, especially in relational research where the empirical material may reveal that initial categories are inadequate. The contribution becomes stronger when readers can see why the revision occurred and how it affected the result.

These standards are not merely procedural ideals. They distribute epistemic authority. A claim whose evidential path can be inspected is easier to contest, reinterpret, update, and reuse. Reproducibility and interpretive traceability therefore support the broader GRE commitments to revisability, methodological pluralism, and re-epistemization across time.

3.17.10 Contribution to Cumulative Knowledge

A GRE contribution should clarify what becomes more knowable because of the study and how that result can enter a cumulative research programme. Novel terminology alone is insufficient. A contribution may refine a concept, establish a new typology, identify a mechanism, map a relational configuration, provide comparative evidence, develop a formal representation, test an intervention, construct a measure, document a boundary condition, falsify an earlier claim, or expose an unresolved contradiction.

These are different forms of cumulative advance.

Cumulative contribution requires relation to prior work. A study should indicate which GRE problem, concept, mechanism, or empirical domain it extends, revises, or challenges. Because GRE is an emerging programme, this relation may initially be internal to the book's preliminary constitution or to a small body of subsequent work. The standard should nevertheless be established early: later research should not repeatedly reinvent the same relational vocabulary without specifying what has changed.

Negative and limiting results are especially important. Demonstrating that a proposed generative mechanism fails under certain institutional conditions can advance the programme by specifying its scope. Showing that two indicators previously treated as proxies diverge can improve measurement. Identifying a case in which downstream generation is negligible can prevent overextension of the framework. Revealing that competing representations yield materially different conclusions can redirect theoretical development. Cumulative knowledge includes disciplined contraction as well as expansion.

A contribution should also preserve reusable analytical objects where possible. Clearly defined categories, documented datasets, mechanism diagrams, typologies, validated measures, formal models, intervention protocols, comparative cases, and explicit boundary conditions can support later synthesis. Reusability does not require standardization of every method. It requires enough conceptual and evidential continuity for results to be compared rather than remaining isolated narratives.

Cumulative knowledge in GRE is expected to remain historically revisable. Concepts adequate to one technological or institutional period may become insufficient as economic subjects, relations, infrastructures, and forms of value change. The purpose of accumulation is therefore not to build an immutable doctrinal core. It is to build a record of concepts, mechanisms, evidence, boundary conditions, disagreements, and revisions from which later inquiry can proceed with greater precision.

Taken together, the criteria in this section provide a practical threshold for recognizably GRE research. A contribution should specify the relation under study, state its scale and boundaries, articulate the generative claim, match evidence to the claim, distinguish representation from relational reality, trace relevant downstream effects, consider plausible alternative mechanisms, disclose normative premises, preserve reproducibility or interpretive traceability, and explain how the result contributes to cumulative knowledge. The criteria remain proportional to the type of inquiry, but they create a common language for criticism across heterogeneous methods.

These standards also shift Chapter 3 from disciplinary constitution toward research development. Once contributions can be evaluated individually, the next question concerns how they can accumulate across projects into a programme that develops concepts, typologies, maps, mechanisms, formal models, simulations, intervention evidence, measures, and revisions over time. The following section therefore turns from the criteria for a single GRE contribution to the architecture of a cumulative GRE research programme.

3.18 Cumulative Research Programme

The preceding section specified the standards by which an individual contribution can be recognized as part of Generative Relational Economics. A research programme, however, requires more than a sequence of individually competent studies. It requires mechanisms through which concepts can be stabilized and revised, cases can become comparable, mechanisms can be accumulated across contexts, formal and computational representations can become reusable, interventions can generate transferable evidence, measures can be improved, and theoretical claims can contract as well as expand. The role of this section is therefore to specify how GRE can develop cumulatively without converting cumulative development into doctrinal closure. Its objective is to identify several forms of accumulation through which a still-emerging research programme can become more precise, more testable, more comparable across domains, and more corrigible over time.

Cumulative development in GRE is expected to be heterogeneous. Historical reconstruction, conceptual clarification, comparative case analysis, mechanism identification, formal modeling, simulation, intervention research, and indicator construction do not accumulate in identical ways. A concept can become more precise without becoming more universal. A mechanism can recur across cases while remaining conditional on institutional context. A formal model can improve analytical discipline without establishing empirical adequacy. An intervention can generate evidence about a relational configuration that cannot be transferred unchanged to another scale. The programme therefore needs forms of accumulation that preserve local differences while still allowing knowledge to travel.

The central commitment is that accumulation should increase the quality of future inquiry rather than merely increase the quantity of publications. A cumulative programme should make later researchers better able to distinguish objects, specify boundaries, formulate mechanisms, compare cases, identify failed expectations, construct representations, and revise earlier claims. Accumulation is therefore closely related to memory: the programme must preserve not only successful formulations but also boundary conditions, null findings, abandoned distinctions, incompatible representations, and reasons for revision. This historical record is part of the epistemic infrastructure through which GRE can remain generative without repeatedly rediscovering its own problems.

3.18.1 Conceptual Development

Conceptual development provides one of the earliest forms of cumulative work in an emerging research programme. GRE depends on terms such as relation, generativity, capacity, subject, field, orientation, propagation, conversion, foreclosure, and generative condition. These terms can guide inquiry only when their meanings become sufficiently explicit for disagreement, comparison, and revision. Conceptual development therefore concerns the progressive clarification of what a term denotes, what it excludes, how it differs from neighboring terms, which empirical indicators can bear upon it, and under what conditions the concept ceases to be useful.

Such development should proceed through distinction rather than inflation. A

concept becomes stronger when researchers can identify nearby phenomena that it should not subsume. Generativity, for example, should not become a general synonym for causation, productivity, innovation, emergence, or social change. Relationality should not become a label attached to any situation containing more than one actor. Orientation should not become equivalent to intention. Power should not become interchangeable with every asymmetry. Conceptual accumulation therefore requires negative space: a concept is partly stabilized by the cases and mechanisms that researchers agree belong elsewhere.

Conceptual development is also historical. A distinction useful in one institutional or technological period may become insufficient when the object changes. The meaning of economic subjecthood may need revision when artificial systems undertake increasingly consequential operational roles. The concept of resource may change when informational, ecological, infrastructural, or symbolic forms become central to production. The concept of value may require further differentiation when heterogeneous value forms interact without stable conversion ratios. GRE should therefore treat conceptual stabilization as provisional achievement rather than final definition.

A cumulative conceptual record should preserve successive formulations and their reasons. Later versions should make visible whether a term was broadened, narrowed, divided, or replaced. This allows conceptual disagreement to become cumulative rather than repetitive. Researchers can then ask whether a difference arises from incompatible definitions, different empirical domains, different scales, or genuinely competing theoretical commitments. Conceptual development becomes part of research infrastructure when it reduces ambiguity while preserving the possibility of revision.

3.18.2 Typology Development

Typologies allow recurrent heterogeneity to be organized without requiring reduction to a single scalar dimension. They are especially important for GRE because many objects of inquiry are structurally plural: economic subjects can differ in kind, relations can differ in direction and persistence, value can take multiple forms, generative effects can propagate through different channels, and interventions can create benefits and harms through distinct mechanisms. A typology provides a way to preserve these differences while making comparison possible.

Typology development should begin from analytically relevant distinctions rather than from the desire to populate a classificatory table. A useful typology changes what can be observed or compared. Distinguishing resource asymmetry from capability asymmetry, for example, matters because possession and effective capacity can diverge. Distinguishing relational dependence from domination matters because dependence can exist without one subject acquiring durable control over another. Distinguishing propagation, conversion, recirculation, dissipation, and extraction matters because downstream value trajectories differ even when an initial allocation is identical.

Typologies should also remain open to overlap. GRE objects are frequently multidimensional, and a single case can instantiate several types at once. A platform may be simultaneously an organizational actor, a field-structuring infrastructure, a rep-

resentational system, and a locus of institutional power. A transfer programme can be allocative, capability-enhancing, dependency-producing, and institution-forming at different stages. Typological clarity therefore does not require exclusive membership unless exclusivity is substantively justified.

Cumulative typology development requires empirical confrontation. Categories should be revised when recurrent cases do not fit, when two categories fail to produce meaningful explanatory differences, or when one category hides internally distinct mechanisms. Cross-case work is especially important because a typology derived from one institutional context may mistake a local classification for a general one. Typologies accumulate when their boundary conditions, empirical uses, exceptions, and revisions are recorded rather than when their labels simply proliferate.

3.18.3 Relational Mapping

Relational mapping concerns the systematic representation of economically consequential connections among subjects, institutions, resources, infrastructures, representations, capacities, and environments. The purpose is not to impose a universal network ontology. It is to make relational structure visible enough that claims about mediation, dependence, propagation, power, or generation can be examined rather than assumed.

Different research problems require different maps. A transaction map may trace flows of money or goods. An authority map may represent legal and organizational powers. A capability map may identify which relations enable access to knowledge, infrastructure, care, finance, or mobility. A representation map may show how classifications and metrics connect institutional decisions to subject positions. A temporal map may represent the order through which one relation conditions a later possibility. Ecological or supply-chain analysis may require several of these layers simultaneously.

Cumulative relational mapping depends on comparability without forced standardization. Researchers should document node definitions, relation types, temporal windows, missing-data assumptions, scale choices, and the meaning of direction or weight where these are used. When mappings from different studies cannot be directly combined, the reasons should be visible. Differences in mapping conventions can then become substantive evidence about how the object itself is differently constituted across contexts.

Relational maps can also accumulate historically. Repeated mapping can show how a configuration changes, which ties persist, which dependencies become concentrated, where new intermediaries emerge, and whether an intervention alters the topology of opportunity or control. Longitudinal mapping is particularly useful for GRE because generative claims often concern changes in the conditions from which later actions become possible. The cumulative product is not a final map of the economy, but a set of documented representations that can be compared, revised, and linked to mechanism claims.

3.18.4 Mechanism Identification

Mechanism identification provides a central bridge between relational description and generative explanation. GRE is concerned not only with whether two conditions are associated, but with how a relation contributes to the production, reproduction, transformation, or foreclosure of later capacities and possibilities. A cumulative programme therefore needs recurrent mechanism families that can be investigated across settings without assuming that the same mechanism operates universally.

Mechanisms may involve resource access, learning, coordination, institutional recognition, bargaining leverage, infrastructural dependence, feedback, expectation formation, classification, imitation, exclusion, risk transfer, ecological regeneration, or many other processes. What makes such a process a useful GRE mechanism is not its novelty of name but its role in connecting a relational configuration to a downstream change. The mechanism should specify intermediate transformations sufficiently clearly that evidence can support, weaken, or reject the claim.

Cumulative mechanism work benefits from decomposition. A broad claim that an intervention ”builds capability” may contain several distinct processes: it may increase material resources, reduce uncertainty, create social recognition, provide technical knowledge, alter institutional eligibility, or change expectations about future access. Disaggregating these processes allows later studies to test whether the same downstream effect arises through different mechanisms or whether similar interventions produce different outcomes because only some mechanism components are present.

Mechanism accumulation should therefore include enabling conditions, inhibiting conditions, competing mechanisms, and failure modes. A mechanism that appears robust in one setting may depend on trust, legal enforceability, technological infrastructure, social norms, or complementary public goods. Recording these conditions turns isolated explanations into a comparative mechanism library. Such a library remains revisable and context-sensitive, but it gives later researchers a stronger starting point than an undifferentiated appeal to relational complexity.

3.18.5 Comparative Case Accumulation

Cases become cumulative when they are documented in ways that permit meaningful comparison. GRE therefore requires comparative case accumulation rather than a collection of richly described but analytically disconnected examples. The purpose of comparison is not necessarily to produce universal laws. It can identify recurring relational configurations, clarify boundary conditions, distinguish mechanisms, reveal alternative pathways, and show how similar interventions generate different outcomes under different institutional or historical conditions.

Comparison can be organized around cases, mechanisms, trajectories, scales, or interventions. Two regions may receive similar infrastructure investments yet generate different capability effects because institutional access differs. Two platforms may use similar algorithms but create different labor dependencies because ownership and exit options differ. Two ecological restoration projects may produce comparable short-term outputs while diverging in long-run regenerative capacity. A com-

parative design becomes especially informative when the axis of comparison corresponds to a plausible mechanism difference.

Cumulative case repositories should therefore preserve more than outcome variables. They should record relational boundaries, subject categories, institutional context, temporal horizon, intervention history, relevant value forms, and evidential limitations. Standardized metadata can help without forcing all cases into identical theoretical categories. The aim is to make later synthesis possible while retaining the contextual features through which generative mechanisms may differ.

Negative and anomalous cases are particularly valuable. A case in which a predicted mechanism fails can identify a missing enabling condition or expose an overgeneralized concept. A case that produces an unexpected downstream effect can reveal a propagation channel absent from the original theory. A cumulative programme should therefore preserve cases that resist prevailing formulations rather than treating them as noise to be excluded from the archive.

3.18.6 Formal Model Development

Formal models can contribute cumulative value by making assumptions, relations, and implications explicit. In GRE, formalization may represent dynamics, networks, allocation processes, bargaining relations, value conversion, capability change, field-like influence, institutional rules, or recursive transformations of generative conditions. The purpose is analytical discipline rather than formalization for its own sake.

A cumulative formal programme should preserve model lineage. Later models should indicate which assumptions are inherited, relaxed, extended, or replaced. If one model treats subject identities as fixed while another allows subject formation, the difference should be explicit. If one model uses scalar value while another represents plural value dimensions, the comparison should identify what explanatory capacity is gained and what tractability is lost. Formal accumulation then becomes a sequence of interpretable modifications rather than a disconnected set of mathematical constructions.

Model families can also help identify which conclusions depend on which assumptions. Robustness across several formal representations strengthens confidence that a result reflects a structural feature rather than an artifact of one specification. Divergence across models can be equally informative when it reveals sensitivity to boundary conditions, topology, time horizon, or behavioral assumptions. GRE should therefore treat model disagreement as a source of theoretical information rather than merely as a problem to be eliminated.

Formal development remains subject to ontological suspension. A model can establish the consequences of stated relations without proving that the empirical economy possesses the model's ontology. Cumulative formal progress therefore requires empirical interpretation and clear links to the concepts or mechanisms represented. Reusable models, documented assumptions, and transparent derivations can become infrastructure for later studies even when empirical validation remains partial.

3.18.7 Simulation and Computational Exploration

Simulation and computational exploration extend formal development when analytic solutions are unavailable, when interaction structures are heterogeneous, or when researchers want to examine the consequences of alternative rules and parameter regimes. GRE can use agent-based models, network simulations, dynamical systems, optimization procedures, synthetic populations, and other computational methods to explore how local relations may generate larger-scale patterns.

Cumulative computational work requires reproducible experimental design. Code, parameter ranges, initialization procedures, random seeds, stopping rules, and output measures should be documented where possible. More importantly, the relation between computational objects and theoretical concepts should remain explicit. A simulated agent may represent a household, firm, algorithm, institution, or abstract decision unit, but that mapping is a modeling choice rather than an ontological fact.

Computational exploration can support cumulative knowledge by identifying candidate mechanisms, sensitivity regions, threshold behavior, path dependence, or unexpected interactions. It can also help discriminate among theories by showing that some verbal mechanism claims are insufficient to generate the observed pattern under plausible assumptions. Such findings remain conditional on the model, but they can direct empirical work toward the variables and relations most likely to matter.

Simulation results should accumulate together with failed parameterizations and negative results where feasible. If a proposed mechanism produces a target pattern only under implausibly narrow conditions, that fact is theoretically relevant. Computational archives can therefore preserve the history of model development, including abandoned specifications, so that later researchers can distinguish genuine theoretical progress from repeated rediscovery of previously rejected configurations.

3.18.8 Intervention Evidence

Interventions provide a distinctive source of evidence because they modify the relational configuration under study. Policy changes, institutional reforms, experimental programmes, platform redesigns, governance mechanisms, public investments, organizational changes, and community initiatives can reveal how relations respond when constraints or enabling conditions are altered. GRE treats such evidence cautiously because intervention effects can be path-dependent, scale-specific, and entangled with adaptation.

A cumulative intervention programme should document design, implementation, context, immediate outputs, downstream effects, unintended consequences, and later structural changes. Evidence about failure is as important as evidence about success. An intervention that produces an initial benefit but creates long-term dependency contributes different knowledge from an intervention whose effects persist after external support is withdrawn. An intervention that changes institutional recognition without altering material capacity reveals a different mechanism from one that changes both.

Intervention evidence also benefits from variation in intensity, timing, sequence, and institutional setting. Comparative intervention research can identify whether an

effect depends on complementary relations, threshold conditions, or prior histories. Where randomized or quasi-experimental identification is possible, it can strengthen causal claims. Where it is not, careful process tracing, comparative design, and longitudinal evidence can still contribute to mechanism understanding if the limits of attribution are explicit.

Cumulative praxis requires preserving correction histories. Researchers should record when an intervention was modified, suspended, reversed, or repaired and why. These histories provide evidence about the adaptability of both the intervention and the governing institutions. They also help later researchers understand which apparent outcomes were produced by the initial design and which emerged through iterative revision.

3.18.9 Measure and Indicator Development

Measures and indicators allow recurrent GRE concepts to become empirically tractable, but measurement should follow conceptual clarification rather than substitute for it. Possible GRE measures may concern relational dependence, capability access, exit conditions, propagation, concentration of generative control, value conversion, institutional recognition, ecological capacity, or forms of generative foreclosure. Each indicator compresses a more complex concept and therefore requires explicit justification.

Cumulative indicator development should include validity, reliability, sensitivity, and domain restrictions. An indicator useful in one institutional setting may fail elsewhere because the same observable carries a different relational meaning. A measure of platform dependence based on revenue concentration may miss infrastructural lock-in. A measure of capability based on resource possession may ignore conversion constraints. A measure of generativity based on output growth may overlook depletion of future enabling conditions. Indicator accumulation therefore depends on comparison with alternative measures and on documented cases where the proxy fails.

Composite indices require particular caution. Combining heterogeneous value dimensions into one score can aid communication or decision-making, but the weighting rule performs substantive evaluative work. GRE should distinguish between an index created for practical coordination and a claim that the underlying values are intrinsically commensurable. Sensitivity analysis can show how rankings or conclusions change under alternative weighting schemes.

A mature cumulative programme can maintain indicator families rather than seeking one universal GRE metric. Different measures may be appropriate for different objects, scales, and purposes. The cumulative goal is not metric unification but increasing clarity about what each measure captures, what it omits, and how it relates to the generative claim being tested.

3.18.10 Theory Revision

Theory revision completes the cumulative architecture because accumulation without revision would convert GRE into a repository of additions rather than a research

programme. Concepts, typologies, mechanisms, models, indicators, and intervention assumptions should all remain revisable when evidence, comparison, formal analysis, or historical transformation shows that earlier formulations are inadequate.

Revision can take several forms. A concept can be narrowed because it was applied too broadly. A typology can be divided because one category contains distinct mechanisms. A mechanism can be reclassified as conditional rather than general. A formal model can replace a fixed parameter with an evolving relation. An indicator can be abandoned because it tracks a proxy rather than the target concept. A normative criterion can be separated from an empirical one when the two were previously conflated. Revision is cumulative when the reason for change is documented and the consequences for earlier findings are made visible.

GRE should also preserve superseded formulations. Historical traceability allows later researchers to understand why a theory changed and whether an earlier version may still be useful in a restricted domain. Erasing theoretical history would make apparent progress difficult to evaluate because researchers could not distinguish genuine correction from terminological replacement.

Theory revision may also be triggered by transformations in the object of inquiry. New technologies, institutional forms, ecological conditions, legal arrangements, or types of economic subject can make previously adequate categories insufficient. A research programme committed to historical dependence should expect some of its own concepts to age. Revisability is therefore not a weakness added to GRE from outside; it follows directly from the claim that economic relations and their generative conditions are historically transformable.

Taken together, the ten forms of accumulation described in this section define a research programme that can grow without equating growth with theoretical expansion. Conceptual clarification can narrow terms. Typologies can remove distinctions that fail empirically. Comparative cases can reveal boundary conditions. Mechanism research can reject attractive explanations. Formal and computational work can expose contradictions. Intervention evidence can show that a promising design generates harmful dependencies. Indicators can be retired. Theory can contract. Cumulative development is therefore the organized capacity to preserve, compare, test, reuse, and revise knowledge across heterogeneous forms of inquiry.

This cumulative architecture also prepares an important disciplinary problem. As GRE develops, researchers will not necessarily converge on one ontology, one preferred method, one formal representation, one account of value, or one definition of generativity. A cumulative programme therefore requires a way to distinguish productive internal plurality from conceptual fragmentation. The following section turns to internal pluralism and competing formulations, asking how divergent approaches can coexist, criticize one another, and become comparable without forcing premature theoretical unification.

3.19 Internal Pluralism and Competing Formulations

The preceding sections have progressively specified the identity, objects, scales, questions, epistemic commitments, praxis, normative interfaces, power problems, contri-

bution standards, and cumulative structure of Generative Relational Economics. A cumulative research programme, however, cannot remain open merely by permitting new topics to be added. It must also preserve the possibility that several incompatible or partially incompatible formulations of the same problem coexist long enough to be compared, criticized, revised, and sometimes rejected. The role of this section is therefore to specify the place of internal pluralism within GRE. Its objective is to distinguish productive plurality from conceptual indeterminacy: GRE can sustain multiple ontologies, methods, formalisms, evidential strategies, value representations, and accounts of generativity without treating every formulation as equally adequate or every disagreement as irreducible.

Internal pluralism follows from the programme's earlier commitments. Ontological suspension limits the authority of any single representational scheme. Methodological pluralism recognizes that different research questions warrant different modes of access. Heterogeneous subjects and values make premature commensuration hazardous. Scale-relative entityhood means that the same economic configuration can be represented differently at different analytical resolutions. The cumulative programme further requires that alternative formulations remain visible so later work can determine which distinctions travel across contexts, which mechanisms recur, and which representations fail. Pluralism is therefore not an exception to GRE's constitution. It is one of the conditions under which the programme can remain corrigible.

Pluralism nevertheless requires discipline. A research programme becomes weak if incompatible claims are retained merely because they use different vocabularies. It also becomes weak if every disagreement is redescribed as a matter of perspective before empirical or conceptual comparison has occurred. GRE should therefore distinguish plurality of representation from incompatibility of prediction, plurality of method from contradiction in evidence, plurality of value from inconsistency in stated normative commitments, and plurality of ontology from unrestricted metaphysical permissiveness. Competing formulations become productive when their objects, boundaries, assumptions, inferential claims, and failure conditions can be made sufficiently explicit for comparison.

3.19.1 Ontological Pluralism

Ontological pluralism in GRE begins from the recognition that economic inquiry can require several kinds of object-description. A firm can be represented as a legal person, an organization, a nexus of contracts, a hierarchy of authority, a network of relations, a bundle of capabilities, an institutionalized process, or a temporally persistent configuration. These descriptions do not necessarily refer to different empirical worlds. They select different features of the same or overlapping configurations for different analytical purposes.

The earlier principle of ontological suspension therefore does not prohibit ontological language. It restricts the movement from analytical usefulness to ultimate metaphysical commitment. GRE can state that a corporation is treated as an economic subject in one analysis, a relational configuration in another, and an institutional field component in a third. Each formulation must explain what distinctions it pre-

serves, what mechanisms it makes visible, and what questions it suppresses. Ontological pluralism is legitimate when alternative object-descriptions improve inquiry without being silently conflated.

This plurality becomes especially important when objects change historically. A category that functions as a relatively stable entity during one period may later require decomposition because its internal relations become explanatory. Conversely, a dense set of relations may become sufficiently stabilized that entity-level treatment is efficient and empirically adequate. GRE therefore permits movement between entity-centered and relational descriptions as the problem changes. The choice is governed by explanatory and evidential adequacy rather than by a requirement that one level possess permanent ontological priority.

Ontological pluralism does not imply that every proposed object deserves equal standing. Some entities may be administratively convenient yet analytically misleading. Some relational categories may be too broad to identify mechanisms. Some field descriptions may erase important discontinuities. Some claims of emergence may simply rename aggregation. Competing ontological formulations should therefore be assessed by the empirical distinctions they sustain, the mechanisms they clarify, the observations they organize, and the errors they make possible to detect.

A plural programme can also contain genuine ontological disagreement. Researchers may disagree about whether a particular social fact should be treated primarily as an emergent property, an institutional rule, a represented category, a distributed relation, or a relatively autonomous object. GRE need not resolve such disagreements through constitutional fiat. It should require the competing formulations to state their consequences. If two ontologies generate indistinguishable descriptions, predictions, or interpretations for the relevant problem, the dispute may remain underdetermined. If they imply different observations, interventions, or normative diagnoses, the disagreement becomes a substantive research question.

3.19.2 Methodological Pluralism

Methodological pluralism concerns the coexistence of different strategies for producing warranted claims. GRE admits historical, interpretive, qualitative, quantitative, causal, comparative, formal, computational, and intervention-oriented inquiry because its objects can be only partially accessible through any single mode. The justification for plurality is therefore epistemic rather than diplomatic. Different methods disclose different aspects of relational and generative processes.

A historical reconstruction can identify how categories, institutions, or subject positions came to exist. Ethnographic or interpretive work can reveal meanings, tacit practices, and situated understandings that are unavailable in administrative data. Quantitative analysis can estimate distributions, associations, heterogeneity, and temporal regularities at scales difficult to observe directly. Causal designs can test specific intervention or mechanism claims under stated assumptions. Formal models can expose logical consequences and structural possibilities. Computational models can explore high-dimensional, adaptive, or path-dependent systems. None of these capacities automatically contains the others.

Methodological pluralism therefore requires claim-method matching. A computa-

tional simulation cannot by itself establish that its mechanism generated an observed historical outcome. A historical narrative cannot by itself estimate the magnitude of a population-level effect. A statistically identified average treatment effect may not explain the meanings through which the treatment was received or the institutional conditions through which it propagated. An interpretive account may clarify subject formation while leaving distributional prevalence unresolved. The value of a method depends on the claim it is used to warrant.

Pluralism also permits methodological competition. Two studies can approach the same generative claim through different designs and produce conflicting evidence. Such conflict should not be resolved automatically by a fixed hierarchy of methods. The programme should examine differences in population, scale, measurement, boundary selection, intervention timing, model specification, and inferential target. Sometimes one method will expose a limitation in another. Sometimes the disagreement will reveal that the original theoretical claim was underspecified.

The strongest form of methodological pluralism is therefore cumulative correction. Methods become mutually informative when they identify each other's blind spots and help refine the target of inquiry. GRE does not require every project to use mixed methods. It requires the programme as a whole to remain open to correction from methods capable of observing dimensions that another approach leaves unresolved.

3.19.3 Formal Pluralism

Formal pluralism extends the same principle to mathematical and computational representation. GRE has inherited resources from dynamical systems, complexity theory, network science, higher-order and multilayer representations, field formalisms, information theory, computation, and simulation. These formalisms organize different kinds of structure. A dynamical system emphasizes state, trajectory, stability, and transformation through time. A network emphasizes patterned relations among identifiable nodes. A higher-order representation can make irreducibly multi-actor interactions explicit. A field representation can describe distributed conditions that vary across a domain. Agent-based or computational models can explore local rules, heterogeneity, and emergent aggregate behavior.

GRE therefore has no constitutional reason to privilege one formal language as the universal representation of economic relations. Formal choice should follow the structure of the research problem. A model of propagation through contractual dependencies may be naturally network-based. A problem concerning distributed accessibility or exposure may be represented more effectively through a field. A question about transition between regimes may require dynamical analysis. A question about heterogeneous adaptive actors may benefit from simulation. Several representations may be needed for the same empirical system.

Formal pluralism also protects the programme from a recurrent category error: mathematical elegance should not be mistaken for ontological authority. Two mathematically distinct representations can sometimes encode the same empirically relevant relation. Conversely, one formalism can fit several empirical situations whose mechanisms differ. Formal equivalence, approximation, simulation, or mapping therefore needs to be distinguished from substantive equivalence of the

represented processes.

Competing formalisms should be compared through their assumptions, representational losses, empirical accessibility, computational tractability, and consequences for inference. A more complex formalism is not necessarily better. Additional dimensions, layers, parameters, or interacting fields can increase expressiveness while reducing identifiability. A simpler model can be preferable when its omissions are explicit and its inferential target is narrow. Formal pluralism is productive when representational choice remains accountable to evidence and purpose.

3.19.4 Quantitative and Qualitative Approaches

Quantitative and qualitative approaches often differ in data structure, inferential form, sampling logic, and the kinds of uncertainty they make visible. GRE treats these differences as analytically important rather than as a division between rigorous and non-rigorous inquiry. Quantitative work can establish patterns across large populations, estimate magnitudes, compare distributions, and model temporal or relational structures. Qualitative work can reconstruct meaning, institutional practice, local causal process, category formation, tacit knowledge, and the situated experience through which economic relations become operative.

The distinction is particularly important for generative analysis. A downstream effect can be quantitatively measurable while its mechanism remains poorly understood. Conversely, an interactional mechanism can be richly documented in a small number of cases while its prevalence, distribution, or aggregate contribution remains uncertain. GRE should therefore resist converting one form of evidence into claims warranted only by the other.

Mixed designs can be valuable when the forms of evidence address complementary parts of the same generative claim. A qualitative study can help identify mechanisms, categories, or boundary conditions that later quantitative work tests across cases. Quantitative anomalies can direct qualitative inquiry toward previously invisible heterogeneity. Administrative or network data can identify patterns of propagation, while interviews or archival evidence reveal why particular pathways existed. Such integration should be designed around a shared research problem rather than around the ceremonial inclusion of multiple methods.

Qualitative and quantitative approaches can also disagree productively about the object itself. A variable that appears stable in a dataset may combine historically different institutional meanings. A locally salient category may have no reliable population-level measure. A statistically robust association may depend on classifications whose social production requires separate analysis. GRE's relational commitments make these disagreements substantive because measurement categories can participate in the relations they represent.

The programme therefore treats quantitative and qualitative approaches as mutually corrective without requiring symmetry in every project. The relevant question is which claims remain unsupported when only one form of evidence is available and whether the resulting limitation materially changes the argument.

3.19.5 Causal and Interpretive Approaches

Causal and interpretive approaches address different but frequently intersecting questions. Causal inquiry asks whether and through what mechanisms a change in one condition contributes to a change in another under specified assumptions. Interpretive inquiry asks how actors, institutions, representations, and practices acquire meaning within a situated historical and relational context. GRE requires both because economic relations can operate through mechanisms whose effectiveness depends on interpretation.

A legal classification, price signal, credential, ranking, or algorithmic recommendation can alter behavior partly because subjects recognize, contest, trust, misunderstand, or strategically use what the representation means. In such cases, interpretation is not merely commentary after causal analysis. It can be part of the causal mechanism. At the same time, the existence of meaning does not establish the magnitude or distribution of its effects. Interpretive adequacy and causal identification remain distinct epistemic achievements.

The same distinction applies to subject formation. Researchers may interpret how a worker, consumer, creditor, beneficiary, or platform participant is institutionally constituted and how that subject position is experienced. A causal study may then examine whether entering that position changes behavior, income, access, or later opportunities. The two analyses can support each other without collapsing into a single method.

Competing causal and interpretive accounts become especially useful when they disagree about where the mechanism lies. A causal model may attribute an effect to incentives, while interpretive evidence suggests that the intervention changed recognition, legitimacy, or perceived obligation. Rather than treating one vocabulary as necessarily deeper, GRE should ask what observable consequences follow from the alternative mechanism accounts and whether both processes operate at different stages or scales.

Causal and interpretive pluralism therefore requires translation without reduction. Researchers should state when an interpretive category enters a causal model, how it is observed, and what is lost in operationalization. Conversely, causal evidence can constrain interpretations by showing that a proposed meaning-making mechanism does not produce the expected distributional or temporal pattern. Productive integration occurs when each approach can expose conditions under which the other's claims fail.

3.19.6 Network and Field Representations

Network and field representations provide a concrete example of formal pluralism because they organize relational structure differently. A network begins from distinguishable nodes and relations among them. It is well suited to questions concerning adjacency, centrality, brokerage, diffusion, dependence, multilayer connectivity, and evolving topology. A field representation describes conditions distributed across a domain and can be useful when influence, accessibility, exposure, salience, or constraint varies continuously or when pairwise ties provide an incomplete description.

These representations can overlap without being interchangeable. A network of financial obligations can identify who depends directly or indirectly on whom. A field representation may instead characterize how liquidity conditions, regulatory exposure, information availability, or market accessibility vary across positions. The network makes discrete relational pathways explicit; the field can make distributed background conditions visible. A system can contain both.

Choice between network and field representation should therefore follow the mechanism. If transmission occurs through identifiable connections, a network may be the natural first representation. If subjects respond to a spatially, institutionally, or symbolically distributed condition, a field can be more informative. Some problems require hybrid representations in which nodes and edges evolve within fields that also respond to network activity.

The competing representations can generate different intuitions about intervention. Network analysis may suggest altering connections, central nodes, or dependency pathways. Field analysis may suggest changing distributed conditions that shape many interactions simultaneously. GRE should not infer that one intervention is superior from the representation alone. The empirical question is which representation captures the mechanisms through which the relevant generative effects actually propagate.

The plurality also reinforces ontological suspension. Network nodes need not be ultimate entities, and fields need not be literal physical fields. Both are representational devices whose adequacy depends on what they permit researchers to observe, explain, predict, or intervene upon.

3.19.7 Scalar and Non-Scalar Value Representations

Value presents a particularly consequential case of internal pluralism. Some economic questions require scalar representation. Prices, costs, quantities, income, expected returns, or index values can support comparison, optimization, aggregation, and accounting. Other forms of value resist stable reduction to one dimension because they involve heterogeneous goods, rights, relationships, capabilities, ecological conditions, meanings, or obligations whose trade-offs are context-dependent or normatively contested.

GRE therefore permits scalar and non-scalar representations of value. The choice must be justified by the evaluative task. A scalar representation can be useful when a common unit is institutionally established, empirically meaningful, and relevant to the question. It becomes misleading when the numerical scale hides changes in what is being valued, who has authority to define the conversion, or which losses cannot be represented adequately by the chosen unit.

Non-scalar representation can preserve plurality through vectors, partial orderings, categorical distinctions, threshold conditions, lexicographic priorities, narrative evaluation, or explicit statements of incommensurability. Such representations do not eliminate the need for decisions. Institutions frequently must act even when values cannot be reduced to a common metric. The analytical task is to distinguish practical commensuration from demonstrated commensurability and to make visible who establishes the conversion rules.

Competing value representations can lead to different judgments about the same intervention. A project may generate positive monetary returns while degrading ecological resilience, increasing dependency, or reducing future option sets. A multidimensional representation can reveal this divergence. Conversely, retaining every value dimension without prioritization can make decision procedures indeterminate. GRE therefore treats value representation as part of the problem rather than assuming that either scalarization or irreducible plurality is universally preferable.

Comparison among value representations should examine what each includes, excludes, weights, converts, and renders visible. It should also ask how the representation itself affects institutional action. An indicator that becomes a target can reorganize behavior; a price can alter the relation it measures; a ranking can generate new incentives and subject positions. Value representation is therefore both epistemic and potentially generative.

3.19.8 Competing Accounts of Generativity

Generativity is the organizing concept most likely to produce internal theoretical disagreement within GRE. The term can refer to several related but distinct phenomena: production of downstream capacities, emergence of new entities or relations, transformation of subject positions, expansion or contraction of future possibilities, creation of new value forms, alteration of institutional pathways, or modification of the effective rules through which later change occurs. These processes can coexist, but they should not be treated as interchangeable by definition.

One account of generativity may emphasize the creation of capacities. Another may focus on the reproduction and transformation of relational structures. A third may treat generativity primarily as alteration of future possibility spaces. A fourth may emphasize recursive change in the mechanisms that produce subsequent outcomes. GRE should allow these accounts to compete because their differences can clarify what exactly is claimed to be generated.

Competing accounts should state their unit of analysis, temporal horizon, baseline, mechanism, and observable consequences. A claim that a relation generates capability requires evidence different from a claim that it generates institutional persistence. A claim that an intervention expands future possibility requires a specification of whose possibilities, over what horizon, under which constraints, and relative to which counterfactual or historical baseline. A claim that a rule transforms its own conditions of reproduction requires evidence beyond ordinary downstream effects.

The programme should also permit the possibility that generativity is not a single natural kind. Different domains may contain several mechanisms that share a family resemblance but cannot be reduced to one formal definition. In that case, cumulative research should develop a typology of generative mechanisms rather than force premature unification. Conversely, if apparently different mechanisms can be shown to instantiate a common structure, theory can become more parsimonious.

Internal competition around generativity is therefore desirable when it increases discriminability. A successful formulation should make it easier to determine when a process is merely productive, causal, adaptive, or reproductive and when a stronger generative claim is warranted. The concept becomes weaker when it absorbs every

form of change and stronger when competing accounts specify different empirical commitments.

3.19.9 Productive Disagreement

A plural research programme depends on disagreement that can change what researchers subsequently do. Productive disagreement is therefore more demanding than the coexistence of opinions. It requires disagreement to be localized sufficiently that evidence, argument, or comparison can alter the standing of competing claims.

Researchers can disagree about concepts, boundaries, mechanisms, measurements, formal representations, empirical generalization, normative premises, or intervention implications. These forms of disagreement should be distinguished because they require different responses. A definitional disagreement may be resolved through conceptual clarification. A measurement disagreement requires validity evidence. A mechanism disagreement may require process tracing, experiments, comparative cases, or temporal data. A normative disagreement may persist even after empirical questions are settled because the disagreement concerns values or justificatory principles.

Productive disagreement also requires preserving losing formulations long enough to understand why they failed. If a model is rejected because its mechanism does not fit observed timing, that reason should become part of programme memory. If a concept is narrowed because it collapsed several distinct phenomena, the earlier broader usage should remain traceable. If two formulations apply at different scales, the outcome is not necessarily victory of one over the other but clarification of boundary conditions.

Disagreement becomes unproductive when formulations shift whenever evidence challenges them, when different vocabularies hide identical claims, when claims are insulated from possible counterevidence, or when normative and empirical disagreements are repeatedly confused. A plural programme therefore needs conventions for making commitments explicit enough that revision is possible.

The social organization of disagreement also matters. Dominant institutions, disciplines, languages, data infrastructures, or publication norms can determine which formulations are visible enough to be contested. GRE's own commitment to pluralism therefore includes attention to the conditions under which alternative formulations can enter the research programme. Inclusion of alternatives, however, does not suspend standards of evidence or argument. Productive pluralism widens the space of contestation while preserving the possibility of criticism.

3.19.10 Conditions for Theory Comparison

Internal pluralism becomes cumulative only when competing formulations can be compared under explicit conditions. Theory comparison in GRE should therefore begin by determining whether the formulations address the same object, scale, temporal horizon, and inferential target. Apparent disagreement can disappear once researchers recognize that one theory describes short-run adjustment while another describes long-run institutional transformation, or that one concerns individual be-

havior while another concerns field-level conditions.

Where the targets overlap, comparison should examine at least six dimensions: conceptual clarity, empirical scope, mechanism specification, evidential support, representational cost, and capacity for revision. Conceptual clarity concerns whether the theory distinguishes its principal objects and mechanisms from neighboring concepts. Empirical scope concerns the domains and boundary conditions within which the theory is expected to apply. Mechanism specification concerns what processes connect conditions to outcomes. Evidential support concerns whether available observations discriminate the theory from alternatives. Representational cost concerns the assumptions, data, computation, and abstraction required to use the formulation. Capacity for revision concerns whether failure can lead to identifiable modification rather than indefinite accommodation.

Predictive accuracy can be important but should not become the sole criterion. Some GRE problems concern historical explanation, interpretation, institutional constitution, normative evaluation, or intervention design where prediction is only one dimension of adequacy. Conversely, conceptual richness should not excuse a formulation from empirical consequences when it makes empirical claims. The criteria for comparison should therefore track the kind of contribution being evaluated.

Theories can also be compared by their generative usefulness for further research. A formulation can be valuable because it produces new measurable distinctions, suggests discriminating cases, clarifies a previously vague mechanism, or exposes a class of interventions whose consequences can be studied. Such usefulness does not establish truth, but it can justify continued investigation when direct adjudication remains incomplete.

Some competing formulations may remain partially incommensurable because they begin from different objects, values, or explanatory purposes. GRE should not manufacture a single ranking when the comparison lacks a common criterion. It should instead identify the dimensions on which comparison is possible and preserve the residual disagreement. Partial comparability is preferable to either false unification or premature declaration of complete incommensurability.

The constitutional role of internal pluralism can therefore be stated compactly. GRE should remain open to multiple formulations while requiring each formulation to expose enough of its objects, assumptions, mechanisms, evidence, values, and failure conditions to permit criticism. Pluralism protects the programme from premature closure; theory comparison protects it from indiscriminate accumulation. Together they allow disagreement to become part of cumulative inquiry.

The existence of a plural and revisable research programme also means that several difficult questions remain unresolved even after its disciplinary constitution has been specified. The following section turns from the permitted diversity of formulations to the substantive open problems that future GRE research must address.

3.20 Open Problems

The preceding sections have specified the preliminary identity, objects, scales, modes of inquiry, epistemic commitments, praxis, normative interfaces, contribu-

tion standards, cumulative structure, and internal pluralism of Generative Relational Economics. A research programme becomes more credible, however, when its unresolved problems are stated with comparable precision. The role of this section is therefore to identify several problems that remain open after the current constitution of GRE has been articulated. Its objective is neither to close those problems through definition nor to convert uncertainty into a rhetorical virtue. The aim is to distinguish questions for which GRE already has an analytical vocabulary from questions for which the mechanisms, measurements, evidential strategies, or normative criteria remain materially underdeveloped.

The open problems considered here concern identification, attribution, measurement, boundary selection, changing transformation rules, heterogeneous value, justice, symbolic reification, governance under persistent asymmetry, and long-horizon evaluation. These problems are connected, but they should not be collapsed. Better identification of a generative relation does not by itself solve downstream value attribution. A useful indicator of generativity does not establish normative desirability. A formally specified transformation rule does not guarantee that the relevant rule remains stable through the period being studied. A governance mechanism that mitigates one asymmetry can create another. The purpose of separating the problems is therefore to make future progress discriminable.

Open problems also differ in the kind of resolution they permit. Some may yield to better data, identification strategies, historical reconstruction, or formal representation. Others arise because economic relations are reflexive, boundaries are purpose-dependent, values are only partially comparable, and future possibilities cannot be observed before they are realized. GRE should therefore allow for the possibility that some uncertainty can be reduced while other uncertainty remains structural to the object of inquiry. A mature research programme needs both ambitions: to improve what can be known and to specify what remains underdetermined.

3.20.1 Identification of Generative Relations

The first open problem concerns the identification of generative relations. GRE frequently asks whether a relation contributes to the production of later capacities, institutions, subject positions, value forms, or conditions of possibility. Such claims are stronger than statements that two variables covary or that one event precedes another. They also exceed the observation that a relation participates in ordinary causal production. A relation becomes generatively relevant when its operation changes what can subsequently be produced, sustained, accessed, recognized, or transformed. The empirical difficulty lies in demonstrating that stronger claim.

Identification requires a specification of the relation, the object said to be generated, the time horizon over which generation occurs, and the mechanism that connects them. These elements can be difficult to observe simultaneously. Some relations operate through repeated interaction rather than singular events. Some produce latent capacities that become visible only when later conditions activate them. Some operate through institutional recognition or symbolic classification rather than directly observable material transfer. Some are distributed across several actors or infrastructures, making bilateral attribution misleading.

A further difficulty is that generative relations may be constitutive rather than merely productive. A worker's access to a professional network, for example, can affect opportunities while also contributing to the formation of recognized expertise, identity, or standing. A credit relation can transfer purchasing capacity while simultaneously generating dependency, reputational records, or future exclusion. In such cases the relation changes properties of the participating subjects and the environment in which later action occurs. Identification must therefore distinguish immediate output from transformation of later possibility.

Progress on this problem will require multiple forms of evidence. Longitudinal observation can reveal whether capacities persist beyond the originating relation. Comparative cases can test whether similar relational configurations produce similar downstream structures under different contexts. Process tracing can identify intermediate mechanisms. Experiments or quasi-experiments can help isolate particular pathways when intervention is possible. Formal or computational models can clarify what observations would discriminate generative mechanisms from ordinary transmission. Interpretive evidence can be necessary when generation operates through meaning, recognition, or institutional classification.

No single identification strategy is likely to cover the full range of GRE objects. The open task is therefore to develop a disciplined family of identification standards. Such standards should make it possible to distinguish a plausible generative hypothesis from a demonstrated mechanism, and a demonstrated local mechanism from a general claim about generativity across contexts.

3.20.2 Attribution of Downstream Value

A second open problem concerns attribution once value has propagated beyond an initial relation or intervention. Economic processes commonly produce effects through chains of mediation. Training can alter later employment, organizational practice, peer learning, and household security. Infrastructure can generate uses that were not anticipated by its designers. Knowledge can be recombined by actors distant from its original producer. Institutional reforms can change incentives, expectations, classifications, and later policy capacities. GRE needs ways to analyze such downstream value without converting every remote benefit into a claim of credit for the initial source.

Attribution becomes difficult because downstream effects are usually co-produced. Later value can depend on complementary resources, independent decisions, institutional environments, accumulated knowledge, ecological conditions, and subsequent interventions. A generative relation can be necessary without being sufficient. It can raise the probability of an outcome without determining it. It can create an enabling condition whose significance varies strongly across contexts. A later actor can transform an inherited resource so substantially that simple origin-based attribution becomes conceptually misleading.

The problem therefore has at least three dimensions. Causal attribution asks whether the earlier relation materially contributed to the later outcome. generative attribution asks whether it altered the conditions from which later value could emerge. Distributive attribution asks how recognition, return, responsibility, or

claims on value should be allocated among contributors. These dimensions should remain distinct because evidence for causal contribution does not settle the distributive question, and normative entitlement cannot be inferred directly from causal ancestry.

Future GRE work requires methods for tracing contribution without assuming additive decomposition. In some domains, contribution analysis may be approximately scalar. In others, interaction effects, complementarities, threshold behavior, or non-substitutable roles make scalar shares unstable or arbitrary. Network and process representations may help locate pathways without requiring a single attribution percentage. Counterfactual analysis can identify whether a contribution changed the set of feasible trajectories. Historical reconstruction can reveal how later actors transformed inherited conditions.

The objective should therefore be calibrated attribution. GRE should become better at saying that an upstream relation enabled, constrained, amplified, redirected, or conditioned later value while preserving uncertainty about the exact share attributable to that relation. Such calibrated language is important both for explanation and for later questions of return, compensation, responsibility, and justice.

3.20.3 Measurement of Generativity

The measurement of generativity presents a related but distinct problem. The concept is attractive because it directs attention toward effects on later productive and transformative possibilities. Yet the concept can become analytically weak if every beneficial downstream effect is redescribed as generativity. Measurement therefore requires a more discriminating account of what is being measured and at which scale.

Several candidate dimensions are possible. One study may measure new capabilities acquired by participants. Another may measure the diversity of subsequent activities enabled by an intervention. A third may examine persistence of effects after direct support ends. A fourth may study whether new actors can enter a domain, whether dependence on a central provider declines, or whether local reproduction becomes possible. A fifth may examine changes in the range of feasible future states. These measures capture different aspects of generativity and should not automatically be aggregated.

The temporal horizon also changes the result. An intervention can generate high short-run activity while degrading future ecological or institutional capacity. Another can impose substantial near-term cost while creating durable infrastructure or knowledge. A third can generate options that remain unused for years. Measurement therefore requires explicit time horizons and, where possible, sensitivity to delayed activation and depreciation.

Baseline selection is equally important. Generativity can be expressed relative to a prior state, a plausible counterfactual, an alternative intervention, or a historically available possibility set. These baselines answer different questions. A project can be generative relative to local past conditions while remaining less generative than another feasible arrangement. A technology can expand one actor's possibilities while narrowing those of another. A scalar score that suppresses these distinctions can obscure more than it reveals.

GRE should therefore resist the premature construction of a universal generativity index. The more promising direction is a family of measures tied to explicit objects: capability generation, institutional reproduction, option expansion, relational diversification, knowledge recombination, ecological regeneration, or transformation of future constraints. Some domains may support quantitative indicators; others may require ordinal, categorical, historical, or qualitative evidence.

The open problem is to determine when these heterogeneous measures can be compared and when they should remain separate. Measurement should increase discriminability while preserving the multidimensional character of generation. A measure becomes useful when it makes a claim more testable or comparable, not merely when it assigns a number to a concept.

3.20.4 Relational Boundary Selection

Every relational analysis requires a boundary, yet the boundary can materially determine the result. A firm can be analyzed through internal employment relations, supply chains, financial dependencies, legal institutions, ecological inputs, community effects, or global infrastructures. A household can be treated as a unit or decomposed into members with different resources, vulnerabilities, and bargaining positions. A platform can be bounded by formal ownership or expanded to include complementors, users, data providers, moderators, advertisers, and regulatory institutions. Each choice creates a different relational object.

Boundary selection is therefore more than a technical preprocessing decision. It affects which mechanisms are visible, which costs are externalized, which subjects count as participants, and which downstream effects are attributed to the focal process. A narrow boundary can produce apparent efficiency by excluding displaced burdens. An excessively broad boundary can make explanation indeterminate by treating nearly everything as part of the system.

GRE currently has principles that help discipline boundary choice: explicit scale selection, ontological suspension, claim-relative objecthood, and attention to downstream effects. These principles do not yet provide a general procedure for deciding how far a relational analysis should extend. The appropriate boundary depends on the claim. A study of contractual propagation may require one boundary; a study of ecological regeneration may require another; a study of institutional recognition may require several overlapping boundaries.

One direction for future work is sensitivity analysis across relational boundaries. Researchers can ask whether the principal inference changes when adjacent actors, longer time horizons, or additional infrastructures are included. Another direction is boundary justification through mechanism: include relations that participate materially in the mechanism under investigation and distinguish them from contextual conditions whose role is secondary. A third is normative boundary review, especially where exclusion from the analytical boundary also removes affected populations from evaluation.

The deeper problem is that boundaries can themselves be generated and contested. Legal categories, accounting rules, administrative jurisdictions, platform architectures, and disciplinary conventions determine what appears internal or external.

GRE therefore needs methods for studying boundary formation while still selecting workable boundaries for empirical research. This is an inherently reflexive task: the researcher must construct a boundary without mistaking that construction for a natural edge of the economic world.

3.20.5 Dynamics of Changing Transformation Rules

GRE places particular emphasis on situations in which the effective mechanisms of change are themselves transformed. This possibility is analytically important because many models assume that states change under a rule that remains sufficiently stable for the period of analysis. Economic history repeatedly presents harder cases: technologies alter feasible production processes, institutions modify incentives and classifications, learning changes decision procedures, political settlements alter property and authority, and adaptive systems modify the relations through which later adaptation occurs.

The open problem is empirical representation of these changing transformation rules. It is relatively straightforward to estimate changing states under a fixed model. It is harder to determine whether parameter drift is sufficient, whether the structure of interaction has changed, whether new variables have become relevant, or whether the model class itself must be revised. A sudden forecasting failure can indicate structural transformation, measurement change, omitted context, or ordinary stochastic variation. The observation alone does not identify rule change.

Different forms of rule transformation should therefore be distinguished. Parameters can change while the functional structure remains stable. Network topology can evolve while node types remain fixed. Agents can learn and alter local decision rules. Institutions can redefine available actions or recognized categories. New technologies can introduce previously unavailable operations. Symbolic changes can alter how subjects interpret the same formal option. More radical transformation can make earlier state variables inadequate because the kinds of economically relevant entities have changed.

Future GRE work requires diagnostics for these levels. Change-point methods, time-varying parameter models, adaptive networks, institutional process tracing, computational learning models, and historical comparison can each contribute. None should be treated as a universal representation. The important question is what evidence warrants movement from a claim of state change to a claim of structural change, and from structural change to transformation of the effective rule of change.

This problem also concerns anticipation. If governance relies on models whose rules can change in response to the intervention itself, policy evaluation becomes recursively difficult. Agents can adapt to incentives, classifications, metrics, and regulatory thresholds. Institutions can learn from being measured. Artificial systems can modify decision environments at high speed. GRE therefore needs forms of intervention design that monitor the stability of the assumed transformation rule rather than merely updating parameter estimates within it.

3.20.6 Heterogeneous Value Comparison

GRE's commitment to heterogeneous value creates an unresolved problem of comparison. Economic decisions frequently require choices among outcomes expressed through different value languages: income, time, health, dignity, ecological integrity, autonomy, knowledge, cultural continuity, security, care, or future option value. Practical governance cannot always defer choice until a complete theory of commensurability is available. Yet forcing these values into a single metric can erase the distinctions that motivated plural evaluation in the first place.

The problem is therefore to determine which forms of comparison are legitimate under partial commensurability. Some values may be monetizable for a specific administrative purpose while retaining dimensions not captured by price. Some can be ordered ordinally without meaningful cardinal distances. Some can be compared only within a domain. Some are subject to thresholds or rights that constrain trade-offs. Some are held by different subjects whose evaluative frameworks do not share a common scale.

GRE needs a vocabulary for these cases because generative effects often cross value domains. A policy can increase income while reducing ecological resilience. A technology can increase productivity while weakening autonomy or interpretive control. An institution can expand access for one population while eroding cultural continuity for another. The analytical challenge is to preserve these transformations without treating every trade-off as either fully aggregable or completely incomparable.

Several approaches are available for future development: vector-valued representation, partial ordering, threshold constraints, lexicographic priorities, multi-criteria analysis, deliberative comparison, qualitative matrices, and domain-specific indicators. Each imposes assumptions. The important task is to state those assumptions and to distinguish practical decision procedures from claims about underlying value equivalence.

Comparison also has a political dimension. Institutions that control the conversion interface between value forms can determine which values become legible enough to enter allocation decisions. Measurement systems, accounting rules, markets, legal standards, and algorithmic ranking can all privilege particular value representations. GRE should therefore study value comparison both as an analytical problem and as an object of economic power.

The open problem is not to eliminate heterogeneity. It is to make decision-relevant comparison possible while preserving residual differences that remain normatively or empirically meaningful.

3.20.7 Generativity and Justice

Generativity and justice intersect without being identical. An arrangement can generate substantial new capacity while distributing access, control, risk, or return unjustly. A restrictive intervention can reduce some forms of generation while protecting vulnerable subjects or preserving future ecological conditions. A relation can be locally reciprocal while depending on historical structures that shape who possesses the capacity to participate. GRE therefore needs a more developed account of how

generative analysis and theories of justice constrain, inform, and revise one another.

One unresolved issue concerns the object of justice. Evaluation can focus on resources, capabilities, recognition, participation, relations, procedures, generated opportunities, or future conditions of generation. These objects can point in different directions. Equal resource distribution can coexist with unequal conversion capacities. Broad participation can coexist with domination inside the participatory process. Expansion of future possibilities for one group can depend on ecological or social foreclosure for another.

A second issue concerns temporal distribution. Generative interventions often move value across time. Present actors can bear costs that create future capacities, while future actors can inherit both benefits and constraints without having participated in the original decision. Justice therefore requires attention to who pays for generation, who controls the generated capacity, who receives later return, and who inherits the risks of failure or lock-in.

A third issue concerns agency and authorship. When value is co-produced through distributed relations, justice cannot rely only on a simple producer-recipient distinction. Contributors can include maintainers, caregivers, communities, infrastructures, knowledge traditions, ecosystems, and future institutions. Attribution uncertainty makes distributive claims more difficult but does not remove the normative problem.

GREthic provides a neighboring domain for deeper normative theory, while GRE retains responsibility for describing the economic relations through which capacities, dependencies, returns, and foreclosures are produced. The open problem is to build interfaces between these domains without allowing normative vocabulary to substitute for economic mechanism or economic description to settle normative judgment automatically.

Progress will likely require multiple justice criteria rather than a single principle centered on generativity. Generativity can become one object of justice—especially where institutions systematically capture others' capacity to generate—but justice also constrains which forms of generation are permissible and how risks, participation, recognition, and future possibilities should be distributed.

3.20.8 Symbolic Reification

GRE relies heavily on analytical concepts such as relation, field, subject, capability, generativity, value, constraint, and possibility. These concepts are necessary for inquiry, yet repeated use can create symbolic reification: a representation introduced to organize observation begins to be treated as if it were the stable object itself. This problem is especially significant for a programme that explicitly distinguishes relations from their representations.

Reification can occur through ordinary scholarly language. A network diagram can encourage researchers to treat nodes as naturally bounded entities even when the nodes are administrative constructions. A capability measure can become identified with capability itself. A field representation can be spoken of as if the measured scalar were literally the distributed social condition. A generativity score can transform a multidimensional hypothesis into an apparently objective property. Institu-

tional categories can become research variables and then return to practice with the authority of scientific classification.

The danger increases when representations become operational. Metrics influence funding, rankings, eligibility, regulation, and organizational behavior. Models can therefore participate in generating the reality they purport to describe. Subjects adapt to categories, optimize against indicators, and reorganize behavior around algorithmic classifications. A representation can acquire causal power through institutional uptake without becoming ontologically complete.

GRE needs practices that keep this reflexive relation visible. Researchers can document category construction, preserve alternative representations, test sensitivity to operational definitions, distinguish latent constructs from measured proxies, and monitor how measures alter behavior after institutional adoption. Historical work can show how categories change. Interpretive inquiry can reveal meanings lost in standardized representation. Formal work can state which properties are assumed rather than observed.

The open problem extends beyond avoiding conceptual error. Symbolic reification can become a mechanism of power when institutions control the categories through which subjects are recognized, evaluated, funded, or excluded. The study of representations therefore belongs within the economic analysis of generative conditions. GRE must remain capable of using symbols and models decisively while keeping open the possibility that its own categories become objects of later revision.

3.20.9 Governance under Persistent Asymmetry

Section 81 treated asymmetry as a durable feature of many economic relations and distinguished it from power. The open governance problem begins where complete equalization is unavailable, undesirable, or itself generative of new dependencies. Differences in expertise, capital, institutional authority, computational capability, ecological exposure, time horizon, or exit capacity can persist even under well-designed institutions. Governance must therefore operate in conditions where symmetry cannot be treated as the endpoint.

One challenge is preventing asymmetry from becoming unreviewable domination. Transparency, contestability, exit, representation, auditing, countervailing institutions, liability, redistribution, and public infrastructure can each constrain conversion of asymmetry into power. Their effectiveness depends on context. Transparency is weak where subjects lack capacity to interpret information. Exit is weak where alternatives are costly or unavailable. Counter-power can create another concentration. Redistribution can reduce resource asymmetry while leaving institutional or epistemic asymmetry intact.

A second challenge concerns dynamic asymmetry. Capabilities change at different speeds. Artificial systems, financial institutions, states, and large platforms can update or coordinate more rapidly than individuals or local communities. Governance mechanisms designed for a slower environment can become ineffective before formal rules change. Persistent asymmetry is therefore partly temporal: the ability to learn, respond, litigate, coordinate, or revise can itself be unequally distributed.

A third challenge concerns productive asymmetry. Some differentiation enables specialization, expertise, delegation, and coordination. Governance that attempts to eliminate every asymmetry can destroy useful capacities or impose high administrative cost. GRE therefore requires criteria for distinguishing asymmetries that are functionally productive from asymmetries that generate dependency, exclusion, capture, or foreclosure. The distinction is empirical and normative rather than definitional.

Future work should compare governance architectures by how they affect conversion mechanisms. Which institutions prevent expertise from becoming unaccountable authority? Which infrastructures reduce dependence without eliminating specialization? Which rights preserve contestability when exit is impossible? Which forms of public or cooperative capacity alter bargaining structure? Which monitoring systems remain revisable when the powerful actors being monitored can adapt strategically?

The open problem is governance that remains effective under durable difference. GRE should study how relations can remain productive and heterogeneous while limiting the recursive accumulation of asymmetry into structures that remove others' capacity to participate, contest, exit, or generate alternatives.

3.20.10 Long-Horizon and Intergenerational Evaluation

The final open problem concerns effects that extend beyond ordinary observational and political horizons. Generative analysis often directs attention toward future capacities, institutional trajectories, ecological conditions, knowledge infrastructures, and path-dependent constraints. These objects can persist for decades or generations. Evaluation therefore faces a fundamental difficulty: the most important consequences may occur after the period in which evidence can be directly collected or the relevant decision-makers remain accountable.

Long-horizon evaluation raises familiar forecasting problems and additional generative-relational problems. Future subjects may possess different preferences, technologies, institutions, vulnerabilities, and value languages. Interventions can change the categories through which later outcomes are evaluated. The relevant counterfactual can also evolve. A policy that appears option-expanding under present technology can become restrictive under a later technological regime, while an apparently conservative intervention can preserve ecological or institutional capacities whose future uses are presently unknown.

Discounting provides one way to compare temporally separated effects, but discount rates encode substantive assumptions and cannot resolve all intergenerational questions. Some future losses concern irreversible ecological damage, destroyed knowledge, institutional lock-in, or loss of option-generating capacity. These may be poorly represented as ordinary delayed consumption effects. GRE therefore needs temporal representations that distinguish delayed value from changes in the capacity to generate future value.

Uncertainty compounds the problem. Forecast distributions may widen with horizon; structural transformation can invalidate the model generating those distributions; unknown future innovations can alter feasible trajectories; and future actors

cannot participate directly in present deliberation. Evaluation must therefore combine prediction with robustness, precaution, reversibility, preservation of options, and explicit treatment of model uncertainty. Different domains will justify different combinations.

Intergenerational analysis also requires attention to inheritance. Future subjects inherit infrastructure, institutions, debts, ecological conditions, knowledge, classifications, and unresolved conflicts. These inheritances shape both their opportunities and the costs of changing course. A generative intervention should therefore be evaluated partly by what kinds of revision it leaves possible for those who come later.

This problem may retain irreducible uncertainty. Future possibility spaces cannot be observed in full, and the values through which future actors judge inherited conditions cannot be completely known. GRE should not treat this uncertainty as a reason to ignore long horizons. It should instead make the uncertainty explicit and examine which interventions preserve enough diversity, reversibility, capacity, and institutional corrigibility to support later adaptation and re-evaluation.

The ten problems in this section define a research frontier rather than a list of defects awaiting simple repair. Some require better measurement and identification; some require new formal or empirical methods; some concern interfaces with normative theory; and some arise from reflexivity, historical change, and the openness of future possibility. Progress in one area can also alter another. Better generativity measures can intensify symbolic reification if their institutional use is poorly governed. Broader relational boundaries can improve downstream attribution while increasing uncertainty. Stronger governance of asymmetry can change the mechanisms whose effects were initially being measured.

GRE should therefore preserve open problems as active components of its cumulative research programme. An unresolved question becomes productive when competing formulations, evidence, failed approaches, and revisions remain traceable. The next section turns from these substantive open problems to the architecture through which the wider GRE programme can organize their investigation across epistemology, methodology, praxis, formalization, governance, knowledge, artificial intelligence, and domain-specific applications.

3.21 Architecture of the GRE Research Programme

The preceding sections have specified the provisional identity, problem-space, objects, scales, modes of inquiry, epistemic commitments, praxis, normative interfaces, contribution criteria, internal pluralism, and open problems of Generative Relational Economics. The role of the present section is different. It organizes those commitments into a research architecture that can support the remainder of the book and, more importantly, a cumulative programme extending beyond this book. Its objective is to identify the principal domains of work that GRE requires, clarify their relations, and show how movement among them can remain coordinated without collapsing them into one method, one ontology, or one normative theory. The architecture is therefore neither a linear sequence nor a departmental division of labor. It is a set of connected research components whose outputs can constrain, revise, or redirect

one another.

The programme can be understood as having several recurrent movements. Epistemological work asks what kinds of relational and generative claims can be warranted. Methodological work develops procedures for observing, reconstructing, comparing, and testing those claims. Praxis links explanation to intervention under incomplete knowledge. Substantive economic work specifies economic objects, allocation processes, value trajectories, temporal organization, power, knowledge, artificial intelligence, and domain-specific mechanisms. Formal work provides representations that can clarify structure or generate implications without acquiring automatic ontological priority. Normative and governance work evaluates how generated capacities, dependencies, harms, and possibilities should be judged and governed. None of these components is sufficient by itself. Their interaction is what gives GRE the possibility of becoming a research programme rather than a vocabulary.

This architecture also gives the later chapters a disciplined relation to Chapter 3. The chapters that follow do not merely expand terms introduced here. They test whether the constitutional claims made in Part I can survive more demanding epistemic, methodological, formal, substantive, and applied development. A concept that proves unusable under empirical inquiry should be revised. A formal representation that cannot preserve relevant historical or interpretive distinctions should be limited. A normative framework that obscures economic mechanisms should not replace explanation. An intervention methodology that generates unanticipated dependency should feed back into the theory of power and praxis. The architecture is therefore recursive: later work is expected to modify the preliminary constitution from which it begins.

3.21.1 Epistemology of Relations

A GRE research programme requires an epistemology capable of supporting claims about relations without assuming that relations are directly given to observation. Economic inquiry usually encounters traces: transactions, documents, prices, classifications, narratives, institutional records, behavioral responses, network data, legal categories, measurements, and model outputs. From such traces, researchers infer relations of dependence, recognition, exchange, authority, mediation, constraint, influence, and generation. The first architectural component therefore concerns the conditions under which these inferences are warranted.

The epistemology of relations must keep at least four layers distinguishable. There is the relation or relational process posited as part of the target situation; there are the observations through which researchers gain partial access to it; there are the categories and representations used to organize those observations; and there are the claims made on the basis of those representations. Confusion among these layers produces many characteristic errors. A network edge can be mistaken for the relation itself. A legal category can be treated as a complete description of social participation. A repeated correlation can be interpreted as a stable generative relation even where the mechanism changes historically. GRE therefore requires explicit accounts of how observations become relational claims.

This epistemic component also has to accommodate different kinds of relational ev-

idence. Some relations are materially instantiated through contracts, infrastructures, ownership, payment, or legal authority. Others are reconstructed from repeated interaction, dependence, interpretation, or institutional practice. Still others concern counterfactual or generative effects that cannot be observed directly because they refer to capacities, alternatives, or future conditions. Evidence sufficient for one kind of relation may be inadequate for another. The programme should therefore resist a single criterion of relational observability.

Epistemology of relations also includes reflexivity. Economic categories can alter the relations they represent. Credit scores change access to credit; rankings alter institutional behavior; classifications determine eligibility; models influence expectations; and public descriptions can reshape coordination. The object of knowledge can therefore respond to the means of knowing. This makes epistemology an economic problem as well as a philosophical one. The programme must study how knowledge practices participate in the relational field whose properties they attempt to establish.

The output of this component is not a final theory of knowledge. It is a set of standards for relational claims: how objects are identified, how boundaries are selected, how observations are linked to relations, how representations are validated, how uncertainty is expressed, and how claims remain open to correction. Those standards provide the epistemic ground on which the methodological components of the programme operate.

3.21.2 Methodology of Relational Inquiry

Relational methodology concerns procedures for studying configurations in which the properties or effects of an object depend materially on its relations with other objects, institutions, environments, or representations. Its central task is to move analysis beyond isolated-unit description without treating every connection as equally significant. A relational study must identify which relations matter, how they are evidenced, what scale they operate at, and which consequences follow from their organization.

The methodological repertoire is necessarily plural. Historical reconstruction can identify how a relation formed and changed. Comparative inquiry can examine why similar entities occupy different relational positions. Network analysis can represent patterned connectivity. Institutional analysis can identify rules that stabilize or authorize relations. Ethnographic and interpretive work can reconstruct how participants understand obligations, identities, and meanings. Econometric and causal designs can estimate effects generated through specified relational exposures. Qualitative process tracing can examine mechanisms that are difficult to reduce to stable variables. None of these methods is intrinsically more relational merely because of its technique. Relationality enters through the structure of the research question and the specification of the object.

A developed relational methodology should make boundary construction explicit. Researchers need criteria for deciding which actors, institutions, ecological conditions, infrastructures, classifications, and temporal histories belong inside the analysis. Because boundaries are analytical choices with substantive consequences, sensitivity to alternative boundaries should become part of methodological practice where

feasible. The same transaction can look efficient within a firm boundary and extractive within a regional labor system; a technological intervention can look productive over one year and capability-destroying over a decade.

Relational inquiry also needs procedures for distinguishing direct from mediated effects. Economic outcomes often travel through chains of institutions, expectations, infrastructures, and social recognition. A transfer to one subject can alter bargaining conditions for another; a platform rule can change incentives through ranking systems; a legal reform can transform behavior through expectations before enforcement occurs. Methodological work must therefore support the reconstruction of mediation rather than stopping at the administrative point of intervention.

The programme should accumulate relational methods through reusable design patterns rather than prescribe one canonical protocol. Useful patterns may concern boundary selection, multi-source evidence, relation typing, temporal reconstruction, counterfactual comparison, cross-scale mapping, or identification of institutional mediation. These patterns become a methodological library that later studies can adapt while preserving transparent assumptions and limits.

3.21.3 Methodology of Generative Relational Inquiry

Generative relational inquiry adds a further question to relational analysis: what later capacities, structures, values, subjects, constraints, or possibilities are produced through a relation, and through what mechanism? This shift changes both the temporal horizon and the object of explanation. The researcher is no longer concerned only with what a relation currently connects or distributes. The inquiry follows how participation in the relation changes the conditions from which subsequent economic processes can occur.

This methodological component therefore requires explicit generative claims. A study should state what is alleged to be generated, over what period, for which subjects or systems, and through which mediating process. Generation may concern skills, trust, dependency, infrastructure, market access, organizational capacity, knowledge, subject positions, ecological resilience, future options, institutional lock-in, or the capacity to generate further value. These are heterogeneous objects, so no single metric can stand in for generativity across domains.

Generative inquiry also requires attention to counterfactual trajectories. The relevant comparison is frequently not simply between treated and untreated units at one time. It may concern how different relational configurations alter later pathways. This creates methodological difficulty because the treatment can change the variables, categories, or institutional environment through which later outcomes are measured. Longitudinal designs, historical comparison, mechanism-based simulation, qualitative reconstruction, and adaptive experimentation may therefore complement conventional causal identification.

A further methodological problem concerns recursion. Generated capacities can alter the relation that generated them. New knowledge changes bargaining power; institutional learning changes governance; accumulated infrastructure shifts future allocation; successful coordination changes expectations; artificial systems can alter the speed and scale of subsequent production. Generative relational methodology

must be capable of tracing such feedback without assuming that the original mechanism remains fixed.

The programme should therefore develop a family of generative research designs rather than one universal method. Their common requirement is disciplined movement from relation to mechanism to generated consequence to altered future condition. Where the chain cannot be established, the study should say so. Where several mechanisms remain plausible, competing explanations should remain visible. This methodological restraint protects generativity from becoming an all-purpose label for any downstream change.

3.21.4 Praxis and Intervention

Praxis connects GRE's explanatory programme to purposive attempts to alter economic relations. The architectural function of praxis is to prevent theory from ending at diagnosis while also preventing intervention from outrunning knowledge. GRE therefore treats intervention as an iterative research and governance process in which action generates new evidence, changes the relational field, and may require revision of both the intervention and the theory that justified it.

A GRE praxis architecture begins with relational and generative diagnosis. The analyst identifies the relevant subjects, institutions, dependencies, constraints, capacities, value trajectories, and asymmetries. Intervention design then specifies which relation or enabling condition is to be changed, what effects are expected, which subjects may bear risks, and what indicators or qualitative observations can reveal downstream consequences. Implementation becomes part of inquiry because it tests assumptions under conditions that may differ from those represented in the initial model.

Adaptive feedback is therefore central. Interventions should include monitoring capable of detecting effects beyond the intended recipient, changes in dependency, emergent exclusion, shifts in power, unexpected conversions of value, and damage to future options. Revision can concern intensity, targeting, institutional design, representation, or even the original diagnosis. Where harm or failure becomes sufficiently probable, withdrawal, reversal, and repair need to remain available.

Praxis also requires institutional design for learning. Organizations often collect data for accountability but not for theoretical correction. GRE would instead treat intervention records, failed mechanisms, participant interpretations, unexpected effects, and reversal attempts as cumulative research materials. This creates a bridge between application-dominant work and research-dominant work. Interventions become sites in which the adequacy of relational and generative hypotheses can be examined.

The praxis component does not imply that every GRE project must intervene. It specifies the architecture required when explanation is translated into action. Its standards are proportional to stakes and uncertainty. The more irreversible, asymmetric, or long-horizon the intervention, the stronger the need for monitoring, contestability, staged implementation, reversibility, and repair capacity.

3.21.5 Economic Objects and Relational Architecture

Substantive GRE begins by reconstructing the architecture of economic objects. Firms, households, platforms, markets, contracts, currencies, technologies, infrastructures, public agencies, communities, and ecological systems can all function as economic objects, but their economic significance depends on relations that constitute access, authority, dependence, recognition, exchange, coordination, and reproduction. The programme therefore needs systematic accounts of how economic objects are stabilized and connected.

Relational architecture concerns more than mapping connections. It asks which relations are constitutive, which are enabling, which are extractive, which are substitutable, and which create dependence or future capacity. It also examines how objects change when their relational architecture changes. A firm can retain a legal identity while its productive relations, knowledge base, ownership, labor dependence, and technological infrastructure transform substantially. An apparently stable object can therefore contain changing generative conditions.

This component also organizes scale. Economic architecture can be reconstructed within organizations, across supply chains, among institutions, between human and artificial subjects, or across economic and ecological systems. At one scale a platform is an entity; at another it is a field of relations among users, advertisers, workers, algorithms, legal authorities, and infrastructures. GRE should be able to move between these representations without presuming that one scale is ontologically final.

A mature programme would accumulate relational architectures comparatively. Which configurations support distributed capability? Which concentrate dependency? Which are resilient to shocks? Which permit exit and revision? Which externalize ecological or social costs? Which generate durable learning? Comparative architectural work can provide intermediate theory between highly local case description and universal claims about markets or institutions.

This substantive component prepares several later programme domains. Allocation changes relational architecture; value moves through it; generative spacetime records its historical and temporal organization; formal models represent selected features of it; governance attempts to alter its asymmetries. Economic architecture therefore functions as a central integrative object without becoming the sole object of GRE.

3.21.6 Relational Allocation

Allocation is conventionally concerned with who receives which resources under specified constraints. GRE retains that question but expands the analytical unit. An allocation also enters a relational configuration and can change bargaining positions, dependencies, recognition, coordination capacity, expectations, and future productive possibilities. Relational allocation is the programme component that studies these mediated effects systematically.

The relevant object is therefore not merely the resource transferred. It includes the route, institutional conditions, attached obligations, timing, visibility, substitutability, and relations through which the allocation is received and used. The same mone-

tary amount can produce different consequences depending on whether it arrives as wage, grant, debt, benefit, prize, investment, family transfer, or platform payment. The relational form can influence autonomy, stigma, risk, reciprocity, and future access even when nominal quantity is identical.

Relational allocation also widens incidence analysis. Effects can propagate beyond the administrative recipient through households, markets, organizations, networks, and institutions. A subsidy can change prices, a training programme can alter labor-market competition, a public infrastructure investment can change land values, and access to computation can reshape research capacity. GRE therefore asks which relations mediate the allocation and how those relations redistribute later opportunities or constraints.

The programme should develop both descriptive and intervention-oriented allocation research. Descriptive work can reconstruct relational incidence and downstream transformation. Formal work can model how allocation changes network positions or dynamic constraints. Comparative work can examine alternative institutional forms for delivering similar resources. Normative work can evaluate whether an allocation expands capability while generating dependency elsewhere. Application-dominant praxis can use these findings to redesign allocation mechanisms.

Relational allocation is thus a bridge between conventional economic analysis and the generative programme. It retains scarcity, incentives, incidence, and trade-offs while extending attention to how allocation changes the relational conditions under which later value and capability are generated.

3.21.7 Generative Value

Generative value concerns value that arises through the capacity of a relation, resource, institution, or process to enable further valuable activity. The concept does not replace exchange value, use value, welfare, capability, social value, ecological value, or other established categories. Its programme function is to make the production of future value-generating capacity an explicit economic object.

Generative value may appear through learning, infrastructure, trust, institutional competence, scientific knowledge, ecological restoration, network access, organizational routines, or the creation of new possibilities for participation. Its effects can be delayed, distributed, and difficult to attribute to one original intervention. The same process can generate several forms of value while also producing harm, dependence, or exclusion. The programme therefore requires plural representations rather than assuming that generative value is one scalar quantity.

Research in this component should address propagation and conversion. Value generated in one domain can move into another: knowledge can become productive capability, social recognition can become market access, infrastructure can become bargaining power, ecological conditions can enable future production, and data can become organizational advantage. Conversion can also be blocked or asymmetrical. Subjects may contribute to a generative process without capturing the value that later emerges from it.

This creates questions of return and distribution. Who receives the benefits of generated capacity? Which relations permit value to recirculate to those who sustained its emergence? Which institutional arrangements enable extraction by actors positioned downstream? How should delayed or diffuse contributions be recognized? These questions connect generative value to political economy and justice without making one normative rule part of the definition of value itself.

A cumulative research programme should develop typologies of generative mechanisms, methods for tracing value trajectories, domain-specific indicators, and comparative institutional studies. It should also preserve cases in which apparently generative investments fail to create durable capacity or create capacity that later becomes harmful. Generative value becomes analytically useful only if it remains distinguishable from the general fact that economic processes have consequences.

3.21.8 Generative Spacetime

Generative spacetime provides the programme's architecture for analyzing how economic relations are organized across heterogeneous spatial and temporal conditions. The term does not imply that social reality literally possesses the geometry of physical spacetime. It identifies a research problem: economic processes unfold through histories, delays, path dependencies, spatial distributions, institutional boundaries, and differently paced subsystems whose relations shape what can be generated later.

Time in GRE cannot be reduced to a neutral index. The order of events can matter. Early access to capital can alter later bargaining power; institutional sequencing can determine which reforms become feasible; technical standards can lock in infrastructure; educational investments can affect capabilities years later; ecological degradation can create long recovery periods. Identical quantities introduced at different moments can therefore have different generative effects.

Spatial organization is similarly relational. Geographic distance interacts with infrastructure, jurisdiction, logistics, language, data access, mobility, and ecological conditions. Digital mediation can reduce some distances while creating new forms of concentration in computation, platforms, standards, or data centers. A generative-spacetime analysis asks how locations become connected or separated through these economic relations rather than treating space as a passive container.

The programme also needs to study heterogeneous temporalities. Humans, firms, financial markets, states, ecosystems, infrastructures, and artificial systems can operate at very different speeds. Their coupling can generate asymmetry. A platform can change an algorithm faster than workers can reorganize; financial capital can exit faster than communities can replace employment; ecological recovery can be slower than investment cycles. Temporal mismatch therefore becomes an economic mechanism rather than merely a descriptive feature.

Generative spacetime should support historical reconstruction, dynamic modeling, spatial analysis, and long-horizon evaluation. Its contribution is to preserve the ordering, location, duration, and temporal coupling of generative processes. It thereby links historical analysis to formal dynamics without reducing one to the other.

3.21.9 Formal Models

Formal modeling provides GRE with tools for making assumptions explicit, deriving implications, comparing mechanisms, and exploring trajectories that are difficult to reason about verbally. The programme can draw on dynamical systems, networks, multilayer structures, agent-based models, optimization, game theory, probabilistic models, field-like representations, simulation, and other mathematical or computational techniques where they are appropriate to the object.

The architectural principle is representational pluralism under ontological restraint. A network model emphasizes connectivity; a dynamical model emphasizes state evolution; a game-theoretic model emphasizes strategic interaction; an agent-based model emphasizes local rules and emergent aggregate patterns; a field representation emphasizes distributed conditions. These models need not be translated into one universal formal language. Their adequacy depends on which features of the economic problem they preserve and which they suppress.

Formal work in GRE should state the status of each construction. Some models are descriptive summaries. Some identify structural possibilities. Some generate comparative statics or trajectories. Some serve as counterfactual laboratories. Some are fitted to empirical data; others are heuristic. A mathematically precise model can remain empirically weak if its variables or mechanisms lack adequate correspondence to the target system. Formal rigor therefore complements rather than substitutes for evidential warrant.

Generativity creates particular formal challenges. The variables, interaction structures, or effective rules may themselves change. Models can represent some forms of adaptation, network rewiring, rule learning, or changing parameters, but the programme should distinguish represented transformation from genuinely unforeseen category change. Where the formal state space excludes relevant novelty, model revision may be more appropriate than adding complexity to preserve a fixed representation.

The cumulative aim is a library of transparent formal models tied to clearly stated empirical and conceptual problems. Comparability should depend on assumptions, mechanisms, observables, and failure conditions, not on adherence to one mathematical paradigm. Formal models should remain instruments through which GRE sharpens explanation, tests implications, and explores possibilities.

3.21.10 Justice, Power, and Governance

Power and justice form a programme component because generative economic relations distribute more than current resources. They shape who can participate, who can exit, whose knowledge counts, who bears vulnerability, which alternatives remain feasible, and who captures value generated through collective processes. Governance concerns the institutional organization of these relations under persistent asymmetry and uncertainty.

Power research in GRE studies conversion mechanisms. Resource, capability, knowledge, institutional, vulnerability, and exit asymmetries become economically consequential when they can be converted into durable influence over others'

options or future conditions. The programme should identify the institutional arrangements that enable or constrain these conversions. Ownership, standards, law, infrastructure, platform design, intellectual property, credit, public authority, and organizational hierarchy can all mediate conversion.

Justice enters as a neighboring evaluative problem rather than a property automatically inferred from generativity. A highly generative arrangement can still distribute participation unequally, impose dependency, externalize harm, or foreclose alternatives. GRE therefore needs interfaces with distributive, procedural, relational, capability-oriented, ecological, and generative approaches to justice while remaining explicit about which normative principles are being used.

Governance research then asks how institutions can organize relations under conditions in which asymmetry cannot simply be eliminated. Relevant mechanisms include contestability, transparency, rights, public capacity, collective organization, auditing, representation, interoperability, liability, redistribution, and preservation of exit or voice. Each can itself generate new dependencies or concentrations. Governance must therefore be evaluated recursively.

This component connects explanation, normativity, and praxis. Its success should be judged not by whether it yields one constitutional ideal but by whether it improves the ability to diagnose power, compare governance architectures, evaluate their generated consequences, and revise institutions as relational conditions change.

3.21.11 Knowledge and Epistemic Economy

Knowledge is simultaneously an input, output, resource, relation, institution, and source of asymmetry. A GRE research programme therefore requires a substantive epistemic economy concerned with how knowledge is generated, validated, stored, circulated, priced, restricted, translated, forgotten, and converted into other forms of value or power.

The economic organization of knowledge affects who can generate further knowledge. Access to education, archives, computation, laboratories, data, journals, languages, expert communities, and institutional recognition shapes future epistemic capability. Knowledge production can therefore exhibit cumulative advantage and generative inequality even when individual information goods are non-rival. Ownership, paywalls, classification, secrecy, data governance, and platform control can influence the relational conditions of inquiry.

Epistemic economy also concerns recognition. Some observations become evidence, some questions become fundable, some methods acquire authority, and some speakers become credible. These processes are partly scientific and partly institutional. They can generate epistemic injustice when subjects are systematically excluded from contributing, being understood, or influencing the categories through which their situations are represented. At the same time, standards of evidence remain necessary; inclusion cannot mean suspension of criticism.

Artificial intelligence intensifies these questions by reducing some costs of synthesis, drafting, search, modeling, and content generation while increasing dependence on data, computation, model access, evaluation infrastructure, and epistemic filter-

ing. Abundance of generated text can make provenance, attention, verification, and question formation scarcer. The economic object is therefore not knowledge alone but the relational infrastructure through which epistemic capability is distributed.

The programme should study knowledge capital, epistemic labor, archive power, verification, provenance, scientific institutions, open infrastructure, education, and the generative conditions of inquiry. It should also examine how its own research practices distribute epistemic participation and authority.

3.21.12 Artificial Intelligence and Radical Asymmetry

Artificial intelligence provides a contemporary domain in which several GRE problems become unusually visible at once: heterogeneous subjecthood, rapid capability change, concentration of infrastructure, epistemic abundance, organizational transformation, power conversion, temporal mismatch, and uncertainty about future generative trajectories. The programme should therefore treat AI neither as a peripheral application nor as an all-explanatory paradigm. It is a demanding empirical case for testing GRE's concepts.

The central economic problem is not simply automation or substitution. AI systems can alter the cost and speed of cognition-like tasks, reorganize knowledge work, modify decision processes, enable new forms of coordination, and change who can produce valuable outputs. The consequences depend on ownership, access, interface design, labor relations, education, regulation, data, compute, and organizational capacity. Similar model capabilities can therefore produce different economic structures under different relational architectures.

Radical asymmetry refers to cases in which capability differences become large enough to transform bargaining, monitoring, production, or institutional response. Such asymmetry can occur among firms, states, workers, consumers, or human and artificial operational subjects. It does not establish moral or ontological equality among those subjects. The research problem concerns how capabilities are converted into economic power and how other subjects retain participation, contestability, learning, and exit under rapidly changing conditions.

AI also complicates the generative horizon. Systems that participate in research, design, education, administration, or cultural production can alter the rate at which new possibilities are generated. They can also narrow possibility through standardization, dependence, concentrated infrastructure, or recursive optimization around existing metrics. Evaluation must therefore attend to both capability expansion and generative foreclosure.

This component should integrate empirical labor economics, industrial organization, innovation studies, political economy, governance, epistemic economy, and technical understanding of AI systems. GRE contributes by coordinating these perspectives around relational and generative mechanisms rather than by replacing their specialized expertise.

3.21.13 Domain-Specific Applications

The final architectural component concerns domain-specific application. A research programme becomes substantive only when its concepts survive contact with cases in which institutions, evidence, values, scales, and mechanisms differ. GRE should therefore be tested across domains rather than developed indefinitely at the level of general vocabulary.

Candidate domains include labor, education, scientific research, health, finance, development, migration, humanitarian systems, urban infrastructure, digital platforms, ecological transition, public administration, innovation, culture, and international economic relations. Each domain brings specialized literatures and methods that GRE must respect. Domain application should begin from the empirical problem and available knowledge, then ask whether relational and generative analysis adds explanatory or practical value.

Applications serve several programme functions. They test concepts against heterogeneous evidence. They expose hidden assumptions imported from one domain into another. They identify mechanisms that may travel across cases and mechanisms that remain local. They provide intervention evidence. They reveal where value categories differ and where normative conflict becomes unavoidable. They can also demonstrate that GRE adds little to an already adequate established analysis, which is itself useful boundary knowledge.

Cross-domain comparison should therefore be careful. Similar labels can conceal different mechanisms. Dependency in finance, caregiving, digital infrastructure, and ecology need not be structurally identical. Generativity in education may concern capabilities and inquiry; in ecological restoration it may concern system resilience and future option spaces; in science it may concern knowledge and question formation. Comparative GRE should look for structural correspondence without presuming equivalence.

Domain-specific work also provides the main route through which the architecture remains corrigible. If concepts repeatedly fail in applied settings, they should be narrowed or abandoned. If new objects or mechanisms recur across domains, the programme can revise its typologies. If governance approaches generate predictable secondary harms, praxis should change. Application is therefore not the terminal stage of the programme. It is one of the principal sources through which the architecture itself evolves.

Taken together, these thirteen components define a preliminary architecture for GRE research. They do not form a pipeline in which epistemology is completed before methodology, methodology before substantive economics, and substantive economics before application. Work can begin in any component and move among several. An empirical anomaly can force epistemic revision; an intervention can reveal a new mechanism; a formal model can expose an ambiguous concept; a domain-specific case can require new governance categories; a normative conflict can reveal that a value representation is too coarse.

The architecture therefore functions as a coordination device. It indicates where a research question sits, which neighboring components are likely to constrain it, what forms of evidence or representation may be required, and how results can return to

the wider programme. It also gives the remaining parts of the book a common orientation: ontology and epistemology, research praxis and methodology, application-dominant intervention, substantive economic foundations, power and knowledge, artificial intelligence, domain applications, and the later disciplinary return are connected components of one revisable research programme rather than independent theoretical excursions.

The following section condenses this architecture into a preliminary constitution of GRE. That constitution does not close the field. It states, in compact form, what GRE studies, what it does not need to presume, what it attempts to explain and change, what can count as evidence and contribution, and which questions remain deliberately open to historical and theoretical revision.

3.22 A Preliminary Constitution of GRE

The preceding sections have developed Generative Relational Economics from a provisional disciplinary identity into a structured research programme. They have specified its problem-space, methodological primitives, objects and scales of inquiry, characteristic questions, analytical sequence, account of economic subjecthood, orientation of generation, modes of inquiry, epistemic commitments, praxis, normative interfaces, analysis of power and heterogeneity, disciplinary boundaries, contribution criteria, cumulative programme, internal pluralism, open problems, and wider research architecture. The role of the present section is to condense those commitments into a preliminary constitution. The term *constitution* is used here in a limited methodological sense. It denotes a compact statement of the conditions under which GRE can presently recognize its own objects, claims, evidence, interventions, contributions, and limits. It does not denote a final doctrine, a metaphysical settlement, or a fixed disciplinary code.

The objective of the section is therefore both consolidating and restrictive. Consolidation is needed because a research programme can become diffuse when its concepts expand faster than the criteria governing their use. Restriction is needed because GRE should remain distinguishable from any study that happens to mention relations, emergence, complexity, value, or future possibility. A preliminary constitution states what kinds of questions GRE takes responsibility for, which assumptions it withholds, what forms of explanation it seeks, how intervention enters the programme, what can count as evidence and contribution, and which questions remain deliberately unsettled. The method is synthetic rather than genealogical. No new lineage is introduced here. The section reorganizes the commitments already established in Chapters 1–3 into eight constitutional dimensions: domain, restraint, explanation, praxis, evidence, contribution, openness, and historical revisability.

The constitution is preliminary for a substantive reason. GRE studies processes in which relations, subjects, capacities, value structures, institutions, and conditions of generation can themselves change. A research programme directed toward such objects would contradict its own subject matter if it treated its present categories as permanently settled. Constitutional stability is therefore functional rather than absolute. The programme needs enough continuity for researchers to disagree about

the same problems, compare findings, and accumulate knowledge, while retaining enough revisability to alter its categories when empirical, historical, formal, or normative work reveals that they have become inadequate. The constitution presented below should be read in that spirit.

3.22.1 Domain and Objects of Study

GRE studies economic relations insofar as those relations help generate, reproduce, distribute, transform, or foreclose later capacities, constraints, values, subjects, institutions, trajectories, and fields of possibility. This domain statement is intentionally broader than the study of transactions and intentionally narrower than a general theory of social reality. GRE remains economic because its questions concern allocation, production, circulation, valuation, work, capability, institutional organization, economic power, dependence, resources, infrastructures, knowledge, and the conditions through which subjects participate in material and symbolic economies. It becomes generative-relational when those objects are examined through the consequences of their relational organization for what can subsequently exist, act, acquire value, coordinate, persist, or change.

The programme therefore treats the immediate recipient of an allocation or intervention as only one possible locus of effect. A subsidy may alter supplier capacity, household bargaining, regional infrastructure, expectations, or political legitimacy. An educational resource may change knowledge, confidence, social connection, question formation, institutional recognition, or later opportunity. A platform rule may change not only prices or matching efficiency but also visibility, dependence, subject formation, and the viability of alternative organizational forms. GRE asks which of these downstream effects are materially connected to the original relation and through which mechanisms they are generated. The downstream horizon is empirical and selective rather than indefinitely expansive: a GRE analysis is responsible for tracing consequences where plausible generative pathways and evidential access make them analytically relevant.

The objects admitted to this domain are correspondingly plural. Relatively stabilized entities, subjects, relations, resources, capacities, values, constraints, fields, processes, events, trajectories, institutions, social facts, and symbolic representations can each become objects of GRE inquiry. Their analytical status depends on the local problem. A firm may be treated as an entity in one study, as a field of internal relations in another, as an institutional rule complex in a third, and as a node within a wider production ecology in a fourth. GRE does not require one of these descriptions to exhaust the firm's reality. It requires the researcher to state which object construction is being used, at what scale, for which explanatory purpose, and with what evidential consequences.

The domain also includes heterogeneous subjects. Human persons, households, organizations, public bodies, communities, ecological systems, hybrid arrangements, and artificial operational agents may participate in economically consequential relations under different descriptions and with different normative statuses. Their inclusion within a common analytical field does not establish ontological or moral equivalence. It means only that their interactions can affect allocation, value, capability,

dependence, coordination, and future possibility in ways that economic inquiry may need to represent. The constitution therefore permits heterogeneous participation while reserving questions of personhood, consciousness, legal personality, moral status, and ecological standing for the appropriate neighboring domains and normative arguments.

A GRE study is consequently identified less by a proprietary object than by a characteristic relation between object and question. The same labor market, school, AI system, household, ecological project, financial institution, or humanitarian intervention can be studied through many legitimate economic approaches. It becomes a GRE problem when the inquiry asks how relational organization changes the capacities and conditions from which later economic and social possibilities are generated. This criterion preserves disciplinary openness while preventing the label GRE from becoming synonymous with any broad interest in complexity or interdependence.

3.22.2 Constitutive Restraints

GRE proceeds under several restraints that are constitutive rather than merely cautious. The first is ontological suspension. The programme can use entities, relations, processes, fields, networks, trajectories, categories, and generative structures without declaring any one of them the final metaphysical furniture of reality. Analytical usefulness establishes neither ontological priority nor completeness. A network representation may clarify connectivity; a field representation may clarify distributed conditions; a process description may clarify temporal transformation. Their value depends on the problem and the evidence. GRE therefore permits ontological commitment at the level required for a particular inquiry while withholding stronger closure.

The second restraint concerns explanatory universality. GRE does not presume that every economically relevant outcome requires a generative-relational explanation. Standard price theory, causal estimation, accounting, institutional description, optimization, historical narrative, or domain-specific expertise may already explain the relevant problem adequately. The programme earns analytical relevance where relational mediation, downstream generation, changing capabilities, path dependence, heterogeneous value, shifting subjecthood, power conversion, or transformation of future possibility materially improve understanding. The GRE label should therefore be unnecessary when a narrower account is sufficient.

A third restraint concerns generativity itself. Generation is not presumed to be beneficial, innovative, progressive, emancipatory, or just. Relations can generate dependency, exclusion, vulnerability, ecological degradation, epistemic closure, concentrated power, or the destruction of alternative futures. A highly generative system can reproduce harm more effectively than a weakly generative one. Evaluation must therefore remain separable from description. GRE can identify that a relation generates new capacities or reorganizes a field while leaving open whether that transformation should be encouraged, governed, limited, repaired, or reversed.

A fourth restraint concerns representation. Variables, categories, network edges, model states, indicators, simulations, legal classifications, and textual interpretations mediate access to the object; they are not automatically identical with it. GRE there-

fore distinguishes relational reality from its representation and treats boundary choice, measurement, coding, scale selection, and model specification as substantive parts of inquiry. This restraint is especially important where categories can become performative. Rankings, credit scores, eligibility classifications, productivity metrics, and AI-generated representations may alter the relations they purport to describe. The research instrument can become part of the generative field.

A fifth restraint concerns scalar and historical invariance. GRE does not assume that an object retains the same analytical identity across scale or historical transformation. A configuration that is stable enough to be treated as an entity at one level may decompose into changing relations at another. Categories such as worker, household, capital, platform, intelligence, capability, value, or market can change their institutional content over time. The constitution therefore requires explicit scale, boundary, and historical conditions whenever they materially affect the claim.

These restraints make the programme deliberately non-totalizing. They protect methodological pluralism, disciplinary interfaces, and corrigibility. They also impose costs: GRE must often carry more uncertainty, specify more boundaries, and resist attractive universal formulations. Those costs are accepted because a programme concerned with changing relations and future possibility requires a disciplined distinction between useful analytical commitment and premature closure.

3.22.3 Explanatory Commitments

GRE attempts to explain how economic outcomes and future possibilities arise through relations that mediate allocation, interaction, interpretation, institutional recognition, capability, and value. Its characteristic explanatory move is from a local intervention or observed configuration toward the mechanisms through which effects propagate and reorganize later conditions. This move does not replace causal inference. It expands the range of causal and generative questions that may need to be asked when the object cannot be understood adequately as an isolated unit responding to fixed incentives or constraints.

A generative explanation should identify more than temporal succession. It should specify a plausible mechanism connecting relational conditions to later changes. The mechanism may involve resource transfer, learning, coordination, reinforcement, institutional authorization, recognition, imitation, network exposure, expectation formation, technological complementarity, legal change, ecological feedback, symbolic classification, or another documented process. Claims of generation should remain proportionate to the degree to which such mechanisms can be evidenced. Where mechanism is uncertain, GRE should state the uncertainty rather than substituting the vocabulary of emergence for explanation.

The programme is especially interested in recursive transformation. Economic processes can change the conditions under which later processes operate. A policy can alter not only behavior but institutional trust; a technology can alter not only productivity but the skills and infrastructures required for participation; a market can alter not only allocation but the kinds of actors able to survive within it; an AI system can alter not only task performance but the organization of expertise, attention, and decision authority. In such cases, the effective rule governing later change may differ

from the rule that characterized the earlier system. GRE therefore treats transformation of generative conditions, and where warranted transformation of effective rules, as explanatory objects in their own right.

Explanation also requires attention to propagation, conversion, recirculation, dissipation, and extraction. Generated value can move among subjects and institutions, change form, accumulate, decay, or be captured. Knowledge can become capability; capability can become bargaining power; symbolic recognition can become access; ecological capacity can become economic resilience; public infrastructure can become private rent; care can sustain labor capacity without appearing in market price. GRE does not presume that these conversions are complete or commensurable. It seeks to identify the relations through which they occur and the losses, exclusions, and asymmetries that accompany them.

Power enters this explanatory programme as the conversion of asymmetry into durable influence over others' options, vulnerabilities, representations, exit conditions, or future generative possibilities. Resource asymmetry, capability asymmetry, knowledge asymmetry, institutional authority, vulnerability, and exit conditions can each contribute to power when relational conditions allow them to be converted into leverage. This formulation avoids treating all difference as domination while making the reproduction of asymmetry economically analyzable.

GRE also attempts to explain orientation. Economic systems do not only produce outputs; they distribute attention, visibility, curiosity, legitimacy, funding, search capacity, and institutional recognition. These processes influence which possibilities receive the conditions required for further development. An account of generation is therefore incomplete when it describes capacity while ignoring the mechanisms that direct capacity toward some questions, designs, values, or futures rather than others. Orientation can be intentional, institutional, market-mediated, algorithmic, cultural, or emergent. Its explanation belongs within the economic problem-space when it affects resource allocation and future generative capacity.

The constitutional explanatory commitment can therefore be summarized without reducing it to one model: GRE seeks mechanisms linking relational organization to the emergence, persistence, transformation, distribution, or foreclosure of later economic possibilities. Different studies may instantiate that commitment through historical reconstruction, causal inference, formal modeling, computational exploration, qualitative mechanism tracing, comparative inquiry, or combinations of these modes. The explanatory standard lies in the clarity of the claim and its warrant, not in adherence to one technique.

3.22.4 Praxis and Transformative Orientation

GRE is not constituted only as a descriptive programme. It also includes praxis: the disciplined movement from explanation toward intervention under incomplete knowledge. This practical orientation follows from the object of inquiry. If economic relations shape later capacities, dependencies, values, and possibilities, then allocation and governance decisions participate in the generation of future conditions. The research programme should therefore be capable of informing intervention while remaining explicit about the uncertainty and normative judgment that intervention

introduces.

Praxis begins with diagnosis rather than prescription. A relational diagnosis identifies the relevant subjects, institutions, infrastructures, dependencies, boundaries, and scales. A generative diagnosis asks which of those relations reproduce present conditions and which enable or foreclose change. Intervention design then specifies what is being altered: resources, constraints, access, recognition, information, rights, infrastructure, incentives, coordination mechanisms, or other conditions. This sequence prevents the language of generativity from becoming a license for indiscriminate experimentation.

Allocation is treated within this praxis as a relational intervention. The economic significance of allocating money, rights, infrastructure, education, information, or computational capacity depends on the relations into which the allocation enters. Identical resources can produce different effects under different conversion factors, institutional rules, recognition structures, ecological conditions, and power relations. GRE therefore asks how an intervention changes the field through which resources become capabilities and how those new capabilities affect other subjects and future options.

Intervention generates evidence as well as effects. Feedback, implementation failure, unanticipated dependence, unequal uptake, symbolic reinterpretation, ecological response, and strategic adaptation can reveal relations that were poorly represented in the initial model. GRE praxis should therefore preserve mechanisms for revision during and after intervention. Adaptive governance is valuable where it institutionalizes learning without turning affected populations into uncontrolled experiments. The practical requirement is not endless flexibility but explicit conditions under which evidence triggers continuation, modification, scaling, suspension, or termination.

Withdrawal, reversal, and repair form part of this constitutional praxis. Interventions can become harmful, obsolete, captured, or self-reinforcing in ways that diverge from their original aims. A programme concerned with generative effects must ask whether the conditions produced by an intervention can be undone and what restoration would actually mean after the system has changed. Repealing a rule may fail to recreate the earlier state because capabilities, expectations, infrastructures, relationships, and subject positions have already been transformed. Reversibility is therefore an empirical property, not an administrative assumption.

The transformative orientation of GRE remains normatively open in a specific sense. The programme can analyze which interventions expand participation, capability, resilience, plurality, or future possibility, but it does not derive a complete moral ordering from generativity alone. Normative appraisal can draw on justice theory, ethics, law, democratic processes, domain-specific standards, and the neighboring GREthic programme. Praxis is thus constituted by an obligation to connect explanation with action where useful, paired with an obligation to keep empirical mechanism and normative justification distinguishable.

3.22.5 Evidential Admissibility

GRE adopts evidential pluralism constrained by claim-specific standards. Evidence is admissible when it bears materially on the claim being made and when the path from observation or representation to inference is sufficiently explicit for criticism. The constitution therefore does not privilege one evidential form in advance. Administrative records, prices, transactions, experiments, quasi-experiments, surveys, interviews, ethnography, archives, legal materials, organizational documents, ecological measurements, network data, computational traces, comparative cases, formal implications, simulations, and intervention records can all contribute, but they warrant different kinds and strengths of claims.

Descriptive evidence can establish patterns without identifying mechanisms. Causal designs can estimate specified effects without exhausting interpretation or historical formation. Historical evidence can reconstruct sequence, contingency, and institutional development without producing a universal parameter estimate. Interpretive evidence can establish how categories, meanings, or obligations are understood by participants without by itself identifying every material consequence. Formal models can show what follows from specified assumptions without demonstrating that the target system satisfies those assumptions. Simulations can explore implications, sensitivity, and possible dynamics without becoming observations of the world merely through computational complexity. These distinctions are constitutional because GRE depends on combining modes without conflating their warrants.

Evidence for generative claims requires particular care. A downstream change occurring after an intervention is insufficient by itself to establish generation. Researchers should specify a mechanism, consider alternative pathways, examine temporal ordering, identify relevant mediators, and state the boundary over which the claim is intended to hold. Where direct identification is impossible, triangulation among historical, qualitative, quantitative, formal, or comparative evidence can strengthen the claim while preserving residual uncertainty. The programme accepts graded evidence; it does not require false certainty before relational mechanisms can be studied.

Counterfactual reasoning is often unavoidable. Claims about capability, foreclosure, resilience, opportunity, or future possibility concern alternatives that may never be fully observed. Evidence can include comparison across cases, natural experiments, historical alternatives, participant knowledge, structural models, simulation, sensitivity analysis, or explicit scenario construction. The relevant standard is transparency about which counterfactual is being invoked and why it is credible enough for the intended claim. Counterfactual richness should not be confused with evidential freedom.

Negative and disconfirming evidence also belongs within GRE. Failed interventions, absent downstream effects, unstable mechanisms, measurement failure, non-transportable cases, and situations in which a simpler established theory outperforms a GRE formulation should be retained as programme knowledge. Such evidence narrows the field's domain and improves theory comparison. A research programme that records only successful generative narratives would systematically

exaggerate its own explanatory scope.

Finally, evidence is historically situated. Data availability, categories, archives, measurement systems, institutional visibility, and computational capacity change over time. Some subjects leave extensive traces while others remain under-recorded; some value forms are priced while others are rendered administratively invisible. GRE therefore treats the evidential environment itself as potentially structured by power and institutions. Evidential admissibility includes attention to whose relations can be observed, which histories can be reconstructed, and which absences may reflect the organization of recording rather than the absence of the phenomenon.

3.22.6 Criteria of Contribution

A contribution to GRE is constituted by the structure of its research claim rather than by the presence of GRE terminology. At minimum, a recognizable contribution should specify the relational problem, the relevant scale and boundary, the generative or relational claim being advanced, and the evidence or representation that bears that claim. It should distinguish the modeled or represented relation from the target relation, calibrate its inference to the available warrant, and identify material alternative mechanisms where they are plausible.

A contribution may be conceptual. It can clarify a category, distinguish previously conflated mechanisms, develop a typology, or revise the programme's ontology under suspension. It may be empirical, identifying a generative relation or demonstrating a boundary condition. It may be historical, reconstructing how an economic subject, institution, value form, or generative condition emerged. It may be formal, providing a model that clarifies a mechanism or reveals implications. It may be computational, exploring dynamics inaccessible to analytic derivation. It may be normative, identifying evaluative conflicts or consequences that existing frameworks obscure. It may be practical, producing intervention evidence or governance procedures. No one form is constitutively superior.

GRE contribution also requires downstream discipline. A study need not trace every consequence of an intervention or relation, but it should explain why the chosen horizon is adequate to the research problem and acknowledge plausible effects excluded by that boundary. Where a claim concerns generativity, the analysis should identify what is being generated, for whom or for what system, through which mechanism, over what time horizon, and under what conditions. The term *generative* should carry analytical content rather than function as a general synonym for productive, innovative, or beneficial.

Normative transparency is another criterion. Researchers should distinguish descriptive claims, explanatory claims, forecasts, evaluations, and recommendations. If a contribution favors participation, capability, equality, resilience, pluralism, ecological integrity, autonomy, or another normative objective, the evaluative premise should be stated rather than embedded invisibly in the language of system improvement. GRE can support normatively engaged research while preserving the difference between evidence about consequences and judgment about their desirability.

Contribution further requires reproducibility or interpretive traceability appropriate to the method. Quantitative and computational work should expose data con-

struction, assumptions, code, parameters, and sensitivity where feasible. Historical and qualitative work should make source selection, interpretive steps, category construction, and evidential tensions sufficiently visible for another researcher to understand how the conclusion was reached. Formal work should state assumptions and domains of applicability. Traceability is the general constitutional requirement; exact replication is one method-specific realization.

The final criterion is cumulative relevance. A GRE contribution should leave the programme better able to inquire afterward. It may supply a reusable concept, map, dataset, mechanism, comparative case, formal model, indicator, intervention record, negative result, or theory revision. Cumulative relevance includes contraction. Demonstrating that a concept is too broad, a mechanism fails outside a narrow domain, an indicator systematically distorts value, or an intervention generates recurrent harm is a positive research contribution because it improves the programme's capacity to avoid error.

3.22.7 Open Constitutional Questions

The preliminary constitution deliberately leaves major questions open. The first concerns identification. Generative relations are often distributed, mediated, and historically formed, making it difficult to determine which relation produced which downstream capacity or constraint. Better causal designs, process tracing, comparison, formalization, and computational methods may improve identification, but some relations remain reflexive or multiply realized. The programme does not assume that every generative effect can eventually be assigned to a single source.

A second open question concerns measurement. Generativity can refer to capability formation, relation formation, value propagation, diversification of future possibilities, resilience, subject formation, institutional transformation, or changes in the effective rules of change. These may require different measures and may resist reduction to one scalar index. Measurement research should therefore explore domain-specific indicators, multidimensional representations, and comparative procedures without presuming a universal generativity metric.

A third concerns value. Economic relations can generate several forms of value simultaneously and can convert value across domains imperfectly. Monetary price, capability, symbolic recognition, ecological capacity, care, knowledge, institutional trust, public infrastructure, and future option value cannot be presumed fully commensurable. GRE requires practical ways to compare and govern heterogeneous values while preserving information about what is lost through commensuration. The relation between such comparisons and normative justification remains open.

A fourth concerns boundaries and scale. Relational systems rarely arrive with uniquely given analytical borders. Expanding a boundary can reveal hidden dependencies while making causal identification harder; narrowing it can improve tractability while externalizing relevant effects. Scale changes can also alter what counts as an entity, mechanism, or outcome. GRE therefore needs stronger procedures for boundary sensitivity, multiscale inference, and the comparison of explanations constructed at different resolutions.

A fifth concerns changing transformation rules. When institutions, technologies,

categories, expectations, or subject capacities evolve, the model adequate to an earlier period may cease to describe the later system. Some of this can be handled through time-varying or adaptive models; some may require changes in variables and model classes themselves. Distinguishing parameter change from structural change, and structural change from the emergence of new relevant categories, remains a central theoretical and empirical problem.

A sixth concerns justice and governance under persistent asymmetry. Economic relations often depend on differences in capability, information, authority, vulnerability, and exit. Equalization can be desirable in some dimensions while infeasible or counterproductive in others. Counter-power can reduce domination while creating new gatekeepers. Governance must therefore organize asymmetry while preserving participation, contestability, learning, and repair. The programme leaves open which institutional forms achieve those aims under different material and cultural conditions.

A seventh concerns heterogeneous subjects and artificial intelligence. Operational agency, legal personality, moral status, consciousness, accountability, and economic capability can diverge. AI systems can become economically consequential without resolving philosophical questions about machine subjecthood. GRE needs analytical conventions that allow such systems to be studied as participants or mediators where appropriate while preventing capability measures from silently determining ontological or normative status.

An eighth concerns long horizons. Generative effects can unfold across careers, institutions, ecosystems, and generations. Evidence weakens as horizons extend, while path dependence and rule change make extrapolation increasingly uncertain. Yet short-horizon evaluation can systematically favor interventions that consume the conditions of future possibility. Developing responsible long-horizon analysis without manufacturing spurious precision remains one of GRE's most important open problems.

These questions are constitutional because their unresolved status shapes how the programme should behave. Openness does not imply that anything is permitted. It means that GRE should preserve competing formulations, record uncertainty, compare methods, and allow evidence from later chapters and future research to revise the present constitution. A preliminary constitution identifies the space of legitimate disagreement as much as it identifies present commitments.

3.22.8 Historical Revisability of the Programme

GRE is constituted as a historically situated research programme. Its emergence is connected to changes described in Chapter 1: expanded relational production, globalization, digital mediation, artificial intelligence, ecological constraint, changing scarcity, capability asymmetry, new scientific and computational capacities, and altered conditions of evidence and governance. These conditions make certain relational and generative questions more visible and more tractable. They do not make GRE historically inevitable, universally necessary, or permanently adequate.

Historical situatedness has two implications. First, GRE concepts should be expected to change as the economy changes. Categories useful for contemporary

platform economies, AI-mediated production, or ecological transition may require revision under future institutional and technological arrangements. New forms of subjecthood, coordination, property, value, or infrastructure may emerge. Existing distinctions may lose relevance. A theory of historically changing economic reality should preserve the capacity to revise the categories through which it recognizes that reality.

Second, standards of inquiry can also evolve. New measurement technologies, archives, computational methods, legal institutions, participatory procedures, and epistemic practices can change what relations are observable and what interventions are ethically or practically possible. Methods and evaluative procedures therefore possess histories of their own. GRE should record those histories and remain capable of re-evaluating earlier findings when the epistemic resources available to later inquiry change. Revisability applies to methods and standards as well as to substantive theory.

Revision should nevertheless remain disciplined by programme memory. The replacement of one concept by another should preserve the reasons for the change; abandoned indicators, failed models, negative cases, and superseded mechanisms should remain accessible where possible. Otherwise a field can mistake forgetting for innovation. Cumulative knowledge requires both inheritance and correction. A historically revisable constitution therefore needs archives of its own revisions.

The present constitution can be revised through several routes. Empirical anomalies can show that a proposed relation does not operate as expected. Comparative work can reveal that a mechanism is culturally or institutionally specific. Formal work can expose inconsistency or hidden assumptions. Intervention can reveal unanticipated dependence or harm. Normative inquiry can show that an apparently desirable generative process rests on unjust relations. Historical analysis can demonstrate that a category treated as natural is institutionally recent. Domain applications can reveal objects that the existing typology cannot adequately represent. Each route provides a legitimate basis for constitutional amendment when the evidence is strong enough.

Revisability also protects GRE from disciplinary self-insulation. The programme should remain in dialogue with mainstream economics, political economy, economic sociology, complexity and evolutionary economics, capability approaches, ecological economics, legal and institutional analysis, philosophy, computer science, and other relevant fields. GRE has no constitutional entitlement to retain a concept merely because it originated within the programme. Where neighboring theories explain a problem better, GRE should borrow, narrow its own claim, or withdraw it. The integrity of the programme depends more on its capacity for correction than on the preservation of a proprietary vocabulary.

A preliminary constitution therefore combines continuity with amendability. GRE presently studies economic relations through their role in generating, distributing, transforming, and foreclosing later capacities and possibilities. It proceeds under ontological suspension, evidential pluralism, boundary and scale transparency, methodological pluralism, normative separability, and explicit attention to power, heterogeneity, historical dependence, and recursive change. It seeks explanations that identify mechanisms, praxis that remains revisable under feedback, contributions that

are traceable and cumulative, and a programme architecture capable of learning from failure as well as success. These commitments are strong enough to coordinate inquiry while remaining open to revision.

Chapter 3 thereby completes the preliminary constitution of Generative Relational Economics and closes Part I. Chapter 1 reconstructed the historical conditions under which the programme becomes intelligible; Chapter 2 reconstructed the intellectual lineages that make its conceptual vocabulary possible; Chapter 3 has stated the provisional research programme that follows from those conditions and inheritances. Part II now turns from constitution to deeper theoretical development. Chapter 4 examines the ontological view of Generative Relational Theory, beginning with the degree and form of ontological commitment that relational and generative inquiry requires. The constitution established here should therefore be treated neither as an endpoint nor as a summary detached from what follows. It is the provisional compact against which the later ontology, epistemology, methodology, formalization, political economy, governance, and applications of the book can be tested and revised.

Chapter 3

Constitution and Research Programme of Generative Relational Economics

Chapter 3 completes the foundational movement of Part I by turning historical emergence and intellectual possibility into disciplinary constitution. Chapter 1 examined the historical conditions under which an economic framework centered on relations, generation, changing capacities, and future conditions of possibility becomes increasingly relevant. Chapter 2 reconstructed the philosophical, economic, social-theoretical, normative, scientific, and formal lineages from which such a framework can draw without treating their differences as reducible to a single doctrine. The present chapter asks a different question: what kind of research programme follows when those historical problems and theoretical resources are organized specifically around economic inquiry? Its task is therefore constitutive. It specifies the provisional identity, objects, scales, questions, epistemic commitments, modes of inquiry, normative interfaces, and boundaries of Generative Relational Economics (GRE).

The term *constitution* is used here in a methodological and disciplinary sense. GRE is still an emerging research programme, and its conceptual vocabulary remains open to revision through empirical inquiry, formal development, comparison with established economics, and criticism from neighboring disciplines. A preliminary constitution therefore does not fix an immutable doctrine. It makes explicit the commitments that currently organize the programme, the questions that distinguish it, the conditions under which a contribution can reasonably be described as GRE, and the domains in which theoretical disagreement remains legitimate. Such specification is necessary for cumulative research. An open programme becomes difficult to evaluate when its objects, boundaries, and standards remain entirely implicit; a rigid programme loses the capacity to learn when provisional commitments are transformed prematurely into protected axioms. Chapter 3 develops an intermediate institutional form: sufficiently explicit to support research coordination and sufficiently revisable to permit theoretical evolution.

The chapter begins from a domain distinction already established at the end of Chapter 2. Generative Relational Theory (GR) supplies a broader orientation toward relations, recursive generation, historical transformation, changing conditions of pos-

sibility, and the possible transformation of effective rules of change. GRE develops that orientation within economics. Its primary concern is therefore economic life: production, allocation, circulation, reproduction, labor, care, ownership, credit, valuation, institutions, technological infrastructures, ecological dependencies, economic power, and the distribution of future capacities. The broader GR framework can interact with law, political theory, education, ecology, history, aesthetics, artificial intelligence, and other domains, while GRE remains responsible for showing why a particular problem is economically significant and how its claims relate to economic evidence and existing economic knowledge.

This disciplinary positioning gives the chapter two complementary functions. The first is selective. GRE requires boundaries because relation and generation are extremely broad concepts. A study does not become GRE merely because it describes a network, identifies an interaction, invokes emergence, or discusses long-run consequences. The programme is organized around more specific analytical questions: how economic relations constitute subjects and objects; how allocations are mediated through relational configurations; how present arrangements generate later capacities, constraints, values, dependencies, institutions, and possibilities; how those effects propagate across scales; how heterogeneous forms of value are converted, circulated, captured, dissipated, or returned; how economic power alters generative conditions; and how the conditions that govern future change can themselves be transformed. The second function is pluralistic. These questions can be investigated historically, interpretively, qualitatively, quantitatively, causally, formally, computationally, normatively, and through intervention-oriented inquiry. GRE does not require a single privileged method or mathematical representation.

The chapter consequently moves from disciplinary identity to problem structure and then from problem structure to research architecture. It first specifies the scope of the emerging programme and the economic problems that motivate it. It then develops a minimal primitive vocabulary for ontological emergence and identifies the heterogeneous objects and scales that GRE may investigate. Subsequent sections formulate characteristic GRE questions and clarify the distinctive analytical movement from allocation through relational mediation, generation, propagation, conversion, recirculation, extraction, and structural transformation. The chapter then addresses economic subjecthood, the orientation of generation, modes of inquiry, epistemic commitments, praxis, normative evaluation, power, heterogeneity, disciplinary boundaries, and criteria for research contribution. Its final movement treats GRE as a cumulative and internally plural programme, states major open problems, maps the architecture of the wider research agenda, and offers a preliminary constitution that can guide later chapters without foreclosing revision.

Several restraints govern this constitutional exercise. Ontological suspension remains the default: useful relational, dynamical, network, field, geometric, or computational representations do not by themselves establish the ultimate ontology of economic reality. Descriptive generativity remains distinct from normative desirability: a relation can generate durable capacities or self-reinforcing structures while also generating domination, ecological damage, exclusion, or vulnerability. Representation remains distinct from represented reality: measures, categories, graphs, models, and simulations are epistemic constructions whose adequacy depends on the local

question and evidence. Finally, disciplinary openness remains reciprocal. GRE can borrow from neighboring traditions, and those traditions can expose GRE's errors, omissions, and domain limits.

The result is intentionally preliminary. Chapter 3 provides enough constitution for the rest of the book to proceed with a stable research language, while leaving empirical, methodological, formal, and normative disagreements available for later development. The subsequent chapters can therefore deepen GRE's ontology, epistemology, methodology, praxis, substantive economics, theories of power and justice, epistemic economy, artificial intelligence, and domain applications without repeatedly renegotiating the programme's most basic disciplinary identity.

3.1 Disciplinary Identity of Generative Relational Economics

The role of this section is to establish the preliminary disciplinary identity of Generative Relational Economics (GRE) before the chapter specifies its problem-space, objects, methods, and standards of contribution. Its objective is to explain what kind of intellectual formation GRE currently is, the scope within which it makes economic claims, and the commitments that give coherence to otherwise heterogeneous research practices. The argument proceeds from the transition between theoretical proposal and research programme to the scope of the field, the priority of economics as its primary domain, the organizing commitments of relation and generativity, and the conditions under which the programme should remain open and revisable. The method is constitutive rather than taxonomic: the section proposes a working disciplinary identity capable of coordinating research without presenting that identity as historically settled.

GRE is best understood at this stage as an *emerging economic research programme*. The phrase marks both ambition and restraint. It indicates an effort to organize a cumulative body of questions, concepts, methods, models, empirical inquiries, and normative debates around a distinctive analytical orientation. It also recognizes that GRE has not acquired the institutional history, stabilized professional community, canonical methods, or settled boundaries associated with an established discipline or mature subfield. Its identity therefore rests primarily on a coherent problem-space and a set of research commitments rather than on institutional recognition.

This distinction matters because the vocabulary of GRE ranges across several domains. Relations are studied throughout sociology, economics, anthropology, network science, political theory, ecology, and philosophy. Generation appears in theories of production, reproduction, development, evolution, emergence, innovation, complexity, and social formation. Value is central to economics and also to ethics, aesthetics, ecology, and political theory. Fields, trajectories, networks, capabilities, institutions, subject positions, and historical transformations already possess rich literatures of their own. GRE gains disciplinary identity neither by collecting these vocabularies under a new label nor by claiming ownership over their objects. Its identity arises from the specific economic questions produced when relational constitution and downstream generation are treated together as sustained objects of inquiry.

A characteristic GRE inquiry therefore asks how an economic arrangement changes more than the variables administratively attached to its immediate recipient or transaction. An allocation of money, land, information, compute, credit, legal recognition, care, education, infrastructure, or technological capability enters an existing relational configuration. The allocation can alter capacities, dependencies, bargaining positions, recognition, expectations, institutional practices, ecological conditions, or access to later opportunities. These changes can propagate through further relations, be converted into other forms of value or constraint, become self-reinforcing, dissipate, or transform the conditions under which subsequent economic action occurs. GRE treats these downstream and relationally mediated effects as part of the economic object rather than as automatically external to it.

The programme remains compatible with narrower analyses when they are adequate to the question. A price model, accounting identity, causal estimate, institutional comparison, historical interpretation, network representation, ethnography, or simulation can each provide the most appropriate access to a local problem. GRE does not require every study to represent the full relational and generative field. Its disciplinary claim is instead that certain economically consequential phenomena become visible only when analysis can move between immediate allocation and the relations through which future capacities and constraints are produced. This claim defines a research orientation rather than a mandatory universal model.

3.1.1 From Theoretical Proposal to Research Programme

A theoretical proposal can be organized around a small number of concepts. A research programme requires a wider architecture. It must identify recurring problems, specify objects of inquiry, permit methods appropriate to different forms of evidence, distinguish stronger from weaker claims, accumulate comparative findings, expose itself to revision, and provide criteria through which researchers can disagree productively. GRE enters this second task in Chapter 3.

The transition is significant because relation and generativity can otherwise remain suggestive but underspecified. A relational statement may simply observe that economic actors are connected. A generative statement may merely report that one event has consequences for another. A research programme needs sharper questions. Which relations are constitutive of the economic situation? What entities and subject positions are stabilized through them? Which changes can reasonably be attributed to a relation or configuration rather than to coincident conditions? Through what mechanisms do effects propagate? Which forms of value are generated, converted, captured, returned, or destroyed? How do effects vary across scale and historical time? Under what conditions does a generative process reproduce itself? When does it alter its own conditions of continuation? What evidence would count against a proposed account?

These questions turn GRE from a vocabulary into a programme of inquiry. They also make possible disagreement internal to GRE. Researchers can disagree about whether a particular relation is constitutive or incidental, whether a claimed downstream effect is causal or interpretive, whether a state-space model preserves the relevant distinctions, whether a value conversion is commensurable, whether an in-

tervention strengthens capability or dependence, or whether a historical transformation changes only outcomes or changes the effective rules through which outcomes are produced. Such disagreements are productive when the disputed objects, assumptions, scales, and evidential standards are made explicit.

A research programme also requires cumulative structure. One study may identify a recurring relational mechanism; another may test whether it travels across institutional contexts; a third may formalize the mechanism; a fourth may show where the formalization fails; a fifth may examine its normative consequences; and an intervention study may alter the relation and observe how the surrounding system responds. The contribution of GRE lies partly in making these inquiries legible to one another. Historical interpretation, qualitative evidence, quantitative estimation, formal modeling, and normative analysis can then address different aspects of a shared problem without being forced into a single epistemic hierarchy.

The programme should therefore distinguish several levels of theoretical commitment. Some propositions will function as organizing hypotheses: for example, that present economic relations can generate future capacities and constraints that are not well represented by immediate allocation alone. Others will be domain-specific empirical claims: a particular credit architecture may generate dependence under specified institutional conditions. Still others will be methodological proposals, formal representations, normative arguments, or exploratory analogies. Treating these levels as equivalent would weaken the programme. GRE becomes more rigorous when the standing of each claim is stated locally and can change through evidence or criticism.

The term *research programme* also protects GRE from premature closure. The field can contain competing accounts of generativity, alternative formal representations, and disagreements about value while retaining a recognizable common problem-space. A programme is strengthened when rival formulations expose assumptions that one formulation had made invisible. Internal plurality therefore becomes part of disciplinary development rather than evidence that the field lacks identity.

GRE's transition from proposal to programme can consequently be summarized through four requirements. It needs a stable enough vocabulary to support communication, a sufficiently explicit problem-space to distinguish relevant contributions, methodological openness appropriate to heterogeneous evidence, and institutionalized revisability through which its own categories can change. Later sections of this chapter elaborate each requirement. The disciplinary identity established here supplies their common orientation.

3.1.2 Scope of the Emerging Field

The scope of GRE is defined by an intersection rather than by a single class of objects. The first component is economic: the inquiry concerns production, allocation, exchange, circulation, reproduction, labor, care, ownership, credit, institutions, technology, ecological dependence, valuation, power, or other processes that materially organize economic life. The second component is relational: the analytical object includes relations or configurations through which subjects, capacities, constraints, values, and opportunities are constituted or mediated. The third component is gen-

erative: the inquiry examines how those relations contribute to later states, possibilities, structures, or rules of change.
