Towards Generativity Epistemic Infrastructure: Standards, Protocols, and the Recording of Generative Trajectories

Wanhong HUANG

30 September 2026

Abstract

The proliferation of representations creates a practical difficulty for inquiry: a retained statement, an authentic source, an institutionally accepted classification, and a warranted account of reality can diverge. This paper develops an epistemic infrastructure response grounded in the Generative Relational research programme. The proposed object of standardization is the accountable recording, examination, presentation, contestation, and revision of generative trajectories, including their conditions, alternatives, contributions, and practical consequences. The argument distinguishes theoretical foundations, operational record roles, epistemic representation, evaluation, jurisprudence, governance, and technical implementation. It reconstructs a standards-development architecture and examines three experimental specifications for record graphs, coordinated transactions, and event-defined spacetime projections. A Git binding preserves accepted recording revisions, while explicit event relations define partial orders of represented occurrences. Predecessor-closed event selections determine the applicability of retained accounts and the resulting relational topology. The paper gives finite formal results for these constructions, analyzes failures involving conflicting chronology and uncertain scope, and follows a synthetic community inquiry through record creation, correction, and historical reconstruction. Source inspection, existing validation dossiers, and bounded re-executed software checks support engineering claims; institutional effectiveness and factual warrant require additional evidence. A comparison with established standards-development practices and provenance resources identifies potential interfaces without asserting equivalence or affiliation. The resulting contribution is an inspectable research and implementation architecture, accompanied by versioned documentary appendices, for developing standards that preserve the conditions of future recognition, reinterpretation, and practical continuation.

Keywords: generativity; epistemic infrastructure; Generative Relational theory; provenance; standards development; record graphs; event partial orders; contestation; Git; institutional governance.

Publication and Evidence Statement

This research working draft presents the programme as it stands in the source corpus frozen for 30 September 2026. The associated governance and standards-track documents remain preparatory working drafts. GR-SPEC-120, GR-SPEC-121, and GR-SPEC-130 are experimental Specifications. Publication of the present paper carries no adoption decision and gives no institution a mandate to represent another constituency.

The main text distinguishes source interpretation, implemented behavior, finite mathematical results, synthetic demonstrations, and prospective evaluation. Documentary appendices reproduce earlier material under its original status. Their inclusion makes the argument inspectable; it does not reconfirm every external reference appearing in the historical documents. External works newly cited in the research text were checked online before drafting and are recorded in `refs/VERIFICATION_LEDGER.tsv`. Local manuscripts have a separate source classification and retain unresolved edition chronology.

The article layout follows the supplied *Knowledge-Capital Expansion in Modernity* template. The original template's documented TeX Gyre Termes fallback is used for compilation. Its earlier article content and licence notice are not transferred to this manuscript. Newly authored programme material follows the repository's MIT licence and contributor attribution; retained source notices and third-party rights keep their respective scope.

OpenAI's Codex assisted source examination, online reference verification, drafting, formal-example construction, and compilation. The author supplied the programme, philosophical orientation, implementation history, and task instructions. This version is prepared for the author's substantive review. The assistance and successful build do not establish independent scholarly review or the author's approval of every formulation.

1 Symbolic Crisis and the Infrastructure of Inquiry

The organizing problem of generativity epistemic infrastructure is the relation between a represented situation and the practices through which that situation becomes recognizable, assessable, and actionable. The programme calls the contemporary instability of these relations a symbolic crisis. The term identifies a family of problems: abundant representations can coexist with weak access to their grounds; inherited categories can remain administratively effective after their descriptive adequacy changes; and apparently authoritative accounts can circulate more readily than the material needed to examine them. Chapter 1 of the supplied Generative Relational Economics manuscripts develops the related diagnosis of representational crisis in its treatment of symbolic abundance, classification, authenticity, and trust [8]. The present paper gives that diagnosis an operational interpretation.

The proposed response begins with a distinction among reality, manifestation, record, claim, assessment, and practical uptake. A social arrangement can exist before it acquires an official name. An observation can register only one aspect of that arrangement. A record can faithfully retain the observation while a later interpretation overstates its implications. An institution can then act on the interpretation. If the interpretation is corrected, the earlier action and its consequences can persist. Recording the final corrected statement alone would leave much of this trajectory unavailable for examination.

1.1 Generative trajectories as a recording object

A generative trajectory concerns changes in the conditions under which further distinctions, relations, capacities, and possibilities can develop. An output is one possible manifestation of that trajectory. A research project can produce a publication while also establishing a method, exhausting a community's willingness to cooperate, creating a reusable dataset, or closing an alternative line of inquiry. These effects can differ in timing, evidential support, and value for affected parties. A useful record therefore connects outputs with the processes and relations through which their significance is assessed.

The word generativity carries an explicit evaluative caution. Expanded capacity can support beneficial activity, coercion, or destructive action. Preserving a generative history supplies material for evaluation; it does not classify that history as good. The programme accordingly retains the perspective, boundary, horizon, and criteria of an evaluation. Competing assessments can remain separately identifiable when agreement is unavailable or when different constituencies ask different questions.

1.2 Research objective and contributions

The research objective is to determine a coherent boundary for standardization and to demonstrate selected technical mechanisms within that boundary. The paper contributes a multilayer architecture linking conceptual sources to recording requirements; a procedural account of standards development and publication authority; an experimental graph, transaction, and temporal protocol; a finite analysis of the semantics of event cuts and retained applicability; and a worked implementation account with explicit evidence limits. The documentary appendices preserve the sources from which the account can be reconstructed.

The central design commitment is warranted revisability. A record should support later examination of the grounds of a claim, the relations it describes, the alternatives retained or excluded, and the consequences of its use. This commitment does not imply exhaustive capture. Collection has costs, and some material requires restriction or disposal. The proposed infrastructure makes the boundary of a record and the consequences of that boundary examinable.

1.3 Scope of the present intervention

The implemented protocol is narrower than the programme's institutional ambitions. It supports private project workspaces, attributed records, independently identified Relations, attached material, atomic revisions, historical inspection, and event-defined topology. It does not supply a tribunal, an independently

DRAFT

authenticated evidence service, a general theory of causal discovery, or a complete privacy regime. The standards-track drafts address broader obligations whose implementation can involve people, organizational procedures, and domain-specific judgment.

The two levels are evaluated separately. A successful software transaction can preserve an account without establishing its truth. A clear proposed review procedure can be drafted before a competent institution is available to operate it. The paper treats each as a contribution with a specified subject and an appropriate evidential burden. Sections 2–5 establish the interpretive and architectural basis; Sections 6–10 develop procedure and representation; and Sections 11–17 address use, implementation, evaluation, and institutional development.

2 Source Corpus and Research Method

The method combines interpretive reconstruction, specification analysis, finite formal reasoning, source inspection, and bounded software verification. Each method answers a different question. Manuscript interpretation establishes the conceptual distinctions the programme seeks to preserve. Specification analysis examines the commitments made by a representation or operation. Formal reasoning identifies consequences under stated assumptions. Executed checks examine selected implementation behavior. None of these methods alone measures public trust, institutional legitimacy, or the effectiveness of an educational or policy intervention.

2.1 Corpus boundaries and version control

The foundation corpus contains seven supplied PDFs: GRE Chapters 1, 4, and 5; two separately retained Chapter 3 files; and the two metamodel papers. The programme manifest assigns stable FM identifiers to these copies. The two Chapter 3 files have related but differing content. The unqualified filename contains a dedicated discussion of access to generative capacities and conditions, while the file marked complete first draft retains an earlier organization of the problem families [9, 10]. The filename alone supplies no verified supersession decision. The paper cites the particular source relevant to each argument and preserves both in the documentary corpus.

The operational corpus comprises the Programme Brief, publication taxonomy, governance drafts, standards-track drafts, experimental Specifications, architecture decisions, planning records, examples, and validation dossiers. The nine-document version 0.3 package contains 754 requirement identifiers. Its preceding version 0.2 supplied the fixed 753-identifier baseline for the recorded review cycle. The two totals refer to different editions and different tasks. A review inventory is also distinct from the number of fields a user must complete in an ordinary record.

The software corpus includes the common Python record protocol and Git store, the generalized web application, and the independently retained academia application. The learning handoff belongs to a separate companion inquiry. Shared motivation does not establish shared serialization or completed interoperability among these systems. The paper identifies interfaces requiring additional work rather than describing source proximity as protocol compatibility.

2.2 Interpretive trace and operational selection

An operational proposal is traced through five stages: the source passage, the distinction at stake, the recording need, the candidate implementation, and the evidence capable of discriminating success from failure. For example, the distinction between a relation and evidence of that relation leads to separately attributed claims and material roles. It does not determine whether a software implementation should use a table, a nested object, or an independently identified assertion. Those choices require an architectural argument and a testable use case.

The existing foundation traceability map performs this translation for motivation, epistemic warrant, revision, praxis, identity, temporal history, and loss. The current paper reconstructs that work while

DRAFT

Table 1: Evidence classes and their interpretive boundaries.

Evidence class	Supports	Additional evidence required
Foundation interpretation	A documented conceptual distinction	Historical precedence, exhaustive theory, empirical generalization
Draft requirement	A proposed obligation and assessment subject	Adoption and operational capacity
Experimental Specification	A precise implementable contract	Independent implementation and broader conformance
Finite construction	A conditional mathematical result	Adequacy of the selected social interpretation
Automated check	Behavior in the executed cases	Untested inputs, security, usability, and institutional effectiveness
Synthetic demonstration	Expressibility and an inspectable workflow	Real-world accuracy and practical outcomes

preserving its provisional status. The six record roles and the event-cut model are operational selections. Their usefulness can be assessed even while the programme retains ontological suspension concerning ultimate constituents of reality.

2.3 Evidence classes and reporting rules

Table 1 summarizes the evidence classes used throughout the paper. A claim about execution names the tested artifact and scope. A claim about a synthetic example concerns the stipulated example. A proposed institutional arrangement is evaluated as a proposal until there is evidence of actual participation, authority, and performance.

External literature was selected for specific interfaces: standards-development procedure, provenance, canonical serialization, event ordering, accessibility, and open-science policy. Bibliographic records and claim support were checked before their insertion into the research text. The review is targeted, rather than systematic or exhaustive. The verification ledger records access limits, including cases where only an authoritative bibliographic record was available. Historical references inside the reproduced programme documents are retained as historical text; their reproduction is a different act from newly endorsing them.

2.4 Reproducibility and interpretive accountability

The paper includes editable section sources, an explicit build process, frozen figures, source hashes, executed-check output, and a documentary inventory. Appendix A explains the appendix volumes and their scope. Appendix D gives reproduction commands and the distinction between a source archive and a running-service backup. These materials enable readers to challenge the account at a concrete point: a mistaken source interpretation, an overbroad requirement, a failing operation, or an unsupported practical inference.

3 Generative Relational Foundations and Operational Translation

The foundational task is to preserve conceptual distinctions while selecting representations suitable for recording. The supplied manuscripts approach change, structure, constraint, and difference as a minimal analytical vocabulary. They also examine richer categories used to describe social facts. These levels have different purposes. A mathematical carrier and an action on that carrier support conditional reasoning; a retained Event account carries attribution, a target description, epistemic qualifications, and a historical place within an inquiry.

DRAFT

3.1 Ontological suspension and mediated manifestation

GRE Chapter 4 distinguishes ontological, relational, and manifestational registers [11]. The registers organize questions concerning reality and access to it. They do not prescribe mutually exclusive bins into which a database can place objects. An administrative form, for example, can be a material object, a manifestation of an institutional practice, and an intervention that changes future relations. The representation chosen for one inquiry need not exhaust these roles.

This architecture places epistemic mediation within the field of inquiry. Observers encounter traces under material, methodological, and institutional conditions. A surviving trace can be informative partly because of its production path, and misleading when the conditions of its production are misunderstood. The same visible absence can result from non-occurrence, failure to observe, prohibited reporting, selective retention, or destruction. These possibilities motivate explicit coverage and missingness descriptions.

GRE Chapter 5 expresses reconstruction through an admissible compatibility set conditioned on manifestations, evidence, circumstances, and auxiliary assumptions [12]. The construction leaves the relevant kind of compatibility open. The present protocol does not implement a universal solver for that set. It seeks to preserve enough of the grounds and alternatives for an assessor to reconstruct a domain-appropriate argument.

3.2 Metamodel structure and enriched social descriptions

Part I of the metamodel uses a carrier, a mechanism semigroup, an action, and a congruence to analyze changes in retained distinctions [13]. A fixed carrier and fixed equivalence provide a bounded mathematical setting. They do not account by themselves for unanticipated new distinctions or new kinds of state. The interpretation of a collapse also requires care: a mathematical loss of distinguishability does not automatically establish social harm.

Part II develops Entity, Relation, Event, Attribute, State, and Process as selected analytical categories [14]. Its explicit scope allows overlap and leaves exhaustiveness open. An entity criterion concerns reidentification across appearances. Relation incidence identifies participants in contextual roles. An event requires an occurrence criterion, rather than merely a difference between endpoints. A state description has a declared sufficiency question, and a process preserves a history whose intermediate structure can matter even when final effects coincide.

The programme's operational role named Property remains terminologically distinct from the metamodel's Attribute until a scoped equivalence is justified. The present paper preserves that unresolved interface. It also avoids identifying a mechanism with a Process record or a formal state with a semantically articulated State account. A future formal semantics can map selected structures across these levels, but the mapping needs explicit assumptions and counterexamples.

3.3 Generativity, orientation, and practical continuation

The programme's generativity concern extends to the direction of inquiry and action. Conditions can make some questions salient, some collaborations possible, and some continuations difficult to sustain. Chapter 3 treats orientation through attention, curiosity, selection, institutions, and heterogeneous values [9]. A record concerned only with completed outputs can obscure these changes.

An operational account can preserve an enabling encounter, a condition that was maintained, a rejected alternative, a claimed contribution, and an unrealized possibility. Such records remain qualified accounts. A possibility described retrospectively may differ from an option actors could identify at the time. A contribution claim needs grounds connecting a relation to an effect within a declared horizon. A process that opened opportunities for one group may have constrained another. These distinctions guide record content and assessment without requiring a scalar generativity score.

Praxis adds consequences to the archive. Diagnosis, intervention, monitoring, revision, withdrawal, and repair can form iterative practical activity. The manuscripts leave room for different sequences and

DRAFT

methods. Accordingly, the infrastructure supports links among these activities while preserving the authority and evidence associated with each. A recorded intention to repair a loss remains distinguishable from completed repair.

3.4 Translation obligations

Four obligations follow for the standards programme. First, a standardized record needs a declared purpose and boundary. Second, the information that makes an identity, relation, or temporal claim interpretable must remain associated with it. Third, a display needs to disclose the mediation introduced by selection, aggregation, and layout. Fourth, revision needs to preserve the difference between a change in the represented situation, a change in evidence or judgment, and a change in descriptive categories.

These are operational consequences argued from the sources. They remain open to revision where a domain case reveals excessive burden, missing distinctions, or a misleading interface. Their justification is stronger when a counterexample shows exactly what fails without them. A late-recorded early event, a corrected classification with continuing effects, and a relation with more than two participants supply such counterexamples in the later sections.

4 Interfaces with Standards Development and Provenance Resources

The external comparison identifies resources whose scope intersects the programme and specifies the boundary of each connection. The analysis concerns procedural and representational interfaces. It does not establish that the programme reproduces an existing standards body's authority or that its experimental schema implements a certified mapping.

4.1 Procedural models and publication authority

ISO identifies its Directives Part 1 with technical-work procedures and Part 2 with the structure and drafting of documents [16]. This separation offers a useful design principle: the process that authorizes a publication and the rules that make its clauses intelligible require distinct treatment. The programme adapts that separation through its own Charter and two Directives. Detailed numerical rules in the programme are project proposals, rather than assertions about current ISO voting rules.

IEEE describes a six-stage development lifecycle with organizational oversight [15]. The relevant lesson for the present proposal is that drafting, balloting, approval, and maintenance are distinguishable activities. A technically detailed document can remain a draft while participation and review capacity are being established. The programme therefore records publication status independently of implementation maturity.

UN-system instruments have differing functions. ITU-T Recommendations address technical operation and interworking [17]. UNESCO's Recommendation on Open Science addresses policy, infrastructure, participation, and monitoring [23]. The programme can learn from both while distinguishing a technical contract from a recommendatory institutional proposal. There is no single UN format whose visual reproduction supplies institutional standing.

4.2 Provenance and attributed generation

PROV-DM supplies an extensible model of entities, activities, agents, derivation, responsibility, and related provenance structures [21]. PROV-O expresses the model through an ontology suitable for RDF use [20]. These resources are relevant to the production and transformation of records. A prospective export might identify a retained record revision as an entity, a recording operation as an activity, and an accountable recording role as an agent. That mapping would concern the recording process. A represented social event would require a separate mapping decision.

The programme adds questions that a provenance link alone leaves open: the claim for which material is relevant, the grounds of its evidential role, competing interpretations, the practical uptake of a

DRAFT

classification, and the consequences of correction. These questions are compatible with provenance modeling but require additional vocabulary and assessment. A future mapping needs round-trip fixtures for qualification, scope, identity, and lost information. Until such fixtures and independent implementations exist, the relation remains a proposed interface.

4.3 Canonical serialization and conditional publication

RFC 8785 defines a canonical JSON representation under specified constraints [22]. The experimental transaction binding uses that representation when computing a digest of the logical request and verified file metadata. The digest helps distinguish an identical retry from conflicting reuse of a transaction identifier. It supplies neither a signature nor an evidential verdict.

JSON Schema Draft 2020-12 provides the structural vocabulary used by the distributed schema [18]. Cross-record references, resulting-snapshot conditions, and supported module behavior also require semantic checks. Git's conditional reference update supports the publication step of the binding: an accepted branch is advanced only if its previous object identifier matches the expected value [7]. These mechanisms have a concrete engineering role while leaving authorization, institutional responsibility, and retention policy to other layers.

4.4 Event ordering and temporal interpretation

Lamport's account of distributed-system events distinguishes a partial order from total orders constructed for coordination [19]. The comparison is useful for the present design because a display sequence can add order that the source does not establish. The programme's event relations have a different evidential origin: users retain attributed assertions concerning represented occurrences. A communication-based happened-before relation is therefore not imported as a definition of social chronology.

The experimental model uses explicit precedence and predecessor-closed event selections. It does not interpret incomparable events as simultaneous, infer physical duration from graph rank, or execute event transformations to calculate social outcomes. These limits define a tractable topology projection and leave richer interval, causal, and scenario semantics for subsequent work.

4.5 Assessment of the comparison

The comparison locates reusable mechanisms and separates them from the programme's distinctive integration problem. The contribution is the coordinated treatment of epistemic grounds, generative trajectories, revision history, practical response, and publication governance in one inspectable programme. Establishing priority over the wider literature would require a broader review. The present claim is that this particular architecture and its experimental realization can be examined, reproduced, and criticized through the supplied artifacts.

5 Multilayer Architecture and Publication Portfolio

The architectural task is to assign each claim and responsibility to a level at which it can be meaningfully examined. The programme distinguishes theoretical foundations, an operational record ontology, epistemic representation, normative evaluation, jurisprudential status, institutional governance, political economy, and technical realization. The layers interact. Their distinction prevents a result at one layer from silently acquiring authority at another.

5.1 Layer responsibilities

A record that an event occurred concerns a target-level representation. An observer's report of that occurrence introduces source attribution and a method of access. An assessment that the event was unjust

DRAFT

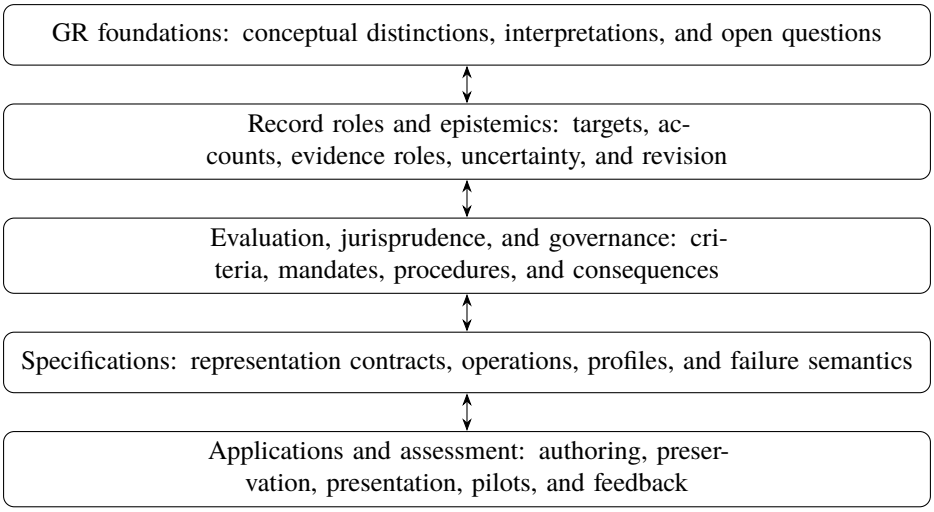

Figure 1: Interacting responsibilities in the programme. Arrows denote design feedback and interpretation, not logical entailment or delegated legal authority. Political-economic questions concerning access, ownership, cost, and participation apply across the arrangement.

applies an evaluative criterion. A claim that a legal duty was violated introduces a jurisdiction, authority, and procedural setting. A retention decision adds institutional responsibility. A JSON serialization supplies an implementation form. Each can be linked to the others while preserving its own grounds.

Figure 1 presents the architecture as connected responsibilities. The vertical arrangement is explanatory, rather than a hierarchy in which a technical layer proves an upper layer. Normative evaluation can question the purposes of collection, while implementation constraints can reveal that a proposed procedure is too costly or discloses more than its purpose warrants.

5.2 Standards-track projects and supporting Specifications

The portfolio begins with GR-100 vocabulary and GR-110 recording requirements. GR-200 concerns epistemic recording, while GR-210 concerns evidence, interpretation, contestation, and disposition. The technical and organizational complement includes information-model requirements, interchange, presentation, conformance, preservation, jurisprudential interfaces, procedural profiles, and institutional use. Some projects have substantive drafts; others remain work items or preliminary scope statements. Their identifiers preserve planning continuity without asserting equal maturity.

GR-SPEC-120 supplies the experimental record graph and module representation. GR-SPEC-130 specifies coordinated transactions and a Git binding. GR-SPEC-121 adds event precedence, temporal extent, and a declared spacetime projection. Their ordering in the portfolio reflects dependencies, rather than a claim that every underlying standard is already adopted. The development pattern begins with a normative problem, identifies a reusable infrastructure need, develops a Specification, tests it in a bounded pilot, and returns findings to the standards-track draft.

5.3 Publication classes and conformance subjects

A Standard is an edition adopted through the programme's operative procedure. A Specification can contain precise requirements while retaining experimental status. A Technical Report develops analysis that may remain exploratory. A manual guides practice. A policy proposal recommends institutional arrangements. A research paper argues for and examines the programme; it supplies no additional conformance authority merely by collecting the documents.

The subject of conformance also needs a declared boundary. A document package can retain the information required for an assessment. A recording practice can be assessed over an actual interval

DRAFT

of activity. A review procedure can be assessed through the handling of cases. A software component can satisfy a specified operation contract. These subjects can be related without being substituted for one another. A parser cannot demonstrate that an affected person obtained meaningful review, and a completed review cannot establish that an export preserves every field.

5.4 Profiles and proportionality

Profiles are a candidate means of relating broad requirements to particular tasks. A research-notebook profile, a community inquiry profile, and an institutional review profile can share identity and revision mechanisms while differing in information sensitivity, evidential expectations, and participant roles. A useful profile identifies inherited obligations, conditional triggers, permitted simplifications, additional requirements, and the exact claim that an assessment supports.

Proportionality concerns retained distinctions as well as volume. A short attributed narrative can sometimes preserve uncertainty better than an extensive form with mandatory confidence scores. Conversely, a consequential institutional determination may require detailed grounds and a review route. The proposed test of adequacy is whether a record supports its declared questions while exposing material omissions, at a burden that participants and custodians can sustain. Selecting those questions remains a substantive institutional and ethical decision.

6 Governance of Standards Development

The governance layer specifies the conditions under which a draft can acquire programme authority. Its purpose is to make the development process itself inspectable: participation, objections, revisions, delegated powers, resource limits, and publication decisions become part of a retained trajectory. The current Charter and Directives are preparatory proposals. Their detailed form does not supply the actual authority or independent review capacity required for adoption [1].

6.1 Founding authority and representation

The proposed founding instrument identifies actual signatories, the resources and decisions over which they have authority, the exact governance editions accepted, their commitments, appointments, and effective conditions. It distinguishes control of a repository from a mandate to represent a profession, country, or community. This distinction matters because an infrastructure can become influential before its governance is broadly representative.

The Charter reserves consequential decisions such as governance amendment, committee mandates, formal work-item initiation, and Standard adoption. Operational duties can be delegated under an explicit scope. A delegation records who can perform an action, under which limits, with what reporting and succession arrangements. Merely naming a committee or assigning an acronym does not demonstrate that competent participants have accepted the responsibility.

6.2 Participation, consensus, and review

Participation needs an intelligible route into the process, accessible material, proportionate preparation costs, and a means of raising relevant objections. The programme's drafts distinguish consideration of concerns from numerical ballot success. A ballot can provide evidence for a decision while leaving substantive objections unresolved. Silence can arise from agreement, exclusion, lack of time, or inability to obtain the source material.

The proposed public-review record links each comment to its disposition, reason, affected text, and reply opportunity. Material changes receive further consideration under the applicable procedure. A neutral procedural reviewer needs actual separation from the contested decision and capacity to perform the task. If the function is unavailable, the limitation affects what the programme can claim about the review. Research and preparatory drafting can continue within their own authority.

DRAFT

This structure is particularly important for a programme concerned with recognition. A process that records objections but systematically prevents them from affecting decisions would produce an impressive archive with weak practical accountability. Future assessment therefore needs evidence of consideration, response, and the consequences of accepted criticism. Comment counts and meeting attendance are insufficient proxies.

6.3 Work-item progression and maintenance

The proposed lifecycle distinguishes preliminary work, proposal, working draft, committee draft, public review, final approval, published Standard, and later review or withdrawal. Each progression has an accountable decision and a defined evidence requirement. A new work-item proposal states the problem, scope, affected interests, relation to existing work, anticipated deliverables, and capacity required. The publication class is selected according to the work's function and maturity.

Maintenance preserves the history of changed requirements. Editorial correction, substantive revision, interpretation, confirmation, and withdrawal have differing effects on users. A conforming implementation can depend on a dated edition; a later edition should not silently change the meaning of its earlier assessment. Withdrawal similarly changes the current status of a publication while leaving its historical use intelligible.

6.4 Ethics, contribution rights, and conflicts

The draft ethics and intellectual-property policy addresses contribution provenance, rights to circulate material, conflicts of interest, confidentiality, and protection of participants. Disclosure of a conflict supplies information for management; it does not by itself supply independent handling. A funding agreement can support infrastructure while also shaping priorities. The governance record therefore needs to expose relevant dependencies and the authority to change or terminate them.

Repository licensing and standards governance have separate functions. The project owner's MIT grant permits reuse of project-authored material within its stated scope. It does not adopt the Charter, authorize use of an external organization's name, or clear third-party material. An implementer can reuse the code while still needing to identify the profile and evidence supporting a particular conformance claim.

6.5 Governance as an object of pilot inquiry

The existing synthetic governance rehearsal exercises ballot arithmetic and procedural cases. Its 18 executed arithmetic cases are useful for checking a bounded rule calculation. They do not demonstrate that a real committee can recruit balanced participation or sustain neutral appeals. A future rehearsal should follow an actual proposal from notice through disposition, including a material objection and a revision, while measuring preparation effort, delays, accessibility, and unresolved interests.

The programme's own history is an appropriate first source for such examination. Changes from the initial outlines to detailed drafts, validation-driven corrections, and implementation-induced questions can be retained with their alternatives and reasons. This reflexive use avoids presenting governance as an external checklist imposed after technical development. It also exposes a difficult possibility: the proposed process may need simplification or additional resources before it can function as intended.

7 Record Graphs, Identity, and Modules

The experimental information model represents a project as a versioned collection of retained accounts. Its design goal is to permit inspectable relations among records while separating represented-target identity, record identity, recording ancestry, and layout. GR-SPEC-120 supplies the contract examined in this section [3].

DRAFT

Table 2: Operational role emphases and discriminating boundary cases.

Role	Recording emphasis	Boundary requiring qualification
Entity	A subject identified across relevant appearances	Same label with disputed continuity
State	An account of conditions under a declared scope	Current accuracy with insufficient history for a later query
Event	An identified occurrence or qualified occurrence claim	Repeated acts with the same endpoint
Process	A temporally articulated course of activity	Similar output reached through different histories
Relation	Participants and contextual roles in a retained account	Partial, higher-order, or contested participation
Property	An attributed characteristic with interpretation	Unknown, inapplicable, or differently scaled values

7.1 Record roles and account qualification

A record has a stable identifier, title, content, primary presentation role, a nonempty set of applied roles, epistemic mode, modality, disposition, modules, and recording attribution. The six roles are Entity, State, Event, Process, Relation, and Property. Role sets can overlap. Their implementation does not turn the roles into an exhaustive metaphysical partition.

The qualification fields answer separate questions. An account can be reported rather than directly observed, concern an intended rather than realized activity, and be contested rather than unreviewed. These combinations are meaningful. An inferred possibility is not necessarily a failed observation, and a contested report is not automatically false. Descriptive grounds provide further method, source attribution, uncertainty, alternatives, conditions, and consequences. Empty text records an omission from that field, rather than substantive absence.

Table 2 gives the operational emphasis of each role and a boundary case. The table summarizes the programme; detailed admissibility and sufficiency remain subjects of the associated drafts.

7.2 Record identity and continuity judgments

A UUID identifies the retained representation within the profile's reference boundary. It does not prove that two appearances concern one continuing social entity. Continuity can depend on a legal rule, organizational practice, historical reconstruction, or a chosen analytical criterion. A merger, split, renamed institution, and unchanged name after replacement supply distinct cases. The record can preserve a continuity claim and its basis while keeping alternatives inspectable.

The initial reference boundary is one project snapshot. A reference resolves to a retained record in that snapshot. This restriction simplifies historical consistency and authorization. It also limits cross-project scholarship and federation. A future external-reference profile would need source version, availability, access, collision, and identity rules; copying a UUID alone would leave those questions unresolved.

7.3 Relations as independently identified accounts

A structured Relation is an ordinary record carrying a supported relation module. Each participant incidence has its own identifier, referenced record, descriptive role, scope, and orientation. The same participant can occupy multiple incidences, and a Relation can itself participate in another Relation. This incidence representation retains information that an unqualified binary edge could obscure.

For example, an arrangement can involve a residents' group, a stewardship team, and a garden, with different roles for permission, responsibility, and subject matter. A later account can qualify that arrangement or describe dependence on another relation. The relation's participant-completeness flag and

DRAFT

limitation text are material: a visible three-node display can otherwise suggest that the account is complete when a participant is unknown or withheld.

The scope distinguishes reference to a record from reference to its represented target. A relation that challenges a description concerns the retained account. A relation describing cooperation concerns represented participants under the account's identification assumptions. Orientation specifies incidence direction for the projection; it does not assign causality. Neutral related-record links remain separate from typed structured relations.

7.4 Versioned modules and conservative extension

A module is a namespaced, versioned component with a required-support declaration. Supported modules include notes, files, relations, event order, and temporal extent. Unknown optional content is retained as opaque data. Unknown required content can prevent a mutation when its constraints cannot be evaluated. This distinction allows extension while avoiding a claim that an implementation has checked semantics it cannot interpret.

Modules are declarative. Their contents do not install executable code or provide arbitrary server paths. The profile bounds module size, record count, operations, file count, and binary size. These are implementation capacity decisions, not properties of GR theory. Increasing them requires new capacity evidence and does not change the conceptual role of a record.

7.5 Material descriptors and graph projections

A file descriptor identifies an acquisition or attachment account separately from its bytes. SHA-256 identifies the retained content; descriptor identity, name, custody attribution, and time supply additional context. Several descriptors can point to identical bytes without supplying independent corroboration. Replacement retains the descriptor while changing its content reference in a new revision. Detachment changes the current link and leaves historical retention subject to the storage binding.

The canonical incidence projection exposes retained records as selectable nodes and participant incidences as edges with their role, scope, orientation, and owning Relation. A historical projection is computed from one source revision. Current titles or modules cannot silently substitute for earlier content. Filtering and layout are additional transformations whose boundaries need disclosure. The graph can therefore support navigation and examination while leaving substantive truth and evidential weight to declared assessments.

8 Claims, Evidence Roles, and Revisable Judgment

The epistemic architecture addresses the grounds on which a retained representation can be used. GR-200 develops the information needed to examine claims, while GR-210 concerns practices of assessment and contestation. The experimental record envelope implements only a bounded part of this wider architecture. A field labeled evidence is a starting affordance; richer material, evidence-role, assessment, and dependency structures remain implementation work.

8.1 Claim boundaries and attributed content

An epistemic package declares its purpose, included claims, collection boundary, responsible role, descriptive regime, and access scope. A source stored in the package does not automatically make every sentence in that source an endorsed claim. The package distinguishes retaining a document, asserting that the document contains a statement, and adopting the statement as a substantive account. This prevents citation and storage from becoming unnoticed mechanisms of endorsement.

A claim reference identifies a formulation and version. It can be local to a narrative dossier and need not be a globally registered software object. Shared method or acquisition context can be referenced by several claims where its applicability is explicit. Exceptions remain associated with the affected claim.

DRAFT

This approach supports proportionate recording without hiding material differences behind a package-wide declaration.

8.2 Evidence as a relation to a claim

A material item can support, challenge, qualify, or fail to discriminate among claims. Its role depends on the inferential target and the conditions of production and preservation. A meeting attendance sheet may support a claim that names were entered. It may provide weaker grounds for counting distinct people who actually participated. Duplicate entries, partial attendance, and retrospective completion can change its use.

An evidence-role assignment therefore identifies the material, claim version, assessor, relevance, limitations, and alternatives. Authenticity and custody can strengthen confidence in what was retained while leaving the substantive inference open. Several documents copied from one source do not become independent evidence because they have different filenames. A generated summary may preserve a useful interpretation while requiring a separate check of its dependence on the underlying material.

8.3 Uncertainty and missingness

Uncertainty can concern target identity, occurrence, measurement, ordering, attribution, scope, or the implications of an intervention. A single numerical confidence field can obscure these differences. Where a quantity is used, the record needs to identify what it measures and the assumptions supporting comparison. The architecture also allows qualitative qualifications when a probability would imply unsupported precision.

Missingness needs an account of the observation and preservation process. Unknown, not collected, withheld, lost, and inapplicable have different consequences. Negative evidence is especially sensitive to that process: absence of a complaint has different force when reporting was accessible, dangerous, or unrecorded. A package can retain a bounded negative-evidence argument, but an empty field supplies no such argument by itself.

8.4 Three dimensions of revision

The programme distinguishes changes in the target situation, changes in evidence or interpretation, and changes in the categories or methods used to describe the situation. The dimensions can coexist in one revision. A new observation can reveal a prior error while an intervention changes the target and a new classification changes the terms of assessment.

Keeping these dimensions visible supports two historical questions: what could reasonably be known at a prior stage, and what can now be said about that stage. The questions can have different answers. A later discovery need not establish that earlier actors ignored available evidence. Conversely, a correction does not erase the practical effects of an earlier classification. The record links revisions to prior formulations, grounds, affected dependencies, and consequential uses.

8.5 Contestation and practical uptake

Contestation requires more than a status flag. An affected actor needs an intelligible route to identify the challenged claim, submit relevant grounds, receive a response, and understand the disposition within the available procedure. The route can involve protected evidence and independent review rather than unrestricted publication. Recording restrictions needs to expose their effect on inspectability without disclosing the protected content.

Practical uptake deserves its own record. A classification can affect access, allocation, participation, or a future opportunity. A corrected description can therefore require a changed decision, notice to downstream users, or a separate remedy. The present architecture keeps the assertion, assessment, decision,

DRAFT

execution, and verification of an action distinguishable. Their connection is essential to an infrastructure concerned with praxis as well as archives.

8.6 Generative attribution

A claim that an encounter or relation generated a later capacity needs a target effect, boundary, horizon, proposed contribution, and examination of alternatives. Temporal precedence is one possible component of that inquiry. It does not determine the contribution by itself. Likewise, a recorded unrealized alternative can help reconstruct selection without proving that the alternative was feasible.

The proposed standardization task is to preserve the information required to examine such attributions under appropriate methods. Historical, qualitative, experimental, computational, and formal inquiry can contribute different evidence. The infrastructure supports traceable disagreement about their interpretation. It does not make one method universally adequate for every generative claim.

9 Coordinated Transactions and the Git Recording Binding

The transaction layer preserves coordinated changes to records, modules, and material under a declared base revision. Its purpose is to prevent a graph or attachment account from becoming partly accepted when one of its dependent changes fails. GR-SPEC-130 defines the experimental contract, including publication, receipt recovery, historical reads, and export boundaries [5].

9.1 Transaction subject and validation sequence

A logical request contains a protocol identifier, transaction UUID, expected head, reason, change categories, and operations. The operation set covers record creation and update, module changes, attachment operations, and explicit legacy migration. The authenticated application supplies recording identity and time separately from source attribution entered in the account.

Validation examines the complete proposed result. Two records created in the same transaction can refer to each other if the final candidate is valid. Sequentially publishing each operation would create an unnecessary intermediate dangling reference and could leave a partial result. Conversely, repeated mutations of one guarded resource can be ambiguous. The profile rejects those cases rather than assigning implicit last-write-wins meaning to operation order.

The pure protocol package prepares a candidate and receipt without accessing a database, Git repository, or web framework. The application checks authorization and actual uploaded bytes. The Git adapter verifies storage closure, bounds resource use, constructs objects, and conditionally publishes one accepted revision. This separation exposes which component is responsible when a check fails.

9.2 Material closure and byte identity

An attachment request declares a part name, descriptor identity, owning record, filename, media type, length, and digest. The supplied part inventory must match the declared operations. Actual byte length and SHA-256 are checked before publication. The bytes written to storage are the same bounded bytes that were checked; validating a pathname and later rereading changed content would break this guarantee.

Each understood file descriptor in the candidate has a corresponding retained asset of the declared identity and size. The adapter refuses undeclared incoming material and incomplete understood closure. Filenames remain descriptive metadata, and media types do not authorize execution. Unsupported modules can limit what the implementation knows about dependencies; an export consequently cannot claim complete recovery of material whose module semantics remain opaque.

DRAFT

9.3 Publication and conditional advancement

The initial binding uses one application-managed bare Git repository per project and one accepted branch. The tree retains a project manifest, record files, content-addressed assets, a protocol manifest, and transaction receipts. These project repositories differ from the four source-code repositories used to distribute the programme and its applications.

The adapter prepares affected trees and a candidate commit, then advances the accepted reference only if its current value equals the expected parent. The logical publication condition is given in Equation 1. Here H is the accepted head at the comparison point, h is the request's expected head, and c is the fully prepared candidate whose parent is h.

$$\text{publish}(H, h, c) = \begin{cases} c, & H = h \text{ and the candidate has passed the binding checks,} \\ H, & \text{otherwise.} \end{cases} \tag{1}$$

Equation 1 describes the accepted-reference transition. Failed preparation can leave unreachable Git objects, but ordinary reads do not treat those objects as accepted history. The binding checks reachability when resolving a requested revision, so a dangling candidate cannot be used as an accepted snapshot merely because its object identifier is known.

Git supports more general branching histories. The current application chooses a linear accepted branch with conflict reporting. A semantic merge of competing social accounts would require an explicit policy for identity, qualification, modules, evidence, and action dependencies. The existence of a Git merge operation supplies no such policy.

9.4 Receipts, retries, and uncertain responses

The request digest is computed from canonicalized logical transaction content and verified file-part metadata. Multipart framing and server-assigned recording time do not determine request identity. A committed receipt includes the original base, actor, reason, change categories, digest, changed-resource summaries, and validation scope. It is stored in the same accepted tree as the effects.

The receipt cannot contain the resulting commit identifier without introducing a self-reference into the content that determines that identifier. The response instead resolves the commit that introduced the receipt path and distinguishes it from the currently observed head. A retry with the same transaction identifier, actor, and logical digest returns the original result. Reusing an identifier for different content or another actor is a conflict.

Receipt lookup precedes rejection based solely on an old base. Otherwise, a client whose first response was lost could be told to reconcile a transaction that had already succeeded. After a publication race, the application checks for an identical committed request before treating the race as an unrelated conflict. A timeout remains an uncertain response until recovery establishes the outcome; it does not prove that no publication occurred.

The guarantee concerns accepted project effects within the binding. It does not promise exactly-once notifications, institutional action, or external file transfer. An administrator with repository access can rewrite or remove history. The current SHA-1 Git object format and SHA-256 asset digests do not provide independent identity authentication, external timestamps, or preservation against that administrator.

9.5 Historical reads and export scope

A read pins one accepted revision and obtains the manifest, selected records, labels, modules, and file descriptors from that snapshot. Historical views remain read-only in the interface. The application separately checks present authorization to inspect that historical content. An object digest or commit identifier is a locator, not a permission token.

Snapshot JSON exports record representations without file bytes or full history. A snapshot ZIP includes understood referenced material at the selected revision. A Git bundle preserves the accepted reachable history, including earlier replaced or detached material and receipts. None of these exports

DRAFT

alone restores accounts, sessions, or application authorization configuration. The distinction between source preservation and service recovery is therefore part of the export contract.

10 Event Partial Orders and Relational Spacetime

The spacetime construction represents relational topology under an explicitly selected event boundary. Space denotes the organization of applicable accounts and their incidences. Time is supplied by retained precedence relations among Event records. Geographic coordinates can be described through appropriate State or Property accounts, but visual layout coordinates have no geographic interpretation by default. GR-SPEC-121 implements this bounded construction [4].

10.1 Recording revision and represented event order

Let S_h be a project snapshot at accepted recording revision h. Its Event-role records form a finite set E_h. Supported non-withdrawn event-order modules supply a set A_h of directed endpoint pairs. Order accounts retain independent identity, attribution, modality, disposition, and grounds. Two accounts can assert the same pair while remaining distinct sources.

The current projection includes contested and non-realized order accounts with visible qualifications. It does not choose a preferred historical scenario. Withdrawn order accounts remain inspectable but do not constrain the active ordering. A future scenario-selection profile could select a declared subset; silently removing inconvenient assertions would change the epistemic meaning of the current projection.

When A_h is acyclic, its transitive closure defines a strict partial order $\prec_h$. Equation 2 specifies that order. A path has positive length, so an event is never its own predecessor in a consistent account.

$$e \prec_h f \quad \Longleftrightarrow \quad \text{there is a positive-length directed path from } e \text{ to } f \text{ in } (E_h, A_h). \tag{2}$$

Equation 2 derives order only from explicit event-order assertions. Git ancestry, recording timestamps, UUID sorting, free-text occurrence descriptions, and display rank do not add constraints. An early event can be entered after a later one without contradiction.

10.2 Cuts and selected boundaries

For a user-selected set $U \subseteq E_h$, the projection includes the selected events and their known predecessors. Equation 3 defines this closure and its frontier.

$$D_h(U) = U \cup \{e \in E_h : \exists u \in U, e \prec_h u\}, \qquad F_h(U) = \max_{\prec_h} D_h(U). \tag{3}$$

The result in Equation 3 is a down-set, or predecessor-closed cut. Its frontier is the set of maximal included events. An explicit empty selection yields the empty cut. An omitted selection in the binding denotes the all-event cut. The distinction is exposed in the response so that a missing parameter does not silently mean a different historical boundary.

Proposition 10.1 (Minimal predecessor closure)**.** *For a finite acyclic event account, $D_h(U)$ is the unique least down-set containing U. The closure operation is extensive, monotone, and idempotent.*

Proof. Every member of U is included. If x precedes a member of $D_h(U)$, then x either precedes a member of U directly or does so by transitivity; hence x is included. Any down-set containing U contains these predecessors and therefore contains $D_h(U)$. This proves minimality and uniqueness. Inclusion of larger selected sets can only add reachable predecessors, which proves monotonicity. Since the result already contains its predecessors, closing it again adds nothing. □

Proposition 10.1 justifies the interface's automatic addition of known predecessors. It does not identify a physical instant. Two incomparable events can both belong to a cut or one can be included while the other is excluded. Neither choice asserts that they occurred simultaneously or independently.

DRAFT

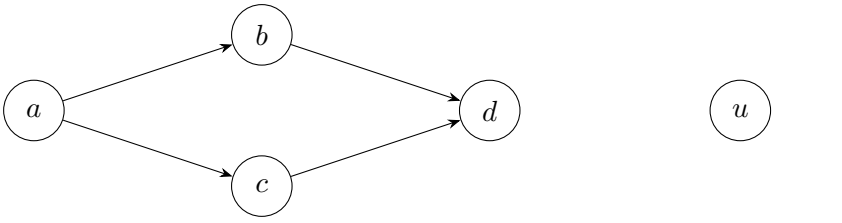

Figure 2: A synthetic event partial order. Arrows encode retained precedence accounts. Horizontal and vertical positions are layout choices with no duration or simultaneity semantics.

10.3 A branching example

Consider events a, b, c, d, u with asserted precedence $a \prec b$, $a \prec c$, $b \prec d$, and $c \prec d$. Event u has no asserted ordering. Selecting b yields $\{a, b\}$; selecting d yields $\{a, b, c, d\}$. The inclusion of c in the second cut follows from its asserted precedence to d, not from its display position.

Figure 2 depicts the example. Placing b and c on one visual level does not establish simultaneity. The same finite partial order permits linear extensions in which either event is first. Event u can occupy several places in an extension because the account supplies no relevant constraints. Appendix B gives additional cuts and contradictory cases.

10.4 Temporal applicability of retained accounts

A temporal-extent module describes a start, end, basis, and optional subject grouping. A boundary can reference an Event, be unknown, or be unbounded within the declared account scope. Absence of the module is a fourth condition, called unscoped. The distinctions are material: unbounded is an affirmative scope statement, while unknown is unresolved information.

Starts are inclusive and ends exclusive. When both bounds are events, supported strict start-before-end reachability is required for determinate interpretation. An equal, reversed, or incomparable pair is diagnosed as indeterminate; the extent itself does not add an ordering assertion. Unknown on either side remains indeterminate under this conservative profile, even where one known boundary would permit a narrower partial conclusion.

For a non-withdrawn account r with supported, determinate bounds, let s_r and t_r denote its start and end. The symbols $-\infty$ and $+\infty$ in Equation 4 are notation for the profile's scoped unbounded declarations, rather than claims of physical eternity.

$$\text{active}_h(r, D) = \big(s_r = -\infty \ \vee \ s_r \in D\big) \wedge \big(t_r = +\infty \ \vee \ t_r \notin D\big). \tag{4}$$

Equation 4 applies only after eligibility and uncertainty checks. The complete classification order is withdrawn, unsupported or unscoped, unusable order or invalid bounds, unknown bounds, not started, ended, and active. Unknown and unscoped accounts remain inspectable outside the default active topology. Their omission provides no evidence that their targets were absent.

10.5 Topology and trajectories

The topology at a cut retains active record nodes from the canonical incidence graph and only edges whose endpoints are active. A Relation node can remain active while one participant lacks determinate applicability. The projection then retains the Relation and reports partial incidence, identifying omitted participant entries. Removing the Relation entirely would conceal an active account; retaining every incidence would invent applicability for an uncertain participant.

DRAFT

Subject trajectories group records through an explicit subject reference and stated continuity basis. They can display successive, overlapping, or competing State and Relation accounts. Grouping does not select one account as true, infer identity from a shared label, or calculate event effects. A transformation semantics would require additional operations, commutation assumptions, and evidence about how recorded events change targets.

Proposition 10.2 (Revision-pinned projection)**.** *For a fixed snapshot, supported projection version, and selected event set, a deterministic projection returns the same order, cut, and applicability classifications independently of the order in which the corresponding records were entered.*

Proof. The event relation is a function of retained order-module content in the fixed snapshot. The cut is a function of that relation and the selection. Applicability is a function of the resulting cut and retained extent modules. Recording sequence is absent from these inputs. Thus permutations of entry history that leave the snapshot inputs unchanged leave these results unchanged. □

Proposition 10.2 concerns the specified inputs. A different snapshot can contain corrected bounds, withdrawn orders, or changed qualifications and legitimately yield a different projection. The result also does not promise identical force-layout pixels under different display engines.

10.6 Contradictions and unsupported semantics

A cycle prevents the active order from defining the required strict partial order. The implementation retains the assertions, identifies involved events and order accounts, and returns null cuts and topology. It does not erase the conflict to construct a convenient timeline. Unsupported retained event-order versions likewise prevent a claim of complete temporal interpretation. An unsupported extent affects the corresponding account's applicability without necessarily invalidating an otherwise understood event order.

These behaviors make representational failure visible. A user can inspect the ordinary graph, review the grounds, and withdraw or revise a mistaken order in a new recording revision. The historical contradiction remains available. The combination of retained conflict and revision-pinned projection supports epistemic reconstruction while preserving the difference between correcting an account and changing the past.

11 Contestation, Institutional Action, and Practical Repair

The praxis interface connects revised judgment with consequences for participants and institutions. Its analytical object is the trajectory from a claim's use to any later challenge, disposition, and practical response. A recording infrastructure can preserve each stage without having the authority to decide the case or execute a remedy. The programme consequently distinguishes an information contract from an institutional mandate.

11.1 A complete contestation episode

A consequential challenge begins with an identified target: an account, assessment, classification, decision, or procedure. Intake records the grounds supplied, the submitter's relevant capacity, access needs, protection constraints, and the requested examination. Admissibility determines whether the declared procedure can hear the issue. Refusal to admit a case is a procedural outcome and need not settle its substantive merits.

Assignment identifies a competent reviewer and relevant conflicts. Notice and response make the material grounds of a prospective decision accessible within protection limits. The assessment distinguishes evidence, criteria, assumptions, unresolved alternatives, and the scope of authority. A disposition records the questions actually decided, reasons, qualifications, and routes for further review. Each stage can fail or remain incomplete, and the record preserves that status.

DRAFT

The proposed procedure allows protected handling. A witness may need restricted access, an intermediary, or a permitted summary. The existence of such protection can limit what an external reader can assess. The released view should expose the resulting limitation without treating secrecy as proof of either credibility or misconduct. A credible review route requires actual arrangements appropriate to the case.

11.2 Correction and downstream dependence

An incorrect field can influence several later decisions. Correcting its present value is only one part of the response. The institution needs to identify affected uses, determine which remain within its control, notify relevant recipients, and record attempted and completed changes. Uncontrolled copies may persist. A correction account should therefore state the reach and limits of its propagation.

Consider a synthetic participation record that counts eighteen entries as eighteen distinct people. A later review finds sixteen distinct attendees. The revised record can preserve the original ledger, explain duplicate entries, change the current count, and identify reports that used the earlier number. Whether the difference affects a decision depends on that decision's criteria. A technical correction can be completed while a disputed allocation remains unresolved.

11.3 Action authority and verification

An action plan distinguishes proposed, authorized, assigned, initiated, completed, verified, failed, and abandoned activity where those differences matter. A reviewer can recommend restoring access without controlling the system that grants it. The record should identify the responsible recipient and the evidence needed to establish execution. A message announcing a remedy is not the same evidence as successful restored access.

Temporal urgency adds another dimension. An institution may take a limited protective action before full examination. The record needs a purpose, authority, duration or review point, notice limits, expected consequences, and later review. The provisional action does not automatically establish a final finding. The infrastructure can help expose these relationships, but the legitimacy of the action remains a contextual legal and normative question.

11.4 Reopening and changed conditions

A case can reopen because of new evidence, an earlier error, changed target conditions, revised categories, procedural defect, or unimplemented action. The grounds can affect the past assessment, current action, or both. A later improvement in conditions does not prove that an earlier report was mistaken, just as a later failure does not alone prove that an earlier decision ignored available evidence.

Closure records which issues are disposed, which actions remain pending, who owns follow-up, and what can trigger reconsideration. Administrative closure and epistemic agreement remain distinguishable. An institution that closes a queue entry while leaving an action unperformed has changed the workflow state; it has not thereby restored the lost opportunity.

11.5 Jurisprudential interfaces

The jurisprudential work items concern the relation between records and rights, duties, authority, jurisdiction, admissibility, and procedure. The paper offers an information architecture for expressing those claims, rather than a legal opinion about a particular jurisdiction. A legally consequential profile would need qualified review of its applicable sources, institutional mandate, procedural safeguards, and conflicts among obligations.

Technical standardization can improve the clarity of an authority claim by requiring a source and scope. It cannot create the claimed authority. The same applies to rights labels and consent fields. A database can record that consent was asserted; whether the underlying agreement is valid and sufficient

DRAFT

depends on circumstances beyond the schema. The programme keeps this distinction visible through separate publication classes and domain-specific assessment.

12 Preservation, Protection, and Access

The preservation problem concerns what future inquiry can recover and under which conditions. The protection problem concerns the effects of collecting, retaining, and disclosing that material. These purposes can support or constrain one another. The programme therefore treats retention and access as governed activities rather than automatic consequences of a storage mechanism.

12.1 Capture boundaries and proportionality

A project first needs a reason to collect a class of material. That reason identifies the questions the material is expected to support, relevant participants, known sensitivities, and possible substitutes. Complete capture is often unavailable and can be undesirable. A useful record can describe a protected source or an absence without retaining the sensitive content itself, provided that the resulting evidential limits remain clear.

Collection choices affect recognition. A system that privileges easily quantified events may make informal care or excluded testimony less visible. A requirement to produce extensive documentation can impose disproportionate costs on people with limited access to tools or institutional support. Evaluation should therefore examine who can contribute, who can challenge a record, and whose activity becomes difficult to represent under the selected categories.

12.2 Preservation and released views

The retained package and a released view have different boundaries. A public display may omit identities, detailed locations, or sensitive testimony. It should state its purpose, source revision, selection rule, and material limitations. The audience needs enough information to understand what the view establishes without assuming access to a complete archive.

Redaction, normalization, transcription, and summarization are transformations. A transformation record identifies input and output versions, operation, responsible role, and known effects on interpretation. A redacted document can remain useful while leaving a particular question unassessable. A summary can preserve a decision's conclusion while losing its qualifications. The infrastructure should make these differences available at the point of use.

12.3 Retention and disposal in a Git binding

The current Git binding retains replaced and detached assets in accepted history. This supports recovery but creates a specific limitation for sensitive information: removing a current link is not historical erasure. Copies, bundles, backups, and previously authorized downloads can extend retention beyond the live repository. A deployment needs a retention arrangement appropriate to these facts before accepting protected material.

Selective erasure would require a separate design. Possible directions include segregated protected storage, encrypted material with governed key destruction, retained tombstones, or controlled history rewriting with a correction record. Each changes the preservation and verification story. Key destruction does not remove every copy of plaintext, and history rewriting changes object identifiers and the evidence available to prior references. The present edition implements none of these as a general compliance solution.

The appropriate engineering response is explicit capability disclosure and proportionate use. Synthetic demonstrations and low-sensitivity private research records fit a different risk profile from consequential institutional dossiers. A successful attachment test should not be used to justify expansion to a more sensitive domain without a protection design and qualified review.

DRAFT

12.4 Authorization, custody, and operational continuity

Project access is enforced by the application, including historical content and file delivery. A retained digest proves a byte-identity comparison within its method; it does not authenticate the actor who supplied the material. A Git bundle preserves objects but omits account and authorization state. A service backup therefore needs additional arrangements, and restoring it requires control over credentials, ownership, and access rules.

Custody extends over time. A maintainer can leave, hosting can end, and a dependency can become unsupported. The institution needs to identify a successor or communicate the limits of continued service. Long-term preservation also requires format inspection, integrity checks, migration decisions, and accessible descriptions of what has changed. Source availability helps, but it does not by itself fund or perform these tasks.

12.5 Threats arising from epistemic use

The main threats include deliberate falsification, mistaken interpretation, misleading presentation, unauthorized disclosure, coercive documentation, and overreliance on apparent validation. Their countermeasures differ. A digest mismatch calls for an integrity response. A well-preserved false claim calls for substantive examination. A complete graph with a misleading legend calls for presentation correction. A person unable to contest a classification needs a usable institutional route.

Threat modeling should therefore begin with concrete actors, resources, actions, and consequences. The paper's engineering checks cover selected operations and failure paths. They do not certify the system against a general adversary or establish that the social costs of recording are acceptable. Those remain deployment-specific evidence obligations.

13 Application Architecture and Domain Interfaces

The implementation architecture separates reusable semantics from application hosting. Common packages implement record preparation, validation, projection, and Git storage. Domain applications provide entry points, user interaction, authorization, and domain-specific interpretation. The repository hierarchy makes the separation visible while allowing coordinated development.

13.1 Source repositories and runtime repositories

The programme root contains the applicative infrastructure as a submodule. The infrastructure repository contains the generalized and academia applications as separate submodules and retains common tools and packages. These four repositories distribute software and documentation. A generalized application's runtime separately manages one bare Git repository for each user project. The distinction is important for both backup and publication: publishing source commits does not publish private project records.

The generalized application supports registration, login, project creation, record authoring, graph inspection, modules, attachments, history, and spacetime views. Its application database manages service-level identities and sessions, while project repositories retain record revisions and material. The storage adapter receives an authenticated actor from the application; it does not discover identity by interpreting a Git author string as independent evidence.

13.2 Common semantic and storage boundaries

The record protocol package validates the final candidate and produces projections from supplied snapshots. Its absence of framework and repository dependencies permits direct testing of semantic behavior. The Git store supplies object construction, bounded reading, accepted-history reachability, material closure, receipt lookup, and conditional publication. The HTTP binding adds transport parsing, file verification, project access, and protection against unauthorized state changes.

DRAFT

Limits belong to their layers. A protocol transaction can have a broader internal JSON bound than the HTTP transport accepts. A storage snapshot can impose a tighter aggregate bound than the pure package. An error should identify the applicable constraint rather than truncate input to make it fit. The capabilities response documents supported versions and limits so that clients can distinguish unavailable features from invalid data.

13.3 Authoring and presentation

The graph interface makes records selectable and Relations inspectable. A user can create a record, connect participants, and examine associated notes or files. Modules organize material around an account without treating every module as a new ultimate ontology class. A record's primary role can guide presentation while its applied role set preserves overlap.

The spacetime interface adds event-order inspection, event-cut selection, temporal-extent editing, applicability classifications, and subject trajectories. Selecting a cut is a read operation. It changes the presentation of a pinned snapshot and does not create a recording revision. Editing an extent or precedence account is a transaction and retains the usual reason, qualifications, and history.

Visual layout requires particular care. A grid can avoid overlap without adding semantics. A force layout can improve navigation while suggesting closeness that the data does not assert. The implementation's presentation contract therefore separates coordinates from target properties, and the worked gallery explains its filtering and local layout choices. Accessible tabular and textual routes remain important for interpreting incidences and temporal qualifications.

13.4 Academia and learning as distinct domain systems

The academia application was migrated into the infrastructure hierarchy with its native protocol and provenance retained. That migration is an organizational change, not a completed semantic conversion to the generalized protocol. An adapter would need to examine signed content, record identity, relation kinds, domain modules, files, authority claims, and unmapped fields. A shared library becomes evidence of interoperability only when independently implemented exchange cases succeed under a specified mapping.

The learning prototype described in the companion paper is a further distinct system. It uses GMD source in an authenticated hosted notebook, SQLite transactions, stable semantic references, and source-derived edges. Its entity kinds such as question, method, and formula are domain authoring categories. They are not a replacement for the generalized six-role model. Its explicit-date timeline also differs from the event-cut topology developed here.

The common research problem concerns retained commitments and derived views. A future cross-domain interface can map a learning document revision into a record package while preserving source occurrences, independent question identity, and review provenance. The mapping needs to expose uncertainty and loss. Presenting the two applications side by side does not establish that such a mapping has already been implemented.

14 Synthetic Demonstration of a Generative Trajectory

River Commons is a synthetic inquiry into the shared care of a garden. It demonstrates an encounter that opens an opportunity, a provisional arrangement, changing accounts of access and responsibility, a later review, and correction of a mistaken chronology. Every person, institution, observation, and material item is invented. The demonstration tests expressibility and inspectable behavior rather than facts about a real community [2].

DRAFT

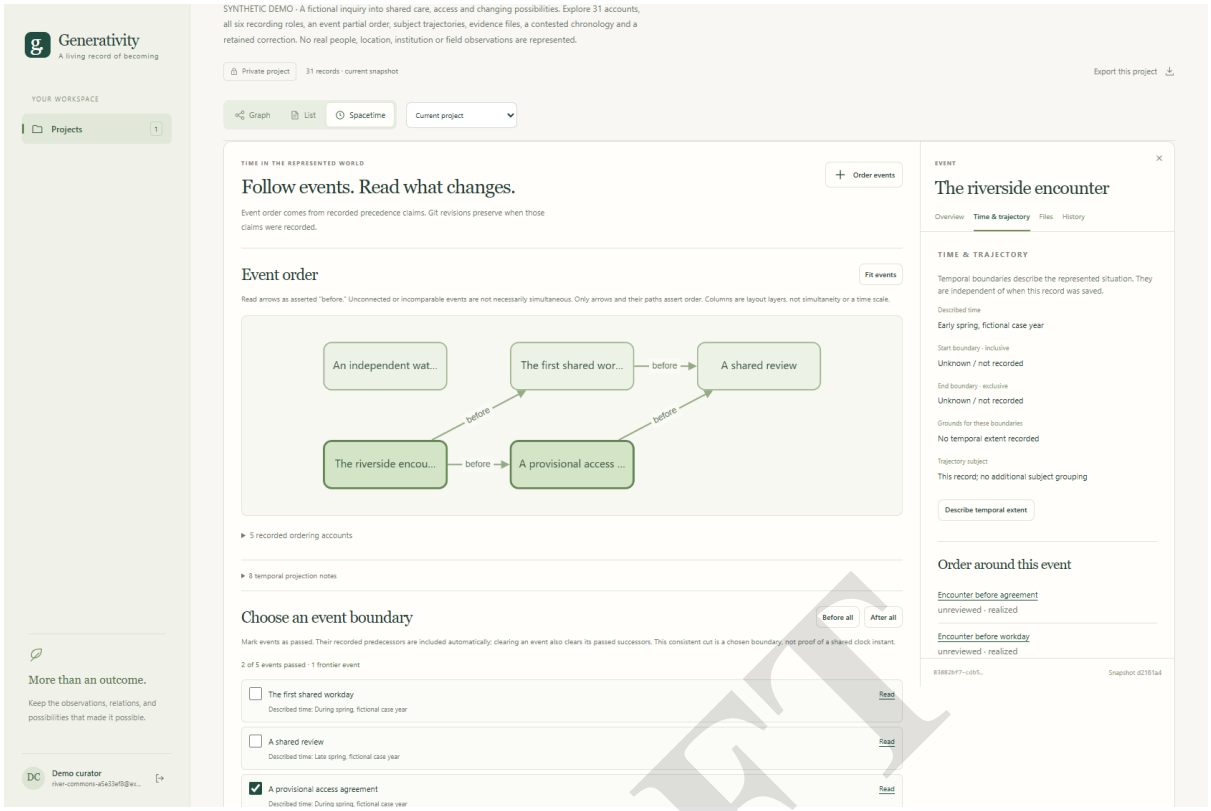

Figure 3: River Commons event-order view from the running generalized application. The later review was recorded first. Explicit precedence supplies the branching structure; layout and recording sequence do not supply physical time. The screenshot uses synthetic data.

14.1 Scenario inventory and recording sequence

The final project has 31 records: four primary Entity accounts, five States, five Events, one Process, twelve Relations, and four Properties. The Relations include seven substantive relationship accounts and five precedence accounts. Four precedence accounts remain active; a fifth is withdrawn after producing a cycle. Six fictional files supply encounter notes, an access memorandum, water observations, a review summary, an attendance ledger, and chronology reconciliation.

The sequence deliberately begins by recording the later review. Earlier encounter, agreement, and workday events are added retrospectively. Scoped States and Relations are then recorded, followed by a contradictory precedence account and its correction. The chronology correction withdraws the claim that the review preceded the encounter. A separate correction changes eighteen attendance entries to sixteen distinct attendees. These revisions concern the account of the stipulated history.

14.2 Event order and incomparable branches

The encounter precedes both the access agreement and the first shared workday. Both precede the review. The agreement and workday have no asserted mutual order. An independent water observation is unordered relative to the four-event structure. Figure 3 shows the actual event-order interface. The display can place events into columns while leaving their incomparability explicit.

Selecting the agreement includes the encounter as a predecessor, giving a two-event cut. Selecting the review includes both branches and the encounter, giving a four-event cut. The independent observation remains outside these selections. An all-event cut would include it without establishing a new relation to the other events. This difference makes the meaning of selection visible to the reader.

DRAFT

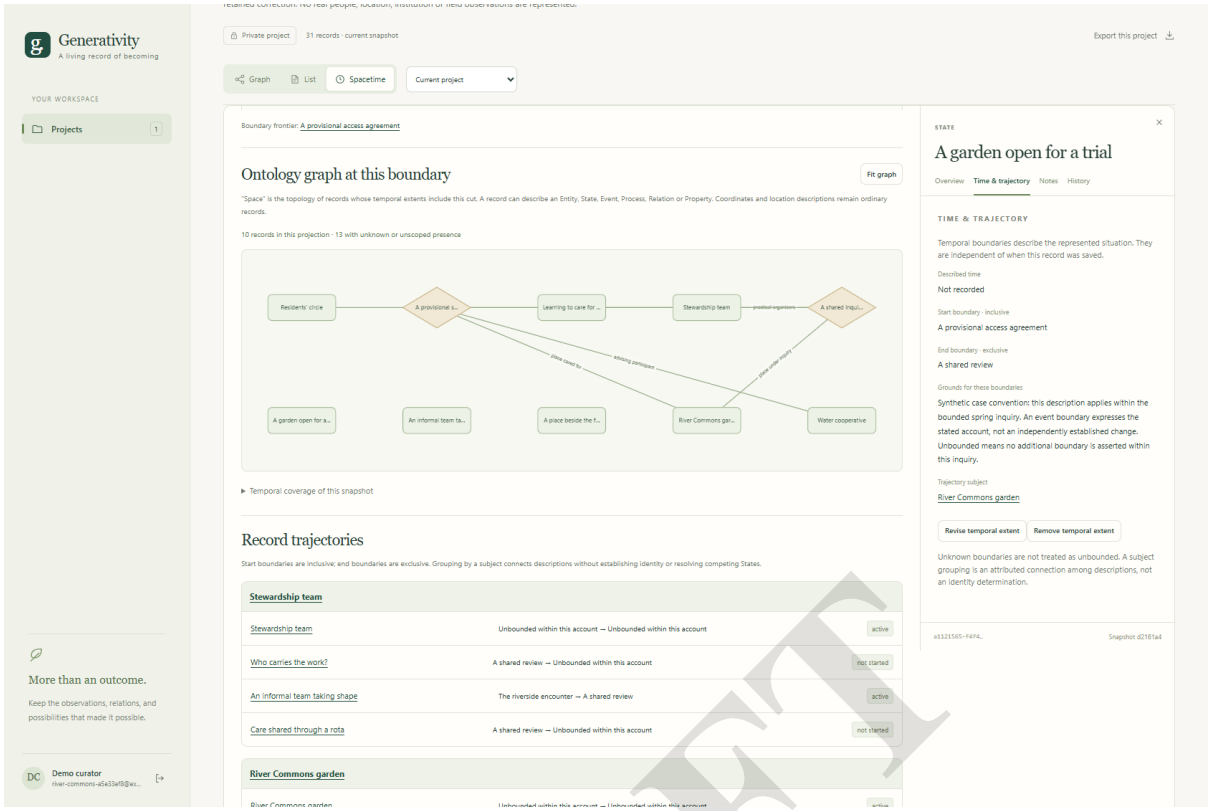

Figure 4: Topology after the access agreement: the encounter and agreement are included, and the trial-access State is selected. The workday is not a known predecessor of the agreement. Unknown and unscoped accounts remain separately inspectable.

14.3 Topology at two event boundaries

The two cuts are projected from the same current recording revision. At the agreement cut, ten records are active in the topology, including trial access and a provisional stewardship arrangement. At the review cut, thirteen records are active, including revised access, a rotating-care State, and renewed stewardship. Figure 4 and Figure 5 preserve the actual boundary labels and selected accounts.

The example also retains indeterminate water applicability and an unscoped proposed capacity. Their separation prevents a complete-looking graph from inventing a definite period for uncertain claims. A geographic description appears as a contextual Property; it does not determine the graph's coordinates. The garden's successive State accounts and the stewardship team's accounts are grouped through supplied subject references with explicit scope.

14.4 Relation identity and preserved disagreement

The provisional stewardship arrangement has its own account and three participant roles. A higher-order relation qualifies an account of access, showing that Relations can themselves be objects of inquiry. A disputed workload Property remains visible beside the accounts of improved coordination. The example therefore permits an attributed gain and an unresolved concern to coexist without forcing a single score.

The historical revision containing the mistaken chronology returns a cycle diagnostic and withholds a consistent cut. The current revision retains the withdrawn order account and uses the remaining active assertions. A reader can compare the grounds and consequences of the correction. Preserving the contradiction is useful precisely because a clean current view alone would conceal the route through which the account became usable.

DRAFT

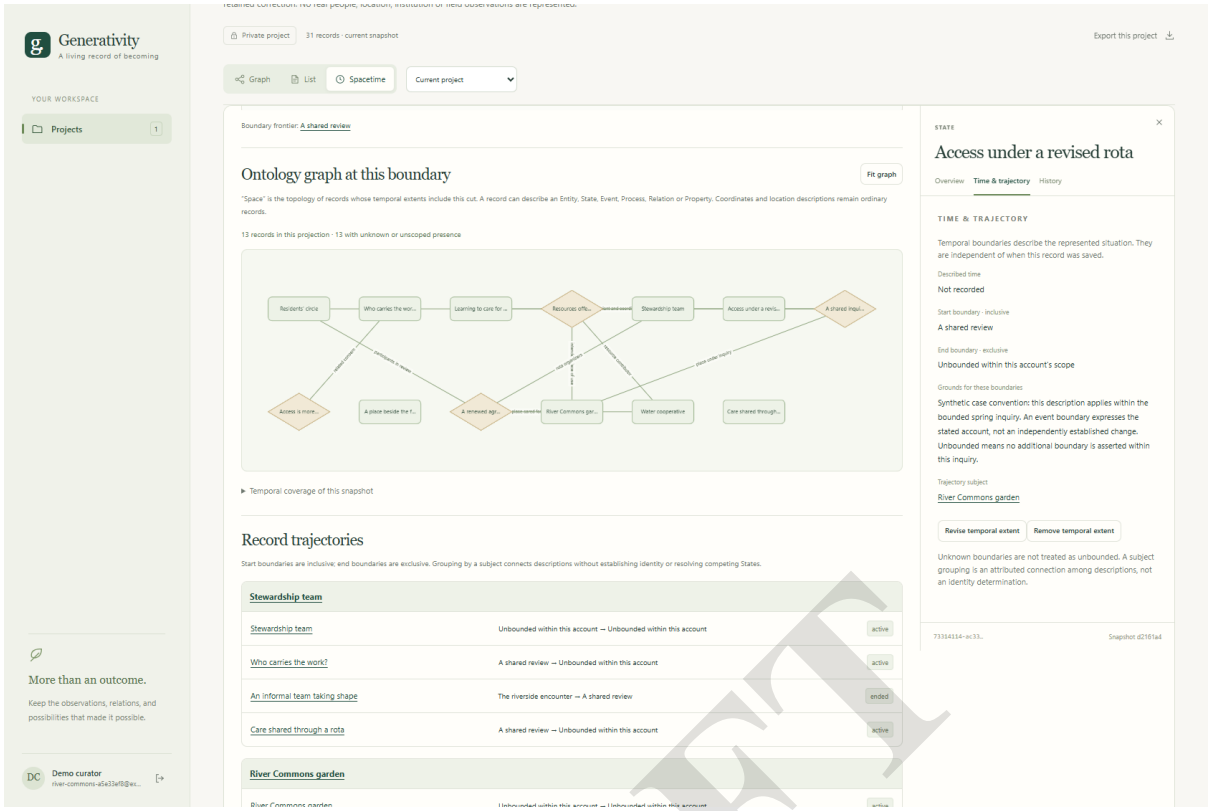

Figure 5: Topology after the review, at the same Git revision as Figure 4. Both branches are included. Revised access and renewed arrangements apply according to retained extents. The difference is a projection of applicability accounts, not an inferred causal simulation.

14.5 Interpretive reach of the demonstration

The demonstration establishes that the implemented representation can express this stipulated story, retain its material, and distinguish its temporal questions. It supplies no evidence that the fictional arrangement was effective, just, or legally valid. It also does not establish that users unfamiliar with the design correctly interpret cuts, partial incidences, or subject groupings. Those are prospective comprehension tasks for evaluation.

15 Verification Results and Evaluation Boundaries

The evaluation separates documentary checks, finite constructions, executable software behavior, and future institutional assessment. This separation permits useful results to be reported without treating one evidence class as a substitute for another. The current checks support a reproducible development state and a bounded implementation account.

15.1 Documentary and synthetic assessment

The publication checker passed for the nine version 0.3 documents. It found 754 unique requirement identifiers and checked source metadata, references, archive hashes, build freshness, and extracted PDF coverage. The documents total 226 pages. These checks establish consistency properties of the publication package. They do not perform a fresh substantive judgment on every requirement or certify accessibility.

The fixed-baseline validation checker passed for 753 version 0.2 identifiers across 116 review groups. The P1 assessment has 208 rows: 54 component rows, of which 53 are fulfilled and one not assessed, and

DRAFT

154 whole-requirement rows, of which 152 are not assessed and two not applicable. The row classes are distinct. A fulfilled component does not make its whole requirement fulfilled. The 18 ballot-arithmetic cases matched their expected results [6].

The interpretation of these numbers is bounded. Review coverage means that an identifier was associated with a review group and recorded disposition. It does not imply independent institutional validation. The synthetic case can reveal a missing field or ambiguous assessment boundary, while the availability of actual reviewers, affected participation, and remedy capacity remains unassessed.

15.2 Re-executed common-package checks

For this paper, the common record-protocol and real-Git storage suites were executed in the existing Windows development environment. All 146 tests passed in the recorded run. The raw output and command are retained in the evidence directory. The scope includes protocol and temporal behavior, transaction preparation, storage operations, and their tested failures. It excludes a fresh application browser run and any real institutional procedure.

The existing spacetime review separately reports 178 non-browser tests and seven browser tests across focused runs, for 185 passing tests in that review cycle. These totals overlap with common-package cases and must not be added to the new 146 as independent coverage. The review includes reverse recording order, incomparable events, predecessor closure, cycles, withdrawn orders, uncertain extents, historical labels, authorization checks, and a topology-overlap correction.

The historical review also records a bounded 1,000-record, 500-event chain and agreement with an independent reachability oracle on 500 deterministic generated graphs. These checks support the implemented traversal and cycle handling in their tested domains. They are not throughput measurements or evidence of performance at arbitrary scale.

15.3 Counterexamples as assessment instruments

Counterexamples are valuable because they expose the consequence of a collapsed distinction. If two independently identified occurrences have the same effect, an endpoint-only history loses occurrence count. If a claim's title changes after an institutional decision, resolving the old view against today's title misrepresents what was displayed. If a temporal extent adds an order merely because both bounds exist, it converts uncertainty into asserted chronology. If a file is detached and presented as erased, the interface misstates retention.

Appendix C organizes these cases by target, expected behavior, and evidence boundary. The schedule can guide independent implementations. It also distinguishes a deterministic invariant from an interpretation requiring human assessment. Correctly retaining an uncertainty field is a software property; whether its wording adequately communicates the uncertainty is a different question.

15.4 Burden, comprehension, and institutional performance

A prospective observed pilot should measure setup, capture, assessment, contestation, protection, revision, participation, and maintenance effort. Time is only one dimension. The record should also identify assistance, interruption, omitted information, abandoned tasks, and reasons participants decline a proposed structure. A shorter record can be more usable while omitting a crucial distinction; a longer record can be precise but practically unsustainable.

Comprehension tasks should ask readers to distinguish a record from its target, a digest from factual warrant, a precedence account from causation, and a cut from simultaneity. Tasks should include plausible misleading cases. A participant who correctly reports that a question is unresolved can outperform one who produces a confident but unsupported ordering.

Institutional assessment requires actual authority, participation, competent review, and practical follow-up. The most relevant outcomes include whether affected people can contest a consequential classification, whether an accepted correction reaches dependent uses, and whether a promised repair

DRAFT

occurs. These outcomes cannot be inferred from source code or clause counts. The present paper supplies a design and evidence basis for such studies while preserving their status as future work.

16 Public Policy and Institutional Development Options

The policy task is to identify feasible institutional settings for testing and maintaining the infrastructure. Technical interoperability, public legitimacy, and sustainable capacity have different requirements. The options below are proposals addressed to research institutions, civil-society organizations, public-interest infrastructure operators, and potentially relevant international organizations. No participation or endorsement is presumed.

16.1 Research and archival pilot

A first option is a bounded research or archival pilot in which a participating institution retains a decision or inquiry trajectory under a declared recording profile. The pilot can use low-sensitivity material and a limited question, such as reconstructing why a method was revised. Its advantages are manageable scope and a concrete archive. Its risks include designer dependence and selection of unusually cooperative cases.

The pilot agreement would identify custodianship, rights, access, review roles, withdrawal conditions, and evaluation questions. Evidence would include both successful reconstruction and failures. A useful failure might show that a required distinction is too costly to capture or that a source cannot be disclosed sufficiently for the intended assessment. Such findings should inform the profile rather than be hidden as implementation inconvenience.

16.2 Participatory institutional review

A second option concerns a real procedure whose classifications affect participants. The infrastructure could support a challenge, reasoned response, correction, and follow-up. This option tests praxis more directly but requires stronger safeguards and an actual authority able to change decisions. The prototype's private-project authorization model would not by itself be adequate for this role.

The design would need differentiated access, representation and assistance, conflicts handling, declared deadlines, and independent review capacity. Evaluation would examine whose concerns enter the record, which influence a decision, and which remain excluded. Participation should include the ability to challenge the categories and recording burden, not only to fill fields chosen by system designers.

16.3 Open-science capacity building

A third option aligns with the policy concern for open infrastructures and inclusive participation articulated in UNESCO's Recommendation on Open Science [23]. A programme of training, example dossiers, translation, and independent prototype development could examine whether the representations travel across disciplines and resource conditions. This is an institutional option, not a claim that the Recommendation mandates the present protocol.

Capacity building would need funding for maintenance and meaningful participation. Releasing code can reduce one barrier while leaving language, hosting, expertise, and time costs intact. A programme should therefore evaluate who can operate the infrastructure, revise its categories, export material, and leave the service without losing essential context.

16.4 Technical liaison and interoperability study

A fourth option is a narrow technical study with implementers of provenance, archives, and domain record systems. The study would define a small set of mapping questions and independent exchange fixtures. Identity, qualification, event order, evidence-role context, and protected omissions are suitable targets. A

DRAFT

failed round trip would be reported as a concrete loss, rather than repaired by silently inventing missing information.

The institutional route could involve informal research collaboration before formal liaison. The programme's own authority and resources should be established before commitments are made in its name. Standards adoption would follow the selected body's procedure and a recorded decision. A successful technical study would supply evidence for that process, not replace it.

16.5 Political economy of the infrastructure

Infrastructure affects the distribution of epistemic work. Someone funds storage, curates categories, maintains validators, answers challenges, and controls presentation defaults. These activities can produce public value while concentrating practical authority. A sustainability plan should disclose costs, dependencies, governance rights, exit routes, and the consequences of loss of support.

The design also needs to resist metric substitution. Counts of records, links, accepted suggestions, or nominally complete fields can become incentives that displace inquiry. A programme concerned with generativity should evaluate the future capacities and constraints associated with its use, including the possibility that documentation demands crowd out participation or experimentation. The appropriate indicators remain domain-specific and open to challenge.

17 Research Agenda and Development Priorities

The next development stage concerns the gap between an inspectable prototype and a sustainable, independently assessable infrastructure. The priorities below follow from the current limits and preserve the standards-first development pattern: a practical or normative need should motivate each new technical mechanism.

17.1 Epistemic model enrichment

The first priority is a more explicit representation of claims, material items, evidence-role assignments, assessments, and dependencies. The existing descriptive fields are useful for small accounts but make certain queries difficult. An assessor may need to distinguish two claims using the same material in different roles or determine which institutional actions depended on a superseded assessment. A model proposal should compare separate objects, qualified assertions, and hybrid structures using the same cases.

Richer structure can increase burden. The evaluation should therefore include reusable shared context, narrative locators, and selective structuring. A technically elegant schema that requires users to repeat a method statement for every sentence would weaken the practical objective. The criterion is recoverability of relevant distinctions under a declared task, rather than maximum decomposition.

17.2 Temporal and scenario semantics

The current event-cut model treats Event records as operational boundary markers. Extended events, overlap, duration uncertainty, and separate onset and completion need further semantics. Competing chronologies also require explicit scenario selection, with recorded inclusion rules and consequences. Such selection should preserve excluded accounts and avoid presenting the preferred scenario as the only possible history.

A future event-effect model would need to distinguish applicability from transformation. If different linear extensions of a partial order produce different results, the model must retain that difference or justify commutation assumptions. The current projection avoids this unresolved task by evaluating retained extents. Formal research can develop the stronger model in a Technical Report before it constrains an implementation profile.

DRAFT

17.3 Identity, migration, and cross-domain mappings

Cross-project identity and domain mappings need tests involving disputed continuity, split and merger, reused labels, signed material, and unknown modules. The academia application's native protocol and the hosted learning profile provide useful contrasting cases. Their different persistence and authority boundaries should be preserved in the mapping argument.

Migration also needs an explicit account of lost information. A new classification can divide an older category into several cases that the retained evidence cannot distinguish. A migration can preserve the old category and mark the new assignment unknown. It cannot reconstruct omitted distinctions by changing field names. Reverse mappings and round-trip fixtures are therefore essential evidence.

17.4 Independent assessment and governance readiness

Independent implementation would test whether the Specifications are sufficiently precise beyond their authoring codebase. Independent procedural review would test a different claim: whether participation, objections, decisions, and maintenance can be handled under the proposed governance. Both require people and resources outside the current drafting process.

The programme should select a small number of discriminating pilots, publish their task definitions and scope, and retain negative findings. Priority should go to cases involving a consequential correction, an uncertain chronology, a protected source, and an unresolved practical response. These cases exercise the integration problem more directly than adding many easy records.

17.5 Accessibility and interpretive usability

Presentation research should examine keyboard operation, assistive technologies, multilingual input, meaningful text alternatives, and the comprehension of graph and temporal views. WCAG 2.2 provides a relevant external reference for web accessibility assessment [24]; current screenshots and scripted browser tests do not establish conformance. The research question also extends beyond interface access to interpretive access: a technically reachable control can still communicate the wrong epistemic meaning.

The intended development outcome is a smaller set of claims supported by stronger evidence. Additional pages, fields, and test counts are useful only where they address a substantive failure or unresolved question. Comprehensive development therefore includes decisions to defer a mechanism, narrow a profile, or revise a requirement when the available evidence warrants that choice.

18 Concluding Account of the Proposed Infrastructure

Generativity epistemic infrastructure concerns the conditions under which people can recover, examine, challenge, and continue a trajectory of inquiry and action. The proposed standards programme gives that concern a layered form. Conceptual sources guide the distinctions, working drafts specify proposed obligations, experimental Specifications define bounded mechanisms, and applications expose those mechanisms to practical use.

The record graph retains independently identified accounts and Relations. The transaction protocol preserves coordinated revisions and recovers uncertain publication outcomes through receipts. The spacetime projection uses explicit event precedence and predecessor-closed cuts to display the applicability of accounts and their relational topology at one recording revision. These mechanisms support historical reconstruction while leaving factual warrant, causal attribution, legal authority, and normative evaluation open to their appropriate forms of examination.

The evidence supports a coherent preparatory corpus, conditional formal results, a functioning bounded implementation, and a reproducible synthetic demonstration. It also identifies material gaps: richer epistemic objects, independent interoperability, governed protection, participant comprehension, sustainable burden, and actual institutional capacity. The documentary appendices make both the developed material and its limitations available for review. The programme can advance through that review

DRAFT

without converting the current prototype into a premature claim of settled standards or comprehensive social knowledge.

A Documentary Corpus and Edition Guide

The documentary appendices preserve the programme's development material as a separately indexed corpus accompanying the research paper. The complete reading edition places the paper first and appends the documentary volumes. A shorter main-paper PDF remains available for ordinary reading. The source inventory records original paths and hashes; the reproduced documents retain their publication-class declarations, and the volume indexes record page locations.

The current-drafts volume reproduces the nine compiled governance and standards-track documents, followed by the current Markdown corpus: the Programme Brief, architecture and planning records, additional standards-track drafts, experimental Specifications, manuals, Technical Reports, policy outlines, templates, examples, and review material. Application documentation is included under a separate group. Placeholders retain their status as placeholders. Including a project README does not turn its roadmap into a delivered feature list.

The foundation volume preserves all seven supplied manuscripts, including both Chapter 3 variants. Their original pagination, titles, notices, and edition ambiguity remain visible. The historical volume preserves earlier publication editions and their associated descriptive material. These reproductions support recovery of conceptual and procedural development. The research text's source hierarchy and claim limits continue to apply.

The source archive includes machine-readable schemas, review matrices, fixtures, and source versions of the reproduced documents where present. Executable application code remains separately versioned; the inventory records its repository reference and includes documentary interfaces rather than treating the entire dependency tree as a paper appendix. Runtime databases, credentials, private project repositories, caches, and development environments are excluded.

The corpus has a defined freeze boundary. Later modifications to the live repository do not silently change the appendix edition. A reader can compare the retained source hash with a later revision and identify the difference. The assembly report distinguishes the original page numbers inside reproduced PDFs from their positions in the combined reading edition.

The distinction between reproduction and endorsement is especially important for external references and notices. Historical documents may contain earlier formulations, licence notices, unverified references, or superseded proposals. They remain part of the preserved record. New scholarly claims in the present main text use the separately prepared verification ledger and do not inherit verification merely from appearing in a reproduced document.

DRAFT

B Finite Event-Cut and Applicability Examples

The examples in this appendix make the operational temporal choices explicit. They use stipulated event accounts and supply no empirical chronology. Their purpose is to help an independent reader reproduce the consequences of the definitions in Section 10.

B.1 Complete cut inventory for a branching account

For the four-event diamond with $a \prec b$, $a \prec c$, $b \prec d$, and $c \prec d$, the down-sets are exactly $\varnothing$, $\{a\}$, $\{a, b\}$, $\{a, c\}$, $\{a, b, c\}$, and $\{a, b, c, d\}$. Adding an incomparable event u gives two variants of each cut: one excluding u and one including it. The resulting twelve cuts distinguish possible selected boundaries without assigning dates or probability weights.

Table 3 gives representative selections and their closures. Selecting all frontier members can recover the same cut as selecting every included event, which explains why the frontier is a useful display summary.

Table 3: Selections, closures, and frontiers in the five-event example.

Requested selection	Included cut	Frontier
$\varnothing$	$\varnothing$	$\varnothing$
$\{b\}$	$\{a, b\}$	$\{b\}$
$\{c, u\}$	$\{a, c, u\}$	$\{c, u\}$
$\{b, c\}$	$\{a, b, c\}$	$\{b, c\}$
$\{d\}$	$\{a, b, c, d\}$	$\{d\}$
$\{d, u\}$	$\{a, b, c, d, u\}$	$\{d, u\}$

B.2 Presence under specified and uncertain bounds

An account with start b and end d is not started at $\{a\}$, active at $\{a, b\}$, and ended at $\{a, b, c, d\}$. An account with start unbounded and end b is active at the empty cut and ended after b is included, within the declared account scope. An account with an unknown end remains indeterminate in the current profile even after its known start is included. An absent extent remains unscoped.

An account bounded by b and c is indeterminate because those events are incomparable. The user can retain that claim and its grounds, but the extent does not establish $b \prec c$. A separate precedence account would be needed to add that constraint. If the added account is later withdrawn, the temporal interpretation can change in a later recording revision while the earlier view remains available.

B.3 Cycle retention and account withdrawal

Adding $d \prec a$ to the diamond creates a cycle. The active order is then unusable for the cut construction, and the projection returns diagnostics with null cut and topology. Withdrawing the $d \prec a$ account restores the diamond if the remaining assertions are supported and acyclic. The withdrawal changes the active constraint set; it does not delete the earlier assertion from recording history.

Duplicate assertions of $a \prec b$ retain separate account identities but supply the same reachability constraint. Withdrawing one duplicate leaves the constraint active if another qualifying account remains. This case demonstrates why the implementation needs both an order-account inventory and an aggregated adjacency structure.

B.4 State trajectories and partial incidence

Suppose a garden State ends at b and a trial State starts at b and ends at d. Inclusive starts and exclusive ends permit a clear boundary transition at a cut containing b. The profile nevertheless allows other competing States with overlapping extents. It supplies no uniqueness axiom selecting a single true State of the garden.

Suppose a Relation is active at the trial cut while a participant is unscoped. The Relation node remains visible, the uncertain participant incidence is omitted from the active topology, and a partial-relation diagnostic identifies that omission. The ordinary record graph can still display the complete retained account. The two views answer different questions and should be named accordingly.

C Prospective Assessment Schedule

The schedule in Table 4 translates central distinctions into discriminating cases. It is informative research guidance, rather than a newly adopted conformance profile. An assessment identifies the edition, subject, evidence, applicability rationale, result, and limitations for each selected case.

An evaluator should retain failed and unassessed cases. Not applicable requires an absent trigger under the declared profile, rather than an unavailable person or missing evidence for an activity that was required. Whole-practice results also need a declared observation interval and responsible assessor. The result of a component check remains associated with that component.

DRAFT

Table 4: Discriminating cases for implementation and practice assessment.

Subject	Case and expected distinction	Evidence boundary
Identity	Rename a record while retaining stable references; compare a disputed target continuity claim	Identifier preservation does not prove target identity
Relations	Retain a three-party account, repeated roles, and a Relation participant	Incidence preservation does not verify the relation
Transactions	Create mutually referring records; reject the whole candidate on a failed dependent operation	Accepted atomic effects within one binding
Retries	Lose a response, repeat the same request, then reuse its ID with changed content	Receipt recovery and conflict distinction
History	Rename and revise current accounts while viewing an earlier revision	Earlier labels, modules, and bytes remain pinned
Time	Record the later event first; add an early predecessor retrospectively	Explicit precedence differs from recording order
Uncertainty	Compare unknown, unbounded, and missing extents	Omission from active topology is not absence
Conflict	Retain a chronology cycle and later withdraw an order account	Historical contradiction remains inspectable
Material	Replace and detach a file, then inspect full history	Current removal differs from historical erasure
Epistemics	Use the same authentic material for two different claims	Evidence roles and their grounds remain separate
Praxis	Correct a classification while a dependent action remains pending	Documentary correction differs from completed repair
Participation	Challenge a category through an accessible review route	Presence of a form does not establish meaningful consideration

For a future real pilot, the evidence package should include task instructions, participant roles and consent arrangements, material-access conditions, observation conventions, interpretive rubrics, and a plan for reporting adverse outcomes. Any numerical threshold should be chosen for a stated purpose before interpreting the result. Graph density, record count, and total clause coverage can describe the artifact, but they are not measures of factual warrant, justice, or generative benefit.

DRAFT

D Reproduction and Artifact Boundaries

The paper directory contains section-level LaTeX sources, figures, references, a verification ledger, and executed-check output. The accompanying tools compile the main papers and assemble documentary volumes. The build uses XeLaTeX, BibTeX, latexmk, Python, Pandoc for Markdown reproductions, and pypdf for assembly and inspection. Compilation has no need for a remote AI provider.

From the programme root, the common-package check can be repeated with the generalized development interpreter and the two common test directories. The exact argument list is retained in `evidence/common-tests.json`. The observed run reported 146 passing cases. The document checks are `tools/check_publications.py` and `tools/check_validation_package.py`; their scope remains as described in Section 15.

The River Commons seeder and gallery capture script remain in the generalized application repository. They create a separate synthetic account and preserve a local recovery manifest outside source control. Reproduction should use isolated runtime storage and the documented local server. The published figures are retained captures with known synthetic fixtures, not newly generated illustrations of an unimplemented interface.

The documentary source archive preserves selected project files and their original relative paths. Its

manifest records hashes and scope. It excludes private runtime state and third-party dependency installations. The source-code repository references and the learning handoff hash identify separate implementation evidence. A compiled PDF or a snapshot archive does not restore the complete running service.

The final validation report checks compilation, unresolved references, labels and citations, displayed-equation discipline, source/PDF page counts, and the assembly inventory. Visual inspection samples the title, dense tables, formal material, screenshots, bibliography, and appendix transitions. These checks support a readable research artifact while leaving comprehensive PDF accessibility assessment and substantive author review explicit.

DRAFT

GENERATIVITY STANDARDS PROGRAM

Programme Charter

Governance Working Draft

Version 0.3 2026-09-22

Standards Programme Charter

WORKING DRAFT FOR REVIEW

This document contains proposed provisions for technical and institutional review. It is not an adopted Standard or an operative governance instrument. Its scope, application conditions and publication status are specified in the text.

Prepared by the Generativity Standards Program. Reference to external publications does not imply endorsement by ISO, IEC, IEEE or any United Nations body.

Foreword

Version 0.3 records the bounded substantive review of the archived 0.2 package. Its requirement text is retained in this coordinated edition; updated references identify the companion 0.3 drafts. The review matrix, synthetic assessments and unresolved readiness questions are documented in `docs/reviews/validation_0.2/README.md`. These activities do not constitute adoption or an independent institutional assessment.

This document establishes proposed governance requirements for the Generativity Standards Program. It is a Governance Working Draft prepared for review, not an adopted Charter or technical Standard. Its authority depends on the founding procedure specified herein. The foundation manuscripts supply conceptual source authority; they do not constitute a governance adoption instrument.

Responsible editor: `UNASSIGNED`. Canonical source: `governance/standards_programme_charter.tex`. Intended readers are founding participants, administrators, reviewers, contributors, and affected people. Version 0.2 develops authority, participation, resources, oversight, transition, and assessment while retaining the requirement identifiers and obligations introduced in version 0.1.

This document is part of a coordinated draft governance package. Numerical development periods and ballot rules are specified in Directives Part 1. This Charter establishes the powers and accountability within which those rules operate.

Bibliography 14

Introduction

The programme responds to instability in the connections among representations, their referents, institutional classifications, and practical trust. Its purpose is to support warranted recognition, reasoned contestation, revision of judgment and action, and preservation of consequential generative trajectories. This includes the conditions under which people can produce evidence, inspect grounds, and influence practices that affect their future possibilities.

The programme's own decisions can shape which accounts are recognized and which infrastructures become authoritative. Governance therefore forms part of the programme's substantive task. Open documents alone do not demonstrate accessible participation; a recorded vote does not establish truth; and a maintained history does not by itself repair the consequences of a mistaken decision. The requirements below assign functions, make their exercise inspectable, and provide routes to correction within the programme's actual authority.

The initial model uses individual contributions and explicitly delegated functions. It permits a small organization without presuming that named committees, independent reviewers, funding, or institutional mandates already exist. A transition to another participation model remains subject to recorded amendment.

1 Scope

1.1 Subject and application

This Charter specifies requirements for the programme's founding, mission, publication authority, participation, appointments, decision accountability, resources, records, external relations, and institutional continuity. The assessed subject is the programme's governance arrangement and its exercise during a declared review period. A work item or publication can supply evidence of that exercise without itself constituting governance adoption.

1.2 Boundaries

The portfolio includes recording, preservation, exchange, presentation, assessment, contestation, revision, and accountable institutional use of generativity-related records. The Charter does not settle a complete metaphysics or create authority over external legal decisions. Its requirements concern decisions and resources within the recorded programme mandate.

2 Normative references

2.1 Coordinated draft dependencies

The following documents contain provisions needed to apply identified requirements of this Charter. The cited editions are Governance Working Drafts, version 0.3. Their listing establishes a draft dependency only. The founding instrument fixes the exact coordinated editions accepted for operation.

Directives Part 1 — Procedures for Development and Maintenance. `governance/directives_part_1.tex`. Provides development stages, review periods, dispositions, ballots, appeals, emergency action, and maintenance procedure.

Directives Part 2 — Structure and Drafting Rules. `governance/directives_part_2.tex`. Provides publication classification, provision structure, traceability, and production requirements.

GR/TC 1 Charter — Generativity Records and Infrastructure. `governance/technical_committee_charter.tex`. Defines committee scope, technical coordination, review, and pilot responsibilities.

Ethics, Conflict-of-Interest, and Contribution Rights Policy. `governance/ethics_ip_policy.tex`. Provides conduct, conflict, impact, contribution, and rights-handling requirements.

2.2 Use of references

CH-042 The founding or amending authority shall identify the exact coordinated governance editions, resolve conflicting provisions, and record the resulting allocation of authority before dependent decisions proceed. A later draft of a referenced document shall not replace the operative edition automatically.

External sources listed in the bibliography are informative. Their citation neither incorporates their procedures wholesale nor grants their institutional authority.

3 Terms and definitions

3.1 Programme authority

A person or constituted body with an expressly recorded mandate to decide specified programme matters. The term identifies the scope of decision power; it does not imply governmental authority or legal

personality.

3.2 Founding instrument

The record of actual signatories, capacities, express commitments, accepted governance editions, effective conditions, appointments, and limits by which the programme adopts its initial governance.

3.3 Delegation

A bounded assignment of a function by an authority entitled to assign it, together with responsibility, limits, duration or review point, and reporting obligations.

3.4 Affected interest

A person, group, practice, or condition materially affected by a proposed programme activity. An identified affected interest does not imply that a particular participant represents it.

3.5 Decision eligibility

Recorded authority to participate in a particular formal decision under announced criteria. It is distinct from the opportunity to contribute or comment.

3.6 Material governance change

A change affecting authority, decision eligibility, participation rights, appeal independence, publication powers, essential resources, or the ability to maintain operative obligations.

3.7 Reserved decision

A decision retained by the programme decision authority rather than assigned to an editor or administrator. Its classification concerns programme accountability and does not establish a legal classification.

3.8 Governance evidence

Records or observed actions supporting an assessment of a governance requirement, identified by version, custodian, access conditions, and relevant limitations.

4 Mission and programme commitments

4.1 Mission application

CH-006 Programme publications shall distinguish metamodel, record ontology, epistemic representation, normative assessment, jurisprudential status, institutional governance, political economy, and technical implementation wherever a requirement or claim depends on more than one of these layers.

CH-007 The programme shall preserve the distinction between theoretical GR concepts and scoped operational requirements. Intentional narrowing, operationalization, or departure shall identify its foundation sources, alternatives, rationale, and recorded architectural decision.

CH-008 Programme publications and public claims shall not present technical conformance, authentic provenance, a programme decision, or a recorded institutional finding as sufficient proof of factual truth, ethical legitimacy, legal validity, or international endorsement.

CH-009 The programme shall identify jurisdictional and institutional authority separately whenever a proposal concerns legal duties, rights, admissibility, liability, or public power. Unresolved applicability shall remain explicit.

CH-003 Each proposed programme work item shall identify the recognition or practical problem it addresses, its intended beneficiaries and affected interests, its anticipated contribution to the mission, and the evidence by which that contribution will be evaluated.

CH-004 Programme evaluations shall distinguish demonstrated improvements in recording, interpretation, contestation, or practical response from broader claims about restored trust, justice, or future generative capacity. A broader claim shall identify its evidence and limitations.

CH-005 The programme shall examine its own classification, recording, decision, and publication practices as potential sources of exclusion, dependency, and concentrated authority. Findings and corrective decisions shall enter the programme's maintained issue record.

CH-043 The programme decision authority shall maintain a current statement of objectives that links active work to the mission, identifies the practical capacities being developed, and distinguishes intended benefits from effects supported by evaluation. Each annual review shall examine whether the active portfolio still addresses those objectives.

4.2 Selection and review of work

CH-044 When prioritizing work, the programme decision authority shall record the relative need, affected interests, alternatives to new standardization, resource demands, dependencies, and consequences of delay. A priority based on available funding shall identify the resulting coverage gaps and influence conditions.

CH-045 Where evidence shows that a programme activity materially undermines participation, inspectability, contestation, or future access, the responsible authority shall examine revision, narrowing, suspension, or closure and record the chosen response and follow-up evidence. Publication volume shall not alone justify continuation.

5 Publication authority

5.1 Classes and approval boundaries

CH-010 Each publication shall declare its class, maturity, version, responsible editor, and decision authority. Specifications, adopted Standards, policy proposals, governance documents, Technical Reports, and manuals shall retain their distinct authority.

CH-011 The programme shall reserve the designation adopted Standard for an edition approved under its operative development procedure. A draft, schema, prototype, protocol, or technically normative Specification shall not acquire that designation through technical completion alone.

CH-012 Standards-track work shall begin with a stated normative problem, scope, terminology, intended requirements, conformance subjects, and relevant constraints. A dependent Specification work item shall identify the reusable technical need that motivates it. Draft requirements and Specifications may co-evolve through pilots and review.

CH-013 A policy proposal shall identify its intended institution or class of institutions, mandate assumptions, institutional alternatives, expected effects, safeguards, and evaluation approach. Its recommendations shall not amend technical conformance requirements outside the standards-development procedure.

CH-014 Formal work-item approval shall depend on the governance launch conditions in this Charter and Directives Part 1. Preliminary source research, draft preparation, synthetic examples, and technical exploration shall retain their preliminary status while those conditions remain unmet.

5.2 Reserved and delegated powers

CH-046 The programme decision authority shall reserve approval of governance amendments, creation or material alteration of committee mandates, formal work-item initiation, Standard adoption, substantive publication maintenance, and agreements creating programme commitments. A delegation of an operational step shall not transfer a reserved decision unless the operative founding or governance instrument expressly permits it.

CH-047 An editor or repository administrator shall exercise only recorded editorial or custodial powers. Technical ability to merge, publish, assign identifiers, change access, or remove material shall not substitute for authorization of a substantive decision.

CH-048 Before an authorized release, the release owner shall verify the applicable adoption or publication decision and the exact artifact set. If the intended public statement exceeds the recorded decision, the statement shall be corrected or referred for a new decision before release.

6 Participation and consideration

6.1 Entry and access

CH-015 The programme shall provide a documented route for interested individuals to contribute proposals and comments and to receive reasoned dispositions. Employment, institutional sponsorship, a proprietary tool account, payment, or travel shall not be a prerequisite for submitting a relevant comment.

CH-016 The participant register shall distinguish participation in an individual capacity from authorized institutional representation. It shall record relevant affiliations, interests, assigned roles, and any limits on a representation mandate, subject to justified protection of sensitive information.

CH-017 For each work item, the coordinator shall identify affected interests, reviewer competence needed, known participation gaps, outreach undertaken, and feasible measures for language, disability, time-zone, connectivity, and resource barriers. Unfilled gaps shall remain visible in progression decisions.

CH-018 The programme shall provide an asynchronous contribution route and a human-readable account of proposed substantive changes. A contribution requiring assistance with format shall be assessed for its substance after proportionate assistance or an accessible alternative has been offered.

CH-049 The coordinator shall publish the purpose and actual availability of each contribution route, the information needed to handle a submission, access and attribution choices, and the process for obtaining assistance. Failed contact, inaccessible material, or unmet accommodation shall be recorded and referred to the responsible review chair.

6.2 Consideration and protection

CH-019 Funding, institutional affiliation, authorship volume, technical access, or control of repository credentials shall not by itself confer decision rights or priority in comment disposition. The decision authority shall assess whether concentrated interests or unpaid-work burdens materially limit fair consideration.

CH-020 Any restriction on participation shall state the conduct or process reason, its scope, duration or review trigger, responsible decision maker, and available challenge route. Restrictions shall not be

imposed solely because a participant disputes a proposal or authoritative interpretation.

CH-050 Before closing a review, the review chair shall examine recorded access failures and participation gaps, determine their materiality to the decision, and document extension, targeted outreach, alternative access, narrowed claims, or deferral as appropriate. The absence of a complaint shall not alone establish adequate access.

CH-051 When an affected person cannot participate through the published format, the coordinator shall offer a feasible alternative or explain the resource limitation and a route to review it. An assisted submission shall preserve the contributor's intended meaning and identify substantive interpretation by the assisting person.

CH-052 The programme shall distinguish endorsement, consultation, contribution, representation, and assent in public accounts. A participant's name, affiliation, or contribution shall not be used as evidence of support for a decision without an established basis for that attribution.

6.3 Decision eligibility

CH-039 Before constituting a decision roster, the programme decision authority shall publish the proposed decision scope, nominations route, closing date, competence or affected-perspective criteria, expected review commitment, and conflict rules. Eligible individuals shall have an accepted bounded role, disclosed relevant interests, agreed applicable conduct terms, and a recorded capacity for the particular decision. Institutional representation shall require an identified mandate.

CH-040 Selection to or exclusion from a decision roster shall have recorded reasons against the announced criteria and an available procedural challenge. The authority shall assess concentrated interests and missing perspectives before fixing the roster. A roster shall not change during a ballot except through the correction and restart rules of Directives Part 1.

CH-053 A change in an eligible person's affiliation, capacity, or material interest shall be assessed before their next affected decision. The coordinator shall record whether the accepted role remains valid, requires a new mandate, or requires recusal or replacement under the operative procedure.

Eligibility establishes a bounded role. It does not give priority to a participant's factual assertion or make institutional status a substitute for reasons and evidence.

7 Organization and accountable appointments

7.1 Required functions

The minimum functional arrangement comprises founding authority, programme decision authority, coordinator and records custodian, committee convenor, editors or work-item leads, independent procedural review, ethics contact and alternate, rights review, release ownership, and maintenance ownership. All actual appointments are `UNASSIGNED` unless separately recorded.

The programme decision authority corresponds to the governance authority in Directives Part 1. The coordinator and records custodian performs the Secretariat function. The neutral procedural reviewer performs the independent appeal-review function. A review chair is assigned to a particular review. Functions can be combined where competence, capacity, and conflict controls permit.

CH-021 An appointment shall identify the person, appointing authority, accepted mandate, decision limits, relevant interests, start date, term or review date, alternate or vacancy arrangement, and removal or replacement procedure. An office shall not be treated as staffed until acceptance is recorded.

CH-022 The programme decision authority shall publish reasons for appointments, renewals, and

removals at a level compatible with necessary protection. A challenged appointment or removal shall have access to neutral procedural review under Directives Part 1.

CH-023 Where one person holds multiple functions, each decision record shall identify the capacity exercised and any resulting conflict. A person shall not conduct the neutral review of their own challenged decision.

CH-024 The programme shall not delegate a decision to an automated system. AI-assisted drafting, summarization, analysis, or validation shall retain an accountable human role responsible for checking the resulting material and recording consequential use.

CH-025 The programme shall not exercise a delegated function while its required responsible role is vacant or recused without an authorized substitute. Unaffected preliminary work may continue with its status declared.

7.2 Acceptance, performance, and replacement

CH-041 An appointment renewal or proposed removal shall receive a recorded grounds statement and an opportunity for the affected person and relevant participants to respond before a final decision. A non-conflicted authority shall decide the matter within its mandate and provide access to neutral procedural review. Urgent temporary protective measures shall follow the ethics policy and emergency procedure, with a stated review point.

CH-054 Before granting operational access for an appointed role, the appointing authority shall confirm the holder's accepted mandate, relevant competence or induction needs, conflict assessment, and knowledge of escalation and protection duties. Credentials shall be limited to the tasks actually assigned.

CH-055 Each role holder shall report inability to perform a material assigned duty, loss of required access, or a conflict preventing performance to the appointing authority. The authority shall assign an authorized substitute, narrow the activity, or defer dependent decisions and record the response.

CH-056 A role handover shall identify pending decisions, deadlines, records and access responsibilities, conflicts, accepted commitments, and unresolved risks. The outgoing and incoming custodians shall verify transferred access and the disposition of credentials; absence of an outgoing holder shall be recorded with recovery actions.

CH-057 Role performance review shall consider completion and quality of assigned duties, handling of objections, protection of records, influence concerns, and resource limits. An adverse assessment shall identify evidence and permit a response before a final appointment action, subject to time-limited protective measures.

8 Founding and decision accountability

8.1 Founding review and express adoption

CH-001 The programme shall identify this document as a Governance Working Draft until a founding adoption record identifies the adopting persons, their actual authority over programme resources and publications, the edition adopted, its effective date, and the scope of that authority.

CH-002 An adoption record shall distinguish the programme's own publication authority from any claim to represent a profession, institution, community, jurisdiction, or international constituency. Each representation claim shall identify its actual mandate and limits.

CH-036 Before founding adoption, the prospective founding signatories shall identify their actual capacities and proposed commitments, publish the exact governance package within cleared rights, identify

proposed appointments and decision-eligibility criteria, and announce a founding review that applies the public-review, comment-disposition, reply, and material-change periods in draft Directives Part 1 as explicit conditions of that founding process.

CH-037 The founding signatories shall execute an adoption instrument only after review dispositions, a governance rehearsal, accepted minimum appointments, and independent assessment of the founding process are recorded. The instrument shall identify each signatory's express agreement, scope of commitment, dissent, outstanding limits, and the exact texts adopted. A person or institution shall not be bound or represented by a signature that lacks actual authority.

CH-038 The founding instrument shall identify the first programme decision authority, its delegated limits, appointment and succession route, and review date. Founding adoption shall not itself approve GR/NWIP-001 or any technical Standard. Subsequent formal adoption and maintenance decisions shall use the applicable ballot and review rules of operative Directives Part 1, distinguishing substantive maintenance from editorial correction and confirmation.

CH-058 The founding review notice shall distinguish the proposed founding signatories from reviewers and commenters, identify the actual resources or functions they can commit, and explain how additional participation or an objection to authority will be considered. A claimed mandate disputed during review shall receive a reasoned disposition before reliance on that mandate.

CH-059 Execution of the founding instrument shall identify the exact agreement accepted by each signatory, any reservation and its agreed effect, verification of assent, and satisfaction of effective conditions. An unsigned field, synthetic signature, or recorded invitation shall not be treated as assent.

8.2 Readiness and decision evidence

CH-026 Each consequential progression, adoption, mandate, or appointment decision shall identify the operative procedure, authority, evidence considered, interests and recusals, alternatives, material objections, reasons, consequences, and review route.

CH-027 A claim of consensus shall include evidence that relevant concerns were considered and that remaining substantial objections received reasoned treatment. Silence, elapsed time, a vote total, or lack of a funded alternative shall not alone establish consensus.

CH-028 Before formal work-item initiation, the governance launch record shall identify the adopted Charter and Directives, committee mandate, ethics and contribution arrangements, public-review route, maintenance and records arrangements, accepted appointments, and an available neutral procedural review route. It shall include the results and dispositions of a governance rehearsal.

CH-029 If neutral review is unavailable for a consequential contested decision, the programme shall defer that disputed progression or adoption decision and record the capacity gap. The programme shall continue research and drafting that do not depend on the contested authority.

CH-060 The governance launch assessment shall classify each required capacity as available and evidenced, limited with a stated consequence, or unavailable. A rehearsal result shall be recorded separately from actual staffing, public review, permissions, and independent-review availability. Unmet mandatory launch conditions shall prevent formal work-item initiation.

CH-061 For a decision involving multiple functions, the decision record shall identify who prepared the evidence, who reviewed it, who decided, and who implements the result. Combined capacities shall be explicit, and the record shall identify which findings depend on independent consideration.

8.3 Amendment and interpretation

CH-030 An amendment to governance shall follow the change and review procedure in Directives Part 1, state its effective date and transition arrangements, and preserve the prior edition. A procedure shall not be changed retrospectively solely to validate a disputed decision.

CH-062 A request to interpret an operative governance provision shall identify the text, affected decision, competing readings, and practical consequences. The governance authority shall publish a reasoned interpretation within its mandate; an interpretation changing authority, eligibility, obligations, or minimum safeguards shall use the amendment procedure rather than operate as an editorial clarification.

CH-063 A governance amendment shall assess pending proceedings and identify the edition governing each transition. A pending participant's opportunity for reply or procedural review shall not be removed by an undisclosed change of rule.

9 Resources and infrastructure

9.1 Funding and expenditure authority

CH-031 The programme shall maintain an inspectable record of material funding, in-kind support, decision-related conditions, and control of essential infrastructure. Restricted details shall have a stated reason for restriction and an accountable reviewer.

CH-032 A funding or hosting arrangement shall not authorize a sponsor to suppress relevant criticism, require adoption of its preferred technical solution, or bypass review. Material changes in support shall trigger a capacity and continuity assessment.

CH-064 Before accepting material support or expenditure commitments, the authorized holder shall record the purpose, amount or nature of support, actual committing authority, conditions, expected benefit, duration, and effect on independence and continuity. A contribution shall not create an undisclosed priority or publication veto.

CH-065 The programme decision authority shall compare planned obligations with available financial, human, technical, and accessibility resources before authorizing an activity. An unfunded essential safeguard or maintenance duty shall be resolved by resourcing, scope reduction, or deferral rather than recorded as an assumed future capacity.

9.2 Custody and continuity

CH-066 The coordinator shall maintain an inventory of essential repositories, identifiers, contact routes, publication locations, build resources, and protected record stores, with accountable custodians, actual access, recovery arrangements, and dependencies on external providers. Sensitive recovery information shall be protected.

CH-067 The responsible custodian shall periodically exercise recovery of essential publication and decision records and record the recovered version, access limitations, failures, and corrective action. The review interval and extent shall reflect identified continuity risks and shall be included in the governance records schedule.

CH-068 Before a change of hosting or custody, the governance authority shall record preservation of identifiers, versions, access restrictions, permissions, and continuity of comment and review routes. Unrecoverable losses shall be disclosed with their effect on pending decisions and publication claims.

10 Records and external relations

10.1 Inspectable institutional history

CH-033 The records custodian shall maintain access to publication status, version history, work scopes, decision reasons, comment dispositions, and correction notices. Protection or deletion of underlying sensitive records shall retain a non-sensitive account of the action and its authority where permitted.

CH-069 The records custodian shall distinguish operative decisions from proposals, superseded decisions, implementation reports, and unresolved questions. Corrections shall link the changed account to the reason and authority, preserving prior material subject to the applicable protection and retention decision.

CH-070 Where a public account omits protected material, the custodian shall record the basis and scope of restriction and the availability of authorized review. The public account shall disclose its limitation without revealing protected existence, identity, or content where that disclosure would defeat protection.

10.2 Liaison, public statements, and agreements

CH-034 An external liaison, pilot, endorsement, submission, or agreement shall identify who is authorized to act, its purpose and limits, and any external institution's actual assent. Participation in the programme shall not be represented as institutional endorsement.

CH-071 An external agreement proposal shall identify the counterparty's actual mandate, authorized programme signatory, commitments and costs, control of resulting material, publication rights, protection duties, review and termination arrangements, and effects on programme independence. Unresolved authority or rights material to the agreement shall prevent execution of the affected commitment.

CH-072 An authorized spokesperson shall distinguish the programme's adopted position from personal analysis, a committee draft, or a policy option. An inaccurate public claim of adoption, affiliation, or representation shall receive a recorded correction through the same relevant communication route where feasible.

11 Oversight, transition, and closure

11.1 Programme review

CH-035 The programme decision authority shall review mission performance, participation gaps, concentrated influence, conflicts, unresolved appeals, review capacity, and maintenance resources at least annually with the programme account required by Directives Part 1 and after a material institutional change. The review shall record remedial actions, owners, and follow-up.

CH-073 The annual governance review shall identify open corrective actions, repeated procedural failures, unresolved capacity gaps, resource concentration, overdue maintenance, and the practical effects of earlier remedies. The authority shall assign owners, review points, and escalation conditions for actions it retains.

CH-074 A material governance failure shall receive an assessment of affected decisions and publications. The governance authority shall record whether renewed participation, independent review, correction, repetition of a stage, or suspension is required; correcting the administrative record shall not alone validate the original decision.

11.2 Transition and orderly closure

CH-075 A transition to institutional or hybrid participation shall identify representation mandates, decision eligibility, related-entity influence, existing participant treatment, resource needs, and appeal independence, and shall undergo Charter amendment before the new model governs decisions.

CH-076 A proposal to suspend or close programme operations shall identify the reason, actual deciding authority, current commitments, pending reviews and complaints, custodial destination of publications and protected records, rights limits, and feasible maintenance or withdrawal arrangements. The transition shall be reviewed under Directives Part 1 before permanent disposition.

CH-077 A closure or suspension notice shall state which activities stop, which publication statuses remain operative or change, the custodian and available contact route, and unresolved matters. It shall not represent loss of operational capacity as erasure of historical decisions or as retroactive cancellation of external uses.

12 Assessment

12.1 Subject, evidence, and findings

CH-078 A governance assessment shall identify the operative or experimentally assessed edition, review period, scope, assessor, interests, and evidence for each applicable Charter requirement. Results shall distinguish fulfilled, not fulfilled, not assessed, and not applicable, with reasons and corrective actions.

CH-079 An assessor shall examine actual records and demonstrated routes relevant to the claim, including appointments, decision authority, access, recusal, independent review, resources, and continuity. A blank template, announced intention, or unperformed rehearsal shall not be accepted as evidence of completed performance.

12.2 Response and follow-up

CH-080 The programme decision authority shall respond to material assessment findings with an action, owner, due or review date, and consequence for dependent decisions. A finding shall be closed only with recorded evidence of the action or a reasoned change of scope, while preserving any unresolved historical effect.

Annex A

(normative)

Minimum governance evidence records

A.1 Common record elements

CH-081 Each governance evidence record shall include a stable identifier, record type, responsible actor, relevant date or interval, applicable governance edition, subject and version, evidence location or access limitation, status, related records, and correction history. Unknown information shall be explicitly identified rather than supplied by inference without attribution.

A.2 Authority and appointment record

The authority and appointment record contains: actual person or body; source and scope of power; accepted capacity; reserved and delegated decisions; start and end or review conditions; interests and management; substitute or vacancy route; contact; and evidence of assent. Where public and protected versions differ, their relationship is identified through the access record.

CH-082 The appointing authority shall maintain the authority and appointment elements in this annex for each operative role and shall update the record when its holder, scope, interests, acceptance, or effective status changes.

A.3 Decision and review record

The decision record contains: question; authority; input editions; evidence and alternatives; participating capacities; conflicts and recusals; material objections and replies; procedure and any ballot reference; reasons; result; conditions; implementation owner; notice; and review route. The review record adds findings, limitations, corrective actions, follow-up dates, and verified completion.

CH-083 The responsible decision maker shall ensure that a consequential decision has the decision and review elements in this annex before it is relied on for progression. Where evidence is restricted, authorized review access and a safe public account shall be identified.

A.4 Continuity and transition record

The continuity record identifies essential resources, their custodians, recovery and access arrangements, test results, dependencies, and unresolved failures. The transition record identifies outgoing and incoming responsibility, transferred obligations, untransferred material, permission limits, notices, and acceptance of custody.

CH-084 The governance authority shall use the continuity and transition elements in this annex when authorizing a transfer, prolonged suspension, or closure and shall record material gaps and their disposition.

A.5 Selection of assessment evidence

CH-085 The assessor shall select evidence appropriate to the requirement using the minimum evidence families in Table A.1. An assessment based on sampling shall identify the population, selection rationale, excluded cases, and limits on conclusions. Documentary completeness shall not replace observation of a route whose actual availability is claimed.

Table A.1 – Governance evidence families and assessment limits

Function	Evidence and method	Limitation requiring separate treatment
Founding and delegation	Inspect actual commitments, mandates, accepted appointments, effective conditions, and edition references.	A signature or role name does not establish authority beyond the scope supported by its recorded basis.
Participation	Inspect notices and accommodation records; exercise public and protected routes with authorized test material.	A working contact route does not demonstrate that affected perspectives were reached or their concerns considered.
Decision and challenge	Trace input versions, objections, replies, reasons, conflicts, independent review, and implementation of remedies.	Procedural completeness does not establish substantive truth or agreement of an absent constituency.
Resources and independence	Inspect support conditions, essential resource control, actual staffing, and response to concentration findings.	Stated independence does not demonstrate that a reviewer is available or free of the relevant interest.
Continuity and records	Observe a permitted recovery exercise and compare restored versions, access controls, identifiers, and unresolved losses.	A successful copy does not establish preservation of meaning, rights, or the ability to resume a pending review.
Transition and closure	Inspect notices, accepted custodial transfer, unresolved commitments, status changes, and accessible contact.	A declared closure does not dispose of external rights or eliminate consequences of earlier programme decisions.

Annex B

(informative)

Application examples and design rationale

B.1 Funding concentration

A prospective host offers free infrastructure subject to exclusive control over publication access. The funding record exposes the condition, while the authority record shows that the host has no adoption power. Review examines an alternative host, portable copies, protected records, and continuity costs. Acceptance depends on resolving the condition consistently with programme independence; the price alone does not determine the result.

B.2 Founding capacity shortfall

Prospective signatories complete draft charters and a synthetic appeal exercise but have no available independent reviewer. The governance assessment records completed drafting and rehearsal separately from missing operational capacity. Source inquiry and document development continue. Formal work-item initiation remains pending until accepted appointments and the actual review route meet the launch requirements.

B.3 Changed representation

A committee participant changes employment during a ballot. The coordinator examines whether the accepted capacity was individual or institutionally mandated and whether the new interest affects recusal or the roster. The applicable Directives determine whether correction requires a restarted ballot. The participant's earlier contribution remains attributed even if their decision capacity changes.

B.4 Basis for the selected model

Open individual contribution lowers initial organizational barriers but can concentrate influence among people able to contribute unpaid time. Bounded appointments, explicit affiliations, assistance routes, and review of missing perspectives address that risk without claiming universal representation. Institutional membership and hybrid chambers remain alternatives requiring demonstrated mandates and administrative capacity.

B.5 Unresolved adoption decisions

OPEN ISSUE Founding signatories, organizational form, actual appointments, neutral-review capacity, operating resources, protected contact routes, and operative contribution terms remain unresolved. This draft supplies the requirements against which their proposed resolution can be reviewed.

OPEN ISSUE The minimum accessibility target, longer-term participation model, and evidence needed to assess societal effects remain subjects for governance and work-item review. The Charter does not assume that successful programme procedure demonstrates restored social trust.

Bibliography

Source and interpretation: Programme Brief, version 0.5; comprehensive development plan, version 0.1; cross-domain programme; foundation traceability map, particularly FT-01 and FT-06. Local paths: `PROGRAMME_BRIEF.md` and `docs/planning/`. These explain the mission and candidate operational direction.

Source and interpretation: Foundation manuscripts: FM-001, `GRE_Chapter_01.pdf`, section 1.14.2–1.14.5, pp. 79–83; FM-003, `GRE_Chapter_03.pdf`, section 3.12, pp. 129–132; FM-005, `GRE_Chapter_05_Complete_First_Draft.pdf`, section 5.18, pp. 150–153. Files are in `foundation_manuscripts/`. These ground the orientation to representational instability, revisable action, and unequal evidential capacities; they do not enact these governance clauses.

Source and interpretation: WTO, Principles for the Development of International Standards, Guides and Recommendations, official presentation of the 2000 TBT Committee decision, consulted 2026-09-22: https://www.wto.org/english/tratop_e/tbt_e/principles_standards_tbt_e.htm. Its treatment of transparency, participation, impartial consideration, relevance, coherence, and resource barriers informs process design. Local requirements and organization are programme proposals, not a claim of WTO recognition.

Source and interpretation: United Nations, National Quality Assurance Frameworks Manual for Official Statistics, 2019: https://desapublications.un.org/publications/united-nations-quality-assurance-frameworks-manual; official overview consulted 22 September 2026. The sector-specific quality-assurance approach informs examination of institutional capacity alongside outputs. Programme governance remains local and does not acquire a national-statistics mandate through this comparison.

Source and interpretation: ISO, Model International Standard, third edition, 2023: https://www.iso.org/iso/model_document-rice_model.pdf. Its formal document organization informs the distinction among front matter, provisions, and annex status. Local scope and authority remain those recorded in this Charter.

GENERATIVITY STANDARDS PROGRAM

Directives Part 1

Governance Working Draft

Version 0.3 2026-09-22

Procedures for Development and Maintenance

WORKING DRAFT FOR REVIEW

This document contains proposed provisions for technical and institutional review. It is not an adopted Standard or an operative governance instrument. Its scope, application conditions and publication status are specified in the text.

Prepared by the Generativity Standards Program. Reference to external publications does not imply endorsement by ISO, IEC, IEEE or any United Nations body.

Foreword

Version 0.3 records the bounded substantive review of the archived 0.2 package. This edition clarifies valid ballots, unsuccessful attributable submissions, nonresponse accounting and retention of an earlier valid ballot; quorum and approval thresholds are unchanged. The review matrix, synthetic assessments and unresolved readiness questions are documented in `docs/reviews/validation_0.2/README.md`. These activities do not constitute adoption or an independent institutional assessment.

This document proposes an executable development procedure for the Generativity Standards Program. Its clauses govern the programme only after explicit governance adoption. It is a **PROVISIONAL Governance Working Draft**, not an adopted Standard, an approved project, or evidence that a committee exists. Its numbered requirements are proposed requirements. A rehearsal can test them without making them operative.

Responsible editor: `UNASSIGNED`. Canonical source: `governance/directives_part_1.tex`. Intended readers are founding participants, procedural administrators, editors, reviewers, affected people, and prospective implementers of the development procedure. The assessed subject is a particular project-development or maintenance procedure and its records, not the substantive truth of a resulting Standard.

This edition expands draft 0.1 while preserving the meaning of D1-001 through D1-058. The additional schedules specify evidence and handling responsibilities rather than constitute programme offices. Draft 0.1 remains a historical publication. The proposed local numerical defaults are unchanged.

Bibliography 23

Introduction

The procedure supports inspectable, revisable recognition and practical action by preserving grounds, alternatives, objections, decisions, and subsequent changes in standards development itself. Its central object is a justified progression decision: who could contribute, what was considered, why a direction was selected, which disagreements remain, and how later correction can occur.

The programme examines standards-development practice without assuming the institutional resources or representative mandate of an established international standards body. Explicit work authorization, documented review, conflict-sensitive decision making, public scrutiny, and maintenance are adapted to actual available capacity. A short procedure can conceal an unavailable role just as easily as an elaborate organizational chart. These Directives consequently make vacancies and failures visible and prevent a document's apparent completeness from substituting for an operative institution.

Public participation and evidential adequacy are related but distinct. A numerical majority cannot establish a substantive fact, and a well-supported technical conclusion does not excuse exclusion from the prescribed process. Standards development can affect access, cost, classification, and future practical possibilities; review therefore examines these consequences alongside implementation and conformance.

1 Scope

1.1 General

These Directives specify development, review, decision, publication, maintenance, and appeal procedures for programme publications. They address officials, editors, contributors, reviewers, affected participants, and assessors. They do not determine the truth of recorded claims, settle GR theory by vote, or confer external legal authority. A procedure assessment identifies its project or decision scope and does not establish programme-wide fulfillment from a single dossier.

2 Normative references

2.1 Draft dependencies

The following companion Governance Working Drafts, version 0.3, provide proposed internal dependencies: the Standards Programme Charter, Directives Part 2, the GR/TC 1 Charter, and the Ethics, Conflict-of-Interest, and Contribution Rights Policy. Their source files are in `governance/`. References are dated to these draft editions for coordinated review; none is represented as adopted. The founding instrument identifies the exact adopted editions and applicable transition arrangements. A dependency change requires review of affected provisions and assessments.

External standards-development and United Nations system publications are informative comparison sources. No external voting rule, institutional mandate, or legal entitlement is incorporated by reference. The programme's own public-review periods and thresholds arise from its governance choice.

3 Terms and definitions

3.1 Operational procedural terms

Governance authority The body or bounded transitional authority constituted by the adopted Charter; its mandate determines which decisions it can take.

Technical committee An actually constituted committee with a bounded project mandate; not a label that itself establishes authority.

Substantive change A change that could alter scope, meaning, duties, permissions, conformance outcomes, interoperability, protection, or practical consequences.

Substantive objection A reasoned concern about technical adequacy, evidence, scope, procedure, rights, participation, harm, or feasibility relevant to the proposed decision.

Consensus assessment A documented assessment of participation, consideration of concerns, remaining disagreement, and grounds for progression. It is distinct from a ballot tally.

Eligible participant A person assigned decision rights under the Charter and recorded for the specific decision; authorship, payment, or attendance alone does not confer those rights.

Calendar day A day counted using the closing time and time zone stated in the notice. A notice states an exact closing timestamp.

4 Founding, responsibilities, and participation

4.1 General

D1-001 The programme shall apply the adopted Charter for decision authority and appointments, these Directives for development procedure, Directives Part 2 for drafting, and the adopted Ethics, Conflict-of-Interest, and Contribution Rights Policy for conduct, conflicts, and rights. A conflict between these instruments shall be referred to the governance authority and resolved before a dependent decision proceeds.

D1-002 Every procedural decision shall identify its accountable decision maker, operative authority and procedure versions, input document versions, grounds, outcome, date, and review or appeal route. Drafting, a repository merge, an ADR, or successful compilation shall not constitute governance adoption or Standard approval.

D1-003 An organizational function without an appointed holder and recorded mandate shall remain `UNASSIGNED`. Formal project initiation and adoption shall remain pending while required authority or an independent appeal route is unavailable. Preliminary research, drafting, and synthetic rehearsals may continue with explicit status labels.

D1-004 Before formal standards-project approval, the founding adoption record shall identify the founding basis, adopted governance texts and versions, participants and capacities, decision method, dissent, transitional limits, review date, and replacement route. Governance adoption shall follow the founding procedure recorded under the Charter, rather than assume that these draft Directives have already authorized themselves.

D1-005 The governance authority shall assign oversight, project progression, public-review administration, release, maintenance, conflict handling, and independent appeal functions. The assignment register shall identify holders, terms, delegated limits, substitutes, and contact routes. Combined roles shall be disclosed; an interested decision maker shall not determine their own procedural appeal.

D1-006 The Secretariat shall maintain an accessible work programme and participation route. A project notice shall identify the problem, scope, current status, available documents, contribution terms, comment routes, decision roles, and intended review dates. Public comment shall not require voting membership or endorsement of the proposal.

D1-007 The review chair shall document outreach to affected interests and relevant expertise, participation barriers, affiliations relevant to dominance, and remaining gaps. The chair shall provide an asynchronous contribution route and record requested accessibility or language accommodations and the response. Lack of response shall not be recorded as consent.

D1-008 Before a formal decision, the chair shall confirm current conflict declarations and apply the adopted recusal procedure. The record shall identify recusals and their effect on eligibility and quorum without disclosing protected details unnecessarily. If conflicts prevent a valid decision or impartial review, progression shall be deferred.

NOTE 1 Participant eligibility and appointment belong to the Charter; conduct and contribution permissions belong to the Ethics, Conflict-of-Interest, and Contribution Rights Policy. These Directives do not grant membership, impose a license, or establish a legal entity.

5 Project initiation and scope control

5.1 General

D1-009 A New Work Item Proposal shall identify purpose, intended users and affected people, publication class, bounded deliverables, exclusions, proposed conformance subjects, alternatives to new standardization,

source basis, dependencies, review expertise, pilot evidence, resource needs, and prospective maintenance responsibility.

D1-010 The proposal shall explain how the work addresses warranted recognition or generative trajectory and identify epistemic assumptions, ethical impacts, legal and institutional boundaries, public-policy implications, accessibility, protection needs, and distribution of recording and implementation burdens. A claimed institutional mandate shall identify its source and limits.

D1-011 The technical committee shall begin with the normative problem and assessment needs. A dependent Specification proposal shall identify the draft requirements requiring reusable technical infrastructure, the implementation alternatives, and intended tests. A protocol proposal shall additionally identify actors, interactions, states, transitions, outcomes, failure handling, and authority boundaries.

D1-012 The authorized project decision maker shall record accept, revise, defer, or reject, with reasons, scope, assigned responsibilities, dependencies, and review milestones. A coordinated proposal shall retain a separate bounded scope and progression record for each deliverable. A technical dependency shall not acquire Standard status through inclusion in a proposal.

D1-013 A proposed expansion beyond approved scope shall receive impact review and an explicit scope decision before dependent progression. A Specification intended for promotion to a Standard shall enter an explicit standards-track proposal and the applicable review stages; technical stability alone shall not authorize promotion.

5.2 Proposal handling and accountable capacity

D1-059 The Secretariat shall register a proposal with an identifier, receipt date, proposer, proposed class, scope version, and handling status. It shall acknowledge receipt within seven calendar days and identify the authority responsible for scheduling its consideration. An incomplete proposal shall receive a specific request for information or a reasoned deferral; registration shall not confer project approval.

D1-060 Before accepting a project, the decision authority shall verify that the editor and maintenance owner accept their responsibilities, required review competence can be obtained, the resource estimate includes participation and protection work, and the work plan states review dates and capacity limits. An unfilled essential role shall be resolved through assignment, a narrower scope, or deferral, rather than entered as an assumed resource.

D1-061 The project register shall distinguish proposed, active, suspended, closed, and completed work and retain the reason for a change of status. A proposer may withdraw a proposal before authorization; withdrawal shall preserve its record and relevant unresolved issues. Suspension or closure of approved work shall be authorized with affected-participant notice and a disposition of dependencies, contributions, and remaining records.

NOTE 1 Acceptance authorizes bounded work, not its expected conclusion. A negative pilot or a well-supported decision that standardization would add excessive burden can justify scope reduction or closure. A sponsor's preferred implementation remains an alternative to evaluate rather than the implicit criterion of success.

6 Stages and progression evidence

6.1 General

The following codes are the programme's local lifecycle. They retain the repository's grouping of review, revision, and withdrawal under stage 90. Specifications have separately declared maturity; stage 60 is reserved here for adopted Standards.

Table 1 – Local development stages and progression evidence

Stage	Local status	Evidence for progression
00	Preliminary	Need, preliminary sources, alternatives, and draft NWIP; no project authority presumed.
10	Proposal	Approved bounded scope, capacity, assignments, dependencies, and review plan.
20	Working Draft	Candidate clauses, source and decision traceability, assessment methods, and example or pilot design.
30	Committee Draft	Integrated requirements, review findings and dispositions, pilot evidence and limitations, proposed public-review package.
40	Public Review Draft	Versioned notice, accessible draft, comments and responses, material-change review, and remaining objections.
50	Final Approval Draft	Frozen approval package, consensus assessment, valid ballot, procedural checks, and appeal handling.
60	Published Standard	Recorded adoption and release authorization, verified publication package, maintenance owner and next review date.
90	Review / revision / withdrawal	Issue and impact evidence; recorded confirmation, correction, amendment, revision, supersession, or withdrawal.

D1-014 Each progression decision shall state the current and proposed stage, evaluate the relevant evidence, identify remaining limitations, and record approval, return for revision, deferral, or closure. A stage label shall not substitute for the decision record. No Standard shall skip public review or final approval by claiming that a prototype or pilot already establishes acceptance.

D1-015 The editor shall retain versioned drafts, a requirement-to-source and assessment map, an issue register, and substantive decision records identifying alternatives, selected direction, rationale, and affected artifacts. GR interpretation shall use relevant foundation manuscripts and preserve unresolved source differences; operational narrowing affecting architecture shall have an ADR.

D1-016 At committee review, named reviewers shall evaluate epistemic adequacy, practical usability, ethical and distributional effects, accessibility, preservation and protection, legal/institutional boundaries, and technical feasibility within declared competence. Missing expertise or evidence shall be reported and resolved, or the scope narrowed, before unsupported requirements advance.

D1-017 Pilot reports shall identify the tested versions, cases and negative cases, methods, participants' roles, failures, burdens, limitations, and resulting changes. Synthetic or author-operated tests shall be labelled accordingly. External institutional participation, access authority, independent validation, and legal validity shall not be inferred from a synthetic rehearsal.

6.2 Stage controls and project records

D1-062 The project lead shall assemble the entry and exit evidence specified in Annex A before requesting progression. The decision authority shall record its assessment of each applicable item, the evidence locator, responsible reviewer, result, and any required action. An inapplicable item shall have a scope-based reason; unperformed work or unavailable evidence shall not be recorded as fulfilled.

D1-063 A Working Draft shall identify open design alternatives and any unresolved requirements or dependencies. A Committee Draft shall integrate the selected proposal, source rationale, assessment method, and issue disposition sufficiently for a reviewer who did not participate in authoring. Neither designation shall imply that open issues have disappeared merely because the document has been renumbered.

D1-064 Before public review, the chair shall verify that applicable requirements have identified conformance subjects and assessment methods, examples are distinguished from obligations, material pilot failures are visible, and unresolved issues are bounded. A requirement whose interpretation depends on unavailable material or an unsettled contradiction shall be revised, narrowed, or withheld from the proposed normative scope.

D1-065 A coordinated package shall identify authoritative locations for shared requirements, exact dependency versions, change propagation responsibilities, and release sequencing. The responsible editors shall assess a material dependency change against affected scopes, tests, examples, and users before progressing any dependent release. Circular references shall not be used to conceal an unassigned obligation or unsupported conformance claim.

D1-066 A meeting used for a consequential decision shall have prior notice, an agenda and accessible materials, an assigned chair, identified participants and capacities, declared conflicts, and a decision record. A person unable to attend shall have the declared asynchronous opportunity to contribute before the decision closes. Meeting attendance alone shall not replace the prescribed ballot, public review, or reply period.

D1-067 The chair shall circulate a proposed decision record for correction of factual inaccuracies and attribute unresolved corrections before using it as progression evidence. An editorial correction to minutes shall not alter the decision taken; a proposed change to that decision shall use the relevant reconsideration or new-decision procedure. The register shall distinguish a proposal, recommendation, authorization, and completed action.

7 Public review and comment disposition

7.1 General

D1-018 Before opening public review, the chair shall freeze a uniquely identified draft and publish its scope, class, maturity, change summary, dependencies, known limitations, review questions, exact opening and closing times, submission routes, and intended treatment of commenter information. Required supporting material shall be accessible to reviewers under workable terms.

D1-019 Public review shall remain open for at least 60 calendar days. The chair shall record outreach, access interruptions, and accommodation needs; a material access failure shall receive an extension sufficient to restore meaningful opportunity, with reasons and revised closing time published.

D1-020 The Secretariat shall accept comments in an accessible free-text route as well as any structured template. It shall assign a stable identifier, record the affected version or topic, requested change if supplied, receipt date, and disclosure preference, and acknowledge receipt within seven calendar days. A comment shall not be rejected solely for lacking technical drafting expertise.

D1-021 The Secretariat shall offer a protected route for justified confidential submissions and explain its access limits. The chair shall arrange competent consideration and publish a safe summary of the issue and disposition where possible. If essential grounds cannot be exposed sufficiently for fair review, the chair shall record the limitation and defer or narrow the affected decision.

D1-022 The responsible review group shall give every in-scope comment a disposition of accepted, accepted with modification, not accepted, or deferred, with reasons and links to affected clauses or issues. Out-of-scope and duplicate comments shall retain identifiers and a reason or linked disposition. Deferral shall identify an owner, next action, and why the unresolved issue does not invalidate proposed progression.

D1-023 The chair shall target initial dispositions within 30 calendar days after review closes. If that target cannot be met, the chair shall publish reasons, interim status, and a new target before it expires. A

target extension shall not deem comments resolved. Commenters shall receive disposition notice and at least 30 calendar days to reply before final approval.

D1-024 The chair shall assess each reply and record remaining disagreement. Late comments shall be logged with reasons for current-cycle consideration or later referral; a newly identified material safety, rights, or validity defect shall receive assessment before adoption regardless of receipt date.

D1-025 A substantive post-review change shall undergo public re-review for at least 30 calendar days, showing the changed text, reasons, effects, and affected dependencies. The chair shall notify previous commenters and newly affected interests. A change that substantially alters the purpose, affected constituency, or conformance subject shall receive renewed scope approval and a full 60-day review.

D1-026 Re-review shall permit comments on changed material and its consequences for unchanged clauses. Further substantive changes shall repeat the applicable review. Editorial changes shall be logged with a reason why meaning and conformance remain unchanged.

7.2 Comment register and review administration

D1-068 The Secretariat shall maintain the comment and disposition register specified in Annex B. A combined response may address duplicate issues only if each original comment remains traceable and its distinct material grounds are considered. Splitting a submission into issues shall preserve the connection to its original meaning. Summary statistics shall not substitute for the disposition of an unresolved substantive concern.

D1-069 A review closure record shall identify the exact closing time, submissions received, submissions awaiting acknowledgement or clarification, late submissions, access failures, extensions, and next steps. The chair shall distinguish closure of intake from completion of dispositions. The count of unresolved comments shall not become zero merely because the public submission window has closed.

D1-070 For each proposed disposition, the review group shall identify the responsible respondent, material evidence, affected requirements, reason, resulting text or decision, and review required by the change. A not-accepted disposition shall address the substantive grounds rather than rely solely on lack of votes, institutional rank, drafting inconvenience, or an unsupported assertion that the issue was already settled.

D1-071 If a submission includes conduct allegations or protected information together with a technical objection, the Secretariat shall separate access and handling while retaining a safe cross-reference. The technical issue shall continue to receive consideration unless a recorded reason requires a stay. Protected reporting shall not confer permission to publish personal details in the public disposition register.

D1-072 When sending a disposition or re-review notice, the Secretariat shall record its intended recipients, authorized route, content version, dispatch time, and known delivery failures. Where a material failure prevents meaningful reply, the chair shall provide a workable alternative or extend the affected reply opportunity and record the resulting progression consequence. A failed delivery shall not be represented as silence by the recipient.

NOTE 1 A long review period does not demonstrate effective participation if a relevant person could not obtain the text, understand the submission route, or receive a response. Accessibility and outreach are assessed through the record of practical barriers and responses, not inferred from the existence of a public URL.

8 Consensus, ballots, and final approval

8.1 General

D1-027 Before recommending progression, the chair shall produce a consensus assessment identifying participation and gaps, objections, attempts at resolution, evidence and alternatives considered, remaining dissent, and reasons for the recommendation. Numerical approval shall not establish substantive truth or by itself dispose of an objection.

D1-028 A sustained substantive objection shall receive reasoned consideration and an opportunity for reply. It shall not automatically confer a veto. Unresolved defects in mandatory procedure, decision authority, rights to participate, or required evidence shall prevent progression until remedied. Other remaining disagreement shall be visible in the approval package and assessed by the authorized decision maker.

D1-029 For adoption, substantive maintenance decisions, and other decisions assigned a formal ballot by the Charter, the Secretariat shall circulate a frozen package and proposed resolution for at least 30 calendar days. It shall state eligible participants, recusals, closing time, threshold calculation, ballot options, and challenge route. Ballots shall be approve, disapprove, or abstain; nonresponse shall be recorded separately.

D1-030 The eligible non-recused roster shall be fixed before ballot opening. Each eligible person shall have one ballot in their declared capacity; proxies and duplicate capacities shall not count. Eligibility corrections or later recusals shall be recorded. A change materially affecting the electorate, quorum, or result shall require a new ballot; membership shall not be manipulated to obtain a desired outcome.

D1-031 Let N be the number of eligible non-recused participants, R valid returned ballots including abstentions, Y approvals, and D disapprovals. A ballot shall meet quorum only if $R \geq \lceil 2N/3 \rceil$. Approval shall also require at least three substantive ballots, $Y + D \geq 3$, and $Y \geq \lceil 2(Y + D)/3 \rceil$. Abstentions shall count for returned-ballot quorum but not the substantive-ballot minimum or approval denominator; nonresponses shall count for neither.

D1-032 The result shall include the frozen roster count, recusals, valid returned ballots, approvals, disapprovals, abstentions, eligible participants with attributable excluded or unresolved attempted submissions but no valid counted ballot, eligible participants without an attributable submission, calculation, minority grounds, and decision. The reconciliation shall distinguish $R = Y + D + A$, I eligible participants with such unsuccessful attempts and no valid counted ballot, and U eligible participants without an attributable submission, with $N = R + I + U$. Unattributable and ineligible submissions shall have a separate protected inventory and shall not be assigned to an eligible participant without grounds. Failure of quorum or threshold shall return the matter for further work or deferral, without deemed approval. A substantive change during ballot shall return to the applicable review stage.

D1-033 Final approval shall require a procedurally valid ballot, reasoned consensus assessment, completed dispositions and reply periods, resolved blocking findings, compatible normative dependencies, rights clearance, maintenance assignment, and an authorized adoption record. The Secretariat shall publish accessible decision notice, notify participants and commenters, and record when the appeal period starts. Release shall await that period and resolution of any appeal affecting adoption or publication.

OPEN ISSUE All numerical values in this draft are local proposals requiring author and participant review before governance adoption. They are not ISO/IEEE rules. A valid three-person ballot does not itself demonstrate stakeholder breadth or independent review capacity; the informative defaults annex identifies these participation-risk choices for explicit review.

8.2 Ballot administration and authorization

D1-073 The ballot notice shall include the exact resolution, frozen text and associated artifacts, consensus assessment, dispositions, remaining objections, eligibility basis, and required calculation. The Secretariat shall provide each eligible person a means to submit one attributable ballot without disclosing unnecessary personal information and shall identify a neutral route for challenges to ballot administration.

D1-074 A participant may replace their own ballot before the declared closing time; the Secretariat shall count only the latest valid submission and retain a protected audit of the replacement. An ambiguous or unverifiable submission shall receive a clarification request and shall not be silently converted to approval or abstention. The last valid submission shall remain counted unless withdrawn or invalidated under an identified applicable rule. A participant with a valid counted replacement shall not also be counted in the unsuccessful-attempt category in D1-032. Ballot validity decisions shall identify the rule applied, grounds, clarification status and available challenge route; unresolved validity shall not be relabelled as absence of an attempted submission.

D1-075 A ballot extension shall be announced before the original close, state the access or participation reason and new closing time, and apply equally to the eligible electorate. An extension shall not change the resolution or threshold or be used solely to solicit a desired result. A frozen package requiring substantive change shall be withdrawn from ballot and returned to applicable review.

D1-076 A non-conflicted person other than the person compiling the tally shall verify eligibility counts, duplicate or replacement handling, recusals, arithmetic, and the consistency of the declared result with the frozen resolution. The verification record shall identify any unresolved discrepancy. A numerical pass with an unresolved blocking procedural finding shall not authorize adoption.

D1-077 The adoption or release authorization shall identify the approved publication class and edition, resolution, vote result where required, consensus rationale, authority exercised, effective date, appeal notice, and conditions affecting release. The release owner shall distinguish this authorization from compilation, distribution, and commencement of an institution's use. An institution's uptake shall not be inferred from programme publication.

9 Procedural appeals and separate complaint routes

9.1 General

D1-034 A participant, commenter, or person directly affected by a programme decision may lodge a procedural appeal identifying the decision, alleged procedural failure, available evidence, and requested remedy. Membership or payment shall not be a condition. The ordinary filing period shall be 30 calendar days after accessible notice of the decision; lack of effective notice or newly discovered concealed procedural failure shall permit a reasoned extension by the independent reviewer.

D1-035 The Secretariat shall acknowledge an appeal within seven calendar days and refer it to an appointed reviewer independent of the disputed decision. The reviewer shall disclose relevant involvement and interests, consider conflict objections, and record independence. The decision's author, a materially interested participant, or a person deciding a related complaint about their own conduct shall not determine the appeal.

D1-036 The reviewer shall state scope, admissibility reasons, record access arrangements, and timetable; provide the appellant and responsible decision maker a meaningful opportunity to reply; and issue a reasoned determination. An initial determination shall be targeted within 30 calendar days of receipt, with reasoned extensions and updated dates notified before expiry. No response or elapsed time shall constitute rejection.

D1-037 An appeal concerning adoption, public-review exclusion, or authority shall pause the affected publication decision. Other appeals shall receive a recorded decision on whether a stay is necessary to prevent prejudice. If no independent reviewer is available, consequential contested progression shall remain pending while unaffected work continues.

D1-038 The reviewer may uphold the process, require disclosure or correction of records, set aside a procedurally defective decision, or remit the matter for renewed participation, review, or ballot. The reviewer shall not substitute a ruling on factual truth, external legal entitlement, or technical merit for procedural review. The accountable body shall record implementation of the remedy before renewed progression.

D1-039 Technical reconsideration, conduct complaints, record-specific access or correction requests, and external legal remedies shall have distinguishable routes. Misrouted submissions shall receive assisted referral rather than silent rejection. Protected conduct handling shall follow the adopted ethics policy; disagreement alone shall not be treated as misconduct. Internal review shall not be presented as replacing external rights or remedies.

9.2 Appeal case management

D1-078 An appeal record shall identify the challenged decision, appellant or protected reference, grounds, requested remedy, receipt and notice dates, admissibility assessment, appointed reviewer, disclosed conflicts, participation opportunities, stay status, outcome, reasons, and implementation responsibility. Refusal to admit an appeal shall receive reasons and the same independence safeguards as a determination on its merits.

D1-079 The reviewer shall distinguish an objection to the substantive proposal from an allegation that the operative process was not followed. A submission containing both shall receive coordinated handling without forcing the appellant to abandon either ground. A procedural remedy shall identify which decision or stage is affected and what evidence is required before the stay can be lifted.

D1-080 A protected appeal shall give each affected party sufficient grounds and opportunity to respond for the determination being made. If disclosure limits prevent fair determination, the reviewer shall narrow the finding, obtain an authorized independent examination, or defer with stated reasons. Confidentiality shall not be described as proof that the undisclosed account is correct.

D1-081 The Secretariat shall track implementation of an appeal remedy and provide the appellant with its status through the permitted route. A remitted decision shall cite the appeal and demonstrate completion of the required reconsideration or repeated stage. Closing the appeal file shall not establish that a correction, new review, or practical remedy has been completed.

NOTE 1 Repeated submissions of the same disposed procedural point can be consolidated with an explanation and a preserved reference. Newly available evidence, a different material procedural failure, or alleged nonimplementation of a remedy requires an assessment of whether the case should be reopened; a previous closure is not a universal bar.

10 Publication and release integrity

10.1 General

D1-040 The release owner shall verify that the exact publication package implements the approved text and decision. The package shall identify edition, date, class, maturity, adoption authority, conformance scope, dependencies, licenses or permissions, known limitations, maintenance contact, next review date, and superseded publications where applicable.

D1-041 The release manifest shall identify authoritative source files, rendered publications, schemas or fixtures where included, their versions and integrity checks, build instructions and tool versions, and

the approval record. A reviewer other than the final editor shall compare the rendered output with the approved source for omitted, altered, or unreadable requirements and record the result.

D1-042 The release owner shall resolve source/build discrepancies before release. Source corrections affecting meaning shall return to substantive review; a rebuild shall not silently change an adopted requirement. Public notices shall distinguish an adopted Standard, a Specification, an informative publication, and a policy recommendation and shall not claim ungranted endorsement or certification.

10.2 Release dependencies and distribution

D1-082 Before release, the owner shall complete the release register in Annex B, including dependency availability, permission basis, source/render verification, accessibility limitations, unresolved issues, appeal status, distribution locations, and withdrawal contact. A dependency that is unavailable on usable terms shall trigger scope revision or deferral rather than an unsupported interoperability claim.

D1-083 A corrected build or accessible alternative representation shall identify its relationship to the approved edition and whether substantive content is unchanged. Where two representations disagree, the owner shall issue a notice, determine the approved content from the decision record, and correct the affected artifacts under the applicable change procedure. A hidden preference for the newest file shall not resolve normative disagreement.

11 Maintenance, review, and withdrawal

11.1 General

D1-043 Every release shall have an assigned maintenance owner, issue intake route, and next review date. The default review interval shall be two years, shortened by a recorded risk-based decision. Loss of ownership, serious defects, changed dependencies, inaccessible implementation rights, or evidence of material exclusion or harm shall trigger earlier review. An overdue review shall be publicly marked and escalated; silence shall not confirm continued suitability.

D1-044 The maintenance owner shall log reported issues, classify their effect, identify affected versions and dependencies, and publish disposition or investigation status. A correction request shall not be rejected merely because the reported behavior matches the current text.

D1-045 A corrigendum shall correct an error without introducing a new obligation, altering intended meaning, or changing a valid conformance outcome. It shall identify the affected text, corrected text, justification, reviewer, and authorization. If semantic effect is uncertain, the change shall use the amendment or revision route. Historical publications shall remain identifiable rather than silently overwritten.

D1-046 An amendment shall make a bounded substantive change to a named edition; a revision shall issue a consolidated new edition. Both shall receive scope approval, assessment of dependent artifacts and users, appropriate pilots, committee and public review, and final approval under these Directives. An incompatible change shall include migration, coexistence, and deprecation information without claiming lossless conversion absent evidence.

D1-047 Periodic review shall invite evidence from users and affected parties and record confirmation, correction, amendment, revision, supersession, or withdrawal with reasons. Confirmation shall require a maintenance report and an authorized decision; it shall not erase known limitations.

D1-048 Proposed withdrawal or supersession shall receive a public notice of reasons, dependencies, transition consequences, and alternatives for at least 60 calendar days, followed by comment disposition, reply, and formal approval. Withdrawn editions shall remain identifiable with status and date; withdrawal

shall not retroactively change what a past conformance claim asserted. Necessary protection of underlying records shall follow D1-052, D1-053, and EIP-039.

11.2 Maintenance decisions and compatibility

D1-084 An issue assessment shall distinguish editorial error, conflicting requirements, implementation defect, changed external dependency, emerging misuse or harm, accessibility failure, and proposed new scope. The maintenance owner shall state the affected editions, current mitigation, evidence required, accountable next action, and review date. Classification shall be reconsidered when new evidence changes the issue's substantive effect.

D1-085 A proposed corrigendum shall be reviewed by a person other than its editor against examples and known conformance outcomes material to the correction. If the parties disagree whether meaning changes, the owner shall preserve the disagreement and use substantive review unless the uncertainty is resolved with recorded grounds. Issuing a corrected file shall not erase the original published error and its applicability interval.

D1-086 An amendment or revision proposal shall assess current users, dependencies, historical records, version negotiation, migration losses, and coexistence needs. The approval record shall distinguish prospective requirements from statements about previous editions. A deprecated feature shall have a reason, affected scope, intended alternative, and transition notice; deprecation alone shall not retroactively change an earlier conformance result.

D1-087 A confirmation decision shall identify the review evidence, known limitations, current maintenance capacity, dependency status, and next review date. If review cannot establish continued suitability, the authority shall select further investigation, narrowing, revision, suspension of programme recommendations, or withdrawal rather than confirm by default. A dormant publication shall remain findable with its actual status.

12 Emergency safeguards and continuity

12.1 General

D1-049 An authorized governance or release holder may issue a time-limited warning or suspend programme distribution or programme recommendations for new use where a documented serious protection, rights, or integrity risk requires immediate action. The action shall state evidence, scope, authority, duration, contact, affected users, and safe public reasons. It shall remain within programme authority and shall not create or amend normative requirements or purport to invalidate external legal decisions.

D1-050 Emergency action shall receive independent review within seven calendar days and expire within 30 calendar days unless the governance authority records a justified extension, next review date, and remedy plan. Unavailable independent capacity shall not authorize emergency adoption. Permanent amendment or withdrawal shall follow the ordinary procedure; protective handling of unlawfully or improperly disclosed material remains governed by the applicable policy and context.

D1-051 A vacant role shall trigger recorded reassignment within the Charter's mandate or deferral of dependent decisions. A temporary substitute shall meet the same conflict and independence conditions. Emergency procedure shall not be used to avoid consultation because ordinary development is late or under-resourced.

12.2 Incident follow-up

D1-088 The owner of an emergency action shall maintain an incident record identifying the triggering evidence, protection decision, consultations, users notified, independent review, expiry or extension, and restoration criteria. At closure, the governance authority shall assess whether ordinary maintenance, a procedural amendment, or further support is needed and publish permitted reasons. Repetition of temporary measures shall not conceal an unresolved need for substantive review.

13 Records, transparency, and external liaison

13.1 General

D1-052 The Secretariat shall preserve linked proposal, draft, comment, disposition, decision, ballot-result, appeal-outcome, release, and maintenance records. Public readers shall be able to follow the grounds and changes of a decision without mandatory access to private correspondence. Record corrections shall retain the prior account and correction relationship where lawful and appropriate.

D1-053 A records schedule shall state purpose, custodian, access category, retention period or trigger, restriction review, and authorized disposition for each record category. Public publication history and safe decision reasons shall be retained durably; sensitive submissions and personal data shall not be retained indefinitely by default. A restriction or deletion shall preserve a safe explanation when permitted, without revealing protected existence or identity.

D1-054 The governance authority shall publish an annual account of active work, decisions, unresolved objections, participation gaps, funding influence, overdue maintenance, and procedural incidents at a level that protects affected people. The account shall distinguish claimed representation from evidenced participation.

D1-055 External liaison shall have an explicit mandate identifying purpose, authorized speaker, commitments permitted, and reporting duties. A policy proposal shall identify its intended institution and review route and remain recommendatory. Liaison, use of external sources, and informal participation shall not imply affiliation, institutional endorsement, or adoption of another body's procedures.

13.2 Publication routes outside Standard adoption

D1-056 Before external release of a Specification or informative publication, the responsible authority shall approve a work-item review plan identifying publication class, maturity criteria, release authority, reviewers and needed competence, public-comment arrangements and period with rationale, objection disposition, appeal route, maintenance responsibility and rights clearance. The release record shall identify fulfillment and remaining limitations. Drafting alone shall not constitute that approval.

D1-057 A Specification release containing technical conformance requirements shall use the technical review, public review, disposition, ballot and appeal rules in this Part, while retaining Specification status and its declared maturity. Its release shall not use stage 60 or imply Standard adoption. Promotion shall require an explicit Standard work-item and adoption decision with review of changed scope, requirements and prior evidence.

D1-058 A Policy or Institutional Proposal shall receive a separate mandate-specific release decision identifying its intended addressee, institutional and affected-interest review, public-comment opportunity, considered alternatives and unresolved objections. Its review plan shall preserve a reasoned disposition and the procedural appeal route in this Part. An informative report or manual shall likewise identify its review and release decision without claiming technical Standard conformance authority.

13.3 Procedure assessment and continuing improvement

D1-089 An assessment against these Directives shall identify the procedure, project and decisions covered, operative or rehearsal editions, assessor and relationship, methods, evidence, and results for every applicable requirement. Documentary checks and observation of performed procedures shall be distinguished. An unobserved action shall remain not assessed when only a designed form or hypothetical record is available.

D1-090 The governance authority shall review procedural failures and participant feedback for recurring barriers, delay, concentrated influence, unavailable remedies, or unmanageable burden. The review shall identify corrective actions, owners, and follow-up evidence. A procedural amendment shall itself follow the Charter's review and transition rules and shall not retrospectively validate a defective decision.

Annex A

(normative)

Stage evidence and procedural schedule

A.1 General

This annex defines the evidence schedule invoked by D1-062. The stage labels apply to Standards-track development; D1-056 through D1-058 define how other publication classes use the applicable controls without acquiring Standard status. Evidence can be held in one coordinated dossier with references rather than duplicated in separate files.

D1-091 The stage dossier shall identify each scheduled evidence item, its location and version, custodian, access limitations, assessment result, and unresolved action. An item may be reused from an earlier stage when the responsible reviewer confirms that its scope and evidence remain applicable. Reuse shall not imply that a later change has been reviewed when it has not.

Table A.1 – Required stage-entry and exit evidence

Stage	Entry and work evidence	Exit and failure disposition
00	Identified problem, preliminary sources, affected interests, and alternatives, including reuse or no new publication.	A registered proposal with limitations; preliminary work retains that label if authority, need, or capacity is not established.
10	NWIP scope, class, conformance subjects, source questions, dependencies, impact and participation analysis, planned evidence and resources.	Authorized scope and accepted assignments, maintenance responsibility, review milestones, and decision rationale; incomplete capacity produces revise or defer.
20	Approved scope and candidate requirements, definitions, source map, ADRs for architectural choices, and assessment design.	Integrated Working Draft suitable for committee examination, with open issues, examples, and planned pilot; an editor's preference alone does not close an unresolved material issue.
30	Reviewer assignments and competence; integrated draft; pilot or other relevant evidence; dependency and rights review.	Committee findings and dispositions, horizontal review, known limitations, exact public-review package and outreach plan. Unsupported requirements return for revision or narrower scope.
40	Frozen Public Review Draft, available dependencies and evidence, notice, submission and protection arrangements.	Comment register, dispositions, replies, required re-review, remaining objections, and consensus assessment. A materially changed text does not advance on comments about its predecessor alone.
50	Frozen Final Approval Draft, eligibility and conflict records, completed review dossier, final resolution and maintenance proposal.	Verified valid ballot, authorized decision, notice and appeal record, resolved release blockers. A failed threshold returns to work or deferral rather than automatic withdrawal of the dissent.

Stage	Entry and work evidence	Exit and failure disposition
60	Release authorization and closed appeal conditions; exact source, render and artifact manifest; accessible status and terms.	Publication notice, maintenance route, next review date and archived decision trace. A build discrepancy prevents release until the applicable corrective process is complete.
90	Issue intake, usage and impact evidence, dependencies, maintenance capacity and review notice.	Reasoned confirmation, correction, amendment, revision, supersession or withdrawal. Substantive changes return through applicable stages; current limitations stay visible during investigation.

A.2 Timing and clock records

D1-092 Every notice governed by a period in Table A.2 shall state the starting event, time zone, closing timestamp, responsible function, extension rule, and next route if the period is missed. The period shall be measured from effective accessible notice or the specified receipt event. A changed closing time shall remain traceable to the prior notice and its reason.

Table A.2 – Local procedural periods and their effect

Action	Proposed period	Meaning and controlling requirement
Proposal, comment, appeal acknowledgement	Within seven calendar days of receipt	Receipt response; not acceptance of the substantive claim. D1-020, D1-035, D1-059.
Initial public review	At least 60 calendar days	Minimum opportunity; access failures can require extension. D1-019.
Material re-review	At least 30 calendar days	Full 60-day review when purpose, constituency, or conformance subject changes substantially. D1-025.
Initial comment disposition	Target 30 calendar days after close	Reasoned extension and updated target before expiry; no deemed resolution. D1-023.
Reply to dispositions	At least 30 calendar days before approval	Material reply assessed; renewed review where resulting change requires it. D1-023/024.
Ballot	At least 30 calendar days	Frozen resolution and roster; controlled extension or restart. D1-029/075.
Ordinary appeal filing	30 calendar days after accessible notice	Reasoned extension for ineffective notice or newly discovered concealed failure. D1-034.
Initial appeal determination	Target 30 calendar days from receipt	Independent handling and reasoned extensions; silence is not rejection. D1-036.
Maintenance review	Default two years	Earlier risk-based review; annual governance review remains separate. D1-043 and Charter.

Action	Proposed period	Meaning and controlling requirement
Withdrawal notice	At least 60 calendar days	Disposition, reply and formal approval follow; an emergency warning is distinct. D1-048.
Emergency review and expiry	Review within seven; expiry within 30 calendar days	Extension requires recorded reasons, next review, and remedy plan. D1-050.

D1-093 A missed acknowledgement or target date shall remain visible as a procedural event with reason, effect, corrective action, and notice to permitted recipients. An extension shall not erase the missed service obligation or cure exclusion retrospectively. An unresolved failure material to fair consideration shall prevent dependent progression until remedied.

Annex B

(normative)

Registers and minimum decision records

B.1 General

The schedule below defines record content, not a mandatory database schema. A protected locator can replace publicly identifying detail when the accountable custodian and basis remain available for authorized review. The applicable retention schedule determines what survives; the record of a disposition does not itself authorize indefinite preservation of its underlying sensitive evidence.

D1-094 The Secretariat shall maintain the registers in Table B.1 for applicable activities. Each record shall have a distinguishable reference, version or correction relationship, responsible custodian, creation time, and permitted access scope. A shared register may satisfy several functions if each required distinction remains retrievable.

Table B.1 – Minimum procedural register contents

Register	Required content in addition to common identification and custody
Work and scope	Need; proposer; class; current scope; exclusions; dependencies; status; assignments; resources; milestones; changes; decision and affected projects.
Roles and eligibility	Accepted capacity; mandate; term; criteria; nomination and selection reasons; interests; recusals; substitute; decision-specific eligibility; challenge and disposition.
Issues and alternatives	Source or trigger; affected clauses; materiality; alternatives; evaluation; selected direction; rationale; remaining uncertainty; affected artifacts; owner and next action.
Comments and dispositions	Submission and issue references; target version; grounds; requested change if supplied; receipt; protection preference; response; reasons; changed text; reply; remaining disagreement; re-review decision.
Consensus and decisions	Participants and gaps; substantial objections; resolution attempts; evidence; rationale; authority; operative procedure; outcome; date; limitations; notification and appeal route.
Ballots	Frozen package and resolution; roster and conflicts; valid and replacement ballots; exclusions and reasons; valid returned, yes, no and abstain counts; eligible unsuccessful-attempt and no-attributable-submission counts reconciled under D1-032; separate unattributable/ineligible submission inventory; calculations; verification; final decision.
Appeals and remedies	Challenged decision; grounds; standing; notice; independent assignment; disclosures; replies; stay; determination; remedy; responsible executor; verification and unresolved implementation.
Releases	Publication class and edition; approval record; dependency versions; source and build manifest; rights and accessibility review; corrections; distribution; appeal status; owner; next review.
Maintenance and incidents	Affected editions; reported issue; classification; severity and limits; interim protection; users notified; review and expiry; compatibility consequences; final disposition and follow-up.

D1-095 A public decision view shall preserve enough permitted information to identify the issue, authority, reasons, outcome, status, and challenge route. An authorized assessor shall be able to locate the underlying protected record when their mandate permits. A restriction that prevents assessment shall produce a stated assessment limitation rather than a presumed pass.

Annex C

(informative)

Proposed defaults and alternatives

C.1 General

These choices make the draft exercisable; they remain **PROVISIONAL** until explicit governance adoption. A future change to operative thresholds or minimum periods needs governance amendment and does not apply retrospectively to an open ballot or review.

Table C.1 – Local defaults, purposes, and alternatives

Proposed default	Purpose	Alternative and evidence needed
60-day public review; 30-day material re-review	Allow asynchronous participation while enabling bounded iteration.	Longer multilingual review or shorter narrow review; test notice reach, access, and actual response burden. Shortening minima needs prior governance amendment.
30-day disposition target and reply period; seven-day acknowledgement	Make receipt and delay visible while preserving substantive consideration.	Different service targets; test volunteer capacity and accessibility needs. A target is not an automatic closure rule.
30-day ballot and appeal periods	Give participants time to read a fixed package and challenge process.	Longer periods for complex work; test availability and remedy effectiveness.
Two-thirds returned-ballot quorum; three substantive votes; two-thirds approval	Prevent adoption based on one affirmative vote and abstentions; require substantial expressed support.	Larger minimum electorate or stakeholder balance conditions. Three voters do not demonstrate constituency breadth; assess actual participation and available competence.
Two-year maintenance review	Require periodic attention without continuous reballoting.	Annual or longer scope-specific review; evaluate dependency change, harms, issue volume, and maintenance resources.
Seven-day emergency review; 30-day expiry	Limit exceptional authority and expose delays.	Shorter periods for urgent privacy incidents; test reviewer availability and restoration of ordinary review.

Annex D

(informative)

Worked progression and rehearsal evidence

D.1 Worked progression

Consider a synthetic proposal for a record-correction protocol. Its first version assumes that only record custodians can challenge a classification. An affected-participant reviewer explains why that scope excludes people whose records are used in decisions. The editor proposes an accessible participant route and identifies the additional authentication and protected-contact infrastructure required. The Specification need follows the normative problem; it is not inferred from an available software library.

The committee records the competing alternatives: custodian-only correction, direct participant submission, and assisted representative submission. Its selected draft uses the latter two within a declared authority boundary. The decision retains the rejected alternative and reasons, including participation burden and risk of exposing identities. A public-review comment then demonstrates that the selected route still requires an unavailable identifier. Removing that prerequisite changes accepted inputs, requiring material re-review and corresponding changes to tests and explanatory examples.

Suppose the later ballot has five eligible non-recused people and four returns: two approvals, one disapproval, and one abstention. The numerical conditions pass because four returns meet the quorum, three substantive votes meet the minimum, and two approvals satisfy the two-thirds threshold. The objection still needs its disposition and consensus assessment. If the disapproving participant identifies a mandatory review omission, that blocking failure prevents approval despite the tally. The case distinguishes evidential reasons, consensus assessment, numerical support, and authority to progress.

A procedural appeal subsequently establishes that the affected reviewer never received the changed draft. The independent reviewer remits the decision for renewed notice and reply. The new decision cites the remedy and evidence that the opportunity was restored. No prior vote is silently relabelled as agreement with a text it did not consider. Publication then identifies the exact approved source, rendered edition, protocol artifact, and maintenance owner. Later correction of an example is evaluated for substantive effect before the owner chooses corrigendum or amendment.

This sequence is a design example only. Its people, comments, votes, appeal, and release have not occurred. The evaluated arithmetic cases in `examples/validation_0.2/p0-governance-rehearsal.md` cover finite calculations, not the operational behavior described here.

D.2 Rehearsal method and evidence

A useful rehearsal records actors as fictional or unassigned, uses identified draft versions, and leaves a complete decision trail. It is not actual public review, proof of representativeness, or governance adoption.

Assessment uses an evidence register with a row for each applicable D1 identifier, the procedure or decision assessed, required record location, reviewer, result (fulfilled, not fulfilled, not assessed, or not applicable), and unresolved action. A not-applicable result identifies the absent trigger. Document inspection assesses notices, disclosures, reasons, and manifests; arithmetic recalculation assesses ballot results; observed exercises assess intake, recusal, reply, appeal, and restoration behavior. Independent procedural review assesses contested fairness and authority. Missing records or unperformed procedures are not counted as fulfillment.

1. Process a bounded NWIP through accept, revise, and defer alternatives. Identify an infrastructure need without presuming a Specification or Standard already exists.
2. Receive an accessible free-text comment, a protected submission, and a sustained minority objection. Show acknowledgement, reasoned disposition, reply, and safe publication.

3. Re-review a material change and demonstrate why a change of constituency restarts full review. Preserve unsuccessful alternatives and source uncertainty.
4. Recalculate a ballot after recusal: with five eligible people, four returns meet quorum; two approvals, one disapproval, and one abstention satisfy the approval threshold. Repeat with two returns and show deferral.
5. Test three returns consisting of one approval and two abstentions. Record failure of the three-substantive-vote minimum even though returned-ballot quorum can be met.
6. Appeal exclusion from review; document independent appointment, conflict challenge, stay, reply, remedy, and renewed decision. Repeat with no independent reviewer and show pending progression.
7. Compare approved source and rendered output, detect an omitted requirement, and prevent release. Distinguish typographic correction from a changed conformance result.
8. Simulate maintenance, incompatible revision, withdrawal, an urgent warning, and role vacancy. Demonstrate that an emergency cannot adopt a Standard.

The rehearsal report records failures, required staffing, elapsed effort, participation and confidentiality barriers, revised clauses, and remaining questions before the founding participants assess readiness.

Annex E

(informative)

Source tailoring and open decisions

E.1 Comparison and local choices

The programme's Brief and comprehensive plan supply the mission and local lifecycle. The comparative planning study supplies the alternatives examined. This draft proposes its own procedures and values; it does not claim ISO, IEEE, or WTO conformity, accreditation, or international representativeness. For the expansion decision and alternatives, see `decisions/ADR-0005-expanded-drafts-and-source-models.md`. The external-model comparison is maintained in `docs/references/drafting_models.md`; neither record substitutes for governance adoption.

ISO's model document informs the separation of foreword, introduction, scope, references, terminology, clauses, annexes, and bibliography. IEEE's procedural material informs the distinction between project supervision, review, ballot, and appeal functions. ITU-T's working-method and author guidance provide a United Nations system comparison for organized technical contributions and Recommendation preparation. These are comparisons of document and procedural functions; this programme has neither those organizations' constituencies nor their institutional powers.

The United Nations National Quality Assurance Frameworks Manual supplies a complementary comparison: attention to institutional environment, production processes, and outputs helps avoid evaluating only the finished publication. D1-060, D1-062, and D1-089 accordingly examine capacity, process evidence, and the limits of the resulting claim separately. This is a programme interpretation, not a declaration that the statistical framework governs generativity standards.

OPEN ISSUE The comparative study records an access gap for the full ISO/IEC Directives Part 1:2026 and Part 2 amendment text. This draft makes no clause-level claim about those unverified texts. Founding authority, actual appointments, contribution terms, neutral review availability, and numerical defaults need explicit resolution before governance adoption.

Bibliography

Source and interpretation: ISO, *International harmonized stage codes*, official webpage checked 22 September 2026, https://www.iso.org/stage-codes.html. The source distinguishes publication, review, and withdrawal; this programme retains its existing local stage 90 grouping. No ISO substage deadlines or voting rules are imported.

Source and interpretation: IEEE SA, *Standards Board Operations Manual*, clause 5, official webpage checked 22 September 2026, https://standards.ieee.org/about/policies/opman/sect5/. Its separation of project supervision, review, and appeals informs comparison. The programme's staffing, deadlines, eligibility, and remedies above are new local proposals, not statements of IEEE requirements.

Source and interpretation: WTO, *Principles for the Development of International Standards, Guides and Recommendations*, official presentation of the 2000 TBT Committee decision, checked 22 September 2026, https://www.wto.org/english/tratop_e/tbt_e/principles_standards_tbt_e.htm. Its process principles inform scrutiny of transparency, participation, relevance, and coherence; no determination of legal status under the TBT Agreement is made.

Source and interpretation: ISO, *Model document of an International Standard*, 2023, https://www.iso.org/iso/model_document-rice_model.pdf. Informative structural model, not a conformance dependency.

Source and interpretation: ITU-T, *Recommendation A.1: Working methods for study groups of the ITU Telecommunication Standardization Sector*, September 2019, official edition/status record: https://www.itu.int/itu-t/recommendations/rec.aspx?rec=a.1; and *Author's Guide*, June 2023, https://www.itu.int/dms_pub/itu-t/oth/0a/0f/T0A0F0000040005PDFE.pdf. Informative organizational and drafting comparisons; no ITU procedure is incorporated.

Source and interpretation: United Nations, *United Nations National Quality Assurance Frameworks Manual for Official Statistics*, 2019, https://unstats.un.org/unsd/methodology/dataquality/references/1902216-UNNQAFManual-WEB.pdf. Informative comparison of institution, process, and output quality; no statistical-system mandate is claimed. The programme's comparison record is `docs/references/drafting_models.md`.

GENERATIVITY STANDARDS PROGRAM

Directives Part 2

Governance Working Draft

Version 0.3 2026-09-22

Structure and drafting rules for programme publications

WORKING DRAFT FOR REVIEW

This document contains proposed provisions for technical and institutional review. It is not an adopted Standard or an operative governance instrument. Its scope, application conditions and publication status are specified in the text.

Prepared by the Generativity Standards Program. Reference to external publications does not imply endorsement by ISO, IEC, IEEE or any United Nations body.

Foreword

Version 0.3 records the bounded substantive review of the archived 0.2 package. Its requirement text is retained in this coordinated edition; updated references identify the companion 0.3 drafts. The review matrix, synthetic assessments and unresolved readiness questions are documented in `docs/reviews/validation_0.2/README.md`. These activities do not constitute adoption or an independent institutional assessment.

This document establishes the proposed editorial and document-engineering rules of the Generativity Standards Program. It is intended for document editors, technical reviewers, terminology maintainers, implementers of associated artifacts and publication assessors.

Responsible editor: `UNASSIGNED`. Canonical source: `governance/directives_part_2.tex`.

This second preparatory draft develops the requirements of Working Draft 0.1 into a publication architecture, drafting method and assessment procedure. Requirement identifiers D2-001 to D2-045 are retained. Additional identifiers designate new provisions. The earlier edition is preserved in the programme's source archive. Neither edition has been adopted as an operative governance instrument.

The foreword, introduction, notes, examples, informative annexes and bibliography provide information. Requirements in the main body and normative annexes are proposed requirements for the declared assessment subject. Their use in a rehearsal does not constitute programme adoption. The publication models consulted include ISO, IEEE and United Nations system materials; their institutional authority and proprietary presentation elements are not incorporated.

Bibliography **21**

Introduction

A standardization programme requires documents whose provisions can be located, interpreted, implemented and assessed consistently. Length alone does not establish completeness. A short document can be complete for a narrow question, whereas a programme-wide recording or procedural document can require extensive definitions, conditions, assessment methods and interfaces.

The first publication cycle identified a recurring weakness: a list of requirements can state desirable outcomes without specifying how an implementer determines applicability, obtains the necessary evidence, handles exceptions or reports a failure. This edition requires those elements to be developed together. Formal drafting is used to increase precision and reviewability, while explanatory material retains a separate role.

The programme also requires distinctions that conventional technical documentation can leave implicit. A statement about a represented event differs from a claim about its evidence, an ethical evaluation, a legal allegation or an institutional decision. A manuscript can supply conceptual grounds without supplying normative authority. A schema can validate a representation without establishing its factual warrant. The drafting rules provide means to preserve these distinctions across publications.

The local publication profile draws selectively on established models. It uses decimal clauses, dated dependencies, separately identified annex status, controlled terminology and explicit assessment subjects. It does not reproduce another organization's foreword, approval process, legal status or branding. The detailed comparison and access record are maintained outside the normative provisions in `docs/references/drafting_models.md`.

1 Scope

This document specifies requirements for the structure, language, terminology, references, associated artifacts and editorial assessment of publications prepared within the Generativity Standards Program.

It applies to governance documents, Standards-track drafts, Specifications, Technical Reports, Manuals and Policy or Institutional Proposals. The applicable structural profile depends on publication class. The assessment subject is an identified publication package comprising the document source, rendered edition and explicitly associated artifacts.

This document does not prescribe a universal theory of generativity, select a technical interchange syntax, confer Standard status or determine the legal effect of a publication. Approval, review periods, release authority and maintenance decisions are governed by Directives Part 1 when adopted. Historical source manuscripts remain source records and are not retroactively edited to meet this document.

2 Normative references

2.1 Dated draft references

For coordinated assessment of this preparatory edition, the following programme drafts supply the provisions explicitly invoked in the text. References are dated to the stated draft version; later changes require dependency review.

- Standards Programme Charter, Working Draft 0.3: CH-010 and CH-011 on publication classes and the limits of Standard designation. Source: `governance/standards_programme_charter.tex`.
- Directives Part 1, Working Draft 0.3: D1-040 to D1-048 on exact-edition publication, correction, revision and maintenance, together with the procedure invoked for the applicable draft stage or publication class under D2-045. Source: `governance/directives_part_1.tex`.
- Ethics, Conflict-of-Interest, and Contribution Rights Policy, Working Draft 0.3: EIP-028 to EIP-031 on artifact-specific terms, source rights and intended distribution, and EIP-039 on custody and protected case information. Source: `governance/ethics_ip_policy.tex`.

These references form a proposed governance package. Listing them does not establish that they are operative. External drafting guides and foundation manuscripts are informative sources unless a particular requirement explicitly incorporates a separately identified technical provision. No ISO, IEEE or United Nations document is a normative dependency of this edition.

2.2 Bounded application and unavailable dependencies

D2-094 For coordinated assessment of this edition, the editor shall apply CH-010 and CH-011 to the publication-class and Standard-status statements required by D2-001 to D2-003; the applicable D1-040 to D1-048 provisions and the identified stage-specific procedure to the publication and change-control subjects invoked by D2-042 to D2-045; and EIP-028 to EIP-031 and EIP-039 to incorporated source material, intended distribution and protected case information where present. The dependency record shall identify the provisions triggered, exact editions, source locators and evidence. An unavailable or incompatible dependency shall leave the affected result not assessed pending resolution.

The incorporated scope concerns the named questions, not an assertion that this publication fulfils each governance instrument in its entirety. A draft without a release decision does not acquire adopted authority through editorial assessment. An absent distribution or case-information trigger can make the corresponding dependency provision inapplicable; missing rights evidence for an intended distribution is not an absent trigger. Programme authority, development procedure, rights and protection, and editorial

assessment remain distinct responsibilities. A conflict is recorded for the competent governance decision rather than resolved by treating a draft as already operative.

3 Terms and definitions

3.1 publication package

identified set of source texts, rendered documents and associated artifacts submitted for a stated review or release purpose

NOTE 1 A package can include a schema, assessment fixture or change record. Inclusion does not make every artifact normative.

3.2 provision

expression in a document that states a requirement, recommendation, permission or explanatory information

3.3 requirement

provision specifying an outcome or condition that is necessary to support the declared claim of fulfillment

3.4 conformance subject

identified object, practice, procedure, system or application against which requirements are assessed

3.5 applicability condition

stated circumstance that determines whether a requirement applies to the declared subject

3.6 normative reference

reference to an identified external provision whose fulfillment is necessary to fulfill an invoking requirement

3.7 informative reference

reference that supplies explanation, conceptual grounds, comparison or further information without adding a conformance obligation

3.8 profile

identified set of application conditions and permitted selections, additions or restrictions relative to specified parent requirements

3.9 editorial correction

change that corrects presentation without changing the meaning, applicability or assessment result of a provision

3.10 substantive change

change that can alter a provision’s meaning, applicability, authority, permitted behavior or assessment result

3.11 assessment evidence

material and recorded reasoning used to support a result for an identified requirement and subject

3.12 hanging paragraph

text attached directly to a clause that also contains numbered subordinate clauses, leaving its structural position ambiguous

4 Publication identity and document architecture

4.1 Identity and standing

D2-001 A publication shall identify its code or other identifier, title, publication class, maturity status, version, responsible editor or unassigned responsibility, and source location near its beginning.

D2-002 A draft shall state that it is not adopted and shall distinguish authoring progress from formally authorized project status. A publication shall not imply ISO, IEC, IEEE or governmental authority without a documented basis.

D2-046 A revision shall identify the preceding edition and summarize substantive changes. The publication package shall preserve a retrievable change relationship and the status of the earlier edition. A new rendering of unchanged text shall not be represented as a new normative decision.

The document identifier and the requirement identifier serve different purposes. A document identifier locates a publication family and edition. A requirement identifier supports the continuity of an obligation across editorial reorganization. A file name or page number is not sufficient to perform both functions.

4.2 Publication classes and audience

D2-003 An editor shall assign one principal publication class and state its intended readers, use and authority. A Standard, Specification, Technical Report, Manual, governance document and Policy or Institutional Proposal shall not be treated as interchangeable classes.

D2-004 A protocol description shall identify its containing publication class. Protocol behavior shall be distinguished from the institutional authority and procedure under which that behavior is used.

D2-005 A Policy or Institutional Proposal shall distinguish factual background, interpretation, objectives, options, mandate, implementation implications and unresolved questions. It shall not create technical conformance obligations through an unapproved policy recommendation.

D2-047 A document containing material of more than one publication class shall identify the principal class and separate the subsidiary material by a stated structural boundary. The editor shall state whether each part defines requirements, supplies guidance or proposes an institutional option.

Technical detail does not make a document an adopted Standard. A Specification can contain exact and testable provisions while retaining Specification status. A policy proposal can recommend adoption or experimentation without defining technical conformance. A protocol is a subject described within a publication, not an additional source of institutional authority.

4.3 Required structural components

D2-006 The scope shall identify the subject of conformance, intended use, relevant environment and exclusions. A claim of conformance shall be assessable within that stated boundary.

D2-007 Normative and informative material shall be distinguishable at clause, annex or artifact level. Notes, examples and informative annexes shall not introduce additional requirements.

D2-008 Every table, figure, annex and associated artifact shall have a stated role and, where interpretation depends on it, a stated authority status. A normative requirement represented in a diagram shall also have an identifiable textual formulation.

D2-048 A technical or governance draft prepared under this document shall contain a title and status statement, a foreword, a scope clause, a normative-reference clause, a terms-and-definitions clause, substantive provisions and an assessment or application clause. It shall identify the role of every annex and associated artifact. An informative bibliography shall be provided when informative external sources are cited.

D2-049 The foreword shall record publication history, responsible preparation and material edition changes without introducing technical requirements. The introduction, when present, shall explain the problem, approach and intended use without creating additional conformance obligations.

D2-050 The scope shall identify both inclusions and material exclusions. It shall not contain requirements that can be located only in the scope or imply applicability to environments for which the document supplies no assessment basis.

The principal body normally begins with Scope, Normative references and Terms and definitions, in that order. A document having no normative references states that fact. It does not populate the clause with a reading list. A vocabulary document can use a more extensive terminology structure, provided that definition entries and vocabulary-application requirements remain distinguishable.

4.4 Clause hierarchy and navigation

D2-051 The editor shall assign decimal clause and subclause numbers, use descriptive titles and place substantive text at an identifiable leaf of the hierarchy. If a clause has subclauses, introductory provisions belonging to that clause shall be placed in a General subclause or another identified subclause.

D2-052 A cross-reference shall identify a stable requirement, clause, table, figure or annex as appropriate. References such as above, below, elsewhere or the latest text shall not be the sole locator of content necessary for interpretation or assessment.

The depth of subdivision follows the complexity of the subject. Repeated one-sentence subdivisions can impair reading; long unstructured blocks can conceal distinct conditions. Editors select a hierarchy that permits a reviewer to identify the actor, trigger, action and evidence without reconstructing a paragraph's unstated scope.

5 Formulation of provisions

5.1 Requirement construction

D2-009 A requirement shall identify the responsible actor or object, the applicable condition, the required behavior or property, and an outcome or evidence by which fulfillment can be assessed.

D2-010 A requirement shall use a stable identifier independent of its displayed section number. An identifier shall not be reassigned to a different obligation after circulation; a withdrawn identifier shall remain traceable.

D2-011 A requirement shall not combine independent obligations whose applicability or assessment differs so materially that one result would conceal another. Related obligations can be grouped when their joint assessment is explicit.

D2-012 Terms such as adequate, appropriate, trustworthy or significant shall have a scoped criterion, declared decision responsibility or assessment procedure when they determine conformance. A broad aspiration alone shall not be presented as a testable requirement.

D2-053 Each requirement shall be linked to at least one discriminating assessment question. The question shall distinguish an acceptable outcome from a materially different outcome that would not fulfill the requirement.

D2-054 Where one identifier groups related obligations, the assessment schedule shall identify the components and record a result for each materially distinct component. Fulfillment of one component shall not conceal an unassessed or failed component.

An obligation normally identifies the responsible subject, any triggering condition, the required action or property and the information needed to determine fulfillment. A requirement can depend on a scoped judgment, but the judgment's criteria, decision responsibility and record are then part of the assessable arrangement. Formal drafting does not require every judgment to be reduced to a number.

5.2 Verbal forms

D2-014 The editor shall distinguish mandatory conditions, recommendations, permissions and capability statements consistently. A recommendation's non-fulfillment shall not be reported as failure of a requirement.

D2-055 The editor shall use shall and shall not for requirements and prohibitions, should and should not for recommendations, may for permission, and can for possibility or capability. Must shall not be used as an alternative requirement verb in programme-authored provisions.

D2-056 A statement of external necessity, including a stated legal constraint, shall identify its source and context. The editor shall distinguish that external constraint from an obligation created by the publication.

The grammatical present can describe a definition, process model or fact. It is not used to conceal an additional obligation. A statement that information can be recorded describes capability; it does not require the information to be retained in a particular record. Permissions are assessed in relation to mandatory limits, not as exceptions to them.

5.3 Conditions, exceptions and incomplete knowledge

D2-013 A permission shall not override a requirement implicitly. Exceptions shall identify the affected obligation, conditions, authority, required record and any limitation on the resulting conformance claim.

D2-015 A conditional requirement shall state its trigger and how applicability is determined. A result of not applicable shall include its reason; it shall not substitute for unavailable evidence or an unperformed assessment.

D2-016 When complete information is not realistically available, a recording requirement shall specify whether a justified unknown, limitation or restricted disclosure satisfies the obligation. It shall not require invented content to complete a mandatory field.

D2-057 A provision permitting an unknown value, unavailable source or restricted disclosure shall state the required declaration, responsible role and assessment consequence. The editor shall distinguish fulfillment of that declaration requirement from resolution of the underlying factual question.

D2-058 An exception shall state its eligibility condition, decision authority, permitted departure, duration or review trigger, required evidence and effect on the resulting claim of fulfillment. An exception shall not be implied solely by a resource limitation.

A conditional requirement remains mandatory when its condition is met. A requirement that has not been assessed is not made inapplicable by the absence of evidence. The document can require a justified declaration of uncertainty while leaving the substantive matter unresolved. It can also require access that the subject cannot provide, in which case the assessment reports the consequence rather than inventing an authorization.

5.4 Completeness and proportionality

D2-059 For each substantive topic in scope, the editor shall identify normal operation, material boundary cases, failure conditions and applicable interfaces. A topic shall not be treated as specified solely because it appears in a list of objectives.

D2-060 Where requirements can impose material recording, review or participation burdens, the document shall identify the intended operating scale and the evidence needed to assess that burden. A reduced profile shall state its limitations and shall not silently claim the coverage of the parent document.

Proportionality is expressed through explicit conditions, profiles and scope. It is not achieved by using undefined terms such as sufficient or appropriate as a substitute for deciding what an implementer records. Conversely, mandatory collection of every available detail can be inconsistent with purpose, protection and feasible participation.

6 Terminology and conceptual sources

6.1 Definition entries

D2-017 An operational definition shall state its scope and shall not imply that it exhausts a broader philosophical concept. A definition imported or adapted from a source shall identify that source, edition and the nature of the adaptation.

D2-061 A definition entry shall identify the preferred term, a unique term locator, the relevant domain where needed, and a definition that distinguishes the concept from adjacent concepts. Notes and examples shall remain separate from the definition.

D2-062 The editor shall use a defined term consistently within its declared scope. A synonym, abbreviated term, deprecated term or narrower profile-specific use shall be identified explicitly rather than introduced as an unexplained substitution.

Definitions describe concepts. They do not contain procedural obligations that belong in requirements. A definition can specify constitutive characteristics, while a later provision states when a conforming application has to record or satisfy those characteristics. Circular definitions and definitions consisting only of synonyms require revision unless the document explicitly identifies an unresolved terminology issue.

6.2 Foundation interpretation

D2-021 A draft shall distinguish occurrence claims, observations, evidence assessments, interpretations, normative evaluations, legal assertions and institutional determinations wherever conflation would strengthen a claim beyond its grounds or authority.

D2-018 For a substantive GR definition, the editor shall record the relevant foundation passage, alternatives, unresolved differences and the rationale for operational use. A material narrowing or departure shall have an Architecture Decision Record before the definition is stabilized for adoption.

D2-019 An operational definition of Entity, State, Event, Process, Relation or Property shall address admissibility, identity, temporal behavior, allowed relations, required and optional information, examples,

counterexamples and unresolved edge cases. A declaration that an item remains provisional shall identify the missing decisions.

D2-020 The editor shall not equate a formal state with an archival State, a mechanism with a Process, or formal change with an Event without an explicit argument and scoped decision. The six record roles shall not be presented as exhaustive constituents of reality.

D2-063 A source trace for a GR-specific operational definition shall identify the manuscript version, passage locator, interpreted distinction, operational narrowing, material alternative and affected provision. A source discrepancy shall remain visible until its disposition is recorded.

The foundation corpus supplies conceptual source authority. It does not determine the programme's approval procedure. A formal model's carrier, transition or mechanism does not automatically supply the identity or metadata of an archival State, Event or Process. A record ontology can support a practical distinction while leaving a deeper philosophical or mathematical question open.

6.3 Translations and mappings

D2-064 A translation or cross-vocabulary mapping used to determine conformance shall identify the source and target editions, responsible reviewer, correspondence asserted and known non-equivalences. An untranslated or unmapped distinction shall not be represented as preserved without supporting evidence.

Translations can be reviewed documents without being authoritative editions. The publication identifies which edition controls interpretation in the declared programme process. Disagreement over equivalence is recorded as a technical issue; an editor does not resolve it by silently changing the source term.

7 References and dependency management

7.1 Normative references

D2-022 An external reference used to support a normative or scholarly claim shall be verified against an identified primary source. Inaccessible text, uncertain edition, incomplete review and unverified compatibility shall be identified rather than reconstructed as fact.

D2-023 A normative reference shall identify the exact document and edition required to apply a requirement, the part relied on and a means of obtaining it. Informative motivation shall be listed separately from normative dependencies.

D2-065 Each normative reference shall be invoked by an identifiable requirement or application rule. The dependency record shall state the incorporated scope, required edition and assessment consequence of an unavailable or incompatible dependency.

The invocation can incorporate a whole profile or a bounded set of provisions. It does not automatically incorporate every recommendation, example or later amendment in the source publication. A draft dependency can be used for preparatory assessment if its status and exact edition are declared; it cannot supply an adopted authority that it does not possess.

7.2 Informative sources and external publication models

D2-024 A draft depending on another draft shall identify the dependency's version and status and the consequences of a change. It shall not imply the dependency has already been adopted.

D2-066 A bibliography entry shall provide enough information to distinguish the cited source and locate the relevant edition. Where an external model is used for drafting or comparison, the source record shall

distinguish directly inspected material from catalogue metadata, secondary description and unavailable text.

An organization's publication name does not establish that every document it issues has the same authority. For example, a technical Recommendation, a statistical manual and an institutional policy proposal can differ in their adoption procedure, audience and implementation effects. The programme therefore records the source's actual class before deriving a local design proposal.

7.3 Dependency review

D2-025 Before approval for publication, the editor shall produce a dependency review identifying incompatible versions, unavailable dependencies, circular requirements and licensing or access constraints material to implementation.

D2-067 A material dependency change shall identify affected requirements, definitions, assessment cases and associated artifacts. The editor shall record whether each affected element remains valid, requires revision or cannot yet be assessed.

A circular reference is not resolved by citing the two documents more precisely. Technical definitions and conformance conditions require a determinate interpretation. Governance instruments can be adopted as a coordinated package, but their allocation of authority, procedure and assessment still needs a documented reading order and conflict rule.

8 Conformance and assessment provisions

8.1 Subjects, scope and claims

D2-031 A draft shall state the limits of its conformance claims, including the distinction between record structure and factual truth, between source authentication and evidential warrant, and between technical conformance and legal or ethical judgment.

D2-026 A claim of equivalence, compatibility or interoperability with another model shall identify its direction, scope, tested cases, unsupported distinctions and known loss. Matching terminology alone shall not justify that claim.

D2-027 The conformance clause shall distinguish the assessed subject, publication edition, profile, applicable requirements, assessment method, assessor and result. It shall distinguish a record, producer, protocol participant, presentation, archive and organizational procedure when their obligations differ.

D2-068 A document allowing more than one conformance subject shall specify the requirement set applicable to each subject or state that the available assessment is partial. It shall distinguish examination of a record from observation of the practice or procedure represented by that record.

A statement about a completed institutional action requires evidence of that action. A narrative describing the action is evidence of an assertion and can be assessed as a record. It is not automatically sufficient evidence that the underlying action occurred or that an affected person received its result.

8.2 Assessment methods and results

D2-032 An automated check shall identify the constraints it actually assesses. A passing automated result shall not be presented as evidence of a human or institutional action that the check did not observe.

D2-028 Each requirement shall have at least one stated assessment method and evidence expectation. Structural checks, protocol tests, human interpretation and procedural review shall have separately identifiable results.

D2-029 A conformance report shall distinguish fulfilled, not fulfilled, not assessed and not applicable results. A missing assessment shall not be counted as fulfillment.

D2-069 An assessment method shall specify its objective, input conditions, procedure, relevant tools or competence, expected observations, result rule and material limitations. The method shall identify the conditions under which an inconclusive or not-assessed result is required.

D2-070 An assessment report shall retain failed and unassessed applicable requirements and their effect on the overall result. A summary shall not replace the underlying requirement-level evidence register.

Automated checks are suitable for such questions as syntax, identifier uniqueness or required structural elements. Evidential relevance, meaningful participation and the adequacy of a protected response can require competent judgment or observation. A document identifies these limits instead of describing every assessment as machine validation.

8.3 Profiles and optional features

D2-030 A profile shall state its parent requirements, additions, permitted restrictions, exclusions and intended users. It shall not silently weaken a parent requirement while claiming unqualified parent conformance.

D2-071 For an optional capability, a document shall state the condition under which associated obligations become mandatory. An implementation selecting that capability shall be assessed against the complete selected requirement set.

Optional selection and optional implementation quality are different questions. A subject can be permitted to omit a feature. If it claims to supply that feature, the relevant correctness, protection and failure-handling obligations apply according to the profile.

9 Information models, protocols and technical artifacts

9.1 Separation of semantics and bindings

D2-036 A schema, API or encoding choice shall be traceable to a stated requirement or interoperability need. Implementation convenience alone shall not be described as a philosophical necessity or universal institutional rule.

D2-072 A data dictionary shall distinguish semantic information requirements from serialization names, storage types and transport behavior. Each mandatory or conditional element shall identify its meaning, applicable subject and permitted absent or unknown states.

An abstract information requirement can be implemented in a narrative dossier, table or technical binding. The existence of a field in one implementation does not make its name or data type normative. When interoperability depends on that choice, a Specification work item provides the explicit binding and its assessment evidence.

9.2 Protocol behavior

D2-033 A protocol Specification shall define its participants, inputs, preconditions, state transitions, observable outputs, effects, refusal and failure cases, recovery behavior, version assumptions and authorization boundaries.

D2-034 An artifact package shall identify the relationship between its prose requirements and its schemas, examples, vocabularies, test fixtures and executable components. Conflicts shall have a documented resolution rule that does not silently amend an approved requirement.

D2-073 A protocol description shall distinguish sending, transport delivery, receipt, acknowledgment, acceptance for processing and substantive disposition when those states have different consequences. A transport success shall not imply institutional acceptance or completion of a remedy.

D2-074 Where concurrent updates or repeated messages are in scope, the protocol description shall specify correlation, version preconditions, duplicate handling, conflict disposition and recovery after interruption. If those behaviors are not specified, the interoperability claim shall identify that exclusion.

An institutional procedure can be implemented manually. A network protocol can support its exchanges but cannot itself assign legal competence, decide an evidential dispute or grant an institutional remedy. The document specifies the interface between technical behavior and the responsible institutional function.

9.3 Associated artifacts

D2-037 Executable validation or rendering shall not silently retrieve unpinned remote resources, disclose protected input or substitute a current external vocabulary for the edition declared in the package. Any required external processing shall be explicit.

D2-035 Examples intended to be valid shall identify the supported profile and expected result. Negative examples shall identify the intended defect. Synthetic evidence shall be labelled as synthetic.

D2-075 Each associated schema, vocabulary, executable example or test fixture shall identify its owner, version, publication class or role, controlling requirements and status. Its release manifest shall state whether the artifact is normative, informative or experimental.

D2-076 A discrepancy between prose and an associated artifact shall be recorded with affected conformance outcomes. The release package shall identify the controlling interpretation or remain pending resolution; implementers shall not be required to infer priority from file format.

10 Presentation, accessibility and contextual statements

10.1 Tables, figures and formulae

D2-077 Every substantive table and figure shall have a unique number, descriptive caption and an explicit reference or structural purpose in the surrounding text. Required information shall not be encoded solely by colour, shape or visual position.

D2-078 A formula used in a requirement or assessment method shall identify its variables, domain, units where applicable, assumptions and interpretation. Undefined quantities and unsupported numerical precision shall remain explicit limitations.

Table headings can state shared conditions, but a condition necessary for conformance is not left to typographic inference. Units and scales are attached to the represented quantity. A percentage without its denominator or a confidence score without an interpretation is insufficiently specified for a substantive assessment.

10.2 Examples and accessibility

D2-038 A publication shall use headings, table labels, link text and readable typography that expose its structure. Essential meaning shall not depend solely on color, visual position or a diagram.

D2-039 An editor shall provide a usable source or alternative reading representation and identify known accessibility limitations of the rendered document. Successful PDF compilation alone shall not establish accessibility conformance.

D2-079 An example shall state whether it is synthetic, adapted or empirical and identify any omitted material that affects its use. Expected behavior in an authored scenario shall remain distinguishable from observed behavior in an executed assessment.

D2-080 The publication assessment shall identify intended reading modes, known barriers and the evidence used to assess accessibility. Availability of source text, PDF text extraction or a successful build shall not alone establish accessibility conformance.

10.3 Legal, ethical and institutional assertions

D2-040 A legal or institutional assertion used in a requirement shall identify the context, asserted source of authority and scope. A proposed model rule or policy option shall be labelled as such rather than described as generally applicable law.

D2-041 The editor shall record cross-domain review findings relevant to scope, including epistemic, ethical, legal, institutional, political-economy, archival, security and accessibility questions. Unavailable competence or unresolved material objections shall remain visible in progression records.

D2-081 A policy or institutional recommendation shall identify the intended decision maker, asserted mandate, feasible alternatives, implementation conditions, affected interests and evaluation approach. Adoption of a technical requirement shall not be presented as resolving those policy choices automatically.

Contextual reviewers assess the questions within their competence. A legal statement identifies its jurisdiction and procedural status; an ethical statement identifies its evaluative grounds and affected interests. An unavailable review remains an identified gap rather than being replaced by a generic assurance sentence.

11 Versioning and publication production

11.1 Source and artifact control

D2-042 Each circulated edition shall identify its canonical source and rendered artifacts. Changes to proposed requirements shall be traceable through the change record, with superseded reasoning retained subject to justified access and retention rules.

D2-043 A release candidate shall be built from the declared source revision, with build instructions, required tooling and an artifact manifest sufficient to reproduce and compare its substantive content.

D2-044 The release check shall detect broken internal references, duplicate requirement identifiers, missing glyphs, visibly clipped material, mismatched status labels and disagreement between declared source and generated artifact. Unresolved defects shall be reported with their effect on use.

D2-082 The editor shall distinguish the canonical authoring source, any generated representation and the exact edition submitted for decision. A release manifest shall identify source and artifact integrity references, build instructions, tool versions and the associated review record.

Byte-identical rendering is not assumed. Compiler metadata and timestamps can change binary output without changing substantive content. Integrity references identify what was actually reviewed; comparison procedures identify whether the intended provisions, identifiers and status survived rendering.

11.2 Amendment and source preservation

D2-045 An editorial correction shall not silently change the substance of a requirement. A substantive change to an adopted normative edition shall use the amendment or revision procedure in Directives Part 1, including affected-artifact and compatibility review. A draft change shall follow the change-control and

re-review rules applicable to its current stage. Changes to a released Specification shall follow its declared maintenance procedure and promotion shall require a separate decision.

D2-083 A changed requirement shall retain its identifier when its continuity is defensible and identify the nature of the change. A withdrawn requirement shall remain traceable. Reorganization shall provide a correspondence map when clause numbering or placement changes materially.

D2-084 An archival source snapshot shall record the source set, edition and integrity references. A historical snapshot shall be marked as historical and shall not replace the current edition's status or dependency declarations.

12 Assessment of a publication package

12.1 Assessment declaration

D2-085 The assessor shall identify the publication package, assessed edition, applicable structural profile, assessment scope, assessor relationship and required competence before issuing an overall result. Missing expertise and unavailable artifacts shall be reported.

D2-086 The assessment shall use the record specified in Annex B and examine the structural schedule in Annex A. Each applicable requirement shall receive an individual supported result.

12.2 Disposition of findings

D2-087 A finding shall identify the affected provision or artifact, the observed defect, its effect on interpretation or assessment, the proposed disposition and the responsible action. A correction shall identify the revised edition and the evidence used to close the finding.

D2-088 An overall publication result shall distinguish structural checks, technical review, source interpretation, cross-domain assessment and authorization for release. Fulfillment of one category shall not be reported as fulfillment of an unperformed category.

Annex A

(normative)

Structural schedule for programme publications

A.1 Application

D2-089 The editor shall apply the structural schedule in Table A.1 according to the declared publication class. A departure shall identify its rationale, alternative location and effect on assessment. The schedule shall not require an empty clause to simulate completeness.

Table A.1 – Structural components and required treatment

Component	Technical or governance publication	Informative or policy publication
Identity and standing	Identifier, title, class, edition, date, responsible preparation and adoption status.	The same identity controls; identify recommendatory or informative authority.
Foreword	Preparation, edition history and principal changes; no technical requirements.	Publication context, responsibility and history where relevant.
Introduction	Optional problem and approach explanation; distinguish it from scope.	Purpose and context can be substantive, with recommendations distinguished from background.
Scope	Subject, intended use, operating environment and material exclusions.	Intended readers, question, context and limits of conclusions.
Normative references	Identify invoked dependencies or state that none apply.	Identify any incorporated requirements separately from a bibliography; no implied conformance authority.
Terms and definitions	Numbered operational definitions and referenced vocabulary.	Define terms needed to avoid ambiguity; do not restate an adopted vocabulary inconsistently.
Substantive body	Requirements, applicability, interfaces, exceptions and failure behavior.	Analysis, evidence, alternatives, recommendations and implementation implications.
Assessment or evaluation	Subjects, requirement sets, methods, result rules and limitations.	Evaluation questions and proposed evidence; distinguish proposed from measured results.
Annexes	Each annex designated normative or informative; references from the body.	Normally informative; any proposed normative model remains explicitly a proposal.
Bibliography	Informative sources and edition locators, distinct from dependencies.	Sources supporting analysis and recommendations, with access limits recorded.
Associated artifacts	Role, version, controlling requirements, integrity reference and maintenance owner.	Role and limitations; no implied normative priority from machine readability.

A.2 Minimum completion review

D2-090 Before submission for final approval, the package review shall determine whether each in-scope topic has a defined subject, required behavior or outcome, applicability rule and assessment basis. An unresolved topic shall be excluded explicitly, retained as an open issue preventing the affected claim, or returned for development.

Annex B

(normative)

Requirement assessment record

B.1 Record components

D2-091 The assessment record shall include the information specified in Table B.1. Protected evidence shall be referenced through a permitted locator and its examination limits shall remain explicit.

Table B.1 – Assessment record information

Component	Required information
Subject declaration	Publication, edition, source set, artifacts, profile, scope and exclusions.
Requirement locator	Stable identifier, containing clause and controlling edition.
Applicability decision	Trigger, determination, basis and any dependency affecting applicability.
Method	Inspection, recalculation, execution, competent review or user task; procedure and conditions actually used.
Evidence	Source or observation locator, relevant portion, acquisition date, access status and assessment rationale.
Result	Fulfilled, not fulfilled, not assessed or not applicable; component results where a clause groups obligations.
Attribution	Assessor, competence, relationship to the author or operator, and actual date.
Limitations	Unavailable evidence, unresolved interpretation, sampling scope and excluded conclusions.
Disposition	Required correction or additional evidence, responsible action, status and closure evidence.

B.2 Result rules

D2-092 Fulfilled shall be reported only when the stated assessment method and evidence support the applicable obligation. Not applicable shall identify an absent trigger. Unavailable evidence or an unperformed assessment shall be reported as not assessed unless another specified result rule applies.

D2-093 An unqualified claim of fulfillment of the declared publication profile shall not be issued while an applicable requirement is not fulfilled or not assessed. A partial result shall identify the assessed subset and excluded conclusions.

Annex C

(normative)

Publication self-assessment schedule

C.1 Method and applicability

D2-095 An assessment of this document or a publication prepared under it shall apply the topical checks in Table C.1 to every applicable D2 requirement, using the record in Annex B. Each requirement and each materially distinct grouped component shall receive its own result and evidence. A grouped table row shall not authorize one undifferentiated result for its identifiers.

The objective is to distinguish inspectable, correctly scoped provisions from plausible wording that loses a necessary distinction. Inputs are the declared source and rendered edition, dependency and source registers, associated artifacts, change history and actual review or build evidence. The assessor examines the identified passages, follows their references and applies the discriminating question in the table. Text searches and build checks support inspection; meaning, source interpretation and contextual authority require relevant review competence. Where execution or user examination is needed, a document describing that activity is not substituted for observing it.

The expected observation is the retained distinction or controlling evidence named in the check. A demonstrated contradiction or missing required component is not fulfilled; an unavailable examination or needed competence is not assessed; an absent stated trigger is not applicable. A fulfilled result requires evidence for every applicable component. The assessor may use a domain-equivalent check with its rationale and equivalent failure condition recorded. Results remain limited to the examined edition, artifacts, uses and procedures.

C.2 Topical checks

Table C.1 – Requirement groups, discriminating questions and evidence

Identifiers	Discriminating assessment question and evidence
D2-001, D2-002, D2-046	Compare title, foreword, metadata and preceding edition. Can a reader distinguish authoring revision from authorized initiation, adoption and an unchanged rebuild? Trace any authority assertion to its record.
D2-003, D2-004, D2-005, D2-047	Follow an implementation rule and a policy recommendation to their containing class and audience. Does a protocol or subsidiary policy passage silently acquire a different authority? Inspect structural boundaries.
D2-006, D2-007, D2-008, D2-048, D2-049, D2-050	Compare scope, body, annexes and associated artifacts. Is any necessary obligation present only in scope, a note, introductory narrative or an unclassified visual? Locate its controlling formulation.
D2-051, D2-052	Walk the clause tree and follow a substantive reference without surrounding conversation. Can its leaf, exact target and edition be identified, or does interpretation depend on an unlocated paragraph or latest text?
D2-009, D2-010, D2-011, D2-012, D2-053, D2-054	Apply a requirement to a normal and boundary case. Can the actor, trigger, criterion and outcome be determined? Compare grouped components with different results and check identifier continuity in the change record.
D2-014, D2-055, D2-056	Search modal verbs and inspect their contexts. Does an optional recommendation become a failure, a capability become an obligation, or an asserted legal necessity lack a scoped source?

Identifiers	Discriminating assessment question and evidence
D2-013, D2-015, D2-016, D2-057, D2-058	Apply an exception and an unknown value to a triggered obligation. Recover authority, permitted departure, review limit and result consequence; distinguish an absent trigger from an unavailable assessment.
D2-059, D2-060	Select a substantive topic and its failure case. Is behavior specified beyond an objective label, and can its burden be examined at the declared scale without assuming a reduced profile preserves full coverage?
D2-017, D2-061, D2-062	Trace a numbered term from definition to use and source. Do notes, synonyms or domain qualifications change its operative meaning without an explicit boundary? Compare an adjacent concept or counterexample.
D2-018, D2-019, D2-020, D2-021, D2-063	Compare an operational GR definition with its manuscript passage and decision record. Does a formal carrier become an archival class, or a source disagreement disappear, without a scoped argument and recorded disposition?
D2-064	Test a translation or mapping on a meaning that is narrower in one edition. Is the difference retained, with reviewer and editions, or silently described as equivalence?
D2-022, D2-023, D2-065	Follow an invoked dependency to the exact primary provision. Can a reader obtain the incorporated edition and determine what failure or inaccessibility means, rather than relying on a reading-list citation?
D2-024, D2-066	Compare the bibliography with access records and draft status. Does catalogue-only or unavailable material appear as directly inspected content, or a dated draft as an adopted authority?
D2-025, D2-067, D2-094	Examine an affected dependency version or unavailable source. Are incorporated clauses, impacted results and resolution recorded, including bounded Charter, Part 1 and ethics obligations? Check for circular or incompatible interpretations.
D2-026, D2-027, D2-031, D2-068	Compare a record-only result with a practice or interoperability claim. Is unobserved performance, lost meaning or legal/factual assurance incorrectly inferred from structure or vocabulary agreement?
D2-028, D2-029, D2-032, D2-069, D2-070	Reconstruct one assessment from its inputs, method and evidence. Can a failed or unavailable component be recovered from the summary, and does an automatic check claim only what it actually examined?
D2-030, D2-071	Select an optional feature and compare the profile to its parent. Are its triggered obligations assessed together, or is selecting the feature used to excuse a correctness or protection requirement?
D2-036, D2-072	Trace a mandatory data element to its semantic need and allowed missing states. Can another encoding preserve the meaning, or is a software convenience presented as a philosophical necessity?
D2-033, D2-034, D2-073, D2-074	Replay a refusal, duplicate or interrupted exchange where applicable. Can participants distinguish delivery, receipt and disposition, identify controlling text and recover without inventing institutional acceptance?
D2-035, D2-037, D2-075, D2-076	Run or inspect an associated fixture against its declared result and controlling edition. Are remote inputs or protected processing explicit, and does a prose/artifact conflict have a recorded resolution?
D2-077, D2-078	Read a table, figure or formula without relying on colour or position. Are role, variables, scale, units, assumptions and controlling textual requirements recoverable? Inspect unsupported numerical precision.
D2-038, D2-039, D2-079, D2-080	Examine source and rendered reading modes and available user evidence. Does an authored example appear as observed performance, or successful compilation as tested accessibility? Record barriers and unperformed examination.

Identifiers	Discriminating assessment question and evidence
D2-040, D2-041, D2-081	Follow a legal, ethical or policy assertion to its context and reviewer. Can mandate, affected interests, alternatives and evaluation be located without assuming technical adoption resolves the political choice?
D2-042, D2-043, D2-044, D2-082	Compare source, manifest and rendered artifact. Can the exact reviewed edition be rebuilt and inspected for omitted provisions, missing glyphs, clipped content, duplicate IDs and incorrect status?
D2-045, D2-083, D2-084	Compare an alleged editorial correction with prior permitted outcomes. If a single character changes an obligation, is substantive review triggered and the earlier edition still locatable?
D2-085, D2-086	Inspect the assessment declaration and its annex records. Are subject, profile, competence and unavailable artifacts identified before an overall result rather than supplied by a generic assurance?
D2-087, D2-088	Trace a finding to correction and closure evidence. Does closure identify the new artifact and actual recheck, and remain separate from unperformed technical review or release authorization?
D2-089, D2-090	Compare an in-scope topic against the structural schedule and final-approval evidence. Is an unresolved gap explicitly excluded, blocking or returned for work, rather than hidden by an empty heading?
D2-091, D2-092, D2-093	Inspect a mixed-result assessment record. Does unavailable evidence remain not assessed and prevent unqualified fulfillment, with protected evidence linked only through permitted locators?
D2-095	Compare this schedule with the completed requirement register. Does each applicable identifier and distinct component have evidence and a result, rather than inheriting a single group pass?

Annex D

(informative)

Drafting examples and discriminating assessments

D.1 A recording obligation

The sentence “The system should contain trustworthy information” does not identify a conformance subject, a meaning of trustworthy or an assessment method. An operational alternative is to require an attributed claim, its scope and version, the evidence role assigned to cited material, and the responsible assessment. The resulting assessment asks whether these distinctions are present and whether the stated evidential reasoning is inspectable. It does not infer that every recorded claim is true.

D.2 A conditional disclosure obligation

A requirement to publish the entire history would conflict with some legitimate protection and retention arrangements. A bounded provision can require the responsible practice to identify permitted public material, the basis of a restriction, its effect on examination and the available review route. The assessor then examines those decisions and the resulting view. The mere existence of a privacy statement is not equivalent to observing that access control was enforced.

D.3 A protocol acknowledgment

A message receipt and a favorable decision are different states. A technical specification can define a receipt identifier, correlation reference and retry behavior. A procedural document can define who determines admissibility and gives reasons. A test that confirms transport delivery establishes neither the substantive decision nor the legitimacy of the deciding body.

D.4 A numerical result

An assertion that an outcome has high confidence is ambiguous unless the assessed question and grounds are stated. Where a number is used, the document identifies the quantity, scale, method, assumptions and scope. Where heterogeneous uncertainties cannot be commensurated, separate descriptions are preferable to an unsupported aggregate score. This is a requirement to preserve meaning, not a prohibition on quantitative methods.

D.5 An editorial correction

Changing a misspelled word without altering meaning can be editorial. Changing a response period, required metadata element, exclusion rule or approval denominator changes permitted outcomes. The latter requires substantive change control even if it occupies only one character. The classification follows the effect of the change, not its visual size.

Annex E

(informative)

Editorial model, differences and unresolved matters

E.1 Selected local model

The programme combines a conventional standards-document structure with its own traceability identifiers and explicit publication classes. ISO's publicly available model provides an example of ordered preliminary elements, numbered requirements and labelled annexes. ITU's authoring guide distinguishes integral annexes from supplementary appendices. This programme instead labels each annex normative or informative, maintaining one alphabetic sequence. The source distinction is preserved in function without adopting two incompatible naming systems.

IEEE's published procedural guidance informs the separation of draft status, normative material and informative support. UN statistical quality guidance supplies a useful comparison for linking institutional arrangements, production processes, output quality and improvement evidence. Those functions are adapted to the programme's own subjects; a statistical quality framework does not supply a universal test of factual truth or generativity.

E.2 Implementation choices

The current authoring system uses TeX sources, a shared preamble and a manifest-driven LuaLaTeX build. Roman pagination distinguishes preliminary pages from the Arabic-numbered main body. Clauses run continuously; annexes have explicit status headings. No target page count, blank filler or enlarged type is used as a completeness criterion. The assessment includes substantive coverage, traceability, counterexamples and known limitations.

E.3 Open matters

The final accessibility target and a tested alternative reading representation remain open. The exact incorporation of licensed external terminology requires rights review. The full IEEE style-manual download and the complete ISO/IEC Directives edition identified in the external register were not retrieved during this revision; no conformity claim is made to unavailable text. Local participation and approval choices remain matters for programme governance rather than editorial styling.

GENERATIVITY STANDARDS PROGRAM

GR/TC 1 Charter

Governance Working Draft

Version 0.3 2026-09-22

Generativity Records and Infrastructure

WORKING DRAFT FOR REVIEW

This document contains proposed provisions for technical and institutional review. It is not an adopted Standard or an operative governance instrument. Its scope, application conditions and publication status are specified in the text.

Prepared by the Generativity Standards Program. Reference to external publications does not imply endorsement by ISO, IEC, IEEE or any United Nations body.

Foreword

Version 0.3 records the bounded substantive review of the archived 0.2 package. Its requirement text is retained in this coordinated edition; updated references identify the companion 0.3 drafts. The review matrix, synthetic assessments and unresolved readiness questions are documented in `docs/reviews/validation_0.2/README.md`. These activities do not constitute adoption or an independent institutional assessment.

This document specifies the proposed mandate and working obligations of GR/TC 1. It is a Governance Working Draft and does not constitute the committee or approve a work item. Version 0.2 retains the original TC requirement identifiers and develops the operational steps, review records, pilot controls, and readiness evidence required to exercise the mandate.

Responsible editor: `UNASSIGNED`. Canonical source: `governance/technical_committee_charter.tex`. Intended readers are the programme decision authority, prospective committee participants, editors, domain reviewers, affected people, implementers, and maintenance owners.

The Charter concerns committee performance and the evidence submitted for programme decisions. Programme authority, formal review periods, voting, and appeals remain governed by the companion programme Charter and Directives. Technical requirements are adopted through those procedures, not through this document's existence.

Bibliography 12

Introduction

Developing infrastructure for warranted recognition requires coordination across several kinds of work. A coherent representation can remain evidentially weak; an accessible presentation can expose protected people; and a successful prototype can rely on an institutional authority that does not exist. Committee work therefore needs explicit responsibilities for source interpretation, requirements, practical procedures, implementation, multidisciplinary review, and evidence of effects.

The committee's organizing task is to preserve distinguishable histories of the situation under inquiry, evidence and judgment, and the categories or methods used to recognize it. Requirements begin with a bounded practical or normative problem. Specifications implement reusable infrastructure where that need is demonstrated. Pilots test the resulting practices and reveal costs, exclusions, loss, and failures as well as successful behavior.

One coordinated committee is proposed initially. Additional working groups are activated by actual scope and accepted participation rather than by a list of anticipated disciplines. Review of epistemic, ethical, institutional, legal, political-economic, archival, and technical issues remains distributed across competent and affected participants, with missing capacity reported.

1 Scope

1.1 Committee subject

This Charter specifies constitution, work-item control, assignment of functions, source and requirements discipline, multidisciplinary review, pilot management, publication progression, and maintenance coordination for GR/TC 1. The assessed subject is an identified committee activity or deliverable-development process within its recorded mandate.

1.2 Limits and portfolio

The proposed scope includes vocabulary, recording requirements, epistemic representation, evidence and interpretation, contestation and revision, institutional use, information models, exchange, presentation, preservation, access, and assessment.

2 Normative references

2.1 Internal dependencies

The following Governance Working Drafts, version 0.3, contain provisions required by this Charter. Their exact operative editions are fixed by the recorded programme adoption and committee mandate.

Standards Programme Charter. `governance/standards_programme_charter.tex`; authority, participation, appointments, resources, reserved decisions, and governance launch.

Directives Part 1. `governance/directives_part_1.tex`; work-item initiation, stages, public review, decisions, appeals, and maintenance.

Directives Part 2. `governance/directives_part_2.tex`; publication structure, normative drafting, dependencies, conformance, and production.

Ethics, Conflict-of-Interest, and Contribution Rights Policy. `governance/ethics_ip_policy.tex`; conflict, protection, substantive impact, and contribution-rights handling.

2.2 Edition control

TC-031 The convenor shall record the governance editions applicable to committee work and identify unresolved conflicts before dependent action. A new draft or external source shall not change an operative committee obligation by implication.

Foundation manuscripts and external documents cited in the bibliography provide informative sources. A technical publication's own normative references are assessed separately.

3 Terms and definitions

3.1 Work item

An authorized bounded activity with a problem, scope, intended outputs, responsibilities, dependencies, review plan, and expected evidence. A preliminary proposal is not an authorized work item.

3.2 Requirement baseline

An identified edition of candidate provisions and their associated source, decision, dependency, and assessment records used for a specified review or exercise.

3.3 Review finding

A recorded assessment of a stated question within a reviewer's competence, identifying evidence, reasons, limits, effect on progression, and requested disposition.

3.4 Blocking finding

A finding that a mandatory procedural, authority, protection, rights, or evidential condition for the proposed progression remains unmet. Its materiality is recorded against that progression, not asserted by a label alone.

3.5 Pilot

A bounded exercise of proposed practices or implementations under a declared purpose, case, authority, permissions, evaluation method, and stopping arrangements.

3.6 Independent evidence

Evidence produced or reviewed with the relevant organizational, authoring, financial, and practical dependencies declared and assessed for the particular independence claim.

3.7 Assessment method

A specified means of evaluating an applicable requirement, including its inputs, procedure, expected evidence, result categories, and limits.

3.8 Coordination issue

A disagreement or dependency spanning deliverables or domains whose resolution affects scope, meaning, implementation, assessment, or authority.

4 Mandate and work programme

4.1 Authorization and entry

TC-001 The committee shall become active only through a recorded mandate under the adopted programme Charter. The mandate shall identify its convenor, responsible decision authority, participating capacities, accepted work items, review resources, and mandate review date.

TC-002 The committee shall develop coordinated recording and practical procedures that support warranted, contestable, revisable recognition and preservation of consequential generative trajectories. Each accepted work item shall state its contribution to this purpose and the limits of its expected effects.

TC-003 Committee work shall distinguish changes in the situation under inquiry, changes in evidence and judgment, and changes in categories or methods of recognition. A technical representation connecting these histories shall preserve their distinguishable meaning.

TC-004 The committee shall retain the distinctions between theoretical metamodel, operational record ontology, epistemic representation, normative assessment, jurisprudential status, institutional governance, political economy, and implementation when defining scopes or allocating work.

TC-005 The committee shall not claim authority to certify substantive historical truth, resolve a complete metaphysics, determine legal rights across jurisdictions, endorse a political choice on technical grounds alone, or mandate unrestricted disclosure of recorded material.

TC-006 The committee shall preserve existing publication identifiers when refining scopes. A proposal to change a publication's class, merge or divide its scope, or introduce a new identifier shall record the reason, dependencies, alternatives, and authorizing decision before the change is treated as operative.

TC-007 A work-item proposal shall identify purpose, scope and exclusions, conformance subjects, affected interests, foundation sources and tensions, existing alternatives, related publications, anticipated Specifications, reviewer competence, practical evidence, and maintenance ownership.

TC-010 A proposed substantive scope expansion shall return to the responsible decision authority with its consequences for participation, sources, dependencies, review, and resources. Work outside the authorized scope shall remain exploratory pending a decision.

TC-032 On acceptance of a work item, the convenor shall create a project record linking the authorized proposal, actual decision, bounded outputs, accepted assignments, resources, milestones, dependencies, and unresolved conditions. The record shall distinguish preliminary drafting already performed from work formally authorized.

TC-033 Before scheduling a progression review, the convenor shall verify that the work remains within its mandate, that required responsibilities are staffed, and that necessary evidence is available. A scope or capacity defect shall receive correction, narrowing, or deferral rather than an unsupported stage label.

4.2 Programme coordination

TC-008 The committee shall record work-item dependencies and allocate requirements to their responsible publication before producing a normative technical binding. A shared requirement shall have one authoritative location, with versioned references from dependent work.

TC-009 Editors shall begin with the normative or procedural need and create a Specification proposal when reusable infrastructure is required to satisfy or assess it. A prototype shall not silently determine a theoretical definition or institutional obligation.

TC-034 The committee shall maintain a dependency register identifying each shared concept, requirement, interface, profile, or artifact; its responsible publication and owner; its exact version; and the consequence of change. Competing normative homes shall be resolved before the affected requirement is stabilized.

TC-035 For a coordination issue, the convenor shall identify affected editors and reviewers, record alternatives and semantic or institutional consequences, and seek an explicit decision within the appropriate authority. Technical convenience shall not resolve a normative, legal, or theoretical disagreement without that decision.

TC-036 A split, merger, pause, or termination of a work item shall identify the fate of requirement identifiers, comments, evidence, responsibilities, dependencies, and publication expectations. The programme decision authority shall authorize the revised scope before dependent formal progression.

4.3 Specification and protocol initiation

TC-037 A Specification proposal shall identify the candidate requirement it supports, the need for a reusable technical contract, implementation alternatives, version assumptions, and the evidence expected from a prototype. An institutional procedure shall identify its actual authority separately from protocol mechanics.

TC-038 Before treating a protocol draft as ready for implementation, its editor shall define participants, inputs, preconditions, state transitions, observable outcomes, refusals, failures, recovery, authorization boundaries, and responsibility for interrupted or conflicting operations. Unresolved behavior shall be marked and excluded from unsupported completeness claims.

5 Organization and conduct of work

5.1 Assignments and competence

TC-011 For each active deliverable, the committee shall record an accepted editor or lead, a maintenance contact, required review competence, available reviewers, and unfilled roles. Multiple roles held by one person shall be declared.

TC-012 A new working group shall have a bounded scope, actual willing participants, an accountable lead, dependencies, intended outputs, and review or closure conditions. Its formation shall not imply autonomous adoption authority.

TC-013 A reviewer shall identify the domain and scope of their assessment, relevant competence or situated knowledge, interests, material limitations, and whether they contributed to the material reviewed. A self-review shall not be labelled independent.

TC-014 Where required expertise or affected perspectives are unavailable, the committee shall record the gap and its material effect on progression. It shall narrow claims, seek additional review, or defer the affected decision when the gap prevents a justified assessment.

TC-039 An editor shall accept responsibility for the deliverable's current baseline, change record, source and requirement trace, pending comments, and progression evidence. A reviewer shall accept a bounded assessment assignment rather than an unspecified endorsement of the entire publication.

TC-040 The convenor shall compare each work item's planned drafting, review, accessibility, protection, and maintenance tasks with actual participant capacity. A shortage affecting mandatory evidence or a safeguard shall change the schedule or scope and be reported to the programme decision authority.

5.2 Meetings and asynchronous work

TC-041 For a substantive committee discussion, the convenor shall circulate the purpose, input versions, questions, expected output, access arrangements, and route for asynchronous contributions before the decision is taken. Participants unable to attend shall have the applicable opportunity to contribute under Directives Part 1.

TC-042 The discussion record shall distinguish persons present from represented institutions, information reported from findings accepted, and recommendations from authorized decisions. Material reasons, alternatives, objections, actions, owners, and affected baseline versions shall be recorded.

TC-043 Where new material changes the basis of a proposed decision during a meeting, the chair shall identify the change and apply the relevant further-review procedure. Attendance or an informal show of support shall not replace required notice, reply, or ballot.

5.3 Handover and group closure

TC-044 An editor or working-group handover shall provide the current baseline, requirement and source registers, unresolved comments and findings, dependencies, permissions, build or assessment instructions, and pending deadlines. The convenor shall verify receipt and record any gap before further reliance on the work.

TC-045 A working group that has no accepted lead or capacity to discharge its mandate shall be reported as inactive or pending reassignment. Its outputs shall retain their actual maturity, and unfinished responsibilities shall be reassigned or explicitly deferred.

6 Source interpretation and requirements

6.1 Foundation and external sources

TC-015 Before introducing or materially changing a GR definition, notation, ontology class, or compatibility claim, the responsible editor shall examine the relevant foundation manuscripts and record exact source locations, terminology, scope, historical differences, and the proposed operational translation.

TC-016 The committee shall preserve unresolved foundation differences rather than harmonizing them silently. A material operational narrowing or departure shall be recorded through an architectural decision with alternatives, rationale, affected publications, and remaining uncertainty.

TC-017 A candidate record-class definition shall identify its definition, admissibility conditions, identity criterion, temporal behavior, permitted relations, required and optional metadata, examples, counterexamples, and unresolved edge cases, or explicitly identify which elements remain under development.

TC-018 An external compatibility or reuse proposal shall identify the exact source and edition, verified relevant provisions, mapping assumptions, exclusions, and evidence needed to support the claimed relationship. Similar terminology shall not alone establish equivalence.

TC-046 The source register shall distinguish source wording, editorial paraphrase, historical variant, operational proposal, and accepted programme decision. Each material interpretation shall identify the relevant passage and version, verification status, and unresolved difference.

TC-047 When a source is revised, newly available, or found to have been misinterpreted, the editor shall identify affected definitions and requirements, assess the consequence, and submit necessary changes through the appropriate procedure. Earlier interpretations and the reason for revision shall remain traceable.

6.2 Requirement formation

TC-048 For each candidate requirement, the editor shall identify the responsible actor or subject, applicability condition, required outcome, assessment method, evidence expectation, source or operational rationale, and related issue or decision. A requirement with unresolved scope or testability shall retain a visible development issue.

TC-049 The editor shall separate independently assessable obligations where one result would conceal different applicability or failure. Recommendations, examples, and explanatory theory shall remain distinguishable from mandatory provisions.

TC-050 Before stabilizing a requirement baseline, the review group shall examine examples, counterexamples, unknown or unavailable information, restricted records, and relevant conflicting interpretations. Required uncertainty declarations shall not be replaced by invented information to complete a record.

6.3 Assessment design and claims

TC-026 A conformance proposal shall identify the assessed subject, edition, profile, applicable requirements, methods, evidence, unresolved findings, and limits of the resulting claim. Syntax checks, semantic interoperability, procedural compliance, usability, and substantive warrant shall receive distinguishable results.

TC-027 The committee shall substantiate an interoperability claim with independent implementation or exchange evidence appropriate to the claim. A single internally consistent prototype shall be reported as such.

TC-051 The requirement-to-assessment register shall identify which findings arise from automated checks, observed human tasks, documentary review, independent implementation, or substantive expert judgment. The reported result shall not claim evidence beyond what the chosen method establishes.

TC-052 A proposed profile shall identify inherited requirements, additions, permitted restrictions, applicability, and assessment consequences. The editor shall identify any divergence that prevents unqualified parent conformance and propose an appropriately bounded claim.

TC-053 An asserted external mapping shall identify direction, supported distinctions, unsupported cases, loss, and the exact tested source versions. An untested mapping shall be labelled proposed rather than interoperable.

7 Multidisciplinary review

7.1 Planning and scope

TC-019 At work-item scoping, before a real pilot, and before publication progression, the committee shall maintain a review dossier covering applicable epistemic, ethical, jurisprudential, institutional, political-economic, archival, privacy/security, accessibility, and technical questions. Each domain shall have findings or an explicit justified statement of non-applicability or unassessed scope.

TC-020 The review dossier shall identify evidence, reviewers and their capacities, affected perspectives, conflicts, alternative designs, findings, dispositions, owners of corrective action, and residual limitations. A metadata field or completed checklist shall not by itself count as domain assessment.

TC-054 The review plan shall state the questions, needed competence and affected perspectives, evidence, review independence sought, access arrangements, and decision points for each applicable domain. It shall distinguish non-applicability from unavailable review capacity.

7.2 Findings and disagreement

TC-055 Each domain reviewer shall classify a finding by the affected requirement or assumption, evidence and uncertainty, consequence for the proposed decision, and proposed disposition. A disagreement about values or policy shall be identified as such rather than converted into an unexplained technical defect.

TC-056 The editor shall respond to each material finding with acceptance, modification, reasoned non-acceptance, or deferral, linking the resulting text or action. A deferred finding shall retain an owner, next action, and explanation of whether progression is prevented.

TC-057 Where reviewers disagree across domains, the convenor shall preserve their respective questions, evidence, competence, and reasons and obtain a decision from the authority competent for the matter. A technical majority shall not substitute for an absent legal mandate or resolve a philosophical source conflict by assertion.

TC-058 Before recommending progression, the convenor shall verify that material findings and replies have been considered and that mandatory authority, evidence, rights, and protection conditions are satisfied. A decision to narrow scope shall identify the excluded behavior and prevent it from appearing in the resulting conformance claim.

7.3 Jurisprudential and policy interfaces

TC-021 A legal or institutional profile shall state its jurisdiction or forum, target action, relevant sources and status, claimed authority, temporal scope, unresolved conflicts, and reviewing competence. Generic technical conformance shall not replace assessment of actual applicability.

TC-022 A policy proposal arising from committee work shall follow the separate policy-publication route and compare plausible institutional options, including existing infrastructure or deferral when relevant. The committee shall not present participation in technical review as assent to a policy recommendation.

TC-059 A jurisdictional or institutional reviewer shall distinguish a party's assertion, an applicable source identified by the reviewer, an institution's operative decision, and an unresolved interpretation. The profile shall state the temporal and contextual limits of that review.

TC-060 For an institutional or international-policy proposal, the committee shall identify which technical findings are evidence for the proposal and which recommendations concern mandate, funding, distribution, oversight, or adoption choices. Unaccepted institutional participation shall remain prospective.

8 Pilot preparation and authorization

8.1 Protocol and evidence plan

TC-023 Before a pilot begins, its record shall identify the case and baseline, questions and success criteria, participants and actual authority, material and access permissions, resource burden, anticipated harms, challenge and correction routes, stop conditions, and responsible reviewers. Synthetic cases shall be labelled synthetic.

TC-024 The initial coordinated demonstration shall exercise a claim and its grounds, a consequential relation or contribution, an alternative or challenge, a reasoned response, a historical revision, a protected or unavailable record, and a presentation that makes their distinct status understandable.

TC-061 The pilot plan shall pin the requirement baseline, artifacts, scenario, input material, evaluation tasks, expected results, assessors, and comparison baseline before results are interpreted. A change during the exercise shall identify the reason and its effect on comparability.

TC-062 For a real pilot, the responsible authority shall verify participant and institutional permissions, rights to material, protection arrangements, accessible challenge routes, available remedy, and stopping authority before the affected activity starts. A planned safeguard shall not be reported as operational without evidence of implementation.

TC-063 A pilot relying on restricted evidence shall identify how authorized assessors can evaluate the relevant requirement and how a public result can communicate limitations safely. Lack of public access shall not be equated with absence of evidence or accepted as proof of adequacy.

8.2 Execution and interruption

TC-064 The pilot operator shall retain observations of performed tasks, relevant inputs and outputs, failures, participant assistance, departures from the plan, and protection incidents, within the approved access and retention conditions. Simulated events shall remain distinguishable from observed real behavior.

TC-065 When a stopping condition is met or an unanticipated material harm or authority defect is identified, the pilot operator shall pause the affected activity, notify the responsible authority, protect necessary evidence, and obtain a recorded disposition before restart. Unaffected activity may continue only within its existing authority and safeguards.

TC-066 A pilot restart shall identify the corrected condition, evidence that the response is operational, changed baseline or scope, required further permissions or notice, and the decision maker. A technically successful repair shall not alone establish restored participant protection.

9 Pilot evaluation and implementation evidence

9.1 Results and learning

TC-025 Pilot findings shall report failed tasks, missing or conflicting evidence, excluded participants, unmet assumptions, and burdens alongside successful behavior. The committee shall trace each material finding to a requirement change, retained decision with reasons, further inquiry, or scope limitation.

TC-067 The evaluator shall report the actual participant population, excluded or unavailable perspectives, resource burden, supported tasks, failed cases, assistance required, uncertainty, and limits on transfer to other contexts. A small cooperative exercise shall not be presented as evidence of general institutional adoption.

TC-068 The committee shall compare pilot results with the declared objectives and assessment criteria and trace each material finding to a requirement change, retained decision with reasons, further inquiry, or narrower claim. Unexpected benefits and harms shall be identified separately from the planned criteria.

TC-069 Where an outcome depends on later institutional action or effects on future capacity, the report shall state whether that action or effect was observed, is pending, or was outside the study period. A corrected record shall not be treated as evidence that downstream consequences were repaired.

9.2 Reproducibility and independence

TC-070 An implementation-evidence package shall identify source and artifact versions, configuration, test material, expected and actual outcomes, access or licence constraints, and instructions sufficient for an authorized reviewer to repeat the relevant assessment. Reproduction gaps shall be disclosed.

TC-071 For an independence claim, the convenor shall record who authored the requirements, implemented the artifacts, selected the cases, performed the assessment, and funded or controlled the work. The claimed degree of independence shall be limited to the separations actually evidenced.

10 Progression, maintenance, and publication

10.1 Readiness dossier

TC-028 For each requested progression decision, the convenor shall assemble the current draft, requirement and source trace, comment dispositions, unresolved objections, multidisciplinary findings, pilot or other assessment evidence, rights-clearance status, and maintenance proposal. The programme decision authority shall apply Directives Part 1.

TC-072 The progression dossier shall identify the requested decision and provide a requirement-by-requirement evidence status, unresolved finding register, dependency review, public-comment status where applicable, source and rights clearance, and implementation or pilot limitations. Missing evidence shall remain visible rather than being treated as tacit approval.

TC-073 Before forwarding a public-review or release package, an assigned reviewer shall check that the source, rendered document, associated artifacts, and declared status agree and that references, identifiers, and essential content remain usable. Material discrepancies shall be corrected through the applicable change procedure.

10.2 Change and maintenance

TC-029 The committee shall retain a link from a corrected or superseded requirement to the prior text, reason, decision, affected dependencies, and migration consequence. Historical decisions shall remain

distinguishable from the current authoritative edition.

TC-030 The committee shall submit scope, participation, resource, and outstanding-risk information at its mandate review and when material conditions change. An inactive or unstaffed work item shall receive an explicit status and continuity disposition.

TC-074 A substantive change shall identify affected requirements, interpretations, assessment fixtures, profiles, dependencies, existing users, and migration consequences. The maintenance owner shall distinguish a correction from an altered obligation and invoke the corresponding Directives route.

TC-075 On evidence of a serious defect or loss of a necessary dependency, the convenor shall notify the authorized maintenance or release holder with the affected versions, evidence, consequences, and proposed interim response. The committee shall not issue a permanent normative change through an informal implementation update.

11 Committee assessment

11.1 Assessment method

TC-076 An assessment of committee performance shall declare the activity, period, mandate and governance editions, assessor, interests, applicable TC requirements, evidence, and result for each requirement. Results shall distinguish fulfilled, not fulfilled, not assessed, and not applicable.

TC-077 The assessment shall include a trace from a selected material problem through source interpretation, candidate requirement, alternatives, assessment method, pilot or review evidence, disposition, and authorized decision. Breaks in the trace shall be recorded with their effect on the claimed readiness.

11.2 Correction and oversight

TC-078 The convenor shall assign owners and review dates for material performance findings and report unresolved scope, participation, capacity, or protection issues to the programme decision authority. Closing an action shall identify evidence of completion and any remaining limitation.

Annex A

(normative)

Committee dossier and record content

A.1 Work-item and baseline record

TC-079 The committee shall maintain a work-item and baseline record containing the authorized problem and scope, decision and mandate, output classes, accepted roles, sources, dependencies, versions, requirements, assessment methods, review milestones, permissions, resources, and remaining conditions. Each substantive update shall identify the responsible actor and reason.

A.2 Source and requirement trace

TC-080 The editor shall maintain a trace for each material requirement identifying its stable identifier, responsible publication, condition and subject, source passage or operational proposal, alternatives, decision rationale, assessment method, evidence, dependency versions, and unresolved question. Superseded interpretations shall remain linked to their replacements.

A.3 Domain finding record

TC-081 A domain finding record shall identify the question, scope, reviewer and competence, relevant interests, evidence and access limitations, assessed alternatives, finding and reasons, progression effect, response, reply, action owner, and closure evidence. A safe public account shall be linked where the full record is restricted.

A.4 Pilot and assessment record

TC-082 A pilot record shall identify its authorization, actual participants, baseline versions, scenario, data and permissions, evaluation tasks, expected and actual outcomes, failures, burdens, deviations, stopping or restart decisions, evidence limitations, and requirement dispositions. Synthetic and independent elements shall be explicitly identified.

A.5 Progression and handover index

TC-083 The convenor shall provide an index linking the current baseline, scope decision, review and comment dispositions, pilot evidence, blocking findings, rights status, artifact manifest, maintenance assignment, and requested decision. The index shall identify unavailable or incomplete elements and their proposed treatment.

Annex B

(informative)

Worked review and implementation cases

B.1 Missing evidence mistaken for non-occurrence

A synthetic institution records an uncalibrated instrument because no calibration field was present. A participant later supplies a restricted maintenance log. The exercise tests whether the representation distinguishes absent metadata from an occurrence claim, whether authorized review can consider the log, and whether the presentation exposes the changed basis without disclosing protected detail. Source and requirements review examine the inference; institutional review examines who can reconsider the consequential decision.

B.2 Technically successful but incomplete exchange

Two implementations exchange a current judgment successfully but omit its prior category and an unresolved objection. A syntax result can remain successful while trajectory and presentation requirements fail. The failure becomes evidence for a changed exchange requirement or an explicitly narrower profile, rather than being hidden by the successful parse.

B.3 Conflicting review considerations

An archival reviewer favors retaining an earlier attribution, while a protection reviewer identifies a risk in public release. Their findings address different questions. The committee examines preservation with restricted access, a safe public correction, and retention limits. A decision states the authority and evidence for each outcome without declaring either archival value or protection irrelevant.

B.4 Deferred theory and bounded implementation

A proposed mapping treats Property and the metamodel manuscript's Attribute as identical. The foundation register retains the difference and identifies the exact operational scope being proposed. An exploratory implementation can test one mapping with an experimental label. Stabilizing it requires the recorded interpretation and architectural decision; implementation convenience does not supply the missing conceptual argument.

B.5 Unresolved matters

OPEN ISSUE Committee appointments, accepted work items, domain-review capacity, actual independent implementers, and real institutional pilot mandates remain unassigned or unapproved. An exercise against this draft does not fill those roles.

OPEN ISSUE Property/Attribute interpretation, manuscript version precedence, and the relation between fixed-carrier semantics and broader emergence remain source questions. Their resolution is separate from the constitution of the committee.

Bibliography

Source and interpretation: Programme Brief, version 0.5; comprehensive development plan, cross-domain programme, protocol plan, and foundation traceability map in `docs/planning/`. These establish the local mission and proposed work architecture.

Source and interpretation: Foundation orientation: FM-001, Chapter 1, section 1.14, pp. 79–83; FM-003, Chapter 3, section 3.12, pp. 129–132; FM-005, Chapter 5, section 5.18, pp. 150–153. Exact files and unresolved source chronology are indexed in `foundation_manuscripts/MANIFEST.md`.

Source and interpretation: ITU-T Recommendation A.1 (09/2019), Working methods for study groups of the ITU Telecommunication Standardization Sector. Official edition and status page, consulted 22 September 2026: https://www.itu.int/itu-t/recommendations/rec.aspx?rec=a.1. The source concerns meetings, study management, coordination, rapporteurs, and contributions. It informs comparison of functional responsibilities; its membership and approval authority are not imported.

Source and interpretation: United Nations, National Quality Assurance Frameworks Manual for Official Statistics, 2019. Official publication overview, consulted 22 September 2026: https://desapublications.un.org/publications/united-nations-quality-assurance-frameworks-manual. It addresses assurance across national statistical systems and different data sources. This committee uses a narrower local comparison: quality questions belong throughout the development process and cannot be reduced to artifact syntax. No official-statistics mandate or UN endorsement is inferred.

Source and interpretation: ISO, Model International Standard, third edition, 2023, https://www.iso.org/iso/model_document-rice_model.pdf; IEEE SA policy comparisons and source-edition limits recorded in `docs/planning/standards_development_comparison.md`. Structural adaptation is separate from adopting those organizations' procedures.

GENERATIVITY STANDARDS PROGRAM

Ethics and IP Policy

Governance Working Draft

Version 0.3 2026-09-22

Ethics, Conflict-of-Interest, and Contribution Rights Policy

WORKING DRAFT FOR REVIEW

This document contains proposed provisions for technical and institutional review. It is not an adopted Standard or an operative governance instrument. Its scope, application conditions and publication status are specified in the text.

Prepared by the Generativity Standards Program. Reference to external publications does not imply endorsement by ISO, IEC, IEEE or any United Nations body.

Foreword

Version 0.3 records the bounded substantive review of the archived 0.2 package. Its requirement text is retained in this coordinated edition; updated references identify the companion 0.3 drafts. The review matrix, synthetic assessments and unresolved readiness questions are documented in `docs/reviews/validation_0.2/README.md`. These activities do not constitute adoption or an independent institutional assessment.

This document specifies proposed programme requirements for conduct, conflict management, ethical impact assessment, contribution rights, and implementation-rights concerns. It is a Governance Working Draft. Version 0.2 preserves the EIP identifiers from version 0.1, clarifies the distinction between the mandatory acknowledgement period and extendible determination target in EIP-014, and adds operational handling, assessment, and evidence requirements.

Responsible editor: `UNASSIGNED`. Canonical source: `governance/ethics_ip_policy.tex`. Intended readers are contributors, affected people, ethics and rights reviewers, project leads, custodians, and the programme decision authority.

Adoption requires the programme's actual authority and recorded procedure. This text is not a licence offer, copyright transfer, patent assurance, or legal determination. The specific organizational and jurisdictional context remains to be established for commitments that depend on it.

Bibliography 17

Introduction

The infrastructure being developed can affect whose experience becomes visible, whose evidence receives consideration, and who can challenge an authoritative account. Programme participation can reproduce unequal access, while publication and preservation can expose people or depend on rights the programme does not hold. Ethical assessment therefore concerns both development conduct and the effects of proposed practices.

This policy separates four inquiries: whether programme conduct meets its rules; whether an interest impairs a particular role; whether a design or pilot has unacceptable or unresolved effects; and whether a proposed use of material has an established basis. Evidence of one does not resolve another. A well-attributed contribution can remain inaccurate; an ethically desirable publication can lack distribution permission; and a contribution from an interested person can still contain relevant evidence.

The policy supplies procedures and records rather than a universal score of ethical adequacy or generativity. It retains value disagreement, limitations of inquiry, and the distinction between internal programme remedies and external legal proceedings.

1 Scope

1.1 Subjects and application

This policy applies to participants acting in programme functions, programme decisions about conduct and conflicts, impact review of work items and pilots, and intake or distribution of contributed material. Its assessed subject is a specified activity, decision, contribution, or handling process under a declared edition.

1.2 Authority boundary

Internal corrective measures concern participation, assigned functions, programme access, and programme publications. Financial compensation, enforceable legal duties, jurisdiction, and findings of legal liability require separately established authority. Contribution rights and legal applicability remain subject to their actual context.

2 Normative references

2.1 Internal provisions

The following Governance Working Drafts, version 0.3, supply provisions needed by this policy. Exact operative editions are fixed through recorded adoption.

Standards Programme Charter. `governance/standards_programme_charter.tex`; appointments, decision authority, participation, resources, reserved powers, and neutral review.

Directives Part 1. `governance/directives_part_1.tex`; handling periods, appeal, emergency measures, release, retention, and maintenance.

Directives Part 2. `governance/directives_part_2.tex`; source discipline, publication claims, dependencies, evidence, and production.

GR/TC 1 Charter. `governance/technical_committee_charter.tex`; domain review, pilot authorization, findings, and progression evidence.

2.2 Application of timing and sources

The mandatory acknowledgement period and the initial-determination target cited in EIP-014 apply the specified Directives provisions to conduct handling without changing its substantive route. Only the initial-determination target has the cited reasoned-extension provision. External sources in the bibliography are informative; no external treaty, recommendation, statute, or institutional policy is incorporated as a generally applicable legal obligation.

EIP-041 The responsible handler shall identify the operative policy and procedure editions for each matter and record any conflict affecting authority, timing, protection, or available remedy. A consequential dependent determination shall await resolution of a material conflict within actual authority.

3 Terms and definitions

3.1 Material interest

A financial, institutional, personal, authorship, funding, or infrastructure-control interest relevant to impartial performance of a specified programme function.

3.2 Conflict-management decision

A reasoned determination of whether an interest affects a particular function and what disclosure, oversight, separation, recusal, replacement, or deferral is required.

3.3 Report

Information submitted concerning possible conduct, protection, conflict, or rights problems. Receipt does not establish the allegation.

3.4 Reported person

A person whose programme conduct is the subject of a report or inquiry. The term does not imply a concluded finding.

3.5 Protective measure

A temporary action intended to limit an identified immediate risk while fair consideration remains incomplete. It is distinct from a final conduct finding or sanction.

3.6 Rights clearance

A scoped programme determination that an identified use of particular material is supported by recorded permissions or another reviewed basis, subject to stated limitations.

3.7 Contribution

Material submitted for a stated programme purpose, including prose, comments, schemas, software, examples, data, or source materials. Submission alone does not establish ownership or a licence for further uses.

3.8 Impact finding

An assessed actual or anticipated consequence of a proposed practice, identifying affected interests, evidence, uncertainty, values, alternatives, and proposed response.

3.9 Retaliation

Adverse programme treatment because a person raised a concern, gave relevant evidence, participated in review, or exercised a permitted challenge route. A reasoned response to independently established misconduct is assessed separately.

4 Responsibilities and readiness

4.1 Assignment and independence

EIP-001 The programme shall identify the adopted edition, effective scope, responsible ethics contact and alternate, protected reporting route, decision authority, and neutral-review route before treating this policy as operational. Until then it shall retain Governance Working Draft status.

EIP-002 The programme shall assess conduct, conflicts, substantive impacts, and contribution rights through distinguishable findings. A favorable finding in one area shall not be represented as clearance in

another.

EIP-042 The governance authority shall assign an ethics contact, an alternate, conflict-decision responsibility, competent rights review, record custody, and neutral procedural review before relying on those functions. Each holder shall accept a bounded mandate and declare interests; an unassigned function shall remain visibly unavailable.

EIP-043 The ethics contact shall receive and triage reports, arrange appropriate consideration, communicate status, and protect access. The investigator or assessor shall examine the stated question; the authorized decision maker shall determine programme findings and remedies. Where functions are combined, the record shall identify resulting limits and independent review needed.

EIP-044 Before opening a protected reporting route, the custodian shall verify restricted access, a safe alternate contact, retention arrangements, incident handling, and the information provided to reporters about confidentiality limits. If the route fails, the custodian shall publish or directly provide a safe alternative and prevent further avoidable disclosure.

4.2 Capacity and access to assistance

EIP-045 The responsible authority shall provide information on feasible assistance with language, access, or submission format and shall record unmet needs and their effect on fair consideration. A person shall not be required to expose protected information publicly to obtain assistance.

EIP-046 A material capacity gap in impartial handling, rights competence, or protection shall be reported to the governance authority with a proposed reassignment, narrower scope, or deferral. Continued drafting within existing permission shall remain distinct from approval of the affected use or finding.

5 Conduct and evidential integrity

5.1 Participation and attribution

EIP-003 Participants acting in programme roles shall not engage in harassment, threats, retaliation, discriminatory exclusion, or coercive disclosure of protected information. Critical disagreement about sources, methods, policy, and requirements shall remain eligible for reasoned consideration.

EIP-004 A participant presenting a factual or source-based claim shall distinguish observation, quotation, interpretation, inference, and proposal where that distinction affects review. Known material errors, fabricated evidence, or falsely attributed sources shall not be retained as support after discovery without correction or explicit disputed status.

EIP-005 Editors shall preserve attribution of material contributions and competing positions within actual permissions and protection needs. Authorship, acknowledgement, evidential reliability, ownership, and decision authority shall remain distinct.

EIP-047 A participant identifying a material error in their earlier contribution shall notify the responsible editor and supply the correction or known uncertainty. The editor shall assess affected arguments, decisions, and artifacts and retain an attributable correction record.

EIP-048 A claim that a contribution was deliberately fabricated or knowingly misattributed shall be assessed through the conduct procedure. A disputed interpretation, incomplete evidence, ordinary error, or unsubstantiated report shall not by itself establish intentional misconduct.

5.2 AI and external processing

EIP-006 A participant using AI assistance for a material draft, analysis, evidence synthesis, or disposition proposal shall identify the consequential assistance and the responsible human reviewer in the development record. The reviewer shall verify material sources and conclusions before relying on them.

EIP-007 Participants shall not submit protected, confidential, or third-party material to a tool or service without an established basis for that disclosure. Uncertainty about such a basis shall be resolved before the disclosure.

EIP-049 A consequential AI-use record shall identify the task, material source categories, transformations relied on, responsible human reviewer, verification performed, and known limits relevant to the resulting claim. Protected prompts or source contents shall not be exposed solely to demonstrate that assistance occurred.

EIP-050 When external processing terms or data handling change materially, the responsible user shall reassess permitted disclosure and reliance before further affected use. A tool's technical availability shall not establish permission to disclose material or confidence in its output.

6 Interests and influence

6.1 Disclosure and assessment

EIP-008 Before accepting a decision or review role and when relevant circumstances change, a participant shall disclose interests that could materially affect, or reasonably call into question, their impartial performance of that role. The disclosure shall include relevant financial, employment, funding, authorship, institutional, personal, and infrastructural-control interests.

EIP-009 The responsible coordinator shall record a conflict assessment, its author, the affected decision, the disclosed interest, protection limits, and the selected management action. Disclosure alone shall not be treated as resolving a conflict.

EIP-010 A person shall not determine the disposition of a complaint against themselves, act as neutral reviewer of their own decision, or independently assess a rights clearance in which they have an unresolved material interest. The alternate route shall be used.

EIP-011 Conflict management shall identify whether disclosure with oversight, separation of roles, partial recusal, replacement, or deferral is required. A recusal shall identify the decision scope and substitute authority without suppressing relevant technical evidence from the recused contributor.

EIP-012 The decision authority shall examine material concentration of funding, affiliation, available unpaid labor, infrastructure access, and agenda control when assessing fair consideration. If the concentration impairs review, it shall record corrective measures and reassess progression.

EIP-051 An interest disclosure shall identify the affected role or decision, nature and duration of the interest, relevant relationships, and protection needs. The conflict assessor shall distinguish an actual conflict, a reasonably perceived conflict needing management, and an interest not material to the stated role, with reasons.

EIP-052 Before the affected decision proceeds, the conflict assessor shall communicate the management decision to the role holder and responsible chair and record any objection. A challenged assessment involving the assessor's own interests shall be referred to the alternate or neutral route.

6.2 Recusal and control measures

EIP-053 A recusal arrangement shall identify prohibited decision participation, permitted factual or technical contribution, access limitations where justified, substitute authority, duration, and reconsideration trigger. The chair shall verify that the recusal was applied and record its consequence for eligibility or quorum.

EIP-054 If an undisclosed material interest is discovered after a decision, the governance authority shall assess the affected procedure and outcome, obtain independent consideration where needed, and record whether disclosure, renewed review, repeated decision, or another remedy is required. Retrospective disclosure shall not alone cure a defective process.

EIP-055 Measures addressing concentrated influence shall identify the actual mechanism, such as agenda control, dependence on one host, repeated affiliations, or unequal time resources, and the proposed response. The assessment shall not treat head count alone as evidence of balanced influence or stigmatize a contributor solely for an affiliation.

7 Report intake and triage

7.1 Receipt and route

EIP-013 The programme shall provide a reporting route to an ethics contact and an alternate independent of a reported person. Its notice shall explain receipt handling, who can access material, limits on confidentiality, possible outcomes, record retention, and the procedural-review route.

EIP-014 A report shall receive acknowledgement, triage, status communication, and a reasoned disposition. The seven-calendar-day acknowledgement requirement in D1-035 and the 30-calendar-day initial-determination target, with reasoned extensions notified before expiry, in D1-036 shall apply to report handling without converting the report into a procedural appeal. An extension of the determination target shall not extend the acknowledgement requirement. Triage shall distinguish immediate protection needs, conduct issues, procedural appeals, substantive technical objections, and record-specific correction or access requests.

EIP-015 A report shall not be rejected solely because its author requests protected handling or lacks a formal role. The reviewer shall record whether limited identity or unavailable evidence constrains investigation and what fair assessment remains possible.

EIP-056 At intake, the ethics contact shall assign a stable identifier, record the reported concern and relevant programme connection, acknowledge the requested protection, identify immediate risk, and explain the next handling step. Requests for additional information shall be limited to what is needed for that step.

EIP-057 Triage shall identify scope, required authority and competence, potential conflicts, available evidence, immediate protection needs, and whether another programme or external route is relevant. A referral shall preserve the original receipt history and explain what the programme will and will not determine.

EIP-058 When a report contains both a technical objection and a conduct allegation, the handler shall provide linked but distinct handling records. The technical concern shall not lose consideration because the conduct allegation is unsubstantiated, and a conduct concern shall not be dismissed solely because the technical proposal is accepted.

7.2 Protected, anonymous, and repeated submissions

EIP-059 The handler shall assess an anonymous or partly identified report to the extent supported by available information and record limits on verification, reply, and remedy. Identity disclosure shall not be demanded without a stated handling need and consideration of a less intrusive alternative.

EIP-060 A repeated submission shall be linked to earlier handling and assessed for new evidence, unaddressed grounds, or changed circumstances. Limits on repetitive or abusive contact shall state the conduct basis, safe route for materially new information, scope, review date, and challenge route. Mere persistence in disagreement shall not establish abuse.

8 Inquiry and fair response

8.1 Scope and evidence plan

EIP-016 Before an adverse conduct finding, the responsible reviewer shall provide the affected person a sufficient account of the concern and an opportunity to respond, using redaction or a protected intermediary when necessary. Where protection prevents a fair determination, that limitation shall remain explicit.

EIP-061 Before a substantive inquiry, the appointed assessor shall state the questions, applicable programme rules, scope, evidence sources, access arrangements, opportunities to respond, intended timetable, and decision authority. A material expansion shall be notified to affected participants with an adequate response opportunity.

EIP-062 The assessor shall distinguish direct information, testimony, contemporaneous records, inference, hearsay, and disputed interpretation where that distinction affects the finding. Relevant contrary evidence and plausible alternative explanations shall be examined; source status alone shall not determine credibility.

EIP-063 The assessor shall document evidential gaps and the reasons material may be unavailable, including protection, loss, or lack of access. An unavailable record or a person's inability to participate shall not automatically be treated as proof of the alleged conduct or its absence.

8.2 Opportunity to respond and protection

EIP-064 A response invitation shall identify the material concern and grounds sufficiently for a meaningful reply, the response route and deadline, available assistance, and the proposed decision scope. If safe disclosure cannot support a fair finding, the limitation shall prevent an unsupported adverse determination.

EIP-065 The assessor shall avoid unnecessary repeated disclosure of sensitive experiences and shall record how protected testimony can be tested fairly through safe summaries, questions, or an authorized intermediary. A summary materially interpreted by another person shall retain that mediation and any confirmation or dispute by its source.

EIP-066 The handler shall obtain an appropriate rights and protection assessment before disclosing case material to an external institution. A claimed obligation to disclose shall identify the competent authority, context, basis, and unresolved questions; the policy itself shall not be treated as creating that obligation.

9 Protective measures and determinations

9.1 Interim action

EIP-017 A temporary protective measure shall identify the immediate risk, authority, limited scope, review point, and route to challenge. It shall be distinguished from a concluded misconduct finding.

EIP-067 The authority issuing a protective measure shall identify less restrictive feasible alternatives, the effect on participation and evidence access, the person responsible for review, and the conditions for ending or modifying the measure. The D1-050 controls shall apply to temporary protective measures under this policy, including participation restrictions: independent review within seven calendar days and expiry within 30 calendar days unless the governance authority records a justified extension, next review date, and remedy plan. Continued restriction shall retain renewed reasons and an available challenge route; temporary protection shall not become a permanent sanction through elapsed time alone. These controls shall not expand the programme's substantive authority.

EIP-068 A person subject to a protective measure shall receive its scope, safe reasons, duration or review point, and challenge route to the extent consistent with immediate protection. Any delayed notice shall be justified and reviewed rather than omitted indefinitely.

9.2 Findings and evidential criterion

EIP-018 A final conduct disposition shall identify the applicable rule, assessed evidence and limits, conflicts and recusals, finding, reasons, proportionate remedy, responsible implementer, and review route. Available programme remedies include correction, facilitated participation, role reassignment, limited access, suspension, or removal under the Charter.

EIP-020 If a fair, sufficiently independent review cannot be provided, the programme shall record that limitation, preserve appropriate protections, and defer the affected consequential determination. It shall not represent inability to investigate as proof that a report is false or established.

EIP-069 For an internal conduct finding, the decision maker shall distinguish substantiated, not substantiated on available evidence, outside mandate, and resolved by an agreed measure without a conduct finding. A substantiated finding shall explain why the alleged conduct is more likely than not on the assessed evidence, address material contrary information and plausible alternatives, and identify limits. A numerical probability shall not be required. Where the assessment does not favor the alleged conduct over its non-occurrence, including an unresolved balance, the allegation shall not be classified as substantiated. This criterion shall not override EIP-016, EIP-020, or EIP-064 concerning fair response and sufficiently independent consideration, and shall not be represented as an external legal finding or burden of proof.

EIP-070 The decision maker shall distinguish the conduct established, any intention or effect separately supported, the rule engaged, and the resulting programme consequence. A serious remedy shall be supported by reasons addressing severity, impact, recurrence, context, and feasible alternatives within programme authority.

EIP-071 A disposition based on an agreed measure shall record the actual agreement, its scope, responsible parties, review point, and treatment of unresolved allegations. Agreement shall not be presumed from silence or obtained by making access to the ordinary complaint route conditional on acceptance.

9.3 Remedies and review

EIP-019 The programme shall monitor agreed remedies and potential retaliation and shall publish a non-sensitive account sufficient to inspect procedural handling. Confidential material shall not be published merely to demonstrate transparency.

EIP-072 A remedy plan shall identify required actions, owners, practical resources, dates or triggers, completion evidence, and consequences of non-performance. Correcting a record, restoring participation, changing a role, and addressing downstream effects shall be distinguished.

EIP-073 The disposition notice shall explain the finding and safe reasons, the operative procedure, available procedural review, and the basis for any restricted evidence. A request concerning substantive reconsideration shall be distinguished from an appeal alleging procedural failure.

EIP-074 A material new fact or demonstrated handling error shall trigger an assessment of reopening, revised remedy, or referral. The record shall retain the original determination and reasons for changed status; reopening shall not silently erase prior reliance or its consequences.

EIP-075 Monitoring for retaliation shall identify a safe contact and review trigger without imposing unnecessary surveillance on participants. A reported adverse response shall receive separate assessment of its connection to protected participation and any independently stated reason.

9.4 Scoped substantive reconsideration

EIP-099 A reporter or reported person may request substantive reconsideration through the ethics contact or non-conflicted alternate on grounds of material new evidence, an identified material error in assessment or application of the conduct criterion, or a remedy materially unsupported by the stated findings. The request shall identify the disposition, grounds, available evidence, and requested change. Mere repetition without identified grounds may receive a reasoned refusal; disagreement shall not itself constitute misconduct. The disposition notice shall explain this scoped route separately from the procedural appeal route.

EIP-100 The ordinary filing period for substantive reconsideration shall be 30 calendar days after accessible notice of the disposition. The non-conflicted reconsideration reviewer may extend that period with recorded reasons for ineffective notice, newly available material evidence, or a previously concealed assessment defect. The ethics contact shall acknowledge receipt within seven calendar days and arrange an initial admissibility or substantive determination targeted within 30 calendar days of receipt, with reasoned extensions and revised dates notified before expiry. Silence shall not constitute rejection.

EIP-101 The governance authority shall assign substantive reconsideration to a competent person or function that did not determine the challenged finding and has no unresolved material conflict, with a mandate identifying the issues and available programme remedies. The reviewer shall give an admissibility decision with reasons and provide affected parties an opportunity to respond to material new grounds before a consequential outcome. An admitted request shall have a notified timetable for replies and reasoned disposition; a change shall have reasons and notice before the affected target expires. If sufficiently independent competence is unavailable, EIP-020 shall govern deferral; reassessment by the original decision maker shall not be presented as independent reconsideration.

EIP-102 The reconsideration reviewer shall identify the record examined, grounds admitted, evidence and replies considered, criterion applied, reasons, outcome, and implementation responsibility. Within the recorded mandate, the reviewer may uphold, qualify, set aside, or remit a conduct finding or remedy for renewed consideration; a remedy outside that mandate shall be referred to its authorized decision maker. The record shall preserve the earlier finding and explain any changed effect, notice, or practical action. Substantive reconsideration shall not determine external legal liability or replace access to procedural appeal under Directives Part 1.

EIP-103 On a substantive reconsideration request, the responsible authority shall record whether an existing remedy requires a stay, modification, or continued operation within programme powers, considering protection, participation, evidence, and consequences. The decision shall have reasons, a review point, and permitted notice. Neither an automatic stay nor automatic continuation shall be inferred solely from the request. Any temporary restriction retained shall remain subject to EIP-067, and implementation of a reconsideration remedy shall be monitored under EIP-072.

10 Ethical impact assessment

10.1 Question, affected interests, and alternatives

EIP-021 Each work item shall assess whose experiences become visible, who can challenge classifications, who bears recording and review burdens, and who gains control or access through the proposed infrastructure. Assessment shall consider relevant alternatives, evidence, and residual uncertainty.

EIP-022 An impact assessment shall distinguish observed effects, predicted effects, value commitments, and institutional choices. It shall identify material tradeoffs involving recognition, privacy, autonomy, unequal participation, maintenance labor, ecological conditions, and future capacities where relevant to the use case.

EIP-024 A proposal involving contribution or generativity return shall distinguish descriptive attribution, normative evaluation, and any proposed allocation of benefits or responsibilities. It shall not infer a monetary amount, entitlement, or contractual obligation solely from a generativity record.

EIP-076 The impact reviewer shall identify the proposed use, affected interests and absent perspectives, decision context, baseline, foreseeable benefits and harms, evidence and uncertainty, and alternatives including reduced collection, restricted access, different institutional arrangements, or deferral where relevant.

EIP-077 Where values conflict, the assessment shall state the values and affected people, reasons for the proposed priority, alternatives rejected, expected distribution of benefits and burdens, and conditions requiring reconsideration. A single aggregate score shall not replace those reasons.

EIP-078 A participation or recognition proposal shall assess whether people can refuse optional recording, challenge an attribution, or obtain an explanation without disproportionate burden. A claimed exception shall identify its actual institutional basis and consequences rather than present coercion as technical necessity.

10.2 Authorization, monitoring, and intervention

EIP-023 Before a real pilot or consequential expansion, the responsible authority shall record its purpose, actual participants and mandate, permitted material, accessible notice and challenge routes, protection measures, monitoring, stop conditions, and capacity to implement correction or repair.

EIP-025 A material unresolved ethical or participation finding shall receive a recorded disposition before the affected publication or pilot decision. Completion of a form shall not alone establish that an impact is acceptable or a remedy effective.

EIP-079 Before relying on mitigation to authorize a pilot or use, the responsible authority shall verify its owner, resources, operational status, and assessment method. Unimplemented mitigation shall remain a condition or limitation and shall not be counted as an achieved safeguard.

EIP-080 Monitoring shall identify observations capable of challenging the intervention rationale, emerging burdens or exclusions, and stopping or revision triggers. Findings shall distinguish absence of observed harm from evidence of absence of harm within a sufficiently examined scope.

EIP-081 After a material protection or ethical failure, the responsible authority shall assess immediate containment, affected people and uses, correction or repair, continued-use conditions, and lessons for requirements. Restart shall depend on recorded evidence addressing the failure, not solely on a revised description.

11 Contribution intake and permission

11.1 Artifact identity and intended uses

EIP-026 For contributed material proposed for incorporation or distribution, the rights register shall identify the artifact and version, contributor and stated capacity, claimed rights holder, source, intended uses, asserted permission or licence, restrictions, third-party components, evidence of authority, and unresolved questions.

EIP-027 A contribution record shall distinguish permission to examine material from permission to incorporate, edit, redistribute, sublicense, or publish it. Repository access, submission of comments, acknowledgement, or the absence of a licence notice shall not alone be treated as permission for those further uses.

EIP-028 The programme shall keep terms for prose, schemas, software, examples, datasets, and foundation manuscripts separately identifiable. A licence applying to one artifact class shall not be presumed to cover the others.

EIP-029 Foundation manuscripts and third-party sources shall retain their recorded source terms. Incorporating a source in the foundation manifest, citing it, extracting concepts from it, or placing it in the repository shall not be represented as relicensing the source.

EIP-082 The contribution handler shall identify the submitted version, source and included components, contributor's stated capacity, intended examination or incorporation, and the scope of any assertion about rights. A claim of ownership or permission shall retain its source and verification status.

EIP-083 Before incorporating material, the editor shall determine whether its intended modification, combination, publication, implementation, or retention is within the reviewed basis. New uses or components shall receive renewed clearance rather than inherit approval from an earlier narrower purpose.

11.2 Clearance and unresolved rights

EIP-030 Before public distribution of an artifact, the designated rights reviewer shall record that the intended distribution and included material are covered by identified permissions or another reviewed basis. Unclear rights shall block the affected distribution, while drafting and review within established permissions may continue.

EIP-031 Where an intended use exceeds available permission, the editor shall obtain suitable permission, replace or remove the material, narrow the use, or retain the affected artifact as restricted. The disposition shall preserve the source and reason without exposing restricted content.

EIP-032 A change in contribution or publication terms shall identify the artifacts and versions affected, authority for the change, contributor acceptance needed, and transition treatment. A new licence shall not be represented as retrospectively covering existing contributions without an established basis.

EIP-084 A clearance decision shall identify the artifact and exact intended use, claimed rights holder and authority evidence, applicable terms and version, third-party components, review competence, restrictions, unresolved issues, and expiry or reconsideration triggers. Clearance shall be limited to that recorded use.

EIP-085 If a rights claim or permission dispute arises after incorporation, the rights contact shall record affected material and uses, preserve appropriate evidence, seek competent assessment, and notify the authorized release holder of any needed restriction or correction. The programme shall not declare the claim valid or invalid solely from its receipt.

EIP-086 A contributor's request to withdraw or change permission shall be assessed against the actual terms, prior uses, downstream distributions, protection concerns, and relevant authority. The response

shall distinguish feasible programme action from uses or rights outside programme control.

12 Terms, implementation rights, and publication

12.1 Selection and acceptance of terms

EIP-033 Before offering contribution terms or choosing publication licences, the programme shall record its organizational and jurisdictional context, intended rights and obligations, artifact classes, alternatives, implementation consequences, and review by a person competent for the relevant rights questions.

EIP-034 The programme shall make operative contribution terms available before requesting assent to them and shall retain the accepted version and scope. A record of assent shall not assert that the contributor holds rights that remain unverified.

EIP-087 The terms-selection record shall compare rights needed for the intended artifact use, contributor interests, implementation and redistribution conditions, attribution, modified versions, translation, dependency compatibility, and maintenance. Prose, code, schemas, datasets, examples, and manuscripts shall receive distinct treatment where their requirements differ.

EIP-088 An acceptance record shall identify who assented, their stated authority, the exact terms and covered contribution, date, and evidence of assent. A form submission or repository action shall count as assent only where the announced process clearly established that meaning and actual acceptance is evidenced.

12.2 Implementation-rights concerns

EIP-035 A participant aware of a potentially material rights obstacle to implementing a proposed requirement shall report the known concern and its basis to the designated rights contact. The report shall distinguish actual knowledge, an asserted claim, and unresolved inference; it shall not be presented as a legal determination.

EIP-036 The programme shall record a material implementation-rights concern, affected requirements, available public information, review competence needed, feasible alternatives, and its disposition before approving an implementation claim that depends on the concern.

EIP-037 No programme participant shall make a licensing promise, patent assurance, rights waiver, or financial commitment on behalf of another person or institution without documented authority. A declaration under another organization's process shall not be represented as a programme agreement without review of its actual scope.

EIP-038 Where implementation rights remain materially unresolved, the responsible decision authority shall narrow the claim, select a reviewed alternative, or defer the affected normative adoption. An empty concerns register shall not be described as proof that implementation is free of third-party rights.

EIP-089 The handling of a potential essential-rights concern shall distinguish notification, factual clarification, specialist assessment, exploration of alternatives, and an authorized decision. A request for information shall not be phrased as a programme licensing commitment or as a determination of validity or essentiality.

EIP-090 Where a technical alternative is proposed to address a rights concern, the committee shall assess whether it satisfies the affected requirement and whether it introduces other material constraints. Selecting an alternative shall not be reported as resolving all implementation rights without the corresponding evidence.

13 Records, oversight, and assessment

13.1 Custody and publication of case information

EIP-039 Ethics, conflict, and rights records shall identify an accountable custodian, access rules, retention or review basis, correction route, and treatment of protected information. Public decision evidence shall avoid unnecessary disclosure while making authority, procedure, and unresolved limits inspectable.

EIP-091 The custodian shall separate public disposition information from protected evidence, restrict access to accepted roles with a handling need, and retain access and disclosure decisions. Changes in custodianship shall verify transfer of restrictions and pending response or retention duties.

EIP-092 Before releasing a case summary, the responsible handler shall assess whether combinations of facts disclose protected identity, existence, or content. The summary shall state material limits on public inspection without creating a false impression that an allegation or rights assertion was conclusively established.

13.2 Review and performance

EIP-040 The programme shall review this policy with the governance review cycle and after a material complaint, rights dispute, change of legal or organizational context, or change in publication arrangements. A revision shall preserve the prior edition and unresolved cases' transition treatment.

EIP-093 An assessment against this policy shall identify the subject, period, edition, assessor and interests, applicable EIP requirements, evidence, and results as fulfilled, not fulfilled, not assessed, or not applicable. Unperformed handling steps and blank templates shall not demonstrate fulfillment.

EIP-094 The governance authority shall review repeated complaints, unresolved conflicts, rights-clearance delays, protection failures, unequal burdens, and remedy effectiveness using protected or aggregated information as appropriate. Corrective actions shall have owners, review points, and evidence of completion.

Annex A

(normative)

Handling records and state transitions

A.1 Minimum case record

EIP-095 A case record shall contain identifier, scope and applicable editions, receipt history, requested protection, roles and conflicts, alleged issue distinguished from findings, evidence and limits, notices and replies, interim measures, decision and reasons, remedy, review route, access and retention basis, and current state. Changes of state shall identify their actor, date, grounds, and linked evidence.

A.2 Case states

EIP-096 The handler shall use the case states in Table A.1, or an explicitly mapped equivalent, so that receipt, examination, pending capacity, determination, remedy, and closure remain distinguishable. A transition shall preserve linked prior states and shall not imply completion of an unperformed step.

Table A.1 – Case state meanings and transition evidence

State	Meaning	Evidence supporting a transition
Received	Submission logged; no finding.	Receipt identifier, safe contact, requested protection, acknowledgement.
Triaged	Scope and route assessed.	Authority, conflicts, immediate risk, referral or inquiry decision.
Under consideration	Evidence and replies being assessed.	Questions, responsible assessor, evidence plan, notices, replies.
Pending capacity or information	A stated limitation prevents the next step.	Missing item or role, action owner, review date, protection retained.
Determined	Authorized finding or scoped disposition recorded.	Reasons, evidence limits, response consideration, remedy and review route.
Remedy under implementation	Agreed or directed action remains open.	Owners, resources, deadlines or triggers, follow-up evidence.
Closed or referred	Programme handling completed or assigned elsewhere.	Closure grounds or referral acceptance, residual limits, reopening/contact route.

A.3 Conflict and impact records

EIP-097 A conflict record shall identify the interest, affected function, assessor and independence, materiality reasons, management action, objection and response, implementation evidence, and review trigger. An impact record shall identify affected interests, evidence, values, alternatives, distributional effects, safeguards, authority, monitoring, and unresolved limitations.

A.4 Rights decision and acceptance records

EIP-098 A rights record shall identify artifact and version, source and components, contributor and asserted authority, intended uses, terms or other reviewed basis, competent assessment, restrictions, decision, acceptance where needed, and reconsideration triggers. Public licence statements shall be checked against that record before release.

A.5 Assessment of timing, findings, and reconsideration

EIP-104 An assessment claiming fulfillment of conduct-handling procedure requirements shall exercise the applicable conditions in Table A.2, identify the tested edition, input and expected outcome, and record performed actions, results, and limitations. A documentary assessment shall distinguish a complete specimen record from evidence that acknowledgement, independent consideration, notice, or remedy actually occurred. Unobserved performance shall remain not assessed rather than fulfilled.

Table A.2 – Conduct-review assessment conditions and limits

Condition	Relevant provisions and evidence	Discriminating result
Receipt and extended inquiry	EIP-014; actual receipt and acknowledgement, determination target, extension reason and notice.	A timely determination extension does not turn an acknowledgement later than seven days into timely performance.
Temporary participation restriction	EIP-017, EIP-067/068; authority, alternatives, independent review, expiry or justified extension and next review.	A restriction cannot continue indefinitely through a missing expiry or be relabelled a final sanction without determination.
Unresolved evidential balance	EIP-016/020/064/069; assessed grounds, contrary material, response opportunity and competence.	An unresolved balance does not substantiate the allegation; a numerical score is unnecessary; the outcome does not assert that the report was false.
Material reassessment request	EIP-099–102; identified grounds, receipt, admissibility, independent assignment, timetable, response and outcome.	A reasoned finding can change within mandate; the original decision maker is not described as independent; mere silence does not reject the request.
Unavailable reviewer or continuing action	EIP-020, EIP-072, EIP-101/103; capacity gap, stay assessment, protection, remedy ownership and verification.	Missing capacity remains visible and the consequential determination deferred; a planned remedy is not reported as completed.

Annex B

(informative)

Worked applications and unresolved choices

B.1 Interested expertise and neutral decision

An implementer funds an editor who proposes an exchange feature. The editor's evidence remains relevant, while the funding and implementation interest require assessment against the decision role. Oversight or separation can preserve the contribution while preventing the editor from determining a complaint about suppression of alternatives. The record shows which capacities were retained and which decisions were reassigned.

B.2 Protected testimony and limited finding

A participant reports exclusion but cannot safely publish identifying details. Intake records the protection need and available evidence. A neutral assessor considers whether a safe summary permits a meaningful reply. If the material cannot be tested sufficiently for an adverse finding, the result remains limited; it is not converted into a conclusion that the account is false. Feasible access improvements can still be considered without pretending that an allegation was proved.

B.3 Rights to read and rights to publish

A manuscript is available to project members for background reading. An editor proposes attaching it to a public package. The contribution record distinguishes examination from redistribution. The proposed attachment awaits a reviewed basis; source interpretation and new drafting continue within actual permission. A licence selected for the new programme prose does not automatically cover the manuscript.

B.4 Record correction and consequential repair

A synthetic pilot corrects an inaccurate attribution after a challenge. The correction record establishes that the current account changed. A separate remedy record asks whether excluded participation, lost access, or other practical consequences were addressed. Where those effects were not examined, the report states the limitation rather than claiming that the corrected text restored the affected person's position.

B.5 Local choices requiring review

The internal evidential criterion for conduct findings is a programme proposal that makes decisions reviewable; it does not purport to prescribe a court's procedure. Remedies remain bounded by actual programme authority. Different organizational contexts could justify revised procedures through the governance amendment process.

The proposed criterion requires a reasoned comparison of the assessed grounds, not a compulsory probability calculation. Alternatives include a more demanding internal threshold for particular findings or leaving the criterion to case-specific choice. The present draft selects an explicit common criterion, alongside fair-response and independence conditions, so that participants can examine its application and request scoped reconsideration. The choice, its error and participation risks, and the local reconsideration periods require review before governance adoption; see `decisions/ADR-0005-expanded-drafts-and-source-models.md`. No finding becomes valid merely because its author asserts that the threshold was met.

OPEN ISSUE Organizational and jurisdictional context, operative contribution agreements, publication licences, patent policy, named contacts, protected infrastructure, and specialist rights-review capacity remain unresolved. The policy supplies conditions for reviewing those choices without making the commitments itself.

OPEN ISSUE Procedural rehearsal needs to test handling burden, neutral-review availability, language and disability access, protected evidence, recusal, rights disputes, and remedy follow-up. Synthetic success does not establish capacity for a live consequential case.

GENERATIVITY STANDARDS PROGRAM

GR-100

Standards-track Working Draft

Version 0.3 2026-09-22

Foundations and Vocabulary

WORKING DRAFT FOR REVIEW

This document contains proposed provisions for technical and institutional review. It is not an adopted Standard or an operative governance instrument. Its scope, application conditions and publication status are specified in the text.

Prepared by the Generativity Standards Program. Reference to external publications does not imply endorsement by ISO, IEC, IEEE or any United Nations body.

Foreword

Version 0.3 records the bounded substantive review of the archived 0.2 package. This edition separates the general metamodel distinction from the conditional mapping check in the V100-011 assessment schedule. The review matrix, synthetic assessments and unresolved readiness questions are documented in `docs/reviews/validation_0.2/README.md`. These activities do not constitute adoption or an independent institutional assessment.

Responsible editor: UNASSIGNED.
Canonical source: `standards/GR-100-foundations-vocabulary/GR-100.tex`

This document is a standards-track Working Draft of the Generativity Standards Program. Its maturity is **PREPARATORY; PROVISIONAL**. It is available for substantive review and experimental assessment. It is not an adopted Standard, evidence of formal project initiation, or approval of GR/NWIP-001. Appointment of an editor, adoption of the governance instruments, work-item approval, review and final adoption require their own recorded decisions. Draft requirement language has no programme adoption or independent legal effect.

Edition 0.2 expanded edition 0.1; both earlier editions remain historical material. Existing requirement identifiers V100-001 to V100-012 retain their meanings. The body supplies candidate normative definitions and requirements. Annex A is a normative assessment schedule. The remaining annexes and bibliography are informative. No informative example or note adds a requirement.

The publication structure separates scope, dated references, numbered terms, requirements, conformance and annexes. Structural resemblance to another organization's publications establishes no affiliation, endorsement or compliance with its development procedures. Foundation manuscripts provide conceptual sources rather than adopted normative authorities.

Bibliography 24

Introduction

The programme responds to instability in the connection between representations, their targets, institutional classifications and practical trust. An authentic or fluent account can be mistaken for a warranted account of what happened. Correction can also erase the history of an earlier claim's influence. Inspectable recording requires these differences to remain expressible before a technical model standardizes interchange.

Reality is not reduced to what a recording institution recognizes. Manifestations, traces, accounts and judgments can disclose a target partially; they can also enter subsequent action and change conditions of further generation. A mistaken classification can remain historically important after its evidential warrant has been rejected. Its occurrence, interpretation and practical effects require distinguishable descriptions.

The foundation manuscripts distinguish abstract metamodel concepts from richer analytical categories and distinguish ontological questions from evidential access. This document uses those distinctions without turning six record roles into ultimate kinds of being. Its operational definitions do not exhaust GR theory. They support partial knowledge, contested identity, overlapping roles, changing categories and revisable interpretation.

Interoperability requires more than shared spelling. One institution can use evidence for an accepted document, another for material bearing on a claim and another for a procedural exhibit. Similarly, a numerical property can be a category code, an ordinal rating or a measurement. A common format does not make their operations equivalent. Vocabulary application therefore includes scope, source, transformation and assessment duties.

1 Scope

1.1 General

This document supplies a bounded operational vocabulary for recording and examining claims about generative histories. It addresses a practical problem: a record can accurately preserve an assertion while the assertion is mistaken, an authentic document can contain an unsupported inference, and a later correction can conceal the historical consequences of an earlier judgment. Inspectable practice requires distinctions among what is claimed to have happened, how it became accessible, what was recorded, what was inferred, and how the account was used.

The scope includes vocabulary use, the separation of levels of description, identity and temporal distinctions, and a candidate description of six record roles. It does not define truth, a complete metaphysics, a universal theory of evidence, legal validity, a universal generativity score, or a machine-readable schema. Domain methods can provide stronger criteria within a declared scope.

GR-110 develops trajectory recording requirements. GR-200 develops the epistemic record package. GR-120 and associated Specifications are intended to resolve technical representation after requirements and cases expose a reusable need. GR-210 is intended to address assessment and contestation procedures. References to these publications identify coordinated draft work; none is an adopted normative dependency.

2 Normative references

2.1 General

There are no external normative references in this edition. All requirements needed for assessment are contained in its body and Annex A. Foundation manuscripts and programme documents in the bibliography are informative sources for interpretation and drafting rationale, not supplementary conformance requirements.

2.2 Dated applications and mappings

An application can identify an additional dated domain vocabulary or profile in its declaration. That source becomes part of the application's own commitments, not a normative dependency of GR-100. The assessment distinguishes fulfillment of this document from fulfillment of that additional source. A current online resource does not silently update the meaning used in an assessed edition.

3 Terms and definitions

3.1 General

The following definitions apply within this document's recording scope. Capitalized Entity, State, Event, Process, Relation and Property name the operational record roles in Clause 5. Lowercase ordinary uses remain possible when their meaning is evident. Terms concerning uncertainty and missingness describe an inquiry rather than settle the truth values of the underlying world.

These definitions support linked descriptions, not a mandatory class hierarchy. Several terms can concern one activity: observation can involve interpretation and inference, and its result can become evidence for another claim. The application identifies these functions rather than treating their coexistence as an error.

3.2 Target

That about which a claim is made.

NOTE 1 A target can be a situation, participant, occurrence, relation, condition, possibility, record, or another claim. Its identification can remain partial or contested. A target reference is an act of reference; it does not establish existence or identity.

3.3 Manifestation

For recording purposes, an identified way in which a difference becomes available to encounter, registration, measurement, expression, or classification under specified conditions.

NOTE 2 This is a limited operational use informed by FM-004; it does not exhaust that manuscript's account of manifestation.

3.4 Representation

A description or arrangement of signs used to describe, classify, model, or otherwise stand for a target.

NOTE 3 Representations can themselves become targets of inquiry and participants in later action.

3.5 Record

An identified retained representation, together with the context needed to interpret its declared recording purpose.

NOTE 4 A record can contain several claims, and several records can concern one target. Retention need not mean public disclosure or indefinite preservation.

3.6 Record package

A declared collection of records and contextual references presented together for a specified purpose and version.

NOTE 5 A package can contain protected components and a restricted or public view. A view's limitations are part of its declared scope.

3.7 Claim

An attributed assertion with identifiable content and target, expressed under a stated scope.

NOTE 6 The assertion can concern an occurrence, a possibility, an interpretation, a value judgment, or institutional or legal status. Recording it does not endorse it. Several parties can assert the same content with different grounds.

3.8 Attribution

A recorded association between a claim or activity and the person, institution, system, or source represented as originating or performing it.

NOTE 7 Attribution can be pseudonymous, unknown, disputed, or mediated through another source.

3.9 Observation

A situated activity of attending to or registering a manifestation through a stated method.

NOTE 8 An observation report is a claim about that activity or its result; "direct" does not mean free of mediation or interpretation.

3.10 Inference

A step that relates identified premises or material to a conclusion under a stated method or reasoning.

NOTE 9 An inferred claim has a different epistemic role from the claim that its premises were recorded.

3.11 Interpretation

An attributed assignment of meaning, classification, or significance within a stated context.

NOTE 10 Interpretation can participate in observation and inference; these terms do not partition human or machine activities into exclusive kinds.

3.12 Judgment

An attributed assessment or determination made using identified grounds and criteria.

NOTE 11 A judgment can assess evidential warrant, ethical acceptability, legal status, or institutional action. These functions carry different bases of authority.

3.13 Assessment

A recorded examination of a specified question using identified criteria and material, with a result and limitations.

NOTE 12 In GR-200 an evidence assessment concerns a claim-relative evidential role. A syntax check concerns a different assessment target.

3.14 Uncertainty

Specified unresolved limitations or alternatives affecting a claim's content, identification, observation, method, interpretation, timing, boundary, or warrant.

NOTE 13 An uncertainty description is itself attributed and scoped. A numerical quantity is one possible representation, not a mandatory universal measure.

3.15 Trace

Material, behavior, testimony, inscription, or another manifestation identified as a remainder or consequence relevant to a target inquiry.

NOTE 14 The proposed connection to its generative conditions is a claim with its own grounds; calling an item a trace does not establish the proposed origin.

3.16 Evidence

A role assigned to identified material in assessing a specified claim, with an account of relevance, reliability, and alternative explanation.

NOTE 15 The material can support, challenge, limit, or fail to discriminate the claim. Evidence is not an intrinsic status permanently attached to a file or person.

3.17 Evidential warrant

The grounds offered for accepting, qualifying, or rejecting a specified claim under stated methods, assumptions, and scope.

NOTE 16 This draft records those grounds without imposing one universal sufficiency rule.

3.18 Provenance

A recorded account of origins, attribution, derivation, custody, or transformations of an identified item.

NOTE 17 Provenance can be incomplete or disputed. Provenance of a claim's expression differs from evidence for the claim's content.

3.19 Authenticity assessment

An assessment of whether an item is what it is represented to be, within a specified question and method.

NOTE 18 Authenticity of an utterance or document does not establish truth of its substantive claims.

3.20 Missingness

A stated condition in which information sought for a recording purpose is absent or unavailable.

NOTE 19 Not observed, not recorded, lost, withheld, unknown, inapplicable, and disputed describe different conditions and are not interchangeable with a zero, false value, or non-occurrence claim.

3.21 Record reference

A designation sufficient to distinguish a record or a particular version within a declared context.

NOTE 20 A reference scheme does not itself determine the identity of the represented target.

3.22 Identity criterion

A stated basis for treating two appearances or descriptions as concerning the same target within an inquiry.

NOTE 21 Identity claims can be contested and criterion-dependent. Similar behavior, equal content, shared names, and common descendants do not alone establish target identity.

3.23 Lineage

A directed account of derivation, succession, or continuation.

NOTE 22 Lineage can branch or merge. Its use does not automatically assert that predecessors and successors are one identical target.

3.24 Target time

The time or interval a claim concerns, including an explicitly unknown or uncertain temporal location.

3.25 Observation time

The time at which an observation or acquisition is represented as occurring.

NOTE 23 It can differ from target time and recording time.

3.26 Recording time

The time at which a record or identified version was made or entered into a recording context.

NOTE 24 It does not automatically date the target occurrence.

3.27 Assessment time

The time of a stated assessment or judgment, distinct from the time to which that judgment applies.

3.28 Descriptive regime

The declared categories, definitions, methods, scales, or boundary choices used to describe a target within an inquiry.

NOTE 25 This is an operational term; it does not require a fixed family of regimes or a particular mathematical construction.

3.29 Revision

An identified change to a representation, claim, assessment, or descriptive regime, with its relationship to an earlier formulation and the stated reason.

NOTE 26 Revision of an account of the past does not itself change the past occurrence.

3.30 Trajectory

A scoped account linking conditions, occurrences, continuations, alternatives, and consequences over a declared temporal or ordering frame.

NOTE 27 A reconstructed trajectory can remain partial and contested; it need not be a single fully ordered sequence.

3.31 Generativity-related claim

In this operational vocabulary, a claim about how relations, conditions, or activity generate, sustain, transform, restrict, or destroy subsequent states, capacities, relations, distinctions, or possibilities.

NOTE 28 This defines the programme's recording subject; it is not a comprehensive definition of GR generativity.

3.32 Generative condition

A condition claimed to enable, constrain, or shape a specified trajectory or possibility.

NOTE 29 Its role needs attribution and grounds; contemporaneous presence alone does not establish contribution.

3.33 Possibility claim

A scoped claim that a continuation was or is available, feasible, blocked, lost, or conjectured under identified conditions.

NOTE 30 An unchosen proposal differs from an evidenced feasible alternative, and each differs from a later imagined counterfactual.

3.34 Contribution

An attributed participation or influence in a specified trajectory or outcome.

NOTE 31 Contribution, credit, causal responsibility, entitlement, and legal liability remain distinct questions.

3.35 Practical uptake

An identified use of a representation or judgment in action, classification, allocation, or institutional decision.

NOTE 32 Its consequences can become new recording targets.

3.36 Generativity return

A research and recording topic concerning claimed return pathways through which generated effects alter conditions of further generation.

NOTE 33 Its operational measurement, evaluative meaning, and any allocation rule remain **OPEN**; no universal quantity or entitlement is defined here.

3.37 Vocabulary application

A named and versioned use of specified terms within a declared document, record package, profile, register or implementation description.

NOTE 34 Its boundary identifies which uses are claimed to follow this document and which belong to external or ordinary-language vocabularies.

3.38 Vocabulary extension

An additional term, narrower operational meaning or application-specific relationship introduced for a declared purpose.

NOTE 35 An extension does not change the meaning of this document's terms in other applications or become a programme term merely through local use.

3.39 Term correspondence

An attributed and scoped relationship between meanings in identified vocabularies or editions.

NOTE 36 Correspondence can be equivalent for a particular use, narrower, broader, overlapping, conditional or unresolved. Similar labels do not establish equivalent meanings.

3.40 Record-role correspondence

An explicit relationship between descriptions using different record roles or different boundaries within one role.

NOTE 37 It identifies which targets or occurrences the descriptions concern and which information is retained, added, omitted or unresolved.

3.41 Actuality or modality statement

A statement of whether a target is claimed as actual, attempted, planned, possible, hypothetical, counterfactual, unrealized or unresolved within a specified frame.

NOTE 38 These qualifications are not a universal exclusive enumeration. An attempted action can have occurred while its intended result remained unrealized.

3.42 Epistemic mode

The way a claim is presented as known, reported, inferred, interpreted, reconstructed, hypothesized or stipulated.

NOTE 39 Epistemic mode differs from actuality or modality and from assessed warrant. An inference can concern an actual occurrence; a direct observation report can be disputed.

3.43 Definedness condition

A condition determining whether a characteristic, classification or operation has an applicable value for a subject under its definition.

NOTE 40 Inapplicability differs from unavailable evidence about an applicable value. A representation can require both a definedness condition and a missingness reason.

4 Vocabulary application and semantic safeguards

4.1 General

V100-001 A vocabulary application shall identify this document and version, its own boundary and version, the terms it uses, and any local extensions or narrower domain meanings. It shall describe departures explicitly and shall not claim unqualified GR-100 vocabulary conformity for a conflicting use of a defined term.

4.2 Reality, manifestation, and representation

The foundation's ontological, relational, and manifestational registers concern different analytical questions. They are not exclusive categories of objects or a mandatory temporal sequence. A practice can operate before its recognition, and a classification can subsequently change the practice. This document does not require every target to receive a philosophical register label.

V100-002 A vocabulary application shall distinguish a represented target, an identified manifestation or trace, a retained record, and a claim wherever it uses those roles. It shall not treat a record identifier, representation, or manifestation as establishing the existence, complete nature, or identity of its target solely by being recorded.

4.3 Claim, observation, inference, and judgment

V100-003 A vocabulary application shall distinguish assertion, observation report, inference, interpretation, and assessment where those functions occur. Where one item performs several functions, it shall identify the functions and their scopes rather than infer one function's warrant from another.

4.4 Trace, evidence, and provenance

V100-004 A vocabulary application shall represent an evidential role relative to an identified claim. It shall keep provenance or authenticity results, evidential assessments, technical conformance, institutional acceptance, and normative or legal judgments distinguishable. It shall not describe success in one of these assessments as success in another without a separately stated argument.

4.5 Identity, time, and history

V100-005 A vocabulary application shall distinguish record reference, target identity, and lineage. A stated identification of targets across appearances shall identify its criterion and the scope in which it is used. Unresolved identity shall remain expressible without forced merger.

V100-006 A vocabulary application shall distinguish target, observation, recording, and assessment times wherever it uses them. It shall preserve uncertainty about time or order rather than derive occurrence order solely from record entry order.

V100-007 An application that represents revision shall distinguish change in the target situation, change in evidence or assessment, and change in the descriptive regime. It shall allow more than one reason to apply and shall not silently replace the earlier formulation with a later one. Where earlier content cannot be retained or disclosed, it shall identify the resulting limit on historical reconstruction.

These are three linked histories rather than three mutually exclusive event types. Publication of a revised classification can change a target situation as well as its description. A later assertion that the earlier situation differed is an epistemic revision; it does not backdate the physical act of correction.

4.6 Generativity and practical consequences

V100-008 An application using generativity-related terms shall identify the claimed change or continuation, affected target or participants, relevant conditions, and scope. It shall distinguish a generative attribution from a value judgment and shall not infer beneficialness, entitlement, or legitimacy from the term “generative” alone.

5 Six operational record roles

5.1 General

These role descriptions are standards-specific proposals, informed by FM-007 and earlier programme vocabulary. They describe how a target is represented for an inquiry. They neither exhaust reality nor require exclusive schema classes. The term Property is retained from the programme; FM-007 uses Attribute. No equivalence between them is asserted.

In the descriptions below, *minimum metadata* means the information required when the role is applied under V100-009. V100-025 distinguishes structural designations and criteria from contextual factual values that permit an explicit unknown or restriction. Common metadata means record reference and version, role, described target, recording responsibility and time, and links to relevant claims and their epistemic context. Referenced context can be shared across a package without duplication.

V100-009 An application of a six-role description shall identify the applied role, its admissibility and identity criteria, the common metadata, and the role’s minimum metadata below. It shall disclose unresolved boundaries and use the temporal meaning associated with the role. Missing information shall retain its stated reason rather than be converted to a substantive negative claim.

V100-010 An application shall allow a target to be described through more than one applicable record role without treating role overlap as evidence of inconsistency. A restriction in an application profile shall state its recording purpose and information limits. A Relation whose own identity, state, properties, or history matters to the declared inquiry shall remain independently referenceable.

V100-025 The application shall supply its reference and version, applied term labels and definition locators. Each applied role shall have an identified role, record reference and version, target designation and responsible recording role; an unresolved target designation shall state the target question or description. These structural designations shall not be replaced by an unknown value. An unavailable contextual factual value may be represented by an explicit unknown, disputed, lost or restricted state, with the stated reason, attributing role and assessment limitation. Required admissibility or identity criteria shall be stated; a provisional assignment with unresolved criteria shall not receive a fulfilled result for a criterion-dependent obligation.

A target designation can identify an unresolved historical subject without establishing its identity. An accountable role can use a protected reference without public disclosure of a person's name. These are supplied designations with declared limits, not empty values. Conversely, a known absence of a required criterion is a recording defect; unavailable evidence for deciding whether an identified criterion is met is an assessment limitation. A fulfilled declaration of unknown context does not resolve the underlying fact.

5.2 Entity

Definition and admissibility. A record role for a focal subject tracked across appearances under a declared continuity criterion. Admissible when the inquiry needs cross-context or cross-time reference; use does not require an unchanging substance.

Identity. The stated reidentification criterion and evidence determine the claim of continuity. A database key identifies a record, not automatically the represented subject. A disputed criterion can remain unresolved.

Temporal behavior. Properties, membership, and relations can change while continuity is asserted. Formation, dissolution, replacement, or uncertain duration can be recorded separately.

Relations to other roles. Participation in Events and Processes; possession of described States or Properties; participation in Relations; lineage links to other Entity descriptions. These are candidate meaningful links, not an exhaustive edge schema.

Minimum metadata. Focal subject and appearances in scope; continuity criterion; temporal scope; attributed identity judgment or unresolved status.

Optional metadata. Names, identifiers assigned by other systems, formation history, known predecessors and successors.

Example and counterexample. An association tracked across a change of premises under a stated organizational continuity criterion. Two unrelated associations sharing a name are not thereby one Entity.

OPEN edge. A split into two successors can preserve lineage while leaving continuity with the predecessor disputed.

5.3 State

Definition and admissibility. A record role for a scoped description of conditions of a target at a stated time or interval. Admissible when the question concerns those conditions rather than an exhaustive inventory of reality.

Identity. Same target, temporal scope, and descriptive regime identify the intended condition description; record versions and conflicting accounts remain distinct. Equality of observed values alone does not establish equality of target conditions.

Temporal behavior. A condition can persist over an interval or be known only at an observation time. Persistence between observations requires a claim. Predictive sufficiency is relative to specified questions and continuations.

Relations to other roles. Conditions of Entities or Relations; preconditions and results of Events; intermediate descriptions in Processes; values articulated through Properties.

Minimum metadata. Target; time or interval; description boundary and regime; conditions described; observation or inferential basis.

Optional metadata. Supported queries, omitted conditions, comparison horizon, warranted persistence interval.

Example and counterexample. A committee's recorded membership on a given date. A timestamped snapshot alone does not establish every member's continuing participation throughout a month.

OPEN edge. A reduced state adequate for a current report can omit historical memory needed for a later operation.

5.4 Event

Definition and admissibility. A record role for an individuated happening or attempted happening under a declared occurrence criterion. Hypothetical, planned, or reconstructed events remain admissible as explicitly qualified targets of claims.

Identity. An occurrence criterion distinguishes event tokens; a description can refer to one event in several records. Repetition of the same operation or outcome does not merge occurrences.

Temporal behavior. Duration, boundaries, sequence, or overlap can be exact, interval-based, partial, or unknown. Failure or interruption does not imply non-occurrence of an attempt.

Relations to other roles. Participants represented as Entities or Relations; changes between States; steps of Processes; Properties of the occurrence.

Minimum metadata. Proposed happening; occurrence and individuation criteria; claimed actuality or modality, such as occurred, attempted, planned, hypothetical, or unresolved; separate epistemic basis, such as reported, observed, or retrospectively inferred; temporal scope; participating targets where known. A retrospectively inferred event can be claimed to have actually occurred.

Optional metadata. Place, before/after conditions, attempted purpose, completion status, links to repeated occurrences.

Example and counterexample. Two separately evidenced permission issuances with the same final status. A formula for the effect of an issuance does not establish that either occurred.

OPEN edge. Different temporal resolutions can treat one prolonged happening as an Event, Process, or several Events; the segmentation rationale matters.

5.5 Process

Definition and admissibility. A record role for activity linked by a declared ordering and criterion of unity. Admissible for goal-directed, recurrent, interrupted, branching, or otherwise connected activity; achievement of an intended endpoint is not required.

Identity. The stated grouping and boundary criterion individuates the process. Equal endpoints or equal modeled composite effects do not establish the same process history.

Temporal behavior. Ordering can be partial; duration and completion can be uncertain. Alternative possible paths remain distinct from the reconstructed actual path.

Relations to other roles. Comprises or links Events and intermediate States; involves Entities and Relations; has scoped Properties; connects to dependent Processes.

Minimum metadata. Unity and boundary criterion; activity in scope; supported ordering; claimed actuality or modality, distinguished from its observational or reconstructive basis; time scope and completion/continuation status.

Optional metadata. Intended purpose, branches, interruptions, excluded steps, retained intermediate conditions.

Example and counterexample. A proposal–revision–authorization sequence with a recorded failed earlier attempt. A factorization of an outcome into mathematically possible operations is not evidence of that history.

OPEN edge. Overlapping practices can belong to several processes; no universal segmentation rule is proposed.

5.6 Relation

Definition and admissibility. A record role for an identified connection, arrangement, or dependence among specified targets or conditions within a stated context. Admissible when its incidence, formation, continuity, or effects are relevant. Potential efficacy requires a further claim.

Identity. A stated criterion distinguishes a continuing arrangement from a renewed or separate one. Equal participants and equal current effects do not alone establish the same relation.

Temporal behavior. Formation, persistence, dormancy, change of terms, and ending are separately attributable. A relation can change while participants remain identified.

Relations to other roles. Participants can be targets described by any relevant role, including other Relations; Events can form or change it; Processes describe its history; States and Properties describe its conditions.

Minimum metadata. Relation reference; participant or condition references with roles; context; relation criterion and temporal scope; stated identity basis.

Optional metadata. Formation history, dependency claims, terms, changing states, prospective effect comparisons.

Example and counterexample. Two separately identified agreements between the same parties, each with its own renewal history. Co-occurrence in a table alone does not establish cooperation, trust, or dependence.

OPEN edge. Uncertain or changing participants can prevent a complete incidence description without eliminating the recorded relation claim.

5.7 Property

Definition and admissibility. Provisionally, a record role for an attributed characteristic or value of a specified subject under a stated definition, time, and context. Admissible when the meaning and subject of the attribution are explicit. This operational use does not resolve the broader Property/Attribute relationship.

Identity. A property assertion is distinguished by subject, characteristic definition, contextual and temporal scope, attribution, and version. A type of characteristic differs from a particular assignment of its value.

Temporal behavior. A value can change with the subject; a later correction can instead revise knowledge of an earlier value. The two histories remain distinguishable.

Relations to other roles. Describes a target represented through any role; measurement or classification can be linked to an Event or Process; multiple conflicting assignments can concern one subject.

Minimum metadata. Subject; characteristic definition; value or explicit missingness state; time and context; method or attribution; scale and unit when used.

Optional metadata. Measurement uncertainty, valid domain, derivation, calibration reference, alternatives.

Example and counterexample. A reported resource quantity for an organization at a specified time. A numbered nominal category is not a measurement permitting arithmetic solely because its code is numeric.

OPEN edge. FM-007's Attribute has explicit domain, interpretation, scale, and definedness conditions. Equivalence to Property, separation, or renaming needs source comparison and a recorded decision.

5.8 Role boundaries and admissibility decisions

Admissibility concerns whether a description can perform the stated recording role. It does not establish the claim about its target. A proposed historical Entity can be admissible as the subject of inquiry while its identity is contested. A hypothetical Event can support counterfactual analysis while its modality excludes it from the asserted actual history. Role metadata and epistemic context preserve both distinctions.

A role's minimum metadata is semantic information, not a prescribed collection of database columns. Shared references can supply context when their version and scope are clear. A narrative dossier can supply information through identified passages. An empty field, unexplained code or link to a changing resource does not necessarily supply an inspectable meaning.

An unknown value can satisfy a duty to disclose unavailable context where a requirement permits it. It does not satisfy a duty to demonstrate continuity, observed occurrence or contribution. A protected identity can use a stable reference without publishing a name; protection does not establish that two references identify one person.

An agreement can be a Relation while tracked as an Entity for continuity. Its negotiation can be a Process; its signing an Event; its operative terms at a time a State described through Properties. These descriptions coordinate different questions. They need not assert six independently existing objects or duplicate a single occurrence six times. A technical profile that restricts overlap needs a route for retaining the distinctions relevant to its declared use.

6 Boundaries between layers

6.1 General

V100-011 A vocabulary application shall distinguish operational record roles from metamodel concepts. It shall not identify a formal carrier state with a record State, a mechanism with a Process, or formal change with an Event without an explicit scoped mapping and argument.

V100-012 A vocabulary application shall keep descriptive, epistemic, evaluative, legal, institutional, and technical assertions distinguishable by their stated question and grounds. It shall not represent technical conformance as automatically creating factual truth, rights, duties, liability, admissibility, jurisdiction, or institutional authority.

The same dossier can connect these assertions. For example, an institutional decision can cite an evidential assessment and an asserted rule, while each remains separately attributable and open to the appropriate

form of review. This is separation of questions and authority, not a requirement for independent databases.

7 Vocabulary management and correspondences

7.1 General

Vocabulary management concerns inspectable meaning across local uses, languages, profiles and versions. A register can be a small table or a documented specification mapping. It need not duplicate a dictionary, but an exact definition and its application scope need to be recoverable. When a source is unavailable, the adopted local wording and that limitation remain visible.

7.2 Terms, sources and local extensions

V100-013 The application shall maintain a term-use register identifying the terms used, their definitions or dated definition references, their recording scope, their source status and the role responsible for interpreting local use. An imported label shall not establish equivalence without an identified correspondence and rationale.

V100-014 A local extension shall identify its purpose, definition, admissibility conditions, relation to existing terms, affected uses and limitations. A conflicting meaning shall use a distinct qualification or label and shall not be presented as an unchanged GR-100 definition.

An extension can address a specialized institutional process without claiming that its categories are universal. For example, a profile can define a reviewed submission within its own procedure. It identifies the relationship to Record and Claim, the criterion for entering the review category and the information the category omits. The label does not imply that the submission is true or that every recording context has the same procedure.

7.3 Languages, editions and mapping

V100-015 A term correspondence across languages, domains or editions shall identify the source and target meanings, direction, scope, responsible attribution and known non-equivalence. A narrower, broader, partial or conditional correspondence shall not be represented as unrestricted equivalence.

A translation can preserve an operational distinction even when ordinary words carry additional meanings in one language. The operational definition travels with the label. Where a translation is contested, alternative formulations and grounds remain available. A terminology register need not require every language to borrow the same word or every application to create a universal dictionary.

Renaming a field does not by itself change meaning. Retaining the same label while changing its definition can change the descriptive regime. The register identifies both situations. A mapping that loses information describes the uses for which the mapped representation remains adequate and the uses it no longer supports. Switching to a finer vocabulary does not recreate distinctions absent from the source material.

7.4 Modality, epistemic function and status expressions

V100-016 An application describing an occurrence or possibility shall distinguish its asserted actuality or modality, the epistemic mode of the assertion and the assessment disposition. It shall preserve combinations such as an actual occurrence inferred retrospectively and a directly reported observation whose accuracy is disputed.

V100-017 Where an application uses fact, verified, valid, confirmed or an equivalent status expression, it shall state the question resolved, applicable criterion, attributed assessor and grounds or assessment

reference. An unspecified status expression shall not erase known uncertainty, an unresolved identity question or the limited scope of a check.

Recorded fact can mean a statement treated as settled by an institution, an asserted occurrence, or a database entry. This document does not make these meanings interchangeable. A historical account can preserve that a claim was institutionally accepted without endorsing its substantive content. Similarly, a valid structure can contain a false claim; a verified signature can authenticate a mistaken statement.

7.5 Correspondence between roles and levels

V100-018 A relied-on correspondence between record roles or descriptive levels shall identify the linked descriptions, intended relationship and use, retained distinctions and known losses or unresolved links. A transformation shall not silently create target identity, occurrence multiplicity or historical detail unsupported by its source.

Table 1 – Role correspondences and distinctions requiring attention

Correspondence	Recording question	Distinction at risk
Event–Process	One prolonged occurrence examined through internal activity; a process treated as a bounded episode	Segmentation, attempts, partial order and intermediate conditions.
Relation–Entity	An agreement or dependence tracked across renewal	Continuity criterion, incidence context and whether renewal creates a separate arrangement.
State–Property	Conditions described through characteristic assignments	Domain, time, omitted conditions and observational or inferential basis.
Process–State	Activity summarized by a resulting condition	Different histories can share an endpoint; the endpoint does not establish the path.
Entity–type	Subjects classified by a shared characteristic	Type equality does not establish token identity or continuity.
Record–target	Several reports linked to a proposed occurrence	Record multiplicity differs from occurrence multiplicity; linkage can remain disputed.

Table 1 is a boundary guide, not an exhaustive allowed-edge schema. A profile can add relationships with stated meanings. An Event description can aggregate several occurrences only when that aggregation is explicit and does not purport to preserve individual occurrence counts or intermediate history. Conversely, decomposing an Event into a possible Process does not establish that the proposed steps occurred.

7.6 Missingness and definedness

V100-019 An application shall distinguish missingness and definedness states material to its use, including zero or false values, unknown values, non-observation, non-collection, inapplicability, disputed assignment and restricted access where present. A mapping that combines these states shall state the loss and shall not infer a substantive negative claim from the combined code.

Unknown is an epistemic condition rather than a third truth value imposed on the world. Inapplicable means the stated characteristic lacks an applicable value under its definition. Not measured means an

applicable measurement was not performed. Withheld concerns access and can coexist with a known value in a protected view. Disputed can describe incompatible assignments with available evidence. These differences affect later counting, assessment and revision.

An application need not claim knowledge of why a value is absent. Unknown reason is legitimate when supported. It also need not reveal protected material's existence to an unauthorized audience. A reduced view can state its collection and access scope while a protected accountable record retains a more specific explanation where permitted.

7.7 Properties, scales and aggregates

V100-020 A numerical Property description shall identify its characteristic definition, applicable domain, scale meaning and unit where relevant. Any arithmetic, weighting or aggregation relied on shall state its interpretation, included population or components and material limitations. Numerical labels alone shall not establish the validity of the operation.

A nominal code supports differentiation, not automatically addition. An ordinal rating supports ordering under its interpretation, not automatically meaningful distances or averages. A measurement with a unit still depends on an instrument, boundary and procedure. The distinctions remain relevant when values have the same software numeric datatype.

An aggregate can change because underlying values change, because composition or weights change, or because a classification rule changes. These are different interpretive questions. A rate can require its numerator, denominator, inclusion criteria and period for interpretation. A pooled increase does not establish improvement for every group; a pooled decrease does not by itself establish causal deterioration in practice. The inference needs its own grounds.

7.8 State sufficiency and retained history

V100-021 An assertion that a State description is sufficient shall identify the question or operation family, comparison horizon, relevant observations, assumptions and known omitted distinctions. Sufficiency for a current report or specified prediction shall not be represented as historical completeness or sufficiency for undeclared continuations.

Two subjects can have the same current reported flag while retaining different conditions that affect a future response. Conversely, a reduced description can predict a selected response while omitting whether the condition arose by agreement or imposition. Predictive and historical purposes need different evidence. A statement of adequacy identifies the question answered, rather than converting that question into a universal account of the subject.

7.9 Identity decisions

V100-022 A relied-on identity judgment shall state whether the proposed relation is identity, similarity, identifier correspondence, succession or another defined relation, and shall preserve material competing criteria and unresolved cases. Automated matching or shared lineage shall not be promoted to target identity without the stated criterion and its supporting attribution.

Organizational registration, membership continuity, operational practice and historical self-description can support different identity inquiries. Agreement under one criterion need not resolve another. A split or merger can be represented by directed lineage without identifying each successor with every predecessor. A shared name does not decide which relation is intended.

Identity also differs from access. Redaction can hide information needed to assess a match while a custodian retains it. A public view can report a scoped assertion and its limits without claiming independent external verification. Lack of disclosure does not justify inventing either identity or non-identity.

8 Conformance

8.1 General

The conformance subject is a declared vocabulary application at an identified edition and boundary. Requirements concerning extensions, numerical Properties, transformations or particular roles are conditional on those features being present. An absent feature can make its specific requirement not applicable. It does not exempt a general safeguard already used elsewhere in the application.

8.2 Declaration and assessment boundary

V100-023 A conformance statement shall identify the application, edition, boundary, GR-100 edition, applied terms, applicable requirements, assessor and evidence. It shall distinguish full fulfillment of applicable requirements from partial assessment and shall not imply assessment of excluded uses or unavailable evidence.

A scope can be small without being vague. A short profile using only Record, Claim, Trace and Evidence identifies those uses and definitions. It does not need examples for an unused Process role. A profile using a numerical Property and an aggregate triggers V100-020 even when its label is score rather than Property. Applicability follows meaning and use, not convenient field spelling.

8.3 Results and mandatory schedule

Fulfilled means that the required evidence was examined and met the check within scope. Not fulfilled means examined evidence demonstrates a failure. Not assessed means necessary evidence, access or method was unavailable or the check was not performed. Not applicable means the triggering feature is absent, with a documented reason. Lack of access is not non-applicability.

V100-024 The assessment shall follow Annex A and retain a result, evidence locator, assessor and reason for every requirement. A failed or unassessed applicable requirement shall prevent an unqualified conformity claim for the declared application. Each not-applicable result shall identify the absent trigger.

V100-026 Where one requirement groups obligations whose results can differ materially, the assessment shall retain a result and evidence for each such component. The overall requirement shall be fulfilled only when every applicable component is fulfilled. A failed or unassessed component shall remain visible in the requirement-level and overall application result.

A vocabulary result does not establish factual truth, philosophical exhaustiveness, effective institutional participation or legal validity. Syntactic checking can assist assessment, but cannot determine whether a term is coherently applied to a contested case. The report distinguishes automatic checks from substantive examination of meaning.

8.4 Maintenance of an assessment

A change in definition, scope, role criterion, correspondence or assessment-relevant use changes the assessed subject. The application identifies the affected edition and results requiring review. Correcting spelling alone need not change semantics; an unchanged label does not prove semantic stability.

An implementation can retain multiple vocabulary editions for historical records. Assessment identifies which meaning governed each record and which mappings support a combined view. A later interpretation does not retrospectively give earlier actors access to the newer vocabulary. If the historical definition cannot be recovered, that is a reconstruction limitation rather than permission to silently substitute the current one.

Annex A

(normative)

Vocabulary assessment schedule

A.1 General

This schedule specifies required assessment checks for applicable features; it does not report executed tests. The assessor examines the declared subject and reports fulfilled, not fulfilled, not assessed or not applicable for each requirement, with an evidence locator. Not applicable requires an absent trigger, not an inconvenient result. Unavailable examination evidence or an unperformed check receives a not-assessed result. A review cannot establish an external fact merely from compliant vocabulary.

Table A.1 – Vocabulary assessment checks

Requirement	Evidence and discriminating check
V100-001	Declaration names version, boundary, terms, extensions. Compare a local "fact" label against its stated meaning; detect an undisclosed conflicting use.
V100-002	Trace a target, manifestation, record, and claim in the subject. An authentic but incorrect report remains representable.
V100-003	Inspect a summary combining observation and inference. Recover which content was registered and which was inferred, by whom.
V100-004	Inspect one material item used differently for two claims. A successful authenticity check does not become a truth result.
V100-005	Inspect a merger, split, or disputed identification. Recover identity criterion and directed lineage without an automatic merger of targets.
V100-006	Inspect a late-entered report. Target time, observation time, recording time, and review time remain distinguishable or explicitly unknown.
V100-007	Compare target change, corrected report, and changed category. Prior meaning and reasons remain recoverable to the declared retention/access extent.
V100-008	Inspect a generative attribution. Scope and affected targets are present; description of expanded capacity is separate from its evaluation.
V100-009	For each applied role, locate admissibility, identity, temporal meaning, and required metadata; inspect a missing value's explicit reason.
V100-010	Inspect a relation with changing terms and an event analyzed as a process. Relevant identity/history and overlapping views remain expressible.
V100-011	Always inspect whether operational record roles remain distinct from metamodel concepts. Separately, if a mapping is asserted, examine its scope and additional premises. An absent mapping makes only the mapping-specific component not applicable.
V100-012	Compare event report, institutional determination, legal assertion, ethical judgment, and technical check. Their distinct grounds remain visible.
V100-013	Inspect the term-use register, source status and dated definitions; a reused label has an argued correspondence.
V100-014	Examine a local extension's definition, admissibility, scope and limits; it does not silently replace a core meaning.
V100-015	Examine an inter-language or inter-edition mapping; partial correspondence is not represented as unrestricted equivalence.

Requirement	Evidence and discriminating check
V100-016	Compare actuality/modality, epistemic mode and assessment disposition, including an actual but retrospectively inferred occurrence.
V100-017	Inspect uses of fact, verified, valid and confirmed; recover the question, criterion, assessor and grounds.
V100-018	Inspect a correspondence between roles; retained references and stated losses prevent invented identity or occurrence detail.
V100-019	Compare zero, false, unknown, disputed, withheld and inapplicable values before and after a mapping.
V100-020	Examine numerical meaning, units, scale and aggregation; recover included population and weighting interpretation.
V100-021	Examine a sufficiency claim; recover the supported question, operations, horizon and omitted history.
V100-022	Examine an identity decision with alternative criteria; distinguish identifier matching, similarity, lineage and identity.
V100-023	Check the conformance statement's edition, boundary, terms and evidence; excluded uses do not acquire a result.
V100-024	Check the complete assessment register; every exclusion has an absent-trigger reason and every fulfilled result has evidence.
V100-025	Check mandatory designations and criteria separately from unavailable contextual facts; an unknown declaration does not resolve a criterion or replace a reference.
V100-026	Inspect a grouped requirement with one unassessed or failed component; its other fulfilled components do not produce an overall fulfilled result.

A.2 Execution and evidence record

The assessor first identifies the application and term-use register, then the feature-triggered requirements. For an applicable check, the evidence includes the definition or dated reference and an actual use. A boundary case is included when needed to distinguish alternative meanings. A documented equivalent case is acceptable when it tests the same distinction in the application's domain. An empty template or undocumented expert understanding is insufficient evidence of actual vocabulary use.

The register records subject version, requirement identifier, applicability, evidence locator, observed result, assessor, date and unresolved limitation. Component results follow V100-026. One evidence item can support several requirements, but their results remain separate. Assessor disagreement identifies whether it concerns meaning, factual material, scope or the assessment method. Restricted evidence receives a scope statement; unavailable required examination evidence receives a not-assessed result rather than an inferred pass. Assessment of an allowed unknown-context declaration follows V100-025 and remains separate from assessment of the unresolved fact.

Annex B

(informative)

Worked vocabulary cases

B.1 Initial distinction cases

1. A clerk records that a request arrived late. An attributed entry record can support a reported recording time, subject to the relevant clock, integrity and acquisition-context checks. Whether the request itself arrived late requires identifying the receipt-time source, applicable deadline and inference. The record, target event and deadline assessment remain distinguishable.
2. A later witness report changes the assessment of the arrival time. That is a revision of the account. A later extension of the deadline changes a governing condition. A new definition of "arrival" changes the descriptive or institutional rule. One dossier can contain all three histories without conflating them.
3. Two administrations reuse an office name. An application follows their records under the same catalogue heading while recording replacement and disputed institutional continuity. Shared cataloguing does not decide Entity identity.
4. A new procedure reduces review time and makes some participants unable to contest an error. A generativity record can preserve both the increased processing capacity and the restricted capacity for correction; an ethical judgment states its own affected parties and criteria.

B.2 One agreement and several roles

A fictional agreement links a cooperative and a laboratory. It is a Relation for questions of commitments and access and is tracked as an Entity for continuity after personnel changes. Negotiation and amendment form a Process, signing is an Event, operative terms on a date form a State description and a reported access limit is a Property assignment. These descriptions need not compete for a single exclusive class.

Renewal creates a boundary question. The parties and title continue while terms change substantially. Participants can describe the same agreement, an archive can retain a new document and a legal analyst can ask a separate continuity question. The application retains the criteria and their grounds rather than deriving a universal identity resolution from the shared title. A technical edge that records only an active connection can support a current-status query while losing formation and dispute history.

B.3 Changing composition in an aggregate

A programme reports participation rates for two groups. Both groups improve in a later period, while the population contains a larger share of the initially lower-rate group. The pooled rate can decline despite each group's improvement. This is a stipulated comparison problem, not evidence about a real programme.

The Property description retains population, denominator, definitions, weights and periods. A question about the same people over time additionally needs identity linkage. A question about institutional composition can instead treat entry and exit as part of the process. The scalar alone does not establish which question is relevant or whether the outcome is fair.

B.4 Missing, withheld and inapplicable

One form records a zero reading, another says no measurement was performed, another withholds an existing value, and another concerns a subject for which the characteristic is inapplicable. A conversion maps every case to an empty cell. That table can have a limited use, but it cannot claim preservation of the distinctions or support a count of zero readings.

A finer vocabulary can recover an omitted value only where retained or newly obtained evidence supports it. Changing notation does not create missing observations. Authorized examination can use a protected source while a public view remains incomplete. The correspondence records the different routes and resulting limitations.

Annex C

(informative)

Foundation trace and drafting rationale

C.1 General

Page numbers below are one-based pages in the supplied PDFs. FM identifiers are those in `foundation_manuscripts/MANIFEST.md`. The definitions here are operational proposals rather than quotations or claims that the manuscripts prescribe this recording model.

Table C.1 – Foundation passages and operational decisions

Source	Preserved distinction and draft application
FM-004, §4.2, pp. 11–14; §4.6, pp. 43–45	Registers answer different questions; manifestation is broader than representation, and recognition need not precede relational reality. Basis for V100-002; no exclusive philosophical register schema.
FM-005, §5.4, pp. 28–31	Trace, target relation, and evidence differ; evidential force is target-relative. Basis for V100-003/004 and GR-200 evidence-role requirements.
FM-005, §5.17, pp. 141–142	Uncertainty concerns several dimensions and need not have one scalar measure. Basis for the uncertainty definition and GR-200.
FM-005, §5.20, pp. 168–174	New evidence, intervention, historical revision, and category revision differ. Basis for V100-006/007; three linked histories are an operational organizing proposal.
FM-007, p. 2; §7, pp. 26–29; §8, pp. 32–33	Roles overlap; identity criterion, lineage, participant incidence, and relation continuity require distinct information. Basis for V100-005/009/010 and Entity/Relation proposals.
FM-007, §9, pp. 37–38, 43; §12, pp. 56–57	Occurrence differs from effect; histories differ from endpoints and possible factorizations. Basis for Event/Process proposals.
FM-007, §10, pp. 43–44; §11, pp. 52–53, 56	Attribute domain/scale and State sufficiency are scoped. Basis for Property/State proposals, with Property/Attribute unresolved.
FM-003, §3.10.9, p. 115; §3.13, pp. 141–142	Generativity has no fixed normative sign; effects vary across subjects and time. Basis for V100-008, without a universal measure. Both Chapter 3 variants remain independently preserved.

The main alternatives were a complete philosophical definition, an exclusive six-class schema, or a limited operational vocabulary. This draft selects the third provisionally because initial cases need distinguishable claims and histories before a technical model can be justified. A programme decision record accompanies this drafting choice; adoption and technical realization remain separate decisions.

C.2 Additional analysis in edition 0.2

FM-007, sections 10.4–10.10, PDF pages 45–50, distinguishes partial definedness, overlapping classifications, scale interpretation, aggregate behavior and changing composition. V100-019/020 preserve these meanings without importing the formal constructions or equating Attribute with Property. The manuscript's arithmetic examples are stipulated constructions, not empirical validation of this vocabulary.

FM-007, sections 17.1–17.2, PDF pages 78–80, distinguishes within-regime consistency from cross-regime alignment and explains the inability of a coarse description to recover omitted distinctions by relabeling. V100-015/018 preserve correspondence limits without claiming that a fixed regime catalogue anticipates every future distinction.

FM-005, sections 5.4.4–5.4.8, PDF pages 32–35, distinguishes observation, inference, latency, hiddenness and negative evidential warrant. V100-016 distinguishes a target's claimed actuality from its inferential accessibility. Missing evidence is not proof of concealment, and inference is not a weaker kind of reality. Sections 5.18.1–5.18.5, pages 152–156, examine visibility, classification power and institutional legibility. The extension requirements make classifications inspectable without assuming that maximal visibility is desirable.

The provisional term Generativity return identifies a programme recording topic, not an asserted equivalence with a manuscript-defined quantity. FM-005, section 5.17.3, PDF page 145, discusses uncertainty in recirculation claims, including conversion or transfer, return pathways and effects on later generative conditions. That passage supports questions to record, while the terminology's wider definition, measurement and evaluative interpretation remain unresolved.

Annex D

(informative)

Unresolved issues and development evidence

D.1 General

- **OPEN — Property/Attribute.** Compare FM-007 with sustained programme usage and test conflicting value assignments, undefined values, and nominal scales before deciding equivalence, separation, or a terminology change.
- **OPEN — Claim representation.** Compare independently identified claims, attributed assertions within records, and hybrids using disagreement, revision, restricted access, and round-trip examples. This draft requires distinguishability, not a seventh ontology class.
- **OPEN — Role overlap and profiles.** Test overlapping Event/Process and Entity/Relation descriptions. No exclusive schema typing or full cross-role relation vocabulary has been adopted.
- **OPEN — Identity.** Domain-specific criteria and disputed linkage need examples beyond names and administrative identifiers; branching continuity does not have a universal resolution.
- **OPEN — Generativity and return.** Test possibility, foreclosure, contribution, and return pathways without presuming a universal metric or a normative entitlement.
- **OPEN — Source chronology.** Chapter 3 editorial precedence remains unresolved. This draft cites particular passages without declaring one variant authoritative over the other.

GENERATIVITY STANDARDS PROGRAM

GR-110

Standards-track Working Draft

Version 0.3 2026-09-22

Generativity Recording Requirements

WORKING DRAFT FOR REVIEW

This document contains proposed provisions for technical and institutional review. It is not an adopted Standard or an operative governance instrument. Its scope, application conditions and publication status are specified in the text.

Prepared by the Generativity Standards Program. Reference to external publications does not imply endorsement by ISO, IEC, IEEE or any United Nations body.

Foreword

Version 0.3 records the bounded substantive review of the archived 0.2 package. This edition distinguishes dispute disposition from occurrence/modality in R110-012 and adds conditional recirculation-recording requirement R110-112 with an assessment route. The review matrix, synthetic assessments and unresolved readiness questions are documented in `docs/reviews/validation_0.2/README.md`. These activities do not constitute adoption or an independent institutional assessment.

This document specifies proposed requirements for generativity record packages and the practices that create, use, and maintain them. It is a preparatory Standards-track Working Draft. It is not an adopted Standard and does not establish that a formal standards project has been initiated.

Responsible editor: `UNASSIGNED`. Canonical source: `standards/GR-110-recording-requirements/GR-110.tex`. Intended readers are recording practitioners, participants in inquiry, record custodians, institutional users, implementers, and assessors.

Version 0.2 retained R110-001 through R110-034 and updated their dated draft dependency to GR-200 version 0.2. That edition developed operational planning, capture, attribution, alternatives, practical response, custody, presentation, and assessment. Normative annexes specify semantic information and assessment schedules. Informative annexes provide authored examples and a source-to-proposal explanation.

The proposed requirements are available for review and controlled exercises while programme governance develops. Their fulfillment concerns the stated recording practice and evidence. It does not certify factual truth, beneficial generativity, complete history, or external legal validity.

Introduction

A final output can survive while the relations, judgments, alternatives, and conditions that made it possible become inaccessible. An account of a current result can also conceal mistaken assessments, changing categories, unrecognized contributions, or the loss of capacities elsewhere. This document addresses those problems through bounded and revisable recording.

A generativity package connects three distinguishable histories: changes in the situation being investigated; changes in evidence, interpretation, and judgment; and changes in categories, methods, or institutional recognition. A classification can enter the situation and alter access or action. Its practical effect does not establish that its description was warranted, and its later correction does not demonstrate repair of earlier consequences.

The recording objective is therefore more specific than accumulating observations. A reader needs to identify the asserted transformation, whose account it is, how earlier conditions are said to connect to it, which grounds support that connection, and what remains unavailable or disputed. A practice needs arrangements for proportionate collection, protection, challenge, correction, custody, and intelligible presentation.

The foundations support several forms of generative inquiry. A relation can enable, constrain, maintain, amplify, mediate, or stabilize an effect, and its role can change over time. A generative trajectory can cross several relations and carriers rather than follow one persistent object. The clauses below operationalize the recording of such accounts; they do not impose one causal theory, universal measurement scale, or exhaustive graph of possible futures.

1 Scope

1.1 Included subjects

This document specifies requirements for an identified generativity record package and the responsible recording practice. It covers purpose and boundary, material claims, record identity, time, generative accounts, contributions, alternatives, changes in distinctions, practical uptake, revision, protection, custody, and presentation.

The package contains the retained representation and its declared limits. The practice includes people or institutions, methods, assigned responsibility, collection and review actions, custody, and user-facing behavior. Full assessment of the declared scope examines both documentary material and applicable practice obligations. A package-only examination is a partial assessment under this edition; no reduced package-conformance profile is defined.

1.2 Excluded claims and implementations

The document does not require an exhaustive world history, unrestricted observation, a particular database, cryptographic mechanism, interchange format, common metric, or mandatory category-theoretic semantics. Narrative dossiers, tables, and technical systems can satisfy the same semantic obligations where the required distinctions and behavior remain inspectable.

It does not establish ownership, a compensation entitlement, a legal duty to disclose, or the authority of an external institution. Contextual legal and policy assertions are recorded with their grounds and status. Full GR-120, GR-130, GR-140, GR-150, GR-160, and GR-400 publications are not prerequisites for applying the bounded manual assessment in this draft.

2 Normative references

2.1 Dated draft dependencies

The following Standards-track Working Drafts supply provisions invoked by this document:

GR-100, Foundations and Vocabulary, version 0.3. `standards/GR-100-foundations-vocabulary/GR-100.tex`. The incorporated scope is Clause 3's terms, Clause 5's record-role meanings when used, and the result-category meanings in 8.3. This reference does not impose a separate claim of GR-100 vocabulary-application conformity.

GR-200, Epistemic Recording Framework, version 0.3. `standards/GR-200-epistemic-recording/GR-200.tex`. Provides the applicable requirements for the bounded epistemic record package required by R110-005, including package-level obligations.

These are draft dependencies, not adopted Standards. An assessment identifies their exact versions and the incorporated requirements. A later change requires dependency review.

2.2 Related documents

GR-210, Evidence, Interpretation, and Contestation, version 0.3, provides a complementary procedural draft. It is not a blanket dependency of this document. A claim to fulfill a GR-210 procedure requires a separate assessment. Programme governance controls publication development and adoption; it does not automatically supply the mandate of an institution using a package.

3 Terms and definitions

3.1 Generativity record package

An identified collection assembled for a stated inquiry or practical purpose, with a scope, inventory, responsible recording practice, attributable material claims, and history relevant to that purpose.

3.2 Recording practice

The responsible people or organization, methods, decisions, and custody arrangements used to assemble, assess, present, and maintain a package.

3.3 Material claim

An assertion relied on to explain a consequential relation, generative effect, decision, classification, assessment, or revision within the declared purpose. Materiality is determined by that reliance and the selection rationale; it is not a truth status.

3.4 Generative account

An attributed account of how conditions or relations enabled, maintained, transformed, or constrained subsequent capacities, relations, distinctions, constraints, or possibilities. This operational term permits recording an account whose substantive warrant remains disputed.

3.5 Generative contribution role

The asserted target-relative function of a relation, actor, or configuration in an account, such as enabling, triggering, mediating, amplifying, stabilizing, substituting, or constraining. Roles can overlap and change; they are not new record-ontology classes.

3.6 Generative carrier account

An account of a persisting or transmitted condition through which an earlier contribution is connected to a later effect, including any transformation of that condition. This is a recording expression informed by FM-005, Definition 5.100, rather than a new mandatory class.

3.7 Possibility-field account

A bounded account of the alternatives or pathways represented as accessible, constrained, opened, or foreclosed for specified subjects under stated conditions. It does not claim to enumerate the complete possibility field of reality.

3.8 Practical uptake

Reliance on an identified claim, classification, or assessment in a stated action or decision, distinguished from mere receipt or availability of the information.

3.9 Recording horizon

The period covered by collection or reconstruction. It can differ from the period over which a claimed effect is expected or assessed.

3.10 View

A selected or transformed presentation of package content for an identified purpose and audience, with declared relation to source versions and material limitations.

3.11 Declared limitation

An explicit account of a collection, knowledge, access, method, temporal, or assessment constraint. Declaring a limitation does not automatically satisfy an obligation requiring evidence that remains missing.

4 Planning and responsibility

4.1 Purpose, boundary, and selection

R110-001 A package shall identify its purpose, intended users, subject matter, boundary, relevant time horizon, recording practice and package version.

R110-002 The recording practice shall state the selection criteria for included material and identify known omissions material to the purpose, including unavailable perspectives, uncollected information and limits of reconstruction.

R110-003 The package shall distinguish an inventory of retained records from an assertion that the underlying history is complete. The existence of a record shall not be used as proof of its represented content.

R110-035 Before systematic capture or reconstruction, the recording practice shall identify the questions the package is intended to support, the decisions or uses anticipated, and the information needed to examine them. The collection plan shall distinguish necessary detail, conditional detail, and material excluded from collection with reasons.

R110-036 The plan shall identify temporal horizon and resolution, observational boundary and scale, included perspectives, source types, expected gaps, and relevant relations outside the boundary treated as context. A change of boundary or scale material to interpretation shall be versioned and explained.

R110-037 The practice shall assess feasible recording, assessment, protection, and participation effort for the declared purpose. If essential work exceeds available capacity, it shall narrow the scope, obtain capacity, or report an unmet requirement; resource limits shall not justify invented content or an unqualified assessment claim.

The selection plan makes the account usable and bounded. An inquiry into a maintenance collaboration can require the work that sustained access without documenting every interaction among its participants. Selection becomes misleading when exclusions material to the stated account disappear from view.

4.2 Responsible functions and operating conditions

R110-004 The recording practice shall assign responsibility for capture, assessment, custody, access decisions and correction, recording combined roles and relevant conflicts. An automated component shall not substitute for an unassigned responsibility.

R110-038 Each assigned function shall identify the responsible person or organization, accepted task, authority and access needed, relevant interests, and a contact or continuity arrangement. Where a function cannot be performed, the practice shall record the limitation and its consequence for current use or assessment.

R110-039 The recording plan shall identify when capture is contemporaneous, retrospective, automated, or assisted and how consequential selections or transformations will be checked. Automated output shall retain its relationship to source material and accountable review.

R110-040 A material expansion of purpose, audience, source collection, or practical use shall receive renewed scope and protection assessment before the affected activity begins. The package shall identify the change and distinguish earlier permission and evidence from authority for the new use.

R110-041 The practice shall maintain the package inventory, current responsible functions, known dependencies, and active review or correction routes through the declared maintenance period. A decision to stop maintenance shall identify its date, reason, custodial disposition, and consequences for users.

5 Capture, identity, and epistemic integration

5.1 Intake and trace preservation

R110-042 On incorporating material, the practice shall record its source, acquisition or creation time, received version or identifying characteristics, method of capture, relevant production context, and permitted use. Unverified source assertions shall remain attributed rather than represented as established provenance.

R110-043 A transcription, translation, summary, selection, annotation, or reconstruction shall identify the source material, responsible transformer or method, material changes, and known loss or uncertainty. A derived account shall remain distinguishable from its source.

R110-044 When several materials derive from a common source, the package shall retain known derivation relationships relevant to evidential independence. Multiple copies or repeated citations shall not be presented as independent corroboration without additional grounds.

R110-045 The practice shall identify collection or extraction errors that can materially affect interpretation, including temporal aggregation, omitted context, unresolved attribution, and unsupported precision. Correction of an extraction shall not silently alter the underlying source record.

5.2 Package and claim dependency

R110-005 The package shall identify its material claims and assessments as a bounded epistemic record package assessed against GR-200 Working Draft 0.3, including that draft's package-level obligations. It shall identify the assessed claim set, dependency versions, applicable requirements, evidence, exceptions and results; a claim-level check alone shall not establish fulfillment of the package dependency.

R110-046 The assessed material-claim set shall include claims relied on for generative connections, identity, alternatives, category change, and practical consequences, not only claims supported by convenient evidence. Exclusion of a relied-on claim shall be identified as a limitation of the assessment rather than omitted from the declared set.

R110-047 The package shall link each material claim and relevant assessment to the applicable GR-200 records and results. The dependency assessment shall cover all applicable obligations for that bounded epistemic package; successful individual claim checks shall not substitute for package-level evaluation.

5.3 Identity and temporal meaning

R110-006 Each retained record and version shall be distinguishable within the package, and a reference shall identify its intended target sufficiently for the declared use. A record identifier shall not itself establish identity of the represented person, event or relation.

R110-007 A continuity or identity judgment material to the trajectory shall identify its criterion, responsible source, supporting grounds and known dispute. Merger, succession and common labels shall not silently be treated as identity.

R110-008 The package shall distinguish the represented occurrence or validity time from observation, recording and later assessment times when their difference is relevant. Uncertain intervals and unsupported ordering shall remain explicit.

R110-009 Represented observations, actions, relations, states and properties shall retain the information needed to distinguish their operational roles. A relation with a material history, status or properties of its own shall be identifiable as a recordable subject.

R110-048 A disputed identification, apparent duplicate, split, merger, or succession shall retain the alternative interpretation and the decision or uncertainty governing linkage. The practice shall distinguish correction of a record identifier from revision of a judgment about the represented subject.

R110-049 The temporal account shall identify relevant ordering, interval, resolution, and uncertainty, including where observations leave gaps. A claimed continuous relation shall state its continuity criterion and evidence; continuity of a label, manifestation, or file shall not alone establish continuity of the relation.

R110-050 When a reconstruction uses categories or evidence unavailable to earlier actors, it shall identify that retrospective basis and retain the earlier terminology or a supported account of it where material. The reconstruction shall not attribute later knowledge or intended outcomes to earlier actors without grounds.

6 Generative accounts and attribution

6.1 Target and connection

R110-010 For each generative account, the package shall identify the target capacity, relation, constraint, distinction or possibility; the relevant actors or configuration; the comparison or earlier condition; and the temporal and contextual scope.

R110-011 The account shall state how the proposed enabling, maintaining, transforming or constraining contribution connects earlier conditions to the target, with grounds, method and limitations. Temporal precedence or a diagram edge alone shall not be presented as establishing that connection.

R110-012 An account shall distinguish the asserted occurrence or modality of an effect, such as realized, intended, possible or unrealized, from its epistemic basis, such as observed, reported, inferred or reconstructed, and from the assessment or dispute disposition. Unresolved actuality shall remain explicit. A realized past effect can be retrospectively inferred; its contribution attribution can remain disputed. The recording practice shall not manufacture an observed outcome where follow-up evidence is absent.

R110-014 When an enabling encounter, decision or judgment is material to the account, the package shall identify its represented role, relevant conditions and the claim connecting it to subsequent developments.

R110-051 A generative account shall distinguish the existence or occurrence claim about its target from the attribution claim connecting candidate contributors to that target. The role, boundary, scale, time horizon, and evidential limits of the attribution shall remain inspectable even when the target change is well supported.

R110-052 Where association, sequence, or co-occurrence is used as support, the account shall state that evidential role and assess material alternative explanations, such as selection, common conditions, reverse influence, or changing definitions, or identify their unresolved status. Association shall not be relabelled as a demonstrated mechanism.

R110-053 A mechanism account shall identify the intermediate changes proposed to carry the contribution, their connection to available evidence, and any unobserved or assumed link. Restating the final outcome as an intermediate step shall not be presented as additional evidence.

The meaning of a contribution depends on the target. A network can be associated with income while the stated generative question concerns access to knowledge or a new collaboration. The account identifies the level at which the asserted contribution operates. Different methods can provide different kinds of support without being reduced to one confidence number.

6.2 Alternative contributors and counterfactual reasoning

R110-054 When a counterfactual supports attribution, the account shall identify the focal change, connected conditions allowed to vary, background conditions provisionally held stable, target comparison, time horizon, evidence for plausibility, and material uncertainty. A modeled counterfactual shall remain distinguishable from an observed comparison.

R110-055 Where multiple or distributed contribution is material, the account shall identify the supported roles or organizational pattern, relevant complementarities, substitutions, or feedback, and the limits of allocating effects among participants. Failure to isolate a single contributor shall not force an unsupported sole attribution.

R110-056 A claim of emergent or configurational contribution shall identify the interaction, organization, or dependency said to matter and the evidence supporting its relevance to the target. The label emergent or systemic shall not replace the account of the proposed connection.

6.3 Carriers, delay, and long trajectories

R110-057 For a delayed contribution, the account shall identify the persisting or transmitted condition proposed to connect the earlier relation to the later effect, known transformations of that condition, intervening influences, and the limit of useful attribution. A long interval alone shall not establish either continuity or disconnection.

R110-058 A trajectory containing several generative links shall preserve link-specific contributors, target, grounds, modality, and uncertainty where these differ materially. Evidence supporting one link shall not automatically validate downstream links or the whole trajectory.

R110-059 Where available evidence ceases to support a downstream attribution, the account shall identify that boundary and classify further development as unassessed, conjectured, or separately supported as appropriate. A diagram or narrative shall not hide that change of status.

R110-060 A path-dependence or lock-in claim shall identify the sequence-sensitive condition said to alter later alternatives, its carrier or feedback, and grounds distinguishing historical dependence from persistence under current conditions. Claimed irreversibility shall state the relevant horizon and alternatives considered.

6.4 Branches and contributions

R110-013 Material participants and contributions shall be attributed with their basis and uncertainty. The recording practice shall provide a means to record disputed, collective, indirect or unknown contribution without forcing attribution to one actor.

R110-061 An account of branching shall distinguish opening or constraining a pathway, selecting a branch, and stabilizing a later outcome when those contributions differ. Earlier enabling conditions shall not receive the whole realized history's attribution solely because they preceded it.

R110-062 A contribution record shall distinguish descriptive attribution from acknowledgement, authorship, compensation, ownership, institutional credit, or legal responsibility. Any asserted entitlement or allocation shall identify its separate source, authority, evaluative basis, and disputed or operative status.

7 Alternatives, distinctions, maintenance, and loss

7.1 Alternative and possibility accounts

R110-015 A recorded alternative shall state whether it was considered at the time, inferred retrospectively, modeled or merely proposed, and identify the grounds for any claim of feasibility. Recorded alternatives shall not be presented as exhaustive or equally feasible without supporting grounds.

R110-063 A historical alternative shall identify whether it was evidenced as available to relevant actors at the time, proposed then but infeasible under identified conditions, or introduced retrospectively for analysis. A later technology, category, or institutional option shall not be represented as historically available without grounds.

R110-064 A possibility-field account shall identify the subjects or positions concerned, the selected pathways, the relevant conditions and horizon, and the change alleged in accessibility, cost, probability, or viability. Unenumerated possibilities and limits of comparison shall remain explicit; a bounded list shall not imply exhaustion.

R110-065 Where an option is represented as available, the account shall distinguish formal availability from practical access under material resources, authority, knowledge, timing, or participation conditions. A declared permission alone shall not establish that the affected person could exercise the option.

R110-066 A comparison of earlier and later possibilities shall state whether the compared categories, boundaries, and subjects remain sufficiently consistent for the claimed comparison. If the process generating change or the available distinctions changed, that change shall be represented rather than forced into an unchanged scale.

Alternatives are recorded for their relevance to the inquiry. No branch tree is required. A package can retain evidence of one abandoned option and explicitly state that other pathways were not reconstructed. A possibility claim is stronger than a statement that an observer imagined an option, and its grounds are recorded accordingly.

7.2 Categories and historical reinterpretation

R110-016 A material change in categories, available distinctions or methods shall identify the earlier and later formulation, the reason for change and its effect on interpretation. A new description shall not automatically be represented as a newly existing underlying object.

R110-067 A material classification or method change shall identify its responsible source, effective or asserted period, definitions or rules changed, and consequences for reading earlier records. A later harmonized dataset or view shall preserve a route to the distinctions lost or identify that loss.

R110-068 A retrospective interpretation shall distinguish correction of an earlier error, expansion using later evidence or categories, and subsequent transformation of the represented relation. Where more than one applies, the package shall preserve their separate grounds rather than choose one merely for a simpler history.

The same word can refer to changing institutional arrangements, and different words can describe related practices. A genealogy can therefore connect heterogeneous predecessors without claiming one continuous identity. The package identifies the type of historical account and the limits of the continuity or formation claim.

7.3 Maintenance, depletion, and restriction

R110-017 Known maintenance, depletion, restriction, exclusion or loss material to the declared generative account shall be recorded alongside creation or expansion, or have an explicit collection or protection limitation under R110-002 and R110-026. The account shall distinguish descriptive effects from their evaluation for particular people or values.

R110-069 Where maintaining a capacity or relation is material, the account shall identify the recurring work or conditions asserted to sustain it, the relevant period, and evidence or uncertainty about deterioration in their absence. Lack of a novel final output shall not be used to omit a supported maintenance contribution.

R110-070 A loss account shall distinguish loss in the represented situation from loss of records, visibility, access, institutional recognition, or interpretability. The package shall identify which kind is asserted, its basis and affected subject, without inferring one solely from another.

R110-071 An enabling or constraining effect that differs by participant, position, scale, or horizon shall be scoped accordingly. A short-term benefit shall not erase a recorded longer-term dependency or cost, and a loss to one participant shall not be concealed by aggregate expansion.

R110-072 A normative evaluation of maintained, created, or lost conditions shall identify the evaluator, relevant values, affected interests, grounds, and disagreement. Descriptive generativity and the desirability of its consequences shall remain distinguishable.

7.4 Generativity return

R110-018 Where generativity return is assessed or proposed, the package shall identify the asserted concept, intended recipients, scope, grounds and evaluative basis. Where it is not assessed, that limitation shall be stated without inventing a quantity or entitlement.

R110-073 A generativity-return account shall distinguish the proposed concept and evaluation from any observed transfer, practical response, or legally asserted entitlement. If a quantity is used, the account shall state its meaning, units or scale, calculation or judgment method, horizon, assumptions, and limits on comparability.

R110-112 When a return account asserts recirculation, the package shall distinguish the initial generation, conversion or transfer pathway, return pathway, and asserted effect on later generative conditions. For each stage and material connection it shall identify the claim, actuality or modality, supporting grounds and uncertainty. An unavailable link shall be marked unresolved with its assessment limit; it shall not be inferred solely from another stage. A proposed or completed transfer shall not by itself establish that returned value maintained or renewed generative capacity.

An account can state that generativity return was not assessed. The record of that limitation is assessed separately from any substantive claim about return. No universal distribution rule or monetary equivalent is prescribed.

8 Practical uptake, feedback, and revision

8.1 Decision and intervention accounts

R110-019 When a represented claim or classification informs a decision within scope, the package shall identify the claim version relied on, the decision, the asserted decision authority, its stated grounds and known subsequent response.

R110-074 A practical-uptake record shall distinguish availability or receipt of a claim from actual reliance, the decision communicated, and the action implemented. Each asserted step shall identify its

source and evidence or uncertainty; a delivery acknowledgement shall not establish that a judgment was accepted.

R110-075 When an intervention rationale is within scope, the package shall identify the immediate action, intended generative effect, target relations or conditions, relevant assumptions, beneficiaries and affected interests, and evidence expected to support or challenge the rationale. It shall identify the asserted authority rather than derive that authority from the recording Standard.

R110-076 Where monitoring or feedback is part of the assessed practice, the practice shall identify questions, observations, review points or triggers, responsible recipients, and the decisions that feedback can inform. A collection schedule without a route to consideration shall not be represented as an operative feedback arrangement.

The practical sequence depends on context. A retrospective archive need not operate the intervention it describes. Its package can record an institution's asserted action and the evidence available about it. A practice claiming to provide an operational feedback route needs evidence that the route works within its authority.

8.2 Learning and consequences

R110-077 The package shall distinguish evidence that an action was implemented as intended from evidence that the anticipated transformation followed. Unexpected, delayed, mixed, or unobserved effects shall retain those statuses rather than being treated as success or failure solely from implementation completion.

R110-078 A material feedback record shall identify the observation or testimony, its relation to the intervention rationale, the person or function considering it, and any maintained or revised action with reasons. Where the practice cannot observe consideration or action, that limit shall be reported.

R110-079 When feedback leads to a changed target, method, boundary, objective, or evaluative criterion, the package shall preserve the change and its rationale. Later success criteria shall not be presented as though they governed the original action unless that earlier status is evidenced.

R110-080 An account of withdrawal, reversal, or repair shall distinguish ending an activity, attempting to restore an earlier condition, and addressing residual consequences. It shall identify responsible authority, planned and performed actions, observed effects, and known limits; restoring a rule shall not alone establish restoration of the prior situation.

R110-081 Where a corrective decision has known downstream consequences within the declared scope, the practice shall record follow-up evidence or its absence, including whether affected access, participation, capacity, or dependence changed. A corrected description alone shall not be reported as completed practical repair.

8.3 Revision and challenge

R110-020 A revision shall identify its actor or responsible source, time, target, reason and affected records, distinguishing a change in the represented situation, evidence or interpretation, and descriptive regime. More than one reason can apply.

R110-021 The recording practice shall preserve the intelligible relationship between earlier and later accounts, subject to stated retention and access rules. It shall not retrospectively present earlier actors as possessing evidence or categories first available later.

R110-022 A correction shall identify dependent records or presentations known to the practice, actions taken to correct them and any limits on propagation. The practice shall not assert that uncontrolled external copies were corrected or deleted without evidence.

R110-023 The practice shall provide a declared route for questions, contested attribution and correction requests, identify the responsible recipient and maintain permitted request/disposition records. Availability of the route shall not imply a legal entitlement or a promise of agreement.

R110-082 The declared correction route shall explain how to identify the disputed material, contact the responsible function, request protected handling, and learn the status or disposition. The practice shall test the route within its claimed operating conditions and record failures and remedies.

R110-083 Conflicting correction requests shall remain separately attributable and linked to the affected versions. The practice shall record the responsible determination or unresolved disagreement and shall not silently overwrite one account merely because another was received later.

9 Protection, custody, and preservation

9.1 Authority and proportionate collection

R110-024 The recording practice shall declare the purpose and authority basis for collecting, retaining, accessing and disclosing material within the package, including the applicable policy or institutional context and unresolved constraints. It shall limit collected detail to that justified by the declared purpose.

R110-025 Access and retention decisions shall distinguish content, metadata, derived views and audit traces. Preservation of history shall not automatically require public disclosure or indefinite retention of sensitive material.

R110-084 Before collecting or disclosing sensitive material, the practice shall identify the intended use, actual authority or permission basis, audience, relevant restrictions, and feasible less intrusive information sufficient for the purpose. If the intended use lacks an established basis, that use shall not proceed merely to complete the package.

R110-085 Protection decisions shall consider whether identifiers, relationships, timing, summaries, or combinations of metadata disclose restricted identity, existence, or content. The resulting access arrangement shall distinguish material that can be retained, examined by authorized reviewers, or presented to a particular audience.

9.2 Unavailable information and retention

R110-026 Where material is unavailable, the package shall distinguish known non-collection, loss, destruction, restriction and an unknown reason to the extent that doing so is supported and permitted. It shall not disclose a protected fact merely to label an absence.

R110-086 An unavailable-information declaration shall state only what is supported and permitted, identify its effect on interpretation or assessment, and indicate a review or future-access route where one exists. A protected omission shall not be filled with a false factual explanation.

R110-087 The practice shall identify the custodian, retention period or event-based trigger, access-review point, and authorized disposition for material whose retention or disclosure is controlled. Expiry or withdrawal of access shall trigger review of affected claims, views, and assessment limitations.

R110-088 When interpretability depends on a vocabulary, method, software environment, codebook, or external resource, the package shall identify the relevant version and preservation or availability arrangement. A broken reference or obsolete tool shall be assessed for semantic loss rather than treated only as a display defect.

9.3 Transfer and migration

R110-027 A transfer, migration or custody change performed by the practice shall identify the source and destination versions or custodians, its authority, relevant transformation and known information loss. Unsupported finer distinctions shall not be invented during conversion.

R110-089 Before a transfer or migration, the responsible custodian shall identify the authorized source and destination, material and versions in scope, rights and restrictions to carry forward, transformation rules, expected losses, acceptance criteria, and responsibility if the operation fails.

R110-090 After a transfer or migration, the practice shall compare the resulting material against the declared acceptance criteria, including identity, attribution, versions, temporal distinctions, generative links, uncertainty, access restrictions, and known losses. A successful byte transfer shall not alone demonstrate preservation of meaning.

R110-091 An interrupted or unsuccessful custody operation shall retain a record of completed and incomplete steps, authoritative copies, protection status, recovery actions, and unresolved loss. The practice shall not claim that destination custody is complete before acceptance is evidenced.

9.4 Correction, restriction, and disposal

R110-028 An authorized correction, restriction, retention or disposal action shall have a scoped disposition and an accountable executor. The practice shall record permitted evidence of its result and known limitations without retaining prohibited content solely to prove deletion.

R110-092 An authorized restriction or disposal shall identify the affected content and derived views, permitted evidence of execution, known copies or dependents, and limits of control. The practice shall review public statements and assessment claims that relied on material no longer available, without retaining prohibited information merely to document the action.

10 Presentation and accessible examination

10.1 View identity and mediation

R110-029 A presentation supplied as part of the assessed practice shall identify its source package/version and disclose material selection, reconstruction, uncertainty, disagreement and restriction within the permitted audience. It shall distinguish an attributed claim, an assessment and an institutional determination.

R110-030 A public or reduced view shall not imply that it contains the entire retained package. A validation or provenance result shall state what was checked and shall not be presented as certification of substantive truth or normative legitimacy.

R110-093 Each supplied view shall identify its audience and purpose, source package and version, generation or preparation method, material selection and transformations, and update status. A cached or exported view shall not imply that it reflects later corrections without evidence of refresh.

R110-094 A view of a generative account shall distinguish the status of the asserted effect, the evidential basis for it, and the evaluation of its desirability. A visual edge, color, badge, or position shall not be the sole means of expressing a distinction necessary for interpretation.

R110-095 Navigation from a public or reduced view shall respect the access limits of linked evidence and metadata. Where a material link cannot be exposed, the view shall communicate the permitted limitation without suggesting that the source does not exist or that unrestricted inspection is available.

10.2 User tasks and support

R110-031 The practice shall provide enough accessible explanation for intended users to locate the grounds of a material claim and the relevant review route. A practical assessment shall record observed comprehension barriers and the alternatives or limitations offered.

R110-096 The practice shall assess whether intended users can identify a material claim and its source, distinguish assessment from institutional decision, find relevant uncertainty or alternatives, recognize revision and view limits, and locate the permitted challenge route. Assessment shall record tasks, users or representative role, observed barriers, assistance, and limits.

R110-097 Where a presentation fails a material intended task, the practice shall provide an accessible alternative, correct the presentation, narrow the supported use, or report an unresolved limitation. Successful file rendering or text extraction shall not be reported as demonstrated user comprehension.

11 Assessment and claims

11.1 Declaration and subject coverage

R110-032 A report shall identify the assessed subject, versions of this draft and its dependencies, purpose/profile, applicable requirements, assessor, method, evidence, results and unresolved limitations. Package-only results shall not be presented as assessment of unobserved practice.

R110-033 The report shall distinguish fulfilled, not fulfilled, not assessed and not applicable results for each requirement, with reasons for exclusions. A failed or unassessed applicable requirement shall prevent an unqualified claim that the declared scope satisfies this draft.

R110-034 The report shall distinguish structural or documentary checks from tests of understanding, evidential warrant and institutional performance. It shall not infer truth, complete historical recovery, beneficial generativity or legal validity from structural fulfillment.

R110-098 Before assessment, the assessor shall identify the package baseline, recording practice, purpose, period and environment, applicable requirements, incorporated GR-100 and GR-200 versions, protection limits, assessor competence and interests, and the methods in Annex B to be used. The declaration shall distinguish planned from completed assessment.

R110-099 An unqualified claim for the declared GR-110 scope shall require evidence for all applicable package and practice obligations, including the full applicable GR-200 package dependency. A successful documentary subset or absence of reported failures shall not establish that unobserved practice was performed.

R110-100 A package-only or otherwise partial assessment shall identify the exact assessed subset, methods and evidence, excluded practice claims, and dependency limitations. It shall not use an unqualified label suggesting that the complete recording practice or a reduced conformance profile was assessed.

11.2 Methods and result rules

R110-101 The assessor shall use requirement-level evidence and discriminating cases under Annex B. Where one identifier contains materially distinct obligations, component results shall be retained so that a fulfilled component does not conceal failure or non-assessment of another. A requirement shall be fulfilled only if every applicable component is fulfilled; any failed or unassessed applicable component shall prevent overall fulfillment of that requirement.

R110-102 Fulfillment shall require evidence of the stated obligation under its applicability condition. A missing required declaration shall be reported as not fulfilled; inability to examine whether a represented

action occurred shall be reported as not assessed unless adequate permitted evidence supports a result. Non-applicability shall identify the absent trigger.

R110-103 Where assessment uses sampling, the report shall identify the population, selection method, covered risks, excluded cases, and limits on extension of the findings. Cases selected only because they already appear complete shall not support a general claim about an unexamined practice.

R110-104 A dependency mismatch, unavailable required evidence, or unresolved interpretation affecting the result shall be recorded with the affected requirements and claim consequence. The assessor shall not substitute a newer dependency silently or count an unsupported exception as fulfillment.

11.3 Reassessment and change

R110-105 A material change to purpose, claim set, generative account, category, protection, custody, presentation, or dependency shall trigger review of affected assessment results. The new report shall identify what was reassessed, what remains supported by prior evidence, and what can no longer be claimed.

The assessment concerns the declared scope. It does not establish that the package contains every important historical fact or that every recorded interpretation is correct. A requirement to preserve uncertainty can be fulfilled while the underlying generative attribution remains contested.

Annex A

(normative)

Semantic information schedule

A.1 Application

R110-106 The recording practice shall provide the semantic information in Table A.1 when its stated trigger applies, by content in the package or a permitted reference to identified material. The schedule shall be implemented without treating its labels as mandatory serialization field names or ontology classes.

R110-107 For each scheduled information group, the package shall identify its applicable subject, version, source or responsible actor, temporal scope where relevant, access status, and relationship to the material claims it supports. Information shared across records may be referenced when the intended scope and target remain unambiguous.

A.2 Information groups

The table specifies semantic content rather than a database schema. An embedded document can supply several groups, but their meanings and responsible sources remain distinguishable.

Table A.1 – Semantic information and applicability

Group	Trigger and subject	Required meaning and relationships
Package context	Each package.	Identity/version; purpose and intended users; subject and boundary; horizon; inventory; selection and omissions; responsible practice; declared dependencies and assessment status.
Source and capture	Material incorporated or transformed.	Source and received form/version; acquisition or creation; capture method; production context; derivation; transformation and known loss; permitted use and verification limits.
Material claim	Reliance within the declared purpose.	Attributed assertion, target, scope and status; grounds, method, alternatives, uncertainty and revision through the applicable GR-200 package; link to the relied-on version.
Identity and time	Identity or timing material to interpretation.	Record/version identity separate from subject identity; continuity criterion and grounds; competing identification; occurrence, observation, capture and assessment times with supported resolution and uncertainty.
Generative account	A generative connection is represented.	Target; candidate configuration and contribution role; earlier or comparison condition; proposed link and grounds; scale/horizon; modality; alternative contributors; known unobserved links and limits.

Group	Trigger and subject	Required meaning and relationships
Return and recirculation	A return account is assessed or proposed; the four-stage detail applies when recirculation is asserted.	Concept, recipients, scope, evaluation and transfer or entitlement status; for recirculation, initial generation, conversion or transfer, return path, later-condition effect, and stage/link-specific modality, grounds and uncertainty under R110-112.
Carrier and branch	Delay, transmission, or branching is material.	Carrier or persisting condition and transformations; intervening influences; pathway opening, selection and stabilization where distinct; branch-specific evidence and uncertainty.
Alternative and possibility	Alternative or changed accessibility asserted.	Whose option; relevant period and conditions; contemporaneous, retrospective or modeled basis; feasibility grounds; changes in access, cost or viability; unexamined options and comparison limits.
Category or method change	A change alters interpretation.	Earlier/later formulations, author or authority, effective period, rationale, correspondence and loss; distinction among new knowledge, revised description and a changed situation.
Maintenance and loss	Material sustaining work or loss within scope.	Capacity or relation sustained/depleted; continuing conditions/work; affected subjects and horizon; kind and evidence of loss; permitted collection limits; evaluation separately attributed.
Practical uptake	Decision or action relies on represented material.	Relied-on version; receipt versus reliance; authority assertion; decision and reasons; intended versus implemented action; anticipated versus observed effects; feedback and disposition.
Revision and challenge	Correction, reinterpretation or request occurs.	Target and prior version; actor/time; reason; permitted request and reply; revised or maintained assessment; known dependents; notification/propagation limits; separate practical remedy.
Protection and custody	Each maintained package and controlled operation.	Purpose and authority basis; custodian; content/metadata/view controls; retention/review triggers; unavailable-information status; transfers, losses, disposal and permitted execution evidence.
View and assessment	A view or assessment is supplied.	Source baseline; audience and purpose; selection/mediation; limits and update status; assessor/method; applicable requirement and component results; dependency status; excluded claims.

A.3 Absence, uncertainty, and restrictions

R110-108 An absent scheduled element shall be distinguished as not applicable with a trigger-based reason, unknown, not collected, lost, destroyed, restricted, or otherwise unavailable only where that status is supported and permitted. An unavailable contextual factual value, including historical capture time or source-production context, may be represented by such a typed declaration identifying the responsible or attributing role, known reason, and effect on interpretation or assessment. Package and record references and versions, purpose and scope, accountable recording role, and relationship locators needed to identify asserted claims, contributions, assessments, and revisions shall not be replaced by unknown values. Required reasoning, criteria, and results of the package's own assessment shall remain explicit. Fulfillment of a contextual declaration obligation shall not establish the unavailable fact or fulfillment of an examination or action that could not be performed.

Annex B

(normative)

Requirement assessment schedule

B.1 Method and evidence register

R110-109 The assessor shall maintain a register for every applicable requirement, including R110-106 through R110-111, with subject/version, trigger, method, evidence locator, assessor and competence, component results, overall result, limitations, and needed action. The register shall use the discriminating assessment families in Table B.1 and identify any justified equivalent method.

Inspection examines the actual package and controlled records. A competent content review examines the grounds and distinctions asserted; it does not certify all historical truth. An observed task tests what the practice or user actually does under identified conditions. A lifecycle exercise uses authorized fixtures to assess access, revision, transfer, or disposal. Synthetic exercise results remain separate from evidence of live institutional action.

B.2 Assessment families

Table B.1 – Assessment families and discriminating outcomes

Requirements	Method and evidence	Outcome distinguishing fulfillment from failure
001–004, 035–041	Inspect scope, selection, inventory, accepted roles, resources, and maintenance record.	Boundary and omissions are explicit; no complete-history claim or automated substitute for missing responsibility.
042–045	Trace captured and derived material to its source and inspect transformations.	A summary and repeated copies remain distinguishable from the source and independent corroboration.
005, 046–047	Reconcile material-claim inventory with the complete applicable GR-200 package assessment.	Relied-on claims and package obligations are covered; isolated claim checks do not stand for the dependency.
006–009, 048–050	Compare disputed identity, an uncertain interval, and a historical category against their records.	Record identity, continuity judgment, time uncertainty and retrospective interpretation remain distinct.
010–012, 014, 051–056	Review a target and attributed contribution with an alternative explanation or unobserved link.	Occurrence, mechanism, association, counterfactual and model-based grounds retain their respective strength and limits.
057–060	Follow a delayed or multi-link account and examine a claimed persistence mechanism.	Uncertain carriers or downstream links remain uncertain; persistence alone does not establish lock-in.
013, 061–062	Examine collective/disputed attribution, branch contributions, and a separate credit or rights claim.	No forced sole attribution or automatic ownership/entitlement; branch formation and realization remain distinct.

Requirements	Method and evidence	Outcome distinguishing fulfillment from failure
015, 063–066	Compare a contemporaneous alternative and a retrospective proposal, including practical access.	Historical availability, imagination, permission and feasible access are not conflated.
016, 067–068	Reconstruct a change of category and an earlier account under its original information.	A revised description does not silently create a past object or erase the prior semantics.
017, 069–072	Review sustained capacity, record loss, and different effects across groups or horizons.	Maintenance remains visible; loss kinds and normative evaluations are separately grounded.
018, 073, 112	Inspect any return account and its measurement or entitlement basis. For a recirculation claim, remove evidence for its return path or later-capacity effect while leaving a transfer record.	Concept, transfer, evaluation and legal assertion remain distinct. An unsupported recirculation link remains unresolved; transfer alone does not demonstrate renewed capacity. Only the recirculation-specific obligation is inapplicable when no recirculation is asserted.
019, 074–081	Trace decision, implementation, intended effects, feedback and a corrective action.	Receipt is not reliance; implementation is not beneficial effect; record correction is not completed repair.
020–023, 082–083	Exercise the permitted challenge route and inspect linked revisions and requests.	Earlier grounds survive within retention limits; conflicting requests remain attributable; propagation claims have evidence.
024–026, 084–088	Inspect authority, purpose, permissions, protected views, retention and unavailable information.	Required distinctions remain interpretable without disclosing protected content or inventing an absence reason.
027–028, 089–092	Exercise an authorized migration or lifecycle action and compare source/destination meaning.	Loss, failed steps, access control, disposal evidence and uncontrolled copies are correctly reported.
029–031, 093–097	Perform stated reader tasks using the actual view and available assistance.	Users can locate grounds and challenge routes; untested comprehension and inaccessible features remain limitations.
032–034, 098–111	Inspect the scope, complete result register, dependencies, methods and change review.	Failed/unassessed obligations prevent an unqualified claim; package-only and synthetic evidence remain bounded.

B.3 Execution and result integrity

R110-110 An exercised assessment shall record initial conditions, input and output versions, relevant permissions, performed steps, expected discriminating outcome, observed result, interruptions, and limitations. A described fixture or expected outcome without execution shall be recorded as a planned test rather than observed fulfillment.

R110-111 The assessor shall state the requirement-level consequence of each material failed task, inconsistent record, unavailable evidence item, or unresolved dependency. A remedied result shall retain the earlier finding, corrective action, new evidence, and remaining limit; a favorable summary shall not conceal it.

Annex C

(informative)

Worked recording cases

C.1 Contested funding decision

This synthetic case concerns a public research fund that rejects an application after an AI-assisted summary treats missing calibration metadata as evidence that calibration did not occur. The community applicants later provide testimony and a restricted maintenance log. The package contains the initial claim and its grounds, the inference from missing information, the decision that relied on it, the challenge, authorized consideration of a supplied nonpersonal log excerpt, and the subsequent assessment. The described original log remains unavailable for examination in this fixture.

The revised factual assessment is distinct from the institution's decision whether to reconsider funding. A separate classification review examines whether the original scoring categories excluded relevant knowledge. The public view identifies permitted limits on the log without publishing protected content. A reader can distinguish the old judgment, current assessment, policy question, and pending practical response.

A documentary check can assess these distinctions in an authored package. Testing the practice additionally requires observing the contact route, authorized access, notifications, and reader tasks. The synthetic case does not establish that a real institution changed its decision or that interrupted research capacity was restored. The existing fixture is `examples/validation_0.2/p1-contested-decision.md`.

C.2 Maintenance, delay, and distributed contribution

A synthetic laboratory collaboration produces little new output during a year of instrument maintenance, training, and preserving shared access. A later discovery relies partly on those capacities. The account separates evidence that the maintenance occurred, its role in sustained capacity, the later discovery, and the attributed connection between them.

Training, functioning equipment, and retained procedures are possible carriers in the account. Their supported roles can differ, and the discovery can also depend on later collaborators or changed methods. No mandatory percentage allocation follows. An earlier contributor's loss of access remains visible even if the aggregate output increases. Recognition or compensation proposals require their own evaluative and institutional grounds.

C.3 An alternative that became visible later

An archive contains a proposal rejected under historical eligibility rules. Years later, a new category makes its significance easier to recognize. The reconstruction preserves the earlier categories and decision context, the later interpretive method, and evidence concerning options actually available at the earlier time.

The new account can be better supported without implying that the earlier actors possessed the later concept. An alternative technologically imaginable today is labelled retrospective unless period-specific evidence supports historical availability. A claim that the original choice caused lock-in needs evidence of changed transition conditions, such as accumulated dependencies or switching costs, rather than the persistence of the chosen arrangement alone.

C.4 Migration and loss of interpretation

A synthetic custodian exports a package into a format that preserves current claims but omits former versions and uncertainty in temporal ordering. The files transfer successfully. Assessment nevertheless identifies loss relevant to reconstruction and treats the destination as a reduced representation.

A repair can preserve the missing relationships in an accompanying dossier without requiring one prescribed schema. The migration record identifies the source, transformed representation, remaining loss, and accepted custody. If the earlier source cannot be retained under applicable permission, the package states the resulting limitation rather than implying lossless preservation.

Annex D

(informative)

Foundation interpretation and unresolved issues

D.1 Source-to-proposal relationship

FM-005 section 5.13, pp. 105–113, develops target-relative generative attribution through association, mechanism, counterfactual reasoning, multiple contribution, distributed organization, delay, branching, and emergence. R110-051–R110-062 translate this into attributable recording of a proposed connection and its limits. The standard does not turn every account into a warranted attribution merely because the required information is present.

FM-005 section 5.14, pp. 113–122, distinguishes relational continuity from chains of generative contribution and treats path dependence, genealogy, historical evidence, alternatives, and re-epistemization. R110-049–R110-050, R110-057–R110-060, and R110-063–R110-071 preserve those distinctions operationally. The term possibility-field account denotes a bounded representation; it does not redefine the broader theoretical possibility field.

FM-003 section 3.12, pp. 129–141, treats praxis through diagnosis, enabling and constraining conditions, intervention, downstream tracing, feedback, adaptation, withdrawal, reversal, and repair. R110-074–R110-081 record the corresponding distinctions where they occur within scope. The source's sequence is heuristic; this draft does not impose one intervention lifecycle on every archive or practice.

FM-005 section 5.17.3, p. 145, distinguishes uncertainties concerning initial generation, conversion or transfer, the return path, and effects on later generative conditions. R110-112 operationalizes these distinctions only when a recirculation claim is made. It does not define every generativity-return account as recirculation or establish a distributional entitlement. A planned transfer to a maintenance team can be recorded as proposed while both delivery and any later effect remain unassessed.

D.2 Open conceptual and implementation questions

OPEN ISSUE The programme has not established a universal measure of generativity or generativity return, a mandatory causal-identification method, or exhaustive minimum historical coverage. Purpose-specific burden and usefulness require pilot evidence.

OPEN ISSUE The relation of Property to the metamodel manuscript's Attribute and the chronology of the two Chapter 3 files remain unresolved. This draft retains operational terminology without claiming that the variants are identical or that one supersedes the other.

OPEN ISSUE No common serialization, permanent identifier service, certification scheme, or full presentation/access profile is selected here. Reusable implementation needs enter separate Specification work items; limited assessment does not acquire full conformance by naming a future profile.

OPEN ISSUE The required evidence for effective practical repair, independent implementation, and sustained human comprehension remains use-context dependent. An initial synthetic exercise can expose missing procedures but cannot demonstrate those outcomes generally.

GENERATIVITY STANDARDS PROGRAM

GR-200

Standards-track Working Draft

Version 0.3 2026-09-22

Epistemic Recording Framework

WORKING DRAFT FOR REVIEW

This document contains proposed provisions for technical and institutional review. It is not an adopted Standard or an operative governance instrument. Its scope, application conditions and publication status are specified in the text.

Prepared by the Generativity Standards Program. Reference to external publications does not imply endorsement by ISO, IEC, IEEE or any United Nations body.

Foreword

Version 0.3 records the bounded substantive review of the archived 0.2 package. Its requirement text is retained in this coordinated edition; updated references identify the companion 0.3 drafts. The review matrix, synthetic assessments and unresolved readiness questions are documented in `docs/reviews/validation_0.2/README.md`. These activities do not constitute adoption or an independent institutional assessment.

Responsible editor: UNASSIGNED.
Canonical source: `standards/GR-200-epistemic-recording/GR-200.tex`

This document is a standards-track Working Draft of the Generativity Standards Program. Its maturity is **PREPARATORY; PROVISIONAL**. It contains proposed requirements for review and experimental assessment, not an adopted Standard, a formally initiated project or an institutional or legal authorization. Governance adoption, editor appointment, work-item approval, review and final publication require separate recorded decisions.

Edition 0.2 develops the initial framework into a fuller requirements document. Existing identifiers E200-001 to E200-026 retain their meanings; additional requirements specify claim structure, evidential context, uncertainty, revision, mediated use and assessment. Annexes A and B are normative within the proposed draft. The remaining annexes and bibliography are informative. Historical edition 0.1 is preserved rather than rewritten.

The publication follows a structured requirements format with scope, dated references, numbered terms, operational requirements, conformance and annexes. It does not claim ISO, IEEE, ITU or United Nations approval or affiliation. Conceptual sources inform the distinctions; resemblance of publication structure does not establish conformance with another body's development procedure.

Introduction

A representation can be authentic while its substantive content is mistaken. A classification can be applied consistently while failing to represent the situation relevant to a decision. A corrected record can improve current knowledge while leaving practical consequences of the earlier judgment unresolved. These are different problems, and a single verified-fact status cannot preserve their differences.

This document addresses the recording conditions for examining such problems. The epistemic record package links assertions, attributed sources, observations and reasoning, material, evidence roles, assessments, uncertainty, challenges and revisions. It supports inquiry into actual, possible, hypothetical and disputed targets without assigning all of them the same epistemic status. It records grounds for an assessment without prescribing one universal method of reaching substantive truth.

The programme's wider purpose concerns generativity: how relations and activity create, maintain, transform or restrict subsequent conditions and possibilities. The existence of a relation and an outcome does not establish the contribution linking them. Similarly, institutional uptake does not establish evidential warrant, and the ability to record a challenge does not establish effective access to review. Requirements for representation and requirements for institutional practice therefore remain connected but distinct.

The framework is deliberately independent of serialization. A small narrative dossier can distinguish claim versions and evidential roles through stable local references. A larger implementation can use structured objects or qualified statements. Choosing an encoding does not justify erasing an alternative, merging an unresolved identity or hiding an assumption. Specifications are developed when reusable implementation needs emerge from these requirements.

1 Scope

1.1 General

This draft defines the minimum information needed to examine who asserts what about a target, through which observations and reasoning, on which material, within what scope, with what uncertainty, and with what history of assessment and revision. Its organizing problem is the separation of a convincing or authentic representation from a warranted account of the represented situation.

The requirements concern a declared *epistemic record package*, which can include records, claim references, source locators, assessments, and protected components. The package can be textual, tabular, or implemented in software. This draft does not choose between claims as separate objects, attributed assertions within records, or a hybrid. A claim reference can be a local label and locator; it need not be a globally registered identifier.

GR-100 version 0.3 supplies the draft vocabulary. GR-110 adds requirements for generative trajectories and practical consequences. GR-210 is intended to govern the practice of assessment, challenge, and disposition. This document records those activities when present; it does not substitute a complete adjudication process, guarantee an appeal right, or set an evidential sufficiency threshold for every domain. GR-160 and GR-400 are intended to elaborate protection and institutional use. None of these drafts creates jurisdiction, a legal duty, or factual certainty.

2 Normative references

2.1 Dated draft reference

The following referenced document supplies this edition's operational meanings: Generativity Standards Program, *GR-100 — Foundations and Vocabulary*, Standards-track Working Draft, version 0.3, available at `standards/GR-100-foundations-vocabulary/GR-100.tex`. The incorporated scope is Clause 3's terms, Clause 5's record-role meanings when used, and the result-category meanings in 8.3. This reference does not impose a separate claim of GR-100 vocabulary-application conformity. It is a dated draft dependency, not an adopted Standard. If an incorporated meaning is unavailable or incompatible, the affected assessment is not assessed until the dependency is resolved. A later GR-100 edition does not silently change the meanings used here.

2.2 Other publications

There are no external normative references. GR-110 and GR-210 identify coordinated recording and procedural work, but their requirements are not imported into GR-200. A report claiming conformity to more than one publication identifies and assesses each dependency separately. Foundation manuscripts and external drafting models in the bibliography are informative.

3 Terms and definitions

3.1 General

The terms in GR-100 Working Draft 0.3 apply. The following terms specify their use for this document. These information structures are semantic recording units; they do not introduce new metaphysical classes or determine whether an implementation uses objects, wrappers or attributed statements.

3.2 Epistemic record package

An identified and versioned collection of claim content and linked context assembled for a declared inquiry, practical use and collection boundary, with an inventory or selection rule, responsible role and access scope.

3.3 Included claim

A claim designated as part of the assessed package, rather than merely occurring within an external source cited by it.

NOTE 1 Assertions attributed to another source remain assertions to be examined, not endorsements by the package owner.

3.4 Material information

Information capable of changing a reasonable examination of the declared claim, its warrant or its consequential use.

NOTE 2 Materiality is relative to the declared purpose; its selection rationale is inspectable and does not establish truth.

3.5 Claim reference

A designation that distinguishes an assertion and its version within the package.

NOTE 3 It supports links to evidence and assessment without itself establishing target identity or prescribing a globally registered identifier.

3.6 Material item

An identified source, portion, pattern or result proposed for use in an inquiry.

NOTE 4 It can be a trace, testimony, observation, record, comparison or intervention result. Its inclusion does not establish an accepted evidential role.

3.7 Evidence-role assignment

An attributed relationship between identified material and a specified claim, together with an assessment of relevance, limitations and alternatives.

NOTE 5 Supporting, challenging, qualifying and non-discriminating roles concern that relationship rather than an intrinsic status of the material.

3.8 Assessment record

An identified account of a question examined, the criteria and material used, the responsible assessor, timing, result, uncertainty and limitations.

NOTE 6 An assessment record can itself become a target of a later claim or challenge.

3.9 Dependency

A stated relationship through which a claim, assessment, representation or action relies on another identified item or version.

NOTE 7 Derivation, inferential reliance, shared-source dependence and practical uptake have different meanings and are identified separately where material.

3.10 Coverage statement

An account of the scope within which observation, collection, source examination or assessment was performed, including known omissions and exclusions.

NOTE 8 Coverage does not necessarily coincide with the scope of a substantive target claim.

3.11 Negative-evidence claim

A claim whose grounds include nonappearance of an expected trace.

NOTE 9 Its warrant depends on stated production, detection, coverage and preservation conditions; a missing value alone does not establish non-occurrence.

3.12 Transformation record

An account of a material change between a source representation and a resulting representation, identifying the input, output, operation, responsible role and known preservation or loss of meaning.

3.13 Released view

A representation selected from a package for a specified audience and purpose under stated access and disclosure conditions.

NOTE 10 Its completeness and inspectability are assessed against its declared boundary, not assumed from its source package.

3.14 Epistemic context

The attributed observations, methods, assumptions, evidential roles, uncertainty, perspective and temporal and descriptive scope required to interpret a claim.

NOTE 11 Shared context can apply to several claims when the inheritance and any exceptions are explicit.

4 Package declaration and recording boundary

4.1 General

The conformance subject is one named, versioned epistemic record package within a declared purpose, collection boundary, and access scope. Requirements apply to its included claims and assessments, with conditional requirements triggered by the relevant activity. An external source is not required to satisfy these rules merely because it is cited; the package's assertions about it and uses of it are within scope.

E200-001 The package shall declare its reference and version, responsible recording role, intended use, target and collection boundary, included claim set or selection rule, access scope, relevant descriptive regime, and the GR-200 draft version used. It shall identify exclusions and limits that materially affect interpretation.

E200-002 The package shall associate every requirement with an assessment result and an evidence locator. A claim of conformity to this draft shall identify its package boundary and applicable requirement set, and shall disclose failures, unassessed requirements, and restrictions that prevent assessment. It shall

not represent technical or recording conformity as proof of factual truth, evidential sufficiency, ethical acceptability, or legal validity.

An assessment result is fulfilled, not fulfilled, not assessed or not applicable with a reason. Only requirements whose stated trigger is absent can be marked not applicable. A package with failures or unassessed applicable requirements can report partial assessment, but not full conformity. This draft has no certification or accreditation scheme.

"Material" in this document means capable of changing a reasonable examination of the declared claim, its warrant, or its consequential use. The package's selection rule states how materiality was judged. Unknown, not collected, withheld, lost, and inapplicable can be explicit informational states where a value is unavailable. They disclose a limitation rather than establish the unavailable value or a substantive negative conclusion.

4.2 Semantic units and shared context

E200-027 The package shall provide the applicable information in Annex A for its declaration, included claims, material items, evidence-role assignments and assessments. Information supplied through shared context shall have an identifiable scope and version, with claim-specific exceptions explicit. A reference shall resolve within the declared assessment arrangement or carry an availability limitation.

These units need not be separate software objects. A table row can contain a claim and refer to shared acquisition context; a narrative passage can identify an assessment and its sources. E200-027 requires an inspectable association without reliance on undocumented assumptions. Reusing one context statement is acceptable when it actually applies to the linked claims. A package-wide uncertainty statement cannot conceal a material difference between a direct observation and a distant reconstruction.

External sources do not enter the assessed claim set merely because every sentence in them is quoted or stored. The package distinguishes the source material, the claim that the source contains a statement and any adopted substantive assertion. The resulting collection boundary is finite and declared. It is not a requirement to reproduce or assess every upstream publication, every possible objection or the entire history of an institution.

An assessment of this document can be recorded in a linked report outside the substantive claim set under examination. The report identifies the exact subject package and edition. Its statements about conformity do not automatically become evidence for the package's substantive claims.

5 Claim content, attribution and method

5.1 Claim identity and content

E200-003 Each included claim shall have a reference that distinguishes its content and version within the package, stated assertion content, an identifiable target or an explicit unresolved target description, and a link to its recording context. Different assertions or versions shall remain separately referenceable where their attribution, grounds, or disposition differ.

5.2 Attribution

E200-004 Each claim shall identify its represented originating actor or source and the role responsible for entering it into the package. Where these differ, the attribution chain shall distinguish origin from transcription, quotation, translation, summary, or adoption. Unknown, pseudonymous, restricted, or disputed attribution shall be explicit.

5.3 Modes and modality

E200-005 Each claim shall state its epistemic mode and relevant perspective: for example observation report, testimony, inference, interpretation, retrospective reconstruction, hypothesis, simulation, or normative or institutional judgment. Combined modes shall identify the distinct contributions rather than present inferred content as directly observed. A claim about an occurrence or possibility shall distinguish its asserted actuality or modality from its epistemic basis; retrospective inference can concern an actual occurrence.

5.4 Method and reasoning

E200-006 Each claim shall identify its acquisition or reasoning method, material premises and assumptions, relevant method version when one is used, and known transformations from source material to assertion. Where this information is unavailable, the package shall state the limit and shall not claim reproducibility or direct observation on that basis.

5.5 Boundary and scale

E200-007 Each claim shall state the boundary, scale or level of aggregation, contextual conditions, and temporal horizon relevant to its interpretation. It shall identify known omissions or selection conditions that materially limit generalization. A narrowed scope shall not be silently presented as a claim about a broader target.

5.6 Temporal scope

E200-008 Each claim shall distinguish target time from the times of observation or source acquisition, recording, and assessment where applicable. Time values shall carry their applicable meaning and known uncertainty or resolution. Unknown order shall remain distinguishable from asserted simultaneity and from recording order.

5.7 Target identity

E200-009 A claim that reidentifies a target across appearances shall identify the identity criterion, the appearances linked, the responsible attribution, and the evidential basis or stipulation. A proposed split, merger, succession, or disputed match shall not silently merge record identity, target identity, and lineage.

NOTE 1 A testimony can be preserved without claiming its reporter is infallible. Requiring attribution does not require public disclosure of a protected person's name. A role or pseudonymous reference, its protection status, and an accountable custody arrangement can provide the appropriate recording context.

5.8 Compound claims and qualifiers

E200-028 Where one expression contains assertions with materially different targets, attribution, temporal scope, modality or evidential grounds, the package shall distinguish the components and their qualifications sufficiently for separate assessment and revision. A conjunction or summary shall not silently transfer warrant from one component to another.

The expression "the meeting occurred and secured lasting cooperation" contains an occurrence claim and a claim about a later relational effect. Evidence for attendance might support the first while leaving the second unresolved. The components can remain in one document if their references and qualifications are distinguishable. The requirement does not demand logical atomization of every sentence; it applies where shared wording would otherwise conceal a material difference.

5.9 Relayed speech, quotation and translation

E200-029 Where a claim is quoted, translated, paraphrased or relayed, the package shall distinguish the attributed source expression from the recorder's rendition or interpretation, identify the available source context and material transformations, and state uncertainty about attribution or meaning. A quotation's presence shall not be treated as endorsement by its recorder.

A testimony can identify an experience available to a situated participant while leaving causes or other participants' intentions unresolved. A summary can be accurate for one question while omitting qualifications needed for another. Selection, transcription, translation and interpretation can each affect the path from source to assertion. The package records the relevant path instead of claiming that the reported wording is an unmediated view of the target.

5.10 Observation and acquisition context

E200-030 For an observation or measurement claim, the package shall identify the observer or acquisition system, observed feature, method, relevant instrument or procedure version, observation window and conditions materially affecting recognition, detection or recording. Known limitations in coverage, resolution or calibration shall be stated where relevant to the claim.

This requirement is proportional to the claim. A report that an inscription was seen can cite the observer and inspection context without manufacturing a quantitative measurement protocol. A measurement claim can require units, resolution and an instrument procedure. The package does not imply that a larger dataset removes selection effects or that an automated observation lacks an observer position.

5.11 Inference and reconstruction

E200-031 For a material inference or reconstruction, the package shall distinguish its asserted premises, adopted assumptions, inferential steps needed to examine the conclusion and material unresolved alternatives. An assumed premise shall not be represented as an observed input, and a mathematically possible history shall not be presented as an evidenced occurrence sequence without additional grounds.

An inference can be qualitative, historical, comparative, statistical, computational or mixed. The requirement is an inspectable connection between premises and conclusion, not a universal proof calculus. A researcher can identify a plausible contribution while remaining unable to establish causal sufficiency. A formal model can show consistency under its assumptions without establishing that its stipulated subjects and operations describe the actual case.

6 Material, evidence and uncertainty

6.1 Material identification

E200-010 For each material item invoked in support of, against, or to qualify a claim, the package shall identify the item or pattern, its relevant portion, source or acquisition path, and availability status. It shall distinguish original material, copies, derived representations, and generated material where those differences affect the claimed use.

6.2 Claim-relative evidential roles

E200-011 Each assigned evidential role shall link the material to a specified claim and identify the assessor or attributing source, assessment time, role, and rationale addressing relevance, reliability limitations, and material alternative explanations. An item with no assessment shall be marked unassessed rather than silently represented as accepted support.

The role can be supportive, challenging, qualifying, non-discriminating, or another defined relationship. A single item can support one claim and challenge another. The package need not impose a ranking across all evidence forms.

6.3 Dependence and corroboration

E200-012 Where multiple items are used together as evidence, the assessment shall identify known material derivation or dependence among them and the basis for any asserted independence. Repeated copies, summaries, or citations of one source shall not be presented as independent corroboration solely by their count.

6.4 Absence and non-occurrence

E200-013 A claim of absence or non-occurrence inferred from missing observations or records shall identify the expected observation or recording opportunity, coverage, detection or preservation limitations, and reasoning from the missing material to the claim. If those conditions are not established, the package shall preserve the weaker missingness statement and shall not treat it as established non-occurrence.

6.5 Uncertainty

E200-014 Each claim assessment shall describe material uncertainty and its location, including relevant alternatives, assumptions, identification limits, measurement limits, temporal gaps, or boundary and model limitations. A numerical confidence quantity, if used, shall state what it measures, its method and assumptions, and the scope of its interpretation.

6.6 Competing explanations

E200-015 The package shall record material competing claims or explanations known within its declared collection boundary, their attribution, their relationship to the target claim, and any recorded grounds for excluding or preferring them. If alternatives were not examined, this limitation shall be explicit; silence shall not be presented as evidence that no alternative exists.

An alternative need not receive equal evidential weight merely because it is recorded. Recording a disagreement does not mean that it remains unresolved after a reasoned assessment. The disposition and its grounds remain visible, and an attributed rejected interpretation can remain historically consequential.

6.7 Formation, selection and survival of material

E200-032 Where the production, selection, custody or survival of material affects an assigned evidential role, the assessment shall record the relevant known conditions and gaps, including selective preservation or inaccessible channels. A hypothesis of concealment shall have stated grounds and shall not be inferred solely from missing evidence.

An archive contains what was produced, captured, retained, made accessible and recognized as relevant. Failure at any stage can alter the evidential field. A missing complaint has different implications when a reporting route was usable, when it was dangerous to use, or when submissions were not retained. The package records what is known about those conditions rather than assigning one universal evidential weight to silence.

6.8 Transformation and derived material

E200-033 A material transformation relied on in an assessment shall identify its source and output versions, operation, responsible role and known effects on meaning or inspectability. Extraction, redaction, normalization, deduplication, imputation and generation shall remain distinguishable where their differences affect the claim. Supplied or inferred values shall not be represented as original observations.

A copy can preserve substantive content while changing its custody context. A redaction can protect a person while removing context important to interpretation. A transcript can make a recording searchable while introducing uncertain wording. None of these operations is inherently disqualifying. Their role and limits need to be visible to the assessment that relies on them.

6.9 Combination, aggregation and independence

E200-034 Where a claim relies on combined or aggregated material, the assessment shall state the included units, inclusion and exclusion rules, relevant denominators or weights, and known changes of composition. A claim about independent corroboration, stable population or comparable periods shall identify its basis rather than follow solely from a count, common label or shared format.

Several individually weak traces can jointly constrain a claim when their production paths differ in relevant ways. The opposite is also possible: many records can reproduce the same source, coding rule or institutional selection effect. Neither volume nor diversity of file formats establishes independent evidential pathways. Known dependence remains visible even when its precise quantitative effect cannot be estimated.

6.10 Comparability of uncertainty statements

E200-035 A comparison, aggregation or transfer of confidence quantities or qualitative grades shall state the meanings, assessed claims, scopes, methods and assumptions that support comparability. Incomparable dimensions shall not be silently combined into a universal score. Strong warrant in one dimension shall not erase a material unresolved limitation in another.

Confidence in an occurrence can exceed confidence in a causal attribution or long-term consequence. A numeric model score can concern a prediction conditional on its training and observation regime, while an assessor's confidence concerns a broader institutional claim. Shared numerical range does not establish shared meaning. A package can retain dimensional qualitative assessments without inventing probabilities or forcing all disagreements onto one scale.

6.11 Alternatives and limits of examination

E200-036 The assessment shall distinguish an alternative examined and rejected with grounds, an alternative retained as plausible, and an alternative not examined. Where a conclusion depends materially on boundary, scale, population, method or descriptive-regime choice, the assessment shall identify that dependence and any comparison actually performed. An unperformed sensitivity or alternative analysis shall not be described as completed.

Alternatives can compete for the same explanatory role or concern different parts of a composite process. A rule, network and resource condition can each contribute without being interchangeable explanations. Recording them does not require equal weighting or an exhaustive catalogue. It requires the package to disclose the comparison it actually makes and where a claim exceeds that comparison.

7 Assessment, revision and practical use

7.1 Assessment questions and criteria

E200-016 Each assessment or determination shall identify its question, responsible assessor or decision role, criteria, material examined, result, date, limitations, and relationship to the assessed claim versions. Provenance/authenticity, factual warrant, institutional acceptance, normative evaluation, legal determination, and technical validation shall remain distinguishable assessment functions.

7.2 Substantive revision

E200-017 A substantive revision shall link the prior and revised claim or assessment versions and record who revised it, when, why, and which content or scope changed. The reasons shall distinguish target change, evidence or assessment change, and descriptive-regime change, allowing combined reasons. Historical access shall preserve earlier meaning to the declared retention and protection extent; any unavailable earlier content shall have an explicit reconstruction limitation.

7.3 Descriptive-regime change

E200-018 A change of descriptive regime shall identify the prior and new definitions or methods, grounds for change, affected claim set, and any mapping or transformation used. It shall identify known non-comparability, lost distinctions, or unresolvable mappings; finer classifications shall not be reconstructed from insufficient earlier material as if evidenced.

7.4 Dependent records and actions

E200-019 For a revised claim with known dependent assessments, claims, or consequential uses within the package boundary, the package shall identify those dependencies and record whether each was reviewed, updated, left unchanged with reason, or remains pending or unreachable. It shall not claim that external recipients or institutions have corrected their actions without evidence of that correction.

7.5 Practical uptake

E200-020 Where the package records practical uptake of a claim, it shall distinguish the claim, its assessment, the institutional or other action, the actor responsible, and the asserted basis for acting. Recorded consequences and proposed remedies shall remain separately attributable from the original grounds and intended effects.

7.6 Challenge and disposition records

E200-021 For a challenge received within the package's declared collection boundary, the package shall record the challenged claim version, challenger or protected source reference, grounds and submitted material, receipt context, and current status. A disposition shall record the responsible role, response, reasons, date, unresolved disagreement, and resulting changes or the reason for no change. A challenge without disposition shall remain visibly pending or otherwise explicitly unresolved.

This clause addresses the record of a challenge. Routes for submission, notification, review independence, timeliness, appeal and remedy are procedural matters addressed in the coordinated GR-210 draft and relevant institutional profiles. Their effectiveness requires separate assessment. Merely supplying challenge fields does not demonstrate that a person can effectively contest a decision.

7.7 Criteria, status and temporal validity of an assessment

E200-037 An assessment shall identify the version and scope of its criteria and distinguish the date of examination, the evidential state examined and any stated period or condition of applicability. A later change of criteria or available evidence shall not silently change the recorded meaning of an earlier result.

Supported, rejected, qualified, unresolved and not examined have different meanings when applied to a claim. A procedural status such as closed concerns the case process rather than the claim's truth. An institution's acceptance can authorize an internal action while the underlying evidential assessment remains qualified. The package records these distinctions instead of using one status field as a substitute for them.

7.8 Version identity and concurrent interpretation

E200-038 Where more than one revision or interpretation of the same earlier item is retained, the package shall identify their predecessor relationships, responsible sources and whether a preferred current version has been designated within a stated scope. It shall preserve material unresolved branches and shall not treat latest recording time alone as evidential precedence.

Version history can branch. Two reviewers can correct different parts of a description, or disagree about the interpretation of the same material. A later administrative designation can select one version for use without establishing that every competing claim has been factually disproved. The designation, its authority and its grounds remain separately identifiable.

An editorial correction that preserves meaning can be recorded as such. A changed target, evidential ground, qualification, criterion or scope requires the substantive revision context of E200-017. Replacing an artifact for formatting does not automatically create a new historical occurrence or erase the earlier asserted content.

7.9 Intervention and reflexive effects

E200-039 Where intervention, publication, observation or classification is claimed to have changed the target situation, the package shall distinguish pre-change observations, the intervention or uptake, subsequent observations and the claim connecting them. An improvement in observation shall not automatically be represented as creation of a new relation, and an intervention-produced change shall not automatically be used as evidence of the earlier unchanged situation.

Discovery and creation can coexist. A new reporting route can reveal previously unrecorded practice and alter that practice by making it visible. A revised eligibility category can change both available distinctions and subsequent access. The package can record combined reasons while preserving their different temporal and evidential bases. It does not require a counterfactual causal experiment where none exists; it records the stated method and limits of attribution.

8 Mediation, protection and layered assertions

8.1 Computational mediation

E200-022 Where computational mediation materially affects a claim's observation, classification, inference, reconstruction, or presentation, the package shall identify the system and available version, its task, supplied source material or its controlled reference, material transformations, output used, and the role responsible for uptake or review. Unavailable system details and resulting limits shall be stated. Generated output shall remain distinguishable from independent source evidence.

This requirement includes rules, statistical models, sensor processing, database transformations, and generative systems when material to the claim. It does not require exhaustive logs of unrelated operations

or disclosure of private credentials. A vendor confidence score does not automatically measure the warranted confidence in the package's substantive claim.

8.2 Protected material

E200-023 Where claim context or evidential material is restricted, the package shall identify the restriction and its asserted basis, responsible custodian or accountable role, assessment consequence, and any available route for authorized examination or challenge. A released view shall identify material omissions at a level permitted by the declared protection arrangement and shall not describe unavailable evidence as independently examined.

If even acknowledging an item is restricted, the released view can describe its assessed scope without exposing item-level existence. The protected package still needs an accountable restriction record. This clause supplies neither permission to disclose nor a legal retention rule. Where a reviewer cannot assess a required component, E200-002 requires an unassessed result; a protection reason does not turn missing verification into a pass.

8.3 Normative and ethical assertions

E200-024 A normative or ethical assertion shall identify the evaluative question, attributed evaluator, stated criteria or values, affected parties and scope, and material acknowledged tradeoffs or disagreements. It shall remain distinguishable from the descriptive claims on which it relies and shall not treat a claimed generative effect as inherently desirable.

8.4 Legal and jurisprudential assertions

E200-025 A legal or jurisprudential assertion shall identify the asserted legal concept, source or rule relied upon, relevant institutional or jurisdictional context, attributed authority, temporal applicability, and procedural status, or explicitly state which are unresolved. It shall distinguish a descriptive legal analysis, party allegation, institutional determination, model rule, and policy proposal where applicable. Recording the assertion shall not be represented as creating or confirming its legal effect.

8.5 Selected and transformed packages

E200-026 When a package is selected, summarized, exported, or transformed and the resulting package is claimed to conform to this draft, it shall preserve the attribution, claim-version relationships, epistemic qualifications, material disagreement, and access/reconstruction limits required within the resulting declared boundary. Omitted or transformed content and the resulting limits shall be identified; a partial view shall not imply completeness of the source package.

This is an implementation-neutral requirement on the resulting package. Format negotiation, transport, identifiers, validation vocabulary, and machine-readable exchange behavior belong in Specifications prompted by the demonstrated need.

8.6 Computational observation and inferred completion

E200-040 Where computational processing affects evidential coverage, identity, category assignment or missing values, the package shall identify the relevant selection, linkage, classification and completion operations and their known limitations. A generated or imputed relation shall not be presented as an independently observed relation solely because it appears in a structured output.

The term machine-mediated includes a rule-based pipeline or database transformation as well as a learned model. A system can record extensive interactions while excluding people or activities outside its infras-

tructure. A link-prediction result can be a useful candidate for inquiry while remaining an inference. An embedding similarity is not itself evidence that two people collaborated or that two records concern one target.

8.7 Reproduction and availability claims

E200-041 A claim that a material computational result is reproducible or independently reviewable shall identify the available inputs, system or method version, relevant configuration and output, and the procedure supporting that claim. Unavailable internals, changing services, inaccessible data or nondeterministic behavior shall be disclosed where they limit the asserted reproduction or examination.

This requirement does not demand secret credentials, unrelated conversation logs or an invented explanation of a model's internal reasoning. It requires a truthful account of what can be inspected and repeated. A person can review a generated summary against its cited documents without reconstructing every internal operation, but that limited review is described as such. Reproducing the same output does not by itself establish its factual warrant.

8.8 Protected context and accountability

E200-042 Where protected references or substitutes are used, the package shall state the examination they permit, the accountable custody or review role, and their known limits for source identification, context and challenge. A custodian's assurance, an assessor's direct examination and an unavailable source shall remain distinguishable.

Restricted evidence can be handled through an authorized reviewer, an excerpt or a statement of examined scope. Those arrangements can support different questions. A public summary cannot claim full independent inspectability when its readers cannot examine a decisive source. The protected package need not reveal a source's identity to every audience; the restriction and the resulting assessment limitation remain accountable within the authorized arrangement.

8.9 Loss of access and historical reconstruction

E200-043 Where deletion, restriction, loss or a failed reference materially affects later examination of a retained claim, the package shall record the known change, its scope, responsible role or explicit unknown, and the resulting assessment or reconstruction limit. Evidence of a permitted disposal action shall not retain prohibited content solely to prove its removal.

Historical assessment and present inspectability can diverge. An assessor might have examined a source that is no longer available to a later reader. The historical result can remain recorded with the evidence then cited, while the later reader's ability to reassess it is limited. Neither automatic erasure of the earlier examination nor an unsupported assertion of continuing inspectability follows.

8.10 Evaluative scope and policy proposals

E200-044 Where an ethical or policy assessment compares effects across people, groups or periods, it shall identify the compared effects, evaluative criteria, aggregation or tradeoff method if any, and material effects left outside the comparison. A recommendatory institutional or policy proposal shall remain distinguishable from an adopted requirement, an authorized decision and a descriptive finding.

The same intervention can expand one group's capacity while reducing another's access to review. An assessment can favor the intervention under stated values while preserving the adversely affected group's account. Describing a generative effect does not settle its normative sign. A proposal addressed to an international organization also requires a stated intended institution and mandate context when those affect its recommendation; technical recording conformity does not confer that mandate.

9 Conformance

9.1 General

The conformance subject is one declared epistemic record package at a fixed edition, purpose and boundary. This document specifies recording requirements, not proof that every described activity occurred or that an institution's procedure was fair. A package can faithfully record an unsupported or rejected claim when its attribution, status and grounds are clear. Whether a substantive inference is warranted remains an assessment question with its own scope.

9.2 Applicable requirements and information schedules

E200-045 A conformity assessment shall use the semantic schedules in Annex A and the checks in Annex B, documenting the applicable requirements, evidence, assessor, date, result and limitations. Each requirement shall receive a result; an omitted field or unavailable source shall not be treated as an absent trigger for a requirement whose subject is present.

E200-049 Where one requirement groups obligations whose results can differ materially, the assessment shall record the result and evidence for each such component. The requirement shall be fulfilled only if every applicable component is fulfilled. A failed or unassessed component shall remain visible in the requirement-level and overall package result.

General package requirements apply to every assessed package. Claim requirements apply to every included claim. Requirements concerning measurements, legal assertions, machine mediation, transformations, restrictions, revisions or practical uptake apply when those features occur within scope. A package without a legal assertion can mark E200-025 not applicable. A legal allegation lacking a known jurisdiction instead invokes that requirement and records the jurisdiction as unresolved.

9.3 Extent of examination

E200-046 The assessment shall state the extent of examination, including any sampling, inaccessible components and checks performed only automatically. A sampled or partial assessment shall not be represented as exhaustive examination of the package. An unqualified conformity claim shall require a supported fulfilled result for every applicable requirement throughout the declared subject.

Automatic checks can verify presence, reference integrity or structural combinations. They cannot alone establish appropriate inference, meaningful scope, adequacy of an explanation or the source of institutional authority. A larger assessment can use justified sampling to discover defects, but its report remains explicit about the claim that the sample supports. Narrowing the subject to examined cases does not justify describing the result as institutional assurance.

9.4 Result categories and reassessment

The result categories are fulfilled, not fulfilled, not assessed and not applicable with a reason. They have the meanings stated in GR-100, 8.3. A blocked review receives a limitation and an unassessed result; an authorized restriction is not itself evidence of fulfillment of an unexamined requirement.

E200-047 A change to an assessed package, its claimed scope or an applicable dated dependency shall identify the prior assessment, affected requirements and evidence, and any reassessment performed or pending. Previous results shall not silently transfer to materially changed claims, methods, access conditions or transformations.

A report identifies whether it concerns the retained protected package, a released view or both. A view can receive its own bounded assessment if it preserves the requirements applicable to that view and does not

imply access to withheld material. Where a required component cannot be examined, its result remains not assessed. No certification, accreditation or legal evidentiary status is created by these categories.

Annex A

(normative)

Semantic information schedules

A.1 General

This annex specifies the semantic information required by E200-027. It does not prescribe a serialization, field name, datatype or new ontology class. Information can be directly recorded or supplied by a stable contextual reference whose meaning and applicable edition are inspectable. E200-048 distinguishes mandatory structural information from unavailable contextual factual values and identifies the assessment consequence of the latter.

E200-048 The package shall supply its reference and version, declared purpose and boundary, included claim references and content, target designations, accountable recording role, and relationship locators needed to identify each asserted evidence role, assessment or revision. These structural components shall not be replaced by an unknown value. A required contextual factual value that is unavailable may be represented by a typed unknown, uncollected, lost, disputed or restricted declaration identifying the responsible or attributing role, known reason and assessment limit. Such a declaration shall not establish the unavailable fact, replace required reasoning or criteria for the package's own assessment, or produce a fulfilled result for an examination that could not be performed.

An unresolved target designation states what the claim concerns or the identification question under examination, as allowed by E200-003. It is not an invented identity. A protected actor or material can have a controlled reference whose disclosure scope is stated. The structural requirement is an identifiable relationship in the authorized arrangement, not publication of protected identifying information.

For the tables below, unknown contextual values include the actual source person's identity, target time, instrument details, an upstream actor's method, external legal context or unavailable historical content where these cannot be established. The package's own declared assessment method, criterion, inference and result describe what its assessor actually used or determined. An unperformed evidential examination is recorded as not examined; fulfillment of the duty to disclose that state remains separate from any claim that the examination occurred. A known omission of required structural content or assessment reasoning is a recording defect rather than an unknown-context exception.

A.2 Package, claim and material information

Table A.1 – Core semantic information and its governing requirements

Component	Required information when the component is present	Governing requirements
Package	Reference and version; purpose; recording responsibility; target and collection boundaries; included claims or selection rule; access scope; descriptive regime; exclusions; assessment results.	E200-001/002/027/045.
Claim	Distinguishable content/version and target; origin and recording attribution; epistemic mode and relevant modality; method; material assumptions; scope; temporal context; identified unavailable context.	E200-003–008/028–031.

Component	Required information when the component is present	Governing requirements
Identity assertion	Appearances linked; stated criterion; responsible attribution; grounds or explicit stipulation; material dispute; distinction from lineage and record references.	E200-009.
Material item	Reference or controlled locator; relevant portion or identified pattern; source/acquisition path; availability; distinction between original, copy and derived or generated representation.	E200-010/032/033.
Evidence-role assignment	Material and claim-version links; assessor/source; time; evidential role; relevance rationale; reliability limits; material alternatives and known dependence.	E200-011/012/034.
Assessment	Question; assessor or decision role; criteria and version; material examined; result; date; claim versions; uncertainty and limitations; available alternative analysis.	E200-014–016/035–037.

A.3 Conditional information

Table A.2 – Information activated by conditional recording subjects

Trigger	Information required for the triggered subject	Governing requirements
Negative evidence	Expected trace opportunity; production, detection, coverage and preservation conditions; inference and limitations.	E200-013/032.
Revision	Prior/resulting versions; responsible source; time and reasons; changed content/scope; history limits; known dependents and disposition.	E200-017–019/038.
Regime change	Earlier/new definitions or methods; reasons; affected claims; mapping used; non-comparability or lost distinctions.	E200-018.
Practical uptake	Relied-on claim/version; assessment; action and actor; asserted authority or grounds; intended effects; separately attributed consequences or remedy.	E200-020/039.
Challenge	Challenged version; protected or open source attribution; grounds/material; receipt context; status; disposition responsibility, reasons and resulting changes.	E200-021.
Machine mediation	System and available version; task; inputs and outputs used; material operations; uptake/review role; unavailable detail; limits on claimed reproduction.	E200-022/040/041.

Trigger	Information required for the triggered subject	Governing requirements
Protected or lost material	Restriction or loss; asserted basis; accountable role; examination route where available; effect on assessment and later reconstruction.	E200-023/042/043.
Ethical or policy assessment	Evaluative question; attribution; values/criteria; affected parties; comparisons and tradeoffs; limits; recommendatory or operative status.	E200-024/044.
Legal assertion	Legal concept; asserted source; institutional/jurisdictional context; authority; temporal applicability and procedural status, including explicit unresolved components.	E200-025.
Transformed view	Source/resulting versions; selection/transformation; retained attribution, qualification and history; omitted content and limitations; declared audience and boundary.	E200-026/033.

A.4 Link interpretation and unavailable context

A claim reference identifies the asserted version, not merely a mutable latest view. A material reference identifies the portion used where that distinction affects the inference. A criteria reference identifies the governing edition. A shared-context reference identifies which claims inherit it and which exceptions apply. An ambiguous reference does not provide an inspectable link merely because it opens a document.

If the package cannot determine a material value, it records whether the value is unknown, not collected, not applicable, disputed, lost or restricted to the extent supported and permitted. A reason recorded by another source remains attributed to that source. This annex does not require the package to accept an assertion of completeness or authority merely because a custodian supplied it.

Annex B

(normative)

Assessment schedule

B.1 General

This normative schedule specifies the minimum evidence methods for assessing this draft. They specify discriminating checks and failure cases; this draft does not claim these cases have been implemented or passed. Each applicable requirement needs its own result even where several use the same dossier. Human review is necessary for meaning, rationale, and sufficiency of disclosure; structural field validation alone is inadequate.

Table B.1 – Epistemic recording assessment schedule

Requirement	Required evidence and discriminating check
E200-001	Inspect package declaration and selected claim inventory. Check that a consequential excluded record is disclosed by the collection rule or limitation.
E200-002	Inspect result ledger and evidence locators. An inaccessible required component is not assessed; a syntax pass is not labeled a true fact.
E200-003	Retrieve two versions and two conflicting claims concerning Q. Their content and targets remain distinguishable.
E200-004	Follow testimony through a translator or summarizer. Originating source and recorder remain separate, including protected attribution.
E200-005	Inspect C1. Its late-arrival inference is not presented as direct observation merely because L1 was directly read.
E200-006	Recover the entry-time assumption and method for C1. A missing method produces a stated limit, not a reproducibility claim.
E200-007	Compare a single intake desk's coverage with an institution-wide assertion. A known unobserved delivery route remains a limitation.
E200-008	Recover receipt, acquisition, entry, and review times or their explicit uncertainty; out-of-order recording does not reorder events.
E200-009	Examine an organizational replacement using a reused name. An identity criterion and separate lineage prevent automatic merger.
E200-010	Locate the relevant L1 entry and R2 image or controlled locators; derived transcript and original are distinguished.
E200-011	Recover L1's separate evidential roles for entry time and delivery time, including rationale and assessor.
E200-012	Present three copies derived from L1. Assessment detects shared origin instead of counting three independent observations.
E200-013	Remove the log for one delivery channel. No receipt found remains distinct from evidence that no request arrived.
E200-014	Inspect uncertainty about queue delay and a confidence quantity if used. Its measured quantity and assumptions are explicit.
E200-015	Recover C2 and reasons for its disposition. If no alternative search occurred, the absence of search remains visible.
E200-016	Compare log authenticity check, receipt-time assessment, and D1 decision. Their questions, roles, criteria, and results are distinct.

Requirement	Required evidence and discriminating check
E200-017	Retrieve C1 versions and changed grounds. Target change, correction, and category change produce different stated reasons.
E200-018	Apply a category split to records lacking the finer information. Mapping records non-recoverability rather than invented categories.
E200-019	Follow C1 to D1. Pending action review is distinguishable from completed correction and from an unreachable external use.
E200-020	Recover D1, the claimed authority for action, and separately attributed consequences. No automatic remedy is inferred.
E200-021	Trace CH1 receipt through pending and disposed states. A closed status without response, responsible role, and reasons fails.
E200-022	Add a machine summary that invents a link. Recover input, system/version where available, output used, uptake role, and correction.
E200-023	Compare protected dossier and released view. Restriction basis and accountable route are recorded without unauthorized disclosure or a false independent-review claim.
E200-024	Inspect an assessment that exclusion was unfair. Criteria, affected parties, and descriptive premises are distinguishable.
E200-025	Inspect an allegation of unlawful exclusion. Asserted source, jurisdiction, authority, and procedural status are stated or unresolved; no legal effect follows from technical compliance.
E200-026	Examine a textual summary or exported dossier. Correction, dissent, attribution, scope, and protection limitations survive or omissions are explicit.
E200-027	Compare supplied semantic components with Annex A. Resolve shared context and exceptions without inferring undocumented values.
E200-028	Inspect a compound occurrence-and-effect claim. Separate components can receive different assessments and revisions.
E200-029	Follow a translated or relayed statement to its available source context; distinguish quoted content from the recorder's interpretation.
E200-030	Inspect an observation's window, method, observer and detection limits; a broader claim does not acquire unobserved coverage.
E200-031	Recover premises, assumptions and consequential inferential steps; a stipulated process is not mislabeled an observed history.
E200-032	Examine selective preservation and any concealment hypothesis. Missing evidence alone does not establish concealment.
E200-033	Trace an extraction, redaction or imputation to its source and effect; a completed value remains distinguishable from observation.
E200-034	Inspect aggregate populations, denominators, weights and changed composition; repeated or recoded items do not become independent observations.
E200-035	Compare confidence statements across targets or methods; unsupported commensuration and hidden unresolved dimensions are detected.
E200-036	Distinguish rejected, retained and unexamined alternatives; an unperformed sensitivity analysis is not described as completed.
E200-037	Reconstruct assessment criteria and evidence at the time; later rules do not silently change an earlier result.

Requirement	Required evidence and discriminating check
E200-038	Follow two revision branches. Latest entry order alone does not establish evidential precedence or erase disagreement.
E200-039	Separate pre-intervention evidence, intervention, later evidence and effect attribution; discovery differs from creation.
E200-040	Inspect generated links, imputed values and computational selection; structured output is not treated as independent observation.
E200-041	Test a stated reproduction or inspection claim against available inputs, method and configuration; unavailable detail limits the result.
E200-042	Compare custodian assurance, direct authorized examination and unavailable source; their scopes remain distinct.
E200-043	Inspect a formerly accessible source after loss or restriction; the historical assessment and current access limit remain distinguishable.
E200-044	Recover affected parties, evaluative comparisons and omitted effects; a recommendation is not reported as an adopted rule.
E200-045	Check every requirement's result and evidence against both normative annexes; absence of required information is not a missing trigger.
E200-046	Inspect coverage, sampling and automatic checks; partial examination does not acquire an exhaustive claim.
E200-047	Compare a revised package with its prior assessment; affected results are reassessed or explicitly pending.
E200-048	Inspect unknown-context declarations alongside mandatory references/content and reasoning; a missing structural component or unperformed examination does not acquire a fulfilled result.
E200-049	Inspect a grouped obligation with mixed component results; an unassessed or failed component remains visible and prevents overall fulfillment.

B.2 Assessment sequence and retained result

The assessor fixes the package edition, access arrangement and claim inventory before applying the schedule. The assessor identifies present conditional subjects, locates the Annex A information and examines the semantic checks in Table B.1. The result register records the requirement, trigger, evidence locator, observed result, assessor, date and limitation. A domain-equivalent case can test the same distinction when the package does not concern the illustrative delivery case.

One material item can support several checks, but every applicable requirement receives a separate result and materially distinct component results follow E200-049. A counterexample establishes a defect only within the tested scope; a passing case does not establish universal institutional performance. If assessor disagreement concerns the meaning of a claim, its material, criteria or scope, the report identifies that point rather than averaging incompatible conclusions into a numerical result.

Annex C

(informative)

Worked epistemic cases

C.1 A late-recorded delivery

This invented case tests recording distinctions. It supplies no claim about an actual institution or applicable law.

Target. Whether request Q arrived before the deadline specified in a synthetic institution's internal rule R1. The asserted rule and whether it applies are separate claims.

C1 version 1. Clerk A reports that Q arrived after the deadline, inferred from entry log L1. Target time is the claimed receipt time; recording time is the later creation of C1. The method assumes entry time matches receipt time.

Evidence use. L1 supports that an entry occurred at the recorded time. Reviewer B records that its support for receipt time depends on the untested assumption about queue delay. Three copies of L1 are not independent corroboration.

Alternative C2. A protected participant reports earlier delivery; a receipt image R2 is available to an authorized reviewer. The public view identifies restricted evidence and the scope of examination without naming the participant.

Action D1. The institution records exclusion of Q using C1 and R1. This is an attributed institutional act. Its occurrence, justification, and any claimed legal effect remain separate.

Challenge CH1. The participant challenges C1 and provides R2. The record includes the challenged version and receipt time of the challenge; a pending challenge is not displayed as a completed review.

C1 version 2. Review establishes that the entry occurred later than the claimed delivery. The assessed receipt time changes; the entry event does not. The revision links its grounds to R2 and records the continuing uncertainty. C1 version 1 and D1 remain identifiable historical records.

Dependency review. D1 is marked for review. Until a later action is evidenced, correction of C1 is not displayed as restoration of Q's participation. The record can identify consequences of the interval of exclusion separately.

Regime change. If the institution later defines arrival by a different channel, the change of rule/category has its own effective interval. It does not silently recode earlier evidence or establish that earlier actors used the new meaning.

C.2 Generated relationship and shared-source dependence

A fictional analysis receives three documents: an intake entry, its automated summary and a report that cites the summary. The summary adds a claim that two named organizations coordinated their decisions. The intake entry only records that messages were exchanged. The package keeps the communication occurrence, the inferred coordination and the later report as distinct claims.

The three documents share a derivation path. Their number does not supply independent corroboration. The generated relation has a source and method reference, but that provenance does not establish its content. A reviewer can reject the unsupported coordination inference while retaining evidence of the messages. A later independent account could change the assessment; its independence and target relevance would still need examination.

If a public graph displays only the generated edge, the reduced view needs its inferential qualification and relevant limitation. A caption that describes the edge as observed would lose the distinction. No universal

graph schema is needed to expose this failure; a reader can compare the graph's statement with the source material and assessment.

C.3 Reclassification, intervention and later evidence

A fictional institution broadens its participation category after reviewing evidence that earlier records omitted some forms of contribution. Existing archived material supports reclassification of some earlier cases, while others lack the necessary detail. The new category also changes later access to institutional resources.

The dossier retains three linked changes. The category changed; knowledge of some earlier contributions changed through re-examination; and later resource access changed through practical uptake. The unresolved earlier cases do not acquire a finer classification merely because the vocabulary now provides one. Nor does increased later participation prove that identical opportunities were available earlier.

An ethical assessment can favor the new arrangement while recording its additional reporting burden and effects on different groups. A policy proposal can recommend wider adoption without claiming institutional authority to impose it. The package records these positions and their criteria separately from evidence concerning participation and from the decision that implemented the change.

Annex D

Source trace and drafting rationale

D.1 General

References are to the supplied local PDFs indexed in `foundation_manuscripts/MANIFEST.md`; page numbers are one-based PDF pages. Source passages provide conceptual grounds, not adopted requirements. No external compatibility or legal claim is made.

Table D.1 – Foundation passages and recording requirements

Source	Operational proposal and reason
FM-004, §4.2, pp. 11–14; §4.6, pp. 43–45	E200-003–008 distinguish target, manifestation, representation, and observation conditions. A single undifferentiated fact field cannot preserve these questions.
FM-005, §5.4, pp. 28–31	E200-010–013 assign evidence roles relative to claims and preserve trace paths, alternatives, and dependence. Material presence alone does not establish relevance or independent corroboration.
FM-005, §5.17, pp. 141–142	E200-014/015 preserve dimensional uncertainty and alternatives. A single mandatory confidence score was rejected for this draft because methods and uncertainty sources differ.
FM-007, §7, pp. 26–29	E200-009 separates record references, identity criteria, and lineage, permitting unresolved matches. Administrative identifier equality is insufficient as a universal criterion.
FM-005, §5.20, pp. 168–174	E200-017–020 distinguish evidential, intervention-related, historical, and category revisions, and the historical effects of an earlier representation. Silent overwrite loses those distinctions.
FM-005, §5.19, pp. 160–161, 168	E200-021–023 make machine mediation and contestability inspectable while allowing differentiated access. A declaration that “AI was used” omits material epistemic conditions.
FM-003, §3.10.9, p. 115; §3.13, pp. 141–142	E200-024 separates generative attribution from ethical evaluation and records affected parties and criteria. No universal beneficialness or commensuration is assumed.
Programme Brief, §3A; repository jurisprudential discipline	E200-025 preserves the asserted basis and status of legal claims. This is a recording boundary proposed by the programme, not a legal conclusion derived from a manuscript.

The selected direction is an inspectable claim package with attributed relationships and scoped evidence. Alternatives included a single verified-fact flag, a mandatory new ontology class for every assertion, and a fully specified adjudication process inside this document. The first loses distinctions; the second prematurely fixes implementation architecture; the third conflicts with the planned separation of epistemic representation from GR-210 procedures. The present choice leaves representation and procedural elaboration open while producing requirements that a small synthetic dossier can test.

D.2 Additional foundation analysis for edition 0.2

FM-005, sections 5.4.4–5.4.8, PDF pages 32–35, distinguishes observation, inference, latency, hiddenness and negative evidence. E200-030–032 require an inspectable observational and inferential path and do not infer concealment from silence. Sections 5.17.3–5.17.8, pages 145–150, distinguish generative linkage, boundary, scale, time, model and competing-explanation uncertainty. E200-034–036 preserve those dimensions without a compulsory scalar score.

FM-005, sections 5.18.1–5.18.5, PDF pages 152–156, explains why visibility and institutional legibility are uneven and why greater visibility can itself cause exposure. E200-042/043 separate accountable examination from unrestricted publication. These recording duties do not claim to complete the manuscript's broader account of epistemic justice.

FM-005, section 5.19, PDF pages 162–164, distinguishes computational observation, classification, inference and generated representation. E200-033/040/041 preserve transformations and limits on inspection. A generated description can aid inquiry without becoming an independent source of authority.

FM-007, section 10, PDF pages 45–50, distinguishes partial attributes, numerical scales and changing composition; section 17, pages 78–80, distinguishes regime alignment and recovery of omitted information. E200-034–038 adapt these distinctions to inspectable records without importing a formal model or declaring Property equivalent to Attribute.

D.3 External drafting models

The ISO model document and ITU-T author's guide inform the organization of scope, dated references, terms, clauses and normative or informative annexes. The United Nations National Quality Assurance Frameworks Manual provides a useful comparison for distinguishing institutional conditions, processes and outputs in a quality framework. Here, package recording, assessment performance and institutional effects remain separate subjects. No UN statistical quality indicator or external conformance rule is incorporated through this comparison.

Annex E

(informative)

Unresolved issues and specification needs

E.1 General

- **OPEN — Representation.** Whether claim identity is implemented through objects, qualified statements, wrappers, or hybrids requires disagreement, revision, protection, and exchange cases before a Specification decision.
- **OPEN — Burden.** Initial review needs to measure time and participant burden as well as field completeness. Shared context can reduce duplication; E200-027 addresses the preservation of claim-specific exceptions.
- **OPEN — Evidence assessment granularity.** The minimum useful rationale varies across testimony, measurement, historical interpretation, and routine record entries. Domain profiles need cases and relevant expertise.
- **OPEN — Challenge procedure.** The effective operation of submission routes, standing, accessible participation, impartial assessment, notification, timing, appeals and repair in GR-210 and institutional profiles needs evidence from actual practice. E200-021 records results without establishing that these practices exist or work.
- **OPEN — Retention and restriction conflicts.** Historical reconstruction, deletion, protection, and procedural examination can conflict. Named institutional and jurisdictional profiles need explicit review; this draft imposes no universal retention period or disclosure priority.
- **OPEN — Technical needs.** Independently addressable versions, evidence-role links, dependency notifications, missingness states, controlled locators, and loss-aware transformations are candidate inputs to GR-SPEC-120/130/200. No encoding or transport protocol is adopted here.
- **OPEN — Conformance practice.** The matrix is a review design, not a completed validator or certification programme. Independent reviewers need to test whether the same package yields reproducible assessments and whether affected participants can recover its meaning.

GENERATIVITY STANDARDS PROGRAM

GR-210

Standards-track Working Draft

Version 0.3 2026-09-22

Evidence, Interpretation, and Contestation

WORKING DRAFT FOR REVIEW

This document contains proposed provisions for technical and institutional review. It is not an adopted Standard or an operative governance instrument. Its scope, application conditions and publication status are specified in the text.

Prepared by the Generativity Standards Program. Reference to external publications does not imply endorsement by ISO, IEC, IEEE or any United Nations body.

Foreword

Version 0.3 records the bounded substantive review of the archived 0.2 package. This edition clarifies the limited GR-100 vocabulary dependency while retaining the full applicable GR-200 package dependency. The review matrix, synthetic assessments and unresolved readiness questions are documented in `docs/reviews/validation_0.2/README.md`. These activities do not constitute adoption or an independent institutional assessment.

Responsible editor: `UNASSIGNED`. Canonical source: `standards/GR-210-evidence-interpretation/GR-210.tex`. Intended readers are procedure operators, affected people, reviewers and assessors.

This is a **PROVISIONAL Standards-track Working Draft**. It is not adopted, and preparation does not formally initiate a standards project, authorize an institutional procedure, or establish a legal entitlement. Its requirements are proposals for review and experimental assessment. Draft 0.2 preserves the meaning of C210-001 through C210-032 and extends the procedure declaration, case handling, protection, and assessment schedules. Draft 0.1 remains historical material.

Bibliography 20

Introduction

An account can be authentic, widely repeated, or institutionally accepted and still lack adequate grounds for its substantive conclusion. A person affected by that account also needs a usable route to question it. This document connects the examination of evidence with the practical organization of receipt, response, review, revision, and action. It keeps those functions distinct so that a successful correction of text is not mistaken for a completed remedy and an inclusive procedure is not mistaken for proof of truth.

The foundation manuscripts distinguish trace from evidence, evidential adequacy from epistemic justice, and current knowledge of the past from the past and its historical representations. They also identify unequal capacities to produce, preserve, interpret, and contest evidence. The procedures proposed here operationalize a bounded part of those concerns. They do not claim to exhaust the philosophical concepts or prescribe a single institutional model.

The procedure can be operated with documents and accountable people before a machine protocol is needed. Technical infrastructure becomes useful when case correlation, controlled exchange, version tracking, notification, or concurrent action requires interoperable behavior. Such infrastructure remains subordinate to declared authority and protection. A complete state log cannot establish that a reviewer actually considered the grounds or that an affected person could use the route.

1 Scope

1.1 General

This document proposes requirements for a bounded procedure through which people can question an attributed account, introduce evidence or an alternative interpretation, obtain a reasoned disposition and seek further review. Its subjects are the procedure operated by a named organization or recording practice and the associated case record.

An evidential assessment, a procedural disposition, an institutional action and an externally competent legal finding remain distinct. This draft provides no universal tribunal, evidentiary ranking or legal right to review. A conforming procedure can conclude that the available evidence does not resolve the dispute.

The scope includes a procedure declaration, accessible receipt, case scoping, reviewer assignment, evidential and interpretive examination, participation, reasoned disposition, notification, further review, correction propagation, practical response, closure, and protected retention. It excludes a universal evidentiary ranking, mandatory probability scale, cross-jurisdiction legal remedy, and a claim that procedural conformity proves the underlying facts. Institutional profiles determine the contextual service periods and authority within these boundaries.

2 Normative references

2.1 Dated draft dependencies

For experimental assessment against this edition, GR-100, *Foundations and Vocabulary*, Working Draft 0.3, supplies the terms in Clause 3, the record-role meanings in Clause 5 when used, and the assessment-result meanings in 8.3; this reference does not impose a separate claim of GR-100 vocabulary-application conformity. GR-200, *Epistemic Recording Framework*, Working Draft 0.3, supplies the package and claim requirements invoked by C210-030. The source locations are `standards/GR-100-foundations-vocabulary/GR-100.tex` and `standards/GR-200-epistemic-recording/GR-200.tex`. Both are draft dependencies, not adopted Standards. All applicable GR-200 requirements remain applicable to the bounded claim package; a field-level check does not satisfy package-level obligations.

A dependency revision requires review of affected procedure declarations, claim packages, and assessment results. GR-110 concerns the broader generativity recording package and is a related informative publication here, not a blanket additional conformance dependency. Full GR-300/310/400 profiles remain in development. Directives Part 1 governs the programme's own development procedure after adoption; its periods are not universal periods for institutions using GR-210.

No external legal instrument or United Nations publication is a normative dependency of this edition. Comparative sources in the bibliography inform drafting and assessment architecture without importing institutional powers or policy commitments.

3 Terms and definitions

3.1 Operational procedure terms

The following terms narrow the procedural use in this document without redefining the broader GR concepts supplied by GR-100.

Operator The accountable organization, person, or arrangement that declares and provides the procedure within its stated authority.

Case A distinguishable collection of issues, submissions, review actions, dispositions, and follow-up concerning identified records or decisions.

Case record The retained representation of a case, including its boundaries, versions, access scope, and known missing material. Its existence does not prove that every represented action occurred.

Issue A question capable of receiving a scoped response, such as whether a date is wrong, evidence supports a claim, a category is adequate, or the declared procedure was followed.

Reviewer The assigned person or accountable review function that examines specified issues within declared competence and authority.

Disposition The reasoned procedural outcome for an issue or case. It can maintain a judgment, support revision, record unresolved evidence, refer the matter, or close a procedure without settling the substantive question.

Practical response An authorized or proposed action following review, distinct from recording the disposition and from evidence that the action was completed.

Further review Reconsideration, a procedural appeal, or another declared examination of a previous handling or disposition, with the route's authority and independence stated.

Material grounds Evidence, assumptions, criteria, or reasons capable of changing a reasonable assessment of the issue, its disposition, or its consequential use within the declared scope.

Case state A procedural status indicating completed and pending handling. It is not a truth value, a probability, or an institutional judgment on the underlying claim.

4 Procedure declaration

4.1 General

C210-001 The operator shall publish or otherwise provide an accessible procedure declaration identifying its purpose, eligible users, covered records or decisions, responsible roles, asserted authority, submission routes and exclusions.

C210-002 The declaration shall distinguish technical correction, evidential disagreement, procedural complaint, ethical or conduct complaint and an asserted legal claim, identifying their available handling routes and limits of authority.

C210-003 The operator shall declare response and review periods, their start events, permitted extensions, notice arrangements and the route available when a period is exceeded. The chosen periods shall be justified for the institutional context and affected users.

C210-004 The operator shall declare the information needed to submit a case, the support or alternatives available to users and how restricted evidence or protected identities can be handled. A demand for unnecessary public disclosure shall not be a condition of receipt.

NOTE 1 No universal period is selected here. The programme's own standards-development comments and appeals are governed by Directives Part 1 if adopted; an institution using records has its own declared procedure and legal context.

4.2 Declared authority and service conditions

C210-033 The declaration shall have an identifier, version, effective interval, accountable owner, and accessible change history. It shall identify the normative dependencies and any institutional profile applied, the intended users and languages, and the procedure functions actually available. A named but unstaffed function shall be identified as unavailable rather than presented as an operative review route.

C210-034 For each kind of issue, the declaration shall identify who can receive it, examine evidence, determine a disposition, authorize action, and conduct further review. It shall distinguish an operator's internal policy from a claimed external legal mandate and identify the source, scope, and uncertainty of the latter. Receipt by one function shall not transfer authority belonging to another.

C210-035 The operator shall maintain the service schedule in Annex A, including receipt, acknowledgement, clarification, review, reply, disposition, notification, further-review requests, action follow-up, and closure. The schedule shall identify clock starts, responsible roles, expected periods or deadlines, permitted pauses and extensions, and escalation when service cannot be provided.

C210-036 The operator shall make submission and further-review routes available without requiring a person to accept the challenged account, withdraw an unrelated complaint, or expose unnecessary protected information. Any eligibility limitation, fee, identity requirement, representative arrangement, or technological prerequisite shall have a declared purpose, authority, proportionality rationale, and available alternative or challenge route.

C210-037 Before changing the procedure, the operator shall assess effects on open cases, participation, protection, and remedies. The change notice shall state the new version, effective date, reasons, transition treatment, and how affected users can question the change. A later rule shall not be applied silently to make an earlier handling appear compliant.

C210-038 A profile shall identify its institutional setting, covered actions, authority limits, service periods, available resources, review competence, protection basis, and assessment scope. It shall identify any requirement not met rather than claim full GR-210 fulfillment through a profile that silently removes an applicable obligation.

C210-039 The operator shall assess whether its declared channels and staffing can support the expected cases and urgency. Material capacity gaps shall produce a documented mitigation, narrower service declaration, referral arrangement, or postponement with notice. A backlog shall not be concealed by classifying unexamined submissions as resolved.

NOTE 2 An institution can distinguish a clerical correction desk from a merits-review panel and an external legal forum. A single contact can assist routing, but that convenience does not make it competent to decide each type of question. A profile's named institution is part of the authority claim to verify, not evidence of authority by itself.

5 Receipt and scoping

5.1 General

C210-005 On receiving a submission, the operator shall create a distinguishable case reference and record receipt time, the target record or decision and version if available, the asserted issue and the submitter's attribution or protected-contact arrangement. Receipt shall not be reported as agreement with the submission.

C210-006 The operator shall acknowledge receipt through the declared route or record why acknowledgment is not possible. The response shall explain the next step, expected timing and any missing information needed for further action.

C210-007 Where a case is out of scope, incomplete, duplicated or directed to the wrong recipient, the operator shall record that procedural reason and any available correction or referral route. That outcome shall not be represented as factual refutation.

C210-008 Any restriction on repetitive or abusive submissions shall use declared criteria, record the reason and preserve a route to challenge the restriction. The operator shall not classify a submission as abusive solely because it criticizes an authoritative account or repeats an unresolved material concern.

5.2 Intake, triage, and issue separation

C210-040 The operator shall accept enough information to identify a concern without requiring the submitter to supply a complete evidentiary case or technically correct amendment at receipt. If the target or issue is unclear, the operator shall seek clarification and offer the declared assistance before closing for incompleteness, unless contact is unavailable or a stated protection constraint prevents it.

C210-041 Triage shall identify immediate protection or irreversible-consequence risks, the covered question, required routing, known deadlines, and whether temporary preservation or action review is available within the operator's authority. Triage shall not be presented as a concluded evidential finding. Any urgent measure shall have a responsible actor, scope, reason, review point, and notice appropriate to protection needs.

C210-042 A submission containing several kinds of issue shall be divided into distinguishable questions with linked handling routes and a coordinating contact. A referral shall identify what is sent, on what authority, to whom, and whether receipt or acceptance has been confirmed. The operator shall not describe sending a referral as evidence that the recipient has assumed the case.

C210-043 The intake record shall preserve the submitted meaning and relevant original formulation within protection limits. Translation, transcription, summarization, or assisted reformulation shall identify its responsible role, method, version relationship, and material uncertainty. The submitter shall have a practicable opportunity to correct a material misunderstanding through the permitted contact arrangement.

C210-044 A duplicate-case decision shall identify the related case and explain which issues are shared and which remain distinct. Consolidation shall retain separate attribution, protection preferences, and individual practical consequences where material. A previous disposition shall not automatically dispose of new evidence or a newly identified defect in the previous handling.

C210-045 A request for further information shall specify the missing information, why it matters, who is expected to supply it, available assistance or alternatives, the response period, and the effect of nonresponse. The operator shall not shift responsibility for evidence within its own declared control to a person who lacks access without explaining and addressing that access problem.

C210-046 A case placed on hold shall identify the reason, affected work, responsible owner, next review date, and clock treatment. A hold shall not remove the case from pending-work reporting or imply acceptance, rejection, or abandonment. The operator shall reassess the hold at the stated review point and notify permitted recipients of a material change.

C210-047 When a submitter withdraws a request, the operator shall record its scope, distinguish withdrawal of participation from withdrawal of an evidential assertion, and explain any continuing handling under a separate declared responsibility. Withdrawal shall not be described as proof that the original claim was false or that the person agreed with the challenged decision.

C210-048 Case transitions shall conform to the semantic controls in Annex B. The operator shall record the previous and new state, trigger, responsible actor, time, reason, and next action. Local status labels may differ if their mapping preserves the distinctions between receipt, review, disposition, action pending, and closure.

6 Review responsibilities and participation

6.1 General

C210-009 Before substantive review, the operator shall identify the reviewer or review function, relevant competence, relation to the contested account and conflicts of interest. Material conflicts shall be handled through recusal, reassignment or a disclosed limitation with an appropriate further-review route.

C210-010 The reviewer shall identify the questions within the case, the relevant claim versions, evidence available, known limitations and decision criteria. Factual, normative, procedural and legal questions shall remain distinguishable.

C210-011 Affected parties shall be given an opportunity to respond to material grounds used in the disposition through a procedure consistent with protection and applicable institutional constraints. Where direct disclosure is restricted, the operator shall explain the permitted alternative and its limits.

C210-012 The operator shall record participation barriers known to affect the case, assistance or adjustments offered and material perspectives that could not be obtained. Absence of a response shall not automatically be represented as consent or admission.

NOTE 1 A reviewer cannot promise that every perspective will be available. The proposed obligation is to expose the evidential and procedural consequence of a material gap.

6.2 Assignment, competence, and meaningful response

C210-049 The reviewer assignment shall state the questions delegated, relevant domain competence or situated knowledge, decision limits, availability, and accepted responsibility. Where several reviewers supply different expertise, the record shall identify who integrates findings and who is accountable for the disposition. Unavailable competence shall narrow the finding or trigger additional review, referral, or deferral.

C210-050 The operator shall provide a route to raise a conflict concern and assign its assessment to a person not deciding a complaint about their own interest. The conflict disposition shall identify the concern, relevant evidence, management action, and effect on the case. Disclosure alone shall not be represented as independent handling.

C210-051 An author of the challenged account may explain its sources or participate in a disclosed initial reconsideration, but shall not be described as an independent reviewer of that account. A material unresolved conflict shall not support an unqualified independent-review claim; the available further-review arrangement and its limits shall remain explicit.

C210-052 Before a consequential disposition, the operator shall give affected parties notice of the questions, material grounds proposed for reliance, applicable criteria, response route, and response period to the extent permitted by protection. A later-added material ground shall receive a further response opportunity unless a declared urgent measure requires temporary action with prompt subsequent review.

C210-053 An opportunity to respond shall be assessed in relation to actual access, language, disability, resources, time, and the form of the material. The operator shall record requested adjustments, its response, and unresolved barriers. Merely making a complex dossier available shall not establish that an affected person could meaningfully address the proposed grounds.

C210-054 Where direct participation is unsafe or impracticable, the operator shall assess the declared alternatives, including protected contact, assisted submission, representative participation, or controlled independent examination. The record shall identify the chosen arrangement, its authority and limitations, and any material perspective it cannot provide. Representation shall not be inferred without a basis.

C210-055 A reviewer shall assess testimony in relation to the source's access, claim scope, method, and material limitations rather than institutional status alone. Relevant experience and technical expertise shall remain distinguishable. Giving a person an opportunity to speak shall not be reported as showing that their grounds influenced the decision unless the disposition records how they were considered.

C210-056 If the reviewer and decision authority are different, the authority shall identify the review findings received, any departure from them, the grounds and competence for that departure, and the

additional response opportunity required by new material grounds. A managerial instruction shall not silently replace an evidential assessment while retaining the reviewer's attribution.

C210-057 The operator shall provide a protected route to report retaliation or interference linked to participation and shall record available protective responses within its authority. Such a report shall remain distinct from the factual merits of the original case. A person shall not have to publish the protected allegation to obtain triage or an explanation of the available route.

7 Evidence and interpretation

7.1 General

C210-013 An assessment shall identify the claim under examination, the evidence relied on, how that material bears on the claim, relevant method and assumptions, and known counterevidence or materially plausible alternatives.

C210-014 The reviewer shall distinguish the authenticity or integrity of a source from the warrant it provides for a particular claim. A signed assertion shall not receive an unqualified truth status merely because its signature validates.

C210-015 A conclusion based on missing evidence shall identify the expected trace-production, observation or preservation conditions supporting that inference. Where those conditions are not established, absence of the record shall remain distinguishable from non-occurrence.

C210-016 The assessment shall state uncertainty and its scope without inventing a common probability scale for heterogeneous judgments. Disagreement among assessors shall be attributed and retained where material and permitted.

C210-017 Where a category, method or institutional rule is challenged, the reviewer shall distinguish whether it was applied correctly from whether its adequacy or legitimacy is itself under review. A correct application shall not by itself dispose of a challenge to the rule.

C210-018 A material computational or AI-assisted contribution to the review shall be identified with the inputs or sources available for inspection, its role, relevant limitations and responsible human or institutional uptake. An inaccessible internal process shall not be replaced by an invented explanation.

7.2 Evidence plan and material examination

C210-058 The reviewer shall maintain an issue-to-evidence plan identifying the question, claim versions, relevant criteria, material available, material sought, expected access, alternatives to examine, and known gaps. A change in the plan that materially affects the scope or burden of review shall be recorded and communicated to permitted affected participants.

C210-059 An evidence item used in a disposition shall have a locator or controlled reference, source attribution, acquisition context, relevant version, and any known transformation or custody limitation material to the inference. An unavailable original shall be distinguished from an examined copy, excerpt, testimony about the item, or generated reconstruction.

C210-060 For each material item, the assessment shall state its role relative to the specified claim: support, challenge, qualification, non-discrimination, or another explained relationship. The reviewer shall not give the item a universal reliability status that silently transfers across different claims, times, or contexts. A role assigned by a party shall remain distinguishable from the reviewer's assessment.

C210-061 Where several items are treated as corroboration, the reviewer shall examine known derivation and dependence material to that claim. Copies, summaries, translations, model outputs, and repeated

citations of one source shall not count as independent observations solely because they are separately stored or differently worded. Any asserted independence shall have a stated basis and limits.

C210-062 The reviewer shall identify material alternatives that fit the accessible evidence and state why an alternative is retained, weakened, rejected, or outside the assessed scope. An alternative need not receive equal weight merely because a party proposes it. Failure to examine alternatives shall remain a limitation rather than be reported as evidence that none exists.

C210-063 When an identity, temporal order, measurement, classification, or causal link is contested, the review shall identify the relevant criterion or method and assumptions. Agreement on a record identifier, timestamp, endpoint, or category label shall not by itself resolve the corresponding underlying identity, chronology, trajectory, or causal question.

C210-064 An assessment of a generative contribution shall state the capacity, relation, distinction, constraint, or possibility at issue, the comparison condition, temporal horizon, proposed connection, and evidential limits. A change following an intervention shall be examined for whether it reveals an earlier condition, creates a new condition, or combines both; later observation shall not silently become direct evidence of the earlier configuration.

C210-065 If a rule or category is challenged, the operator shall separate the case-specific application question from the rule-review question and identify the competent recipient for each. A referral of the rule question shall leave its status visible. Rejection under the existing rule shall not be represented as a finding that the rule is adequate, fair, or legally valid.

C210-066 A change in evaluative criteria during review shall identify the earlier and revised criteria, authority, reasons, affected issues, and transition effects. The operator shall provide a response opportunity where the change materially affects a party's case. Historical acts shall retain the criteria actually relied on at the time, even when the present assessment uses a later framework.

C210-067 A numerical score, confidence estimate, or model recommendation used materially in review shall identify what it measures, relevant inputs, method and version where available, assumptions, uncertainty, and role in the decision. A threshold chosen for operational action shall remain distinguishable from an estimate of factual warrant. Unavailable technical details shall qualify the assessment rather than be fabricated.

C210-068 The reviewer shall document the planned examination actually performed, material steps not performed, reasons, and effects on the conclusion. An evidence request sent, an access permission obtained, or a tool available shall not be reported as an examination completed. A finding shall remain bounded by the material and methods actually used.

8 Disposition and practical response

8.1 General

C210-019 The disposition shall state the questions decided, findings and their scope, evidence and reasons, responsible decision function, decision time, remaining disagreement and matters outside its authority.

C210-020 The disposition shall distinguish correction of a record, changed evidential assessment, maintained judgment, changed institutional action, inability to decide and procedural closure. Procedural closure shall not imply epistemic agreement.

C210-021 Where the procedure supports a remedy or practical response, the disposition shall identify the proposed or authorized action, its responsible executor, scope, timing and evidence needed to establish completion. Recording a proposed action shall not establish that it occurred.

C210-022 The operator shall notify the submitter and other relevant recipients through the declared, permitted routes, explain any further-review route and record delivery or known failure. Public notices shall respect the case's disclosure limits.

C210-023 A material correction shall be linked to the earlier account and known dependent views or decisions. The operator shall record which corrections or notices were performed and which downstream effects remain unresolved.

NOTE 1 A corrected classification can leave lost opportunities, costs or harm unremedied. The procedure records the distinction rather than declaring repair complete because a field changed.

8.2 Reasons, notification, and action tracking

C210-069 Each disposition shall address every scoped material issue or state why it remains deferred, referred, withdrawn, or unresolved. The record shall distinguish the parties' positions, the reviewer's assessment, the authorized determination, and any minority or competing assessment retained within protection limits. A single closed-case label shall not conceal different outcomes for different issues.

C210-070 A maintained judgment shall explain why the challenge does not warrant the requested change, including treatment of material contrary grounds. An inability-to-decide disposition shall identify the limiting evidence, authority, or method and any conditions for further review. Neither outcome shall rely solely on institutional acceptance of the original account.

C210-071 An action plan shall distinguish proposed, authorized, assigned, initiated, completed, verified, failed, and no-longer-pursued actions where those differences are material. It shall identify the executor, authority, affected records or persons, due or review date, completion evidence, and route when execution fails. A reviewer lacking implementation authority shall identify the required decision recipient rather than promise completion.

C210-072 When immediate action is taken before full review, the operator shall record the urgency, authority, limited purpose, expected consequences, duration or review point, notice limits, and later examination required. The temporary action shall not be presented as a final evidential finding or remove the remaining opportunity to challenge material grounds.

C210-073 The notification record shall identify the permitted recipient, route, exact disposition or summary version, dispatch time, known delivery status, and any protected information withheld. The operator shall distinguish dispatch, delivery, receipt acknowledged, and substantive response. A delivery failure material to a review opportunity shall trigger the declared alternative or timing correction.

C210-074 A notice of disposition shall give an accessible account of the outcome, material reasons and limitations, action status, further-review route, relevant deadline and starting event, and assistance available. If the full record cannot be shared, the notice shall explain the permitted way to examine or challenge the grounds without overstating the completeness of the summary.

C210-075 Correction planning shall identify known dependent claims, assessments, records, presentations, and decisions within the operator's control or declared notification relationships. For each, the operator shall record correction performed, review pending, no change with reason, notification sent, unreachable recipient, or another explained status. It shall not assert universal propagation beyond the evidenced boundary.

C210-076 A correction shall preserve a distinguishable relationship between the prior and revised account, its reason and authority, and the time of each formulation, subject to protection and retention. The corrected view shall not present earlier decision makers as having used evidence or categories acquired later. A removed sensitive detail shall not be retained in the public history solely to illustrate the correction.

C210-077 A consequential action or remedy shall be evaluated separately from record correction. The follow-up shall identify the intended practical change, evidence of what occurred, unresolved costs or losses, affected perspectives obtained, and limits on causal attribution. An apology, amended field, or scheduled meeting shall not be recorded as restoration of an opportunity without supporting evidence.

C210-078 A case closure shall identify which issues are disposed, which actions remain pending, who owns continuing follow-up, and the conditions for reopening. Where the declared procedure requires action verification before closure, unavailable verification shall prevent that closure claim. Administrative closure shall not erase outstanding obligations, remaining disagreement, or unavailable evidence.

C210-079 If a disposition is itself corrected, the operator shall identify the earlier disposition and notice versions, the error, authority for correction, affected deadlines or actions, and renewed notifications or response opportunities. A substantive change shall receive the review warranted by its effect, rather than be hidden as a typographic correction.

9 Further review, reopening and continuity

9.1 General

C210-024 The procedure shall provide a declared route to request reconsideration of a material error, new evidence or procedural failure, with its scope, competent recipient and limitations. A reviewer of their own contested action shall not be described as independent.

C210-025 A reopened case shall identify the earlier disposition, trigger, changed evidence or criteria, reviewer and new outcome. Later interpretation shall not silently replace the record of what was known or decided earlier.

C210-026 If the operator lacks competence, authority or resources to complete a material step, it shall record the limitation and notify permitted recipients of the available alternative, postponement or closure basis. Passage of time alone shall not establish a finding on the substantive claim.

9.2 Reconsideration, procedural appeal, and reopening

C210-080 The declaration shall distinguish reconsideration of evidence or judgment, review of procedural failure, conduct handling, and an external legal route where one is asserted. It shall state who can request each route, the grounds and scope, responsible recipient, available remedies, timing, and independence arrangements. Routing assistance shall preserve the submitted concern rather than require technical knowledge of the operator's organization.

C210-081 A further-review request shall receive a linked reference, acknowledgement, admissibility decision with reasons, reviewer assignment, timetable, and notice of any effect on action or closure. A refusal to admit the request shall not be represented as substantive refutation and shall identify any remaining challenge route or explicit limit.

C210-082 A person who made the challenged decision shall not be described as independent when reviewing it. An independent-review claim shall identify the reviewer's separation from the disputed handling and relevant interests. If the declared independent function is unavailable, the operator shall disclose the limitation and refrain from claiming that an independent appeal occurred.

C210-083 The further-review authority shall assess whether disputed action needs a stay, temporary qualification, preservation measure, or other protection within its mandate. The decision shall identify urgency, consequences for affected parties, duration or review point, and reasons. Requesting review shall not be assumed either to stop every action or to leave every action unaffected.

C210-084 Further review shall identify the record and criteria reviewed, new material admitted, opportunities for response, questions determined, reasons, remedy, and implementation responsibility. A procedural reviewer acting outside authority to decide factual merits shall remit the appropriate question rather than relabel a procedural finding as a final factual conclusion.

C210-085 Where a remedy requires renewed notice, evidence examination, reassignment, reconsideration, or action, the operator shall record completion evidence before asserting the remedy fulfilled. The renewed disposition shall link the earlier decision and further-review grounds. Repeating the earlier conclusion without performing the required remedy shall not constitute compliance with the review outcome.

C210-086 A reopening assessment shall distinguish newly available evidence, a material error, changed target conditions, changed categories or criteria, procedural defect, and unimplemented remedy. It shall state whether these grounds affect the past assessment, current action, or both. A later event shall not automatically prove that an earlier claim was mistaken under the evidence then available.

C210-087 A reopened case shall preserve the earlier scope, evidence state, disposition, and consequential uses to the permitted extent and identify the new review boundary. New and prior issues may be linked or separated when the reason is recorded. Reopening shall not silently reset an overdue action or delete the history of a missed response.

C210-088 When a service period is exceeded, the operator shall record the missed event, cause, effect, notice, revised target or authorized extension, and available escalation. An extension shall identify who authorized it and why it is consistent with the declared procedure. Repeated extensions shall trigger capacity review and a reasoned alternative, rather than indefinite pending status without accountability.

C210-089 A handover, operator closure, or loss of a responsible function shall identify open cases, pending actions, permitted successor access, affected notices, and continuity limits. Transfer shall require a stated authority and custody record. Where no successor can accept responsibility, users shall receive the available permitted explanation and alternatives; an unavailable service shall not continue to be advertised as operational.

10 Protection and retention

10.1 General

C210-027 The operator shall specify access, retention, correction and disposal arrangements for submissions, evidence, reviewer notes, dispositions and notifications. Content and audit metadata shall be considered separately; history preservation shall not justify retaining prohibited sensitive material.

C210-028 Disclosure, redaction, access withdrawal or disposal affecting a case shall identify its authority, scope, executor and permitted evidence of the action. The operator shall state known limits concerning copies outside its control.

C210-029 A public summary shall distinguish the accessible grounds from material that cannot be disclosed, where that distinction is itself permitted. It shall not claim full independent inspectability when a material evidential restriction prevents it.

10.2 Differentiated access and protected case handling

C210-090 The operator shall distinguish submission content, identity and contact information, evidence, internal working material, disposition, public summary, and audit information in its access and retention schedule. Access shall correspond to an identified purpose and authority. Permission to examine one component shall not be presumed to authorize onward publication or unrestricted reuse of the case.

C210-091 Before relying on protected grounds for a consequential adverse disposition, the reviewer shall assess whether affected parties can receive a sufficient account or a credible authorized alternative examination. If protection prevents fair examination of a material issue, the operator shall narrow the finding, defer it, or state the unresolved limitation rather than claim fully contestable determination.

C210-092 A controlled view shall identify its source case and disposition version, intended audience, material selection or transformation, and permitted limitations. If acknowledging a particular item's existence is restricted, the view shall state its scope at a safe level without exposing that existence. The protected accountability record shall remain available only within its authorized boundary.

C210-093 A suspected unauthorized disclosure, misdirected notification, or compromise of protected evidence shall receive recorded triage, containment within authority, affected-case assessment, permitted notice, and review of whether the evidence or procedure remains usable. Correction of the public copy shall not be described as recall of copies beyond the operator's control.

C210-094 A retention or disposal decision shall assess ongoing review, action, and reconstruction needs against the applicable protection basis, authority, and schedule. The record shall state what is retained or disposed of, when, by whom, and the permitted verification method. It shall not retain prohibited content merely because a review might theoretically occur in the future.

C210-095 An assessor denied access to material required for an applicable finding shall state the resulting limitation. A protected assessment by another authorized competent person may be cited with its scope and independence limits, but shall not be represented as the first assessor's direct examination. Confidentiality shall not convert an unassessed obligation into fulfillment.

11 Conformance and assessment

11.1 General

C210-030 A conformance report shall identify the procedure or case record assessed, operator, institutional context, this draft and dependency versions, applicable requirements, reviewer relationship, evidence and results. It shall identify the case's material claims as a bounded GR-200 Working Draft 0.3 package and report its applicable requirement results, including package-level obligations. A case-record assessment alone shall not establish that unobserved procedural steps occurred.

C210-031 Each applicable requirement shall receive a supported result of fulfilled, not fulfilled or not assessed; a not-applicable result shall give its trigger-based reason. An unqualified claim of fulfillment shall not omit a failed or unassessed applicable requirement.

C210-032 A procedure assessment shall include an ordinary case and relevant failure cases concerning conflict, unavailable evidence, missed timing, restricted disclosure and correction propagation. A case-record-only assessment shall identify the supplied case and the procedural behavior it cannot establish. Reported success shall be limited to the cases and conditions actually exercised.

This edition defines no reduced case-record conformance profile. A case-only report is a partial documentary assessment. Performance obligations remain not assessed when only their records were examined; not applicable requires an absent stated trigger. A procedure claim covers all applicable requirements and the declared GR-200 package dependency. The multi-case rehearsal obligation in C210-032 is explicitly conditional on procedure assessment.

11.2 Assessment plan, results, and limitations

C210-096 Before assessment, the assessor shall define the procedure version, operator and institutional scope, period observed, cases selected, relevant failure conditions, methods, evidence access, and inde-

pendence or author involvement. A sample of cases shall have an explicit selection rationale and limit; a favorable sample shall not be generalized to unexamined settings without supporting grounds.

C210-097 The assessment register shall give each applicable requirement its own result, evidence locator, method, assessor, and unresolved action, distinguishing documentary adequacy from actual performance where both are required. A grouped test may support several results only when its evidence supports each obligation separately.

C210-098 A procedure assessment shall use the minimum coverage schedule in Annex C and justify any additional failure cases arising from the declared context. A synthetic exercise shall identify fictional actors and unperformed external actions. A demonstration of software behavior shall not establish competent human review, meaningful participation, legal authority, or practical remedy.

C210-099 Assessment shall include an intended user's attempt to locate the route, identify the issue, understand the notice and reasons, and determine the next available action under permitted conditions. The report shall record assistance, barriers, failures, and participant relationship to the design. Author familiarity shall not be reported as independent evidence of ordinary-user comprehension.

C210-100 An assessment finding that results in a corrected procedure, case record, or implementation shall identify the changed version, affected requirements, corrective action, and reassessment scope. Results for unchanged material may be reused only with a recorded reason that the change does not invalidate the evidence. A prior pass shall not automatically transfer across a material change.

C210-101 A public assessment summary shall identify the assessed scope, dependency versions, methods, failures and unassessed requirements, protected-evidence limitations, and whether actions were observed or merely documented. It shall not use a certificate, badge, or concise status to imply factual truth, institutional legitimacy, or full procedure fulfillment beyond the evidence.

Annex A

(normative)

Procedure declaration and service schedule

A.1 General

This schedule specifies the information needed to operate and assess the declared procedure. It does not set universal numerical deadlines. The operator supplies actual values, their justification, and the corresponding authority under C210-003/035. An unspecified period is an incomplete declaration, not an unlimited permission to delay.

C210-102 For every applicable service event in Table A.1, the schedule shall specify the responsible role, starting event, period or deadline, notification, allowed pause or extension, and escalation recipient. If institutional constraints impose a different controlling deadline, the declaration shall identify the asserted source and conflict treatment. A service extension shall not be represented as altering an external deadline beyond the operator's authority.

Table A.1 – Procedure declaration and service-event schedule

Event or arrangement	Required declared treatment
Receipt and acknowledgement	Submission routes; minimum intake content; time of receipt; distinction between receipt and agreement; acknowledgement channel and alternative when contact fails.
Clarification and scoping	Assistance; information requested and purpose; response period; inactivity treatment; routing of separate issues; decision on scope with reasons.
Urgent triage	Risks assessed; available temporary protection; authority; duration or review point; notice and later examination; limits on irreversible action.
Review assignment	Accepted reviewer role; competence; conflicts and challenge route; substitute or unavailable-capacity treatment; intended completion or status-update events.
Grounds and reply	Material grounds disclosed or authorized alternative; response period; adjustments; treatment of new material; consequence of failed notice.
Disposition and notice	Decision responsibility; required reasons; delivery arrangements; action plan; notice of further-review scope, deadline, and starting event.
Further review and reopening	Permitted grounds; recipient; independence; admissibility and response events; stay decision; remedy; new-evidence and closure rules.
Action and closure	Executor; due and review points; verification; dependent corrections; remaining action ownership; closure criteria and later contact.
Protection and continuity	Access categories; retention and disposal basis; incident handling; handover authority; limitations when evidence or operators become unavailable.

Annex B

(normative)

Case-state and transition controls

B.1 General

The states below define procedural meaning rather than mandatory serialized values. A procedure can use local terminology or several parallel issue tracks if the mapping remains explicit. State changes concern handling, while claim assessments and institutional actions have separate versions and statuses.

C210-103 A transition shall identify the prerequisite evidence, authorizing role, permitted notification, and continuing work in Table B.1. Skipping a named state shall be permitted only when its underlying obligations are either fulfilled together with another step or inapplicable for a recorded reason. A state label alone shall not serve as evidence that its prerequisite action occurred.

C210-104 Where a case contains multiple issue or action tracks, the overall state shall identify unresolved tracks and their owners. Disposition of one question shall not close another without an explicit reason. Reopening or remitting an issue shall preserve the earlier disposition and its procedural context while identifying the newly pending work.

Table B.1 – Semantic case states and transition conditions

State	Evidence and permitted transition	Meaning not established by the state
Received	Distinguishable submission and receipt time; move to clarification, scoping, or urgent triage with an accountable owner.	Agreement with the assertion or completeness of evidence.
Awaiting clarification	Specific missing information, support, response opportunity, and review point; proceed on receipt or give a reasoned scope or closure disposition.	Falsity, abuse, or abandonment inferred solely from delay.
Scoped / assigned	Questions, target versions, authority, reviewer and conflicts identified; proceed to material examination or a reasoned referral.	Jurisdiction outside the declared mandate or independent review by title alone.
Under review	Examination plan and performed work; material grounds and reply opportunity; pauses remain recorded with review dates.	That every source is authentic or every planned check has occurred.
Awaiting response	Specified grounds and usable response route; proceed after the declared opportunity, addressing barriers and newly raised issues.	Consent, admission, or waiver inferred from nonresponse.
Disposed	Reasoned issue outcomes, limitations, action and further-review notice; proceed to action, review, or permitted closure.	Action completion, truth certification, or agreement by the submitter.

State	Evidence and permitted transition	Meaning not established by the state
Action pending	Authorized executor, action and review point, dependency and verification record; close or escalate under declared criteria.	Remedy completed because it was ordered or scheduled.
Closed / withdrawn	Recorded basis, disposed and unresolved issues, continuing follow-up and reopening route; later reopen with a linked trigger.	Erasure of remaining disagreement, past consequences, or obligations owned elsewhere.
Reopened / remitted	Earlier outcome, trigger, scope, assigned reviewer, and required remedy identified; return to the affected review step.	Retrospective disappearance of the earlier decision or evidence state.

Annex C

(normative)

Minimum procedure-assessment coverage

C.1 General

This schedule applies to a procedure assessment under C210-032/098. For a case-record-only assessment it identifies behavior that the supplied record cannot establish; it does not turn unobserved performance into a not-applicable result. Cases can combine several conditions when each relevant obligation is separately examined.

C210-105 The procedure assessment shall cover each applicable condition in Table C.1, record the input and expected behavior, observe the action claimed, and retain permitted outcome evidence. It shall identify conditions not exercised and their effect on the assessment claim. A fulfilled result shall not be assigned merely because a specimen record contains the expected fields.

Table C.1 – Minimum assessment conditions and discriminating evidence

Condition	Required assessment focus
Ordinary material challenge	Exercise accessible receipt through reasons, notification and stated next action. Trace claim versions and GR-200 package results. Distinguish completed handling from a template showing intended steps.
Conflict or missing competence	Raise an assignment concern; inspect its independently handled assessment, reassignment or limitation, and effect on progression. A title alone does not prove independence.
Unavailable or dependent evidence	Supply a missing original and several derived copies. Observe scope qualification and treatment of dependence rather than invented verification or independent corroboration.
Missed timing or failed notice	Cross a declared target or introduce a delivery failure. Verify status, extension or escalation, renewed opportunity where needed, and absence of deemed substantive agreement.
Restricted material	Compare authorized and permitted reduced views. Check meaningful response alternatives, audit access, and the stated limit where examination cannot be provided.
Category or rule challenge	Separate application from adequacy or authority; trace referral and its acceptance status. Correct application does not alone dispose of a challenge to the rule.
Correction and practical action	Follow a revised assessment to known dependencies and an executor. Distinguish notification, correction, action completion, verification, and unresolved loss.
Further review and reopening	Exercise a procedural or evidential request, stay decision where relevant, reasoned outcome and remedy, and reopening on a distinct trigger. Preserve prior meanings and time boundaries.

Annex D

(informative)

Worked cases and interpretation

D.1 Missing attachment and changed classification

The following case elaborates the synthetic dossier in `examples/validation_0.2/p1-contested-decision.md`. None of its actors, notices, decisions, or remedies represents a live institution. A fictional research fund rejects a water-monitoring application after a generated summary states that the equipment was never calibrated. Its intake extract shows only that a calibration attachment was absent. A technician later supplies testimony and a maintenance-log excerpt, while the protected original contains contact details.

Intake creates a case with three questions: whether calibration occurred, whether the application met the existing documentary rule, and whether that rule gives appropriate recognition to maintenance evidence. The first requires claim-relative assessment. The second requires application of the declared rule version. The third is referred to the function authorized to review the rule. None of these operations alone determines a legal claim or an award of funding.

The reviewer distinguishes the absent attachment from non-occurrence, the generated summary from source evidence, and the log excerpt from independent examination of its original. Testimony and a log can share a source; their number does not establish independence. The protected original receives controlled handling with a safe account of the grounds available for response. If the reviewer cannot examine calibration quality or instrument identity, the disposition preserves those limits even while revising the overbroad statement that no calibration occurred.

The record correction links the old and revised claims. A later rule change records its own effective interval rather than making the earlier decision appear to have used the new rule. Scheduling a renewed eligibility review creates an action-pending state, not an award or restoration of lost training opportunities. Practical follow-up investigates the reported interruption, the scope of attribution, and the actual effect of any later response.

D.2 Protected grounds and unavailable independent review

In a second synthetic case, a person disputes an adverse classification based partly on restricted testimony. The operator cannot safely disclose the witness's identity. It provides a redacted account of the material allegation and explores controlled examination by an independent reviewer. The distinction between protection and warrant matters: hiding an identity does not establish the allegation, while the need to test an allegation does not itself authorize publication of the identity.

Suppose the only available reviewer authored the classification. They can explain their original sources and conduct a disclosed reconsideration, but the operator cannot label that work independent. If a credible alternative examination cannot be arranged, the disposition identifies the unresolved procedural and evidential limits. A narrow temporary protective action can be separately considered within actual authority; it does not convert the disputed allegation into a final finding.

The relevant assessment results remain granular. A documented restriction basis can fulfill a documentary obligation. An unperformed independent review remains not assessed. A case record describing a desired notice does not establish delivery or a meaningful response opportunity. The case can close administratively under declared limits without claiming that the underlying factual disagreement has been resolved.

D.3 Outage, deadline, and later reopening

A third synthetic case concerns a challenge received during a service outage. The original timestamp and failed acknowledgement remain recorded. An extension notice identifies the operational cause, responsible role, revised target and escalation route. If a separate institutional deadline applies, the operator states its asserted source and whether it has authority to alter it; a service notice is not treated as changing external law.

Later material reveals that the original classification depended on a mistaken identity link. Reopening identifies this evidential trigger and the affected past assessment, while preserving the decision and its consequences during the intervening period. The remedy includes checking known dependent views and actions. An unreachable external recipient is recorded as unreachable rather than silently treated as corrected.

Annex E

(informative)

Source rationale and unresolved profile decisions

E.1 Operational interpretation

The synthetic funding case accompanying GR-110 supplies a common example. The procedure's record requirements can be implemented manually before a network protocol is needed. A later Specification would define message correlation, delivery, authorization, concurrent revision and failure semantics in response to demonstrated requirements.

The initial operational direction is recorded in ADR-0004. This expanded procedure remains a programme proposal, not a claim that the foundation manuscripts prescribe these case states, deadlines, or institutional functions. Chapter 5 treats evidence as a role relative to an epistemic target and distinguishes just participation from evidential adequacy. Those distinctions motivate separate assessment of access, method, warrant, disposition, and consequences. The record preserves both a supported conclusion and the limits of the procedure that produced it. For the expansion decision and alternatives, see `decisions/ADR-0005-expanded-drafts-and-source-models.md`. The comparison record is `docs/references/drafting_models.md`.

The choice of explicit schedules follows the need to make a procedure exercisable by someone other than its author. Alternatives include a general right-to-comment statement, a fixed software workflow, or a single universal adjudication model. The first leaves response and remedy underspecified; the other two impose technical or institutional commitments beyond this draft's scope. The selected approach fixes inspectable obligations while profiles specify contextual authority and service arrangements.

The United Nations National Quality Assurance Frameworks Manual provides an informative comparison for separating institutional capacity, process quality, and output quality. Here, the operator and authority declaration, observed review behavior, and resulting case record receive distinct assessment evidence. This translation is a programme design choice; it does not assert that an official-statistics framework creates rights or governs the review procedure. ISO's model document and ITU-T drafting guidance inform publication structure rather than the evidential meaning of a finding.

OPEN ISSUE Service periods, independence arrangements, proof of authority, available remedies, costs and admissible disclosure depend on the institution and require a scoped profile. A synthetic procedure cannot establish their validity in a live jurisdiction.

OPEN ISSUE Abuse handling, protection of vulnerable participants, meaningful access under low resources and the burden of keeping case histories require review with affected users before live deployment.

OPEN ISSUE No reduced profile, universal evidential threshold, legal admissibility rule, or machine protocol is adopted. Domain-specific proof standards, representative arrangements, protected disclosure mechanisms, and independently feasible remedies require their own competent review and recorded authority.

1 Documentary reading edition

This volume reproduces project Markdown documents frozen on 30 September 2026. Original classes, maturity declarations and unresolved questions remain applicable. The original files, links and machine-readable resources are retained in the accompanying source archive. Images are represented here by their descriptions; the archive and research-paper figures preserve the available image material. Earlier citations in these historical texts have not been independently reverified for this reproduction.

2 AGENTS

Original source: `AGENTS.md`.
Original source SHA-256: `dbd19a7bbe98f68337274234181a24a747d843a31680b01b6e148d4cb1f6d2f2`.

2.1 AGENTS.md

This file governs AI-assisted and human-assisted vibe development of the Generativity Standards Program.

2.1.1 1. Mission

Contributors and agents shall help develop a rigorous, inspectable, extensible standards family for recording and presenting generativity without collapsing philosophical theory, mathematical semantics, archival practice, and implementation into a single layer.

2.1.2 1A. Required orientation

Before making a substantive change to the standards programme, read `PROGRAMME_BRIEF.md`.
Use it to maintain consistency about:

- why the standards programme exists;
- what is and is not being standardized;
- how governance, standards, manuals, technical reports, and foundation manuscripts relate;
- the intended development lifecycle;
- the distinction between GR theoretical foundations and operational standardization.

If a proposed change conflicts with the programme brief, do not silently overwrite the brief. Record the issue and determine whether the proposal or the brief should be revised.

2.1.3 2. Architectural invariants

2.1.4 2A. Foundation manuscript discipline

The directory `foundation_manuscripts/` is the primary project-local corpus for recovering GR concepts, terminology, notation, and conceptual history.
When a task materially depends on GR theory, agents should consult relevant foundation manuscripts before:

- defining or redefining a GR concept;
- introducing a new ontology class;
- changing terminology or notation;
- claiming compatibility with earlier GR work;
- writing theoretical background for a standard;
- resolving an apparent contradiction between standards documents.

2.1.5 Source hierarchy

Use the following precedence:

1. governance directives for standards-development procedure;
2. published normative standards for conformance;
3. accepted ADRs for repository architecture;
4. foundation manuscripts for interpretation of GR theory;
5. active drafts and planning documents;
6. examples and exploratory notes.

This hierarchy separates **normative authority** from **conceptual source authority**.

2.1.6 Consistency workflow

For a substantive GR concept:

1. identify relevant foundation manuscripts;
2. extract the manuscript's actual terminology, definitions, notation, and scope;
3. note whether later manuscripts revise or qualify earlier ones;
4. compare the proposed standards text with those sources;
5. preserve unresolved differences explicitly;
6. create an ADR when the standards programme intentionally narrows, operationalizes, or departs from a foundation formulation;
7. update `foundation_manuscripts/MANIFEST.md` when a manuscript is newly added or newly recognized as foundational.

2.1.7 Conflict handling

Do not silently reconcile manuscripts.

If two foundation manuscripts differ:

- preserve both formulations;
- record the tension;
- determine whether the difference is historical development, domain-specific variation, or unresolved disagreement;
- add the issue to `docs/planning/open_questions.md` when necessary;
- avoid converting one interpretation into normative text until a decision is recorded.

2.1.8 Historical consistency

Do not rewrite older GR formulations to make them appear consistent with later ones.

The standards programme should preserve conceptual evolution and make revision traceable.

2.1.9 Terminological stability

When a term already has a sustained meaning in foundation manuscripts, prefer that terminology unless a standards-specific operational definition is needed.

If a narrower operational definition is introduced:

- name the scope explicitly;
- state that the standards use is operational;
- avoid implying that the standards definition exhausts the GR concept.

Preserve these distinctions unless a recorded decision explicitly changes them:

2.1.10 2.1 Metamodel vs record ontology

The deep metamodel concerns:

- constraint;
- change;
- structure;
- difference.

The operational record ontology currently contains:

- Entity;
- State;
- Event;
- Process;
- Relation;
- Property.

Do not describe the six record classes as ultimate constituents of reality.

2.1.11 2.2 Formal substrate vs semantic record

Where the underlying metamodel uses weak notions such as a carrier of states or mechanisms, do not identify them one-to-one with richer archival concepts without argument.

Examples:

- formal change is not automatically a recorded Event;
- a mechanism is not automatically a recorded Process;
- a weak metamodel state is not automatically a semantically articulated record State.

2.1.12 2.3 Standard vs manual vs technical report

- **Standard:** normative and testable where possible.
- **Manual:** practical guidance and examples.
- **Technical Report:** theory, comparison, exploration, mathematical development, or material not ready for normativity.

Agents must move material to the appropriate document class rather than forcing everything into a standard.

2.1.13 2B. Multilayer conceptual discipline

Do not treat ontology as sufficient for the Generativity Standards Program.

When relevant, distinguish at least:

- metamodel;
- record ontology;
- epistemic representation;
- normative/ethical assessment;
- jurisprudential/legal status;
- institutional governance;
- political-economy context;
- technical implementation.

Examples:

- “Event E occurred” is an event-level representation.
- “Observer A reports E” is epistemic.
- “E was unjust” is normative.
- “E violated legal duty D” is jurisprudential/legal.
- “Institution I must retain a record of E under procedure P” is institutional/legal.
- “E is serialized as JSON-LD object X” is technical.

Do not collapse these statements into one field or one level of authority.

2.1.14 Epistemic discipline

When developing recording requirements, ask:

- what is observed;
- by whom or what;
- through which method;
- with what evidence;
- under which perspective;
- with what uncertainty;
- whether the statement is direct, inferred, interpreted, attributed, or retrospective;
- whether competing interpretations exist.

2.1.15 Jurisprudential discipline

Do not imply that a technical standard automatically creates legal rights, duties, liability, admissibility, or jurisdiction.

Legal and jurisprudential proposals should identify:

- the legal concept at issue;
- the institutional or jurisdictional context;
- procedural implications;
- unresolved conflicts;
- whether the text is descriptive analysis, a model rule, or a policy proposal.

2.1.16 2C. Standards and policy-proposal separation

The repository supports both:

1. technical/organizational standards; and
2. policy proposals, including proposals for international organizations.

Agents should keep these publication classes distinct.

A standard may define interoperable requirements.

A policy proposal may recommend institutional adoption, pilots, governance arrangements, capacity-building, or legal/policy experimentation.

For international-organization proposals:

- identify the intended organization or class of organizations;
- respect differences in mandate and authority;
- distinguish descriptive facts from recommendations;
- provide more than one institutional option when reasonable;
- identify implementation risks and safeguards;
- avoid presenting one political choice as inherently required by the technical standard.

2.1.17 2D. Publication-class discipline

Always distinguish among **Specifications**, **Standards**, and **International Political / Policy Proposals**.

2.1.18 Specification

Use for technically precise implementable material that has not necessarily passed the full standards-adoption process.

A Specification may contain normative technical language without being a Standard.

2.1.19 Standard

Use only for material formally adopted through the programme's standards-development procedure.

Do not call a draft, implementation model, schema, or experimental technical document a Standard merely because it is detailed.

2.1.20 International Policy / Institutional Proposal

Use for policy, governance, legal, or institutional options addressed to international organizations or other transnational public-interest actors.

Such proposals are recommendatory. They do not define conformance unless they separately reference an adopted Standard.

2.1.21 Cross-class rules

- A Specification may mature into a Standard only through an explicit promotion decision.
- A Standard may be cited by a Policy Proposal.
- A Policy Proposal may identify a new need for standardization, but it should not directly rewrite technical conformance requirements.
- Every publication should declare its class and maturity status near the beginning.
- When uncertain, classify conservatively and record the question in `docs/planning/open_questions.md`.

See `docs/framework/publication_taxonomy.md`.

2.1.22 2E. Standards-first development rule

The default development order is **Standard first, Specification when needed**.

Begin by defining the normative problem:

- purpose;
- scope;
- terminology;
- requirements;
- conformance expectations;
- institutional, epistemic, ethical, and legal constraints.

When a requirement depends on reusable technical infrastructure, create a Specification work item.

Use this pattern:

Standard Working Draft → identified infrastructure need → Specification → pilot → feedback to Standard

Do not interpret "Standards-first" as requiring a Standard to be finalized before specifications begin. They may co-evolve until the Standard reaches adoption.

Prefer to keep implementation details out of the Standard unless they are genuinely necessary for interoperability or conformance.

2.1.23 3. Normative language

Reserve:

- **shall** for requirements;
- **should** for recommendations;
- **may** for permissions;
- **can** for possibility or capability.

Do not use normative language casually in background or planning documents.

2.1.24 4. Traceability

For every substantive design decision:

1. record the issue;
2. identify alternatives;
3. state the selected direction;
4. record rationale;
5. identify affected documents.

Use `decisions/` for Architecture Decision Records (ADRs).

Do not erase superseded reasoning. Mark it as superseded and link to the new decision.

2.1.25 5. Uncertainty discipline

When a concept is not settled, label it explicitly:

- `OPEN`
- `PROVISIONAL`
- `EXPERIMENTAL`
- `DEFERRED`

Do not convert an unresolved philosophical position into a definitive standard clause.

2.1.26 6. Source discipline

Foundation manuscripts are especially important sources for GR-specific content. Agents should ground GR claims in them rather than reconstructing GR from general model knowledge or from memory alone.

When developing from external standards, papers, or attached source material:

- preserve source terminology accurately;
- distinguish source-derived material from new proposals;
- verify external references before incorporating them into normative or scholarly text;
- do not invent compatibility claims.

2.1.27 7. Ontology discipline

When defining Entity, State, Event, Process, Relation, or Property, each definition should eventually include:

- definition;
- admissibility conditions;
- identity criterion;
- temporal behavior;
- allowed relations to other classes;
- required metadata;
- optional metadata;
- examples;
- counterexamples;
- unresolved edge cases.

Relations must remain first-class recordable objects when their own states, properties, or histories matter.

2.1.28 8. Generativity-specific concerns

The standards family should be able to represent, where appropriate:

- generative conditions;
- contingent encounters;
- branches and alternatives;
- recognition and judgment;
- revision and reinterpretation;
- changes in available distinctions;
- changes in the possibility field;
- enabling and constraining relations;
- contribution and relational provenance;
- generativity return;
- uncertainty, absence, restriction, and loss.

Do not assume that final outputs are sufficient evidence of the process that generated them.

2.1.29 9. Category theory

Category theory is a candidate formal semantics, not a mandatory user-facing ontology.
Agents may explore:

- categories;
- spans and cospans;
- profunctors;
- double categories;
- fibrations/indexed categories;
- functorial observables;
- temporal and versioned structures.

Such proposals belong first in `technical_reports/` unless and until they are stable enough to constrain the information model.

2.1.30 10. Editing style

Prefer:

- explicit structural role at the beginning of sections;
- precise terminology;
- low ambiguity;
- restrained claims;
- short normative clauses;
- examples separated from requirements.

Avoid:

- rhetorical overstatement;
- unnecessary equivalence claims;
- vague words such as “everything,” “always,” or “all” unless logically required;
- replacing historical drafts with cleaned-up narratives.

2.1.31 11. Repository workflow

When making a substantive change:

1. update the relevant document;
2. update `CHANGELOG.md`;
3. create or update an ADR if the change affects architecture;
4. preserve unresolved questions in `docs/planning/open_questions.md`;
5. keep file numbering and publication codes stable.

2.1.32 12. Initial priority

The first priority is not GR-110 itself. It is the standards-development infrastructure:

1. Standards Programme Charter;
2. Directives Part 1;
3. Directives Part 2;
4. Technical Committee Charter;
5. New Work Item Proposal template;
6. Public Review and Comment procedure;
7. IP / ethics / conflict-of-interest policy;
8. Maintenance and versioning procedure.

Only after this governance layer is coherent should GR-100 and GR-110 be treated as formal standards projects.

3 CHANGELOG

Original source: `CHANGELOG.md`.
Original source SHA-256: `1ce87ae62317301dab7cc47dc3d66be5a406898c8b695719843a9828a7ec0cb4`.

3.1 Changelog

3.1.1 0.17 — Reproducible synthetic demonstration and application galleries

- Added the fictional River Commons inquiry to the generalized application: 31 records across all six operational roles, five Events, scoped and competing accounts, six retained materials, retrospective recording and a preserved chronology correction across seven project revisions.
- Added an authenticated API seeder with a separate synthetic account, ignored credentials, staged transaction recovery and checks for role coverage, historical contradiction and cut selection independent of recording history.
- Captured ten actual desktop and mobile interface views and documented their narrative, visible filtering and reproduction. Added gallery sections to the programme, infrastructure, generalized application and web application READMEs; parent repositories retain synchronized preview copies for submodule-safe image rendering.
- Expanded the demo's visualized-spacetime walkthrough: promoted event order, two explicitly labeled ontology cuts and subject trajectories into all four README galleries. Reframed both topology captures to retain the actual selected event frontier and contrast trial access with revised access at the same Git revision.
- Verified the populated demonstration, byte-identical material downloads and read-only screenshot workflow against the local application; an isolated reproduction check recovered an interrupted registration and preserved the complete history on rerun. Results are recorded in the application verification guide. The demonstration is informative synthetic material, not a real-world pilot or an assertion of Standard conformance; academia's native protocol and application remain unchanged.

3.1.2 0.16 — Experimental event order and spacetime topology

- Grounded the requested topology-at-event-cut view in actual foundation manuscript passages, preserving the distinction between occurrence, recording revision, event boundary, continuity, and causal-generative attribution. Recorded the selected alternatives and limits in ADR-0011 and the event-spacetime design.
- Added proposed temporal requirements to the current Markdown GR-120/140 Working Drafts, preserving existing IDs and historical TeX editions. Added experimental GR-SPEC-121 and additive references in GR-SPEC-120/130; no Standard adoption is asserted.
- Specified required version 1 event-order and temporal-extent modules under the existing 0.2 protocol, explicit predecessor-closed cuts, scoped trajectory grouping, active topology and retained contradiction/unknown-scope diagnostics. No automatic conversion of existing records or academia's native protocol is implied.
- Defined a read-only, authorized and revision-pinned spacetime GET/POST binding with bounded selections and anti-forgery protection. Module changes retain the existing accountable Git transaction path; recording order does not become target chronology.
- Implemented the common projection in package 0.3.0 and the generalized application's Spacetime and Time & trajectory controls. Styled the native file chooser and corrected draft, retry and concurrent-qualification preservation issues found during browser review.
- Verified 178 non-browser tests and seven browser tests across focused runs, including a final topology-overlap correction. Refreshed the local preview on 2026-09-27 and confirmed both existing project heads unchanged; see the implementation review. Academia's source and native protocol remain unchanged.
- Recorded Q-45–48 for alternative chronology accounts, interval semantics, subject continuity/effect modeling and participant comprehension. Verification results belong in the separate implementation review; these design changes do not by themselves establish successful checks, factual warrant or whole-programme conformance.

3.1.3 0.15 — Hosted source repository configuration

- Configured the four user-supplied GitHub remotes, replaced local submodule URLs with hosted URLs, and updated repository READMEs and the recursive-clone/development guide.
- Selected the user's Windows SSH identity in repository-local configuration; private key contents remain outside source control. Existing host verification remains enabled.
- Integrated academia's existing remote contributor-attribution commit into the migrated MIT repository, preserving both development histories and the earlier frozen source snapshots.
- Retained the application-to-infrastructure-to-programme publication order and separated source publication from private runtime records. Repository governance, CI and release policies remain open under Q-44.
- Published all four `main` branches and verified their remote references, nested commit pointers and a fresh GitHub recursive clone with 372 matching source files. See the hosted publication record.

3.1.4 0.14 — Independent repositories, nested submodules and MIT licensing

- Established the programme root, infrastructure and two applications as four independently committed Git repositories. Infrastructure pins both application repositories as submodules; the programme pins infrastructure. The enclosing repository's index and references remain unchanged.
- Preserved academia's original source history as actual ancestry and retained its original history bundle. New relocation, documentation and licensing changes are subsequent commits; private record repositories remain outside source history.
- Added boundary-local ignore rules, byte-preserving attributes, comprehensive repository READMEs, a submodule development/publication guide and a read-only structure checker. Local relative URLs support the present workspace; hosted remotes remain deferred at the user's direction.
- Applied the requested MIT grant to project-controlled content, added contributor attribution at each repository boundary and in distributable Python packages, aligned package metadata, and retained third-party and historical notices with explicit scope notes.
- Recorded ADR-0010, Q-44 and independent repository/recursive-clone verification. No application record schema, record bytes, account data or accepted record-history heads were changed.

3.1.5 0.13 — Application infrastructure consolidation

- Accepted ADR-0009 and established common packages plus independently runnable generalized and academia applications under `applicative_infrastructure/`; programme publications remain canonical at the root.
- Relocated the generalized application and record-protocol package, extracted the unchanged Git store into its own tested package, and introduced explicit runtime paths and separate reproducible Python environments.
- Imported academia source with its verified complete Git history bundle, per-file provenance, original README and licensing notices. Preserved native GRRP semantics and kept the original checkout untouched; semantic adapters remain deferred.
- Preserved the existing four accounts, three project repositories, record files and academia key material. Created private pre-migration backups, verified SQLite data and record inventories, and retained the generalized legacy project format without automatic conversion.
- Added setup and launch tools for separate ports 8000/8001, updated active documentation links and recorded migration verification, independent audit and remaining deployment questions. Old generalized source directories are retired into ignored operator backups after verification.
- Verified 128 generalized/common tests including browser journeys; 208 academia Python tests with one platform-specific skip; 91 academia TypeScript tests; production build; isolated deep-path record creation; and both live entry points. Inherited academia npm dependency advisories are recorded for separate maintenance.

3.1.6 0.12 — Experimental record graphs, atomic transactions and retained modules

- Reviewed the current GR manuscripts and the earlier academia application's actual source. Recorded current-manuscript precedence, conceptual mappings, implementation gaps and the separate academia migration boundary; no academia source was copied or modified.
- Added ADR-0008 and a detailed design separating semantic record graphs, Git revision history and local display state. Relations remain records with role-indexed incidences; repeated, unary, cyclic, parallel and higher-order participation is supported within the experimental profile.
- Developed bounded GR-120/130/140/160 Working Drafts for the identified requirements, preserving existing outlines and the coordinated nine-document TeX edition 0.3. Added implementable experimental GR-SPEC-120/130; no Standard adoption or independent interoperability certification is asserted.
- Added an application-independent Python protocol package, packaged JSON Schema, fixtures and CLI validation. Added overlapping roles, versioned modules, whole-candidate validation, RFC 8785 request digests, explicit legacy migration and preservation of opaque optional content.
- Implemented atomic Git transactions for records, modules, receipts and verified file bytes; durable retry recognition, conditional publication, pinned historical reads, bounded batch loading, supported-material ZIP exports and streamed files/history bundles.
- Added interactive graph/list views, visual selection and connection, multi-participant Relation forms, atomic connected-record creation, conditional notes/files/history panels, local layout, visible filters, historical project views and draft-preserving conflict review.
- Extended protocol, real-Git, API and browser checks. Recorded the current limits and unresolved cross-project references, governed erasure, independent custody, accessibility evaluation and academia identity/record preservation work.

3.1.7 0.11 — Experimental Git-backed web workspace

- Added a runnable Flask/Waitress web application with registration, login, logout, private projects and a responsive recording interface.
- Added one bare Git repository per project, structured JSON records, attributed revisions with reasons, historical views, current-snapshot exports and full-history bundles. Compare-and-swap publication prevents silent concurrent overwrites.
- Kept accounts, password hashes, expiring sessions and project authorization in SQLite outside project history; added CSRF, browser-security headers, authentication rate limits and input validation.
- Added API, real-Git and browser verification, reproducible runtime dependencies and local operation instructions.
- Recorded the implementation decision in ADR-0007, exact draft traceability and explicit feature/conformance limits in the application design, and Q-34–37 for collaboration, retention/recovery, richer epistemics and actual contestation. No Standard adoption or whole-practice conformance is asserted.

3.1.8 0.10 — Substantive validation and traced Working Draft 0.3

- Preserved the 0.2 source, tool and review baseline with hashes and copied its generated PDFs/reports before revision.
- Reviewed all 753 baseline requirement identifiers through 116 explicit topical groups, with actual foundation-manuscript passages, operational narrowing, findings and unresolved questions. Added a reproducible per-ID review matrix without treating editorial coverage as conformance.
- Added new P0/v2 and P1/v2 fixtures while preserving the original examples. Executed 18 ballot arithmetic/input cases; all matched the authored expectations. Added 208 P1 assessment rows that separate 54 selected documentary components from 154 whole-requirement coverage results.
- Prepared coordinated Working Draft 0.3: clarified invalid/unresolved ballot accounting, general versus conditional metamodel assessment, effect modality versus dispute dispo-

sition, and GR-210's vocabulary dependency. Added conditional recirculation requirement R110-112 with source rationale, semantic information and a discriminating assessment route.
- Retained the unresolved P1 retention arrangement and unperformed institutional actions explicitly; corrected a premature failure classification when its decision trigger was not established. Added readiness/burden evidence gaps and future measurement design; no participant effort, real procedural success or adoption is invented.
- Added ADR-0006, revision regression cases, Q-31–33, validation tooling, baseline-selectable change comparison, archive-integrity checks, and current publication/navigation updates.

3.1.9 0.9 — Expanded formal Working Drafts and ISO/IEEE/UN source models

- Expanded all nine governance and GR-100/110/200/210 documents to coordinated Working Draft 0.2, with detailed procedures, definitions, application conditions, semantic schedules, assessment obligations and worked examples.
- Added formal Foreword/Introduction, Scope, Normative references, numbered Terms and definitions, decimal clause hierarchy, captioned tables, labelled normative/informative annexes and bibliographies using a shared restrained TeX layout.
- Compared verified ISO publication models, accessible IEEE rules, ITU drafting guidance and UN statistical quality guidance. Recorded actual source access, unsuccessful downloads, and the successfully cached UN NQAF manual without importing external institutional authority or claiming compatibility.
- Preserved the complete 0.1 source/build-tool snapshot with hashes, retained all original requirement identifiers and added a reproducible text change register. Updated dated technical dependencies to 0.2; corrected the ethics acknowledgement/deadline ambiguity through explicit revision.
- Expanded independent-review capacity gates, ethics case handling and reconsideration, information/evidence methods, generative trajectory recording, and correction/maintenance procedures. Internal conduct criteria and proportionality remain proposed choices.
- Extended artifact checks for formal structure, local cross-references, archive integrity and historical ID retention. Added a new review record, ADR-0005 and Q-27–30; preserved earlier review and fixture scope as historical evidence.
- Updated publication navigation, development status, source register and project index. No adoption, appointment, licensing grant, real pilot success or international partnership is represented by these changes.

3.1.10 0.8 — Initial substantive working drafts and TeX publication package

- Developed five governance Working Drafts: Programme Charter, Directives Parts 1 and 2, GR/TC 1 Charter, and ethics/conflict/contribution-rights policy. They cover founding authority, appointments, review, consensus/ballots, appeals, maintenance, rights, records and separate publication-class routes.
- Developed preparatory GR-100, GR-110, GR-200 and GR-210 texts with stable requirement identifiers, bounded conformance subjects, source rationale, assessment methods and unresolved questions. No governance, committee, work item, Specification or Standard is represented as adopted by these edits.
- Separated claimed occurrence/modality from epistemic mode; required material maintenance/loss recording; made GR-200 package dependencies explicit; distinguished partial documentary assessment from observed institutional performance.
- Added shared TeX presentation, a nine-document manifest, WSL/LuaLaTeX build tooling with hashes and reports, PDF requirement-coverage checks and publication navigation. Generated build artifacts are ignored in source control.
- Added synthetic governance and contested-decision fixtures, an unsigned founding-agreement template, a requirement-assessment template, and expanded NWIP/comment/disposition templates without inventing operational evidence or signatures.
- Added Proposed ADR-0004, cross-document review evidence and Q-21–26. Preserved earlier Markdown outlines as historical planning material linked to the developed drafts.

- Updated programme navigation, Programme Brief development status and the project index. Governance adoption, actual appointments and rights terms, domain review, accessibility targets and live pilot evidence remain open.

3.1.11 0.7 — Comprehensive epistemic and practical development planning

- Reframed the programme brief and README around the confirmed motivation: symbolic crisis, warranted recognition, contestation, revision and practical action.
- Added a PROVISIONAL comprehensive plan connecting objectives, the existing publication portfolio, substantive domain work, dependencies, conformance subjects, milestone evidence and an immediate work queue.
- Added a comparative study of ISO/IEC, IEEE and WTO standards-development approaches, with official sources, access/edition limits and explicit local adaptation proposals.
- Added a cross-domain programme for epistemology, archives, jurisprudence, ethics, institutional governance, public policy, political economy and implementation, preserving their different sources of authority.
- Added a draft GR/NWIP-001, governance/pilot planning, protocol/Specification planning, and a verified candidate technical standards landscape. These do not adopt Standards or approve work items.
- Clarified that protocols describe behavior within Specifications or Standards and are not a separate publication authority class.
- Indexed the seven local foundation manuscripts and added source-to-operational-proposal traceability with unresolved terminology, version and formal-scope differences preserved.
- Added Proposed ADR-0003 with alternatives and rationale; retained accepted ADR-0002 as the governing Standards-first decision.
- Marked the earlier preliminary plan as historical and preserved its text, identifying its superseded specification-first wording.
- Added prioritized open questions and updated publication taxonomy, Specification-track guidance and project navigation.
- Added explicit publication-class and non-adoption labels to the existing standards-track and Specification placeholders without changing their identifiers.

3.1.12 0.6 — Standards-first, specifications-on-demand

- Added ADR-0002 establishing Standards as the default starting point.
- Clarified that Specifications are created when Standard requirements reveal reusable technical or infrastructure needs.
- Added the co-evolution loop: Standard WD → Specification → Pilot → Standard revision.
- Updated AGENTS, publication taxonomy, programme brief, preliminary plan, and README.

3.1.13 0.5 — Publication-class separation

- Added a formal taxonomy distinguishing Specifications, Standards, and International Political / Policy Proposals.
- Added `docs/framework/publication_taxonomy.md`.
- Added a new `specifications/` track with preliminary GR-SPEC placeholders.
- Added GR-IPP / GR-IIP identifiers for international policy and institutional proposals.
- Updated `AGENTS.md`, `PROGRAMME_BRIEF.md`, README, planning, open questions, and policy-proposal guidance.
- Clarified that technical precision, standards adoption, and political/institutional recommendation are different forms of authority.

3.1.14 0.4 — Multilayer architecture and policy-proposal track

- Expanded the programme beyond ontology to include epistemics, normativity, jurisprudence, governance, political economy, and implementation.
- Added `docs/framework/multilayer_architecture.md`.

- Added epistemic and jurisprudential background documents.
- Added provisional GR-200/210 epistemic standards, GR-300/310 jurisprudential standards, and GR-400 governance standard.
- Added a separate `policy_proposals/` publication track with an international-organizations folder and policy-brief template.
- Updated `PROGRAMME_BRIEF.md`, `AGENTS.md`, planning, README, and open questions to maintain the distinction between standards and policy proposals.

3.1.15 0.3 — Programme-level Why / What / How brief

- Added root-level `PROGRAMME_BRIEF.md` as the first-read orientation for contributors and reviewers.
- Added explicit Why, What, and How sections covering historical motivation, AI-era context, GR foundations, standards scope, document family, development lifecycle, source discipline, traceability, and pilot-driven implementation.
- Updated `README.md` to point new readers to the programme brief.
- Updated `AGENTS.md` so agents must consult the programme brief before substantive development.
- Linked the preliminary plan to the new brief.

3.1.16 0.2 — Foundation corpus and contextual background

- Added `foundation_manuscripts/` with a source-corpus README and manifest template.
- Added `docs/background/GR_background.md`.
- Added `docs/background/era_background.md`.
- Expanded `AGENTS.md` with foundation-manuscript consultation, source hierarchy, conflict handling, historical consistency, and terminology rules.
- Updated preliminary planning and open questions for manuscript-to-standard traceability.

3.1.17 0.1 — Initial project scaffold

- Created governance, standards, manual, technical-report, template, schema, example, and decision directories.
- Added preliminary background and planning documents.
- Added `AGENTS.md` for AI-assisted vibe development.
- Added provisional publication family and lifecycle.
- Added starter templates for new work items, comments, and architecture decisions.

4 CONTRIBUTING

Original source: `CONTRIBUTING.md`.
Original source SHA-256: `c86bf381512f428d92b523d034ca39f2ca5b1b7add2cc23546c21ffc39457d01`.

4.1 Contributing

This repository is in early standards-design mode.
Before proposing normative text:

1. identify the target publication;
2. check whether the issue is conceptual, procedural, normative, or implementation-specific;
3. add unresolved matters to `docs/planning/open_questions.md`;
4. create an ADR for architecture-level decisions;
5. preserve dissenting or superseded reasoning rather than rewriting history.

Public contribution and consensus procedures will be formalized in Directives Part 1.

4.1.1 Contribution terms and attribution

This repository's project-authored material is offered under the MIT licence, within the scope described in LICENSE.md. By intentionally submitting original work for incorporation, you offer that contribution under those terms while retaining your copyright. State your authority to contribute material on behalf of another rights holder, and identify third-party material and its licence separately. Submission for discussion alone is not an assignment of ownership or permission to redistribute material outside the terms you state.

Include your preferred name or organization and a brief contribution description in CONTRIBUTORS.md when your contribution is incorporated. Existing notices and contributors' attribution are preserved. AI tools can be acknowledged as tools; they are not added as copyright holders.

Application changes belong in the corresponding application repository; shared packages and launch tools belong in `applicative_infrastructure`. Each repository carries its own licence, contributor list and contribution guidance. The programme's draft ethics and IP policy remains a separate governance work item; the MIT grant does not imply its formal adoption.

5 CONTRIBUTORS

Original source: `CONTRIBUTORS.md`.

Original source SHA-256: `804303cad8053868d5c19e769a6ba55b24e583d418730bce11eca5c0c65fdee8`.

5.1 Contributors

Copyright (c) 2026 the contributors listed in this file, for their respective contributions.

Contributor	Recorded contribution
Wanhong Huang	GR foundation manuscripts, programme conception and direction, standards and application design.

Application contributors are also credited in the corresponding submodule contributor files. The foundation manuscript manifest records author attribution for the source corpus.

The MIT licence in LICENSE refers to this list. Contributors retain the rights in their respective contributions; this list does not assign ownership of every file to every person or organization listed.

Add a contributor's chosen name or organization and a brief contribution description when their work is incorporated. Preserve existing attribution. Corrections can be proposed through the same review process as other repository changes.

AI tools have assisted drafting, implementation, and review. They are development tools and are not listed as copyright holders. Third-party components retain their own author and licence notices.

6 LICENSE

Original source: `LICENSE.md`.

Original source SHA-256: `2a99e50c99ca72263b1fce18765149614ed59f5544b836e8acea21a5d39010d0`.

6.1 Licensing scope

Effective date: 2026-09-22. **Licence:** MIT. **Authority:** explicit project-owner instruction to license the four project repositories under MIT and credit their contributors.

The MIT licence applies to the project-authored materials distributed in this repository. The copyright notice credits all contributors listed in CONTRIBUTORS.md, for their respective contributions. The licence text follows the Open Source Initiative MIT text.

Material	Current terms
Programme prose, governance drafts, standards working drafts, specifications, manuals, technical reports and planning documents	MIT for project-authored content. A licence does not change a publication's maturity, adoption or authority.
Schemas, code, examples, validation fixtures and development tools	MIT for project-authored content.
Project-authored foundation manuscripts and associated research material	MIT is an additional grant for the project-authored content in the copies distributed here. Existing document notices remain preserved as part of their publication history.
Application infrastructure and its application submodules	Each repository has its own MIT `LICENSE`, `CONTRIBUTORS.md` and scope notice.
External standards, quotations, reproduced figures, third-party components and other externally authored material	Their respective rights and notices continue to apply; the project does not relicense them.
Private runtime records and material supplied by application users	Not covered by this repository licence merely because the software stores or processes them.

The additional MIT grant for project-authored material does not remove attribution or revoke previously offered permissions. Historical PDFs, archived publications and preserved Git history are not rewritten to conceal earlier terms. When redistributing a project-authored PDF under the additional MIT grant, include `LICENSE`, `CONTRIBUTORS.md` and this scope notice with it so that the additional permission is available alongside the embedded historical notice. Externally authored material within such a document remains subject to its own terms.

This licensing decision implements the owner's repository instruction. It does not adopt the programme's draft governance instruments, establish a new legal entity, assign contributors' copyrights to a maintainer, or license the names and marks of referenced organizations. Future contributions follow the terms in CONTRIBUTING.md; permission for third-party contributions is not inferred from repository access alone.

7 PROGRAMME BRIEF

Original source: `PROGRAMME_BRIEF.md`.
Original source SHA-256: `2b591eab10c23cbdacffa2cab5e525f0af7766446f207680ff0d2f7cb847d3a8`.

7.1 Programme Brief

7.1.1 Why, What, and How We Develop the Generativity Standards

Status: Preliminary programme brief
Version: 0.5
Document class: Informative programme-level background

7.1.2 1. Purpose of this brief

This document gives a concise orientation to the Generativity Standards Program.
It answers three questions:

1. **Why** is a standards programme needed?
2. **What** is being standardized?
3. **How** will the standards be developed, reviewed, published, and maintained?

It is intended to be the first document read by new contributors, reviewers, collaborating organizations, and AI agents before they enter the more detailed governance, theoretical, or technical documents.

7.1.3 2. Why

7.1.4 2.0 Symbolic crisis, recognition, and practical action

The programme's organizing motivation is the symbolic crisis: instability in the connections among symbolic representations, their referents, institutional classifications, and practical trust. GRE Chapter 1, section 1.14, develops this diagnosis. It includes fabricated representations as well as sincere but outdated, partial, or inadequate categories. It does not imply that every representation has become unreliable.

The programme develops epistemic and practical infrastructure through which people and institutions can recognize reality, investigate factual claims, examine their grounds, contest interpretations, revise judgments and action, and preserve the trajectories through which knowledge and future possibilities develop. Archival loss and AI provenance are important components of this broader problem.

Reality, manifestation, representation, evidential warrant, institutional acceptance, and normative legitimacy remain distinguishable. Reality can precede recognition; records and classifications can also enter social relations and change what happens later. Technical conformance, authentic provenance, or institutional acceptance does not by itself establish that a substantive claim is true.

The infrastructure consequently concerns both what changes and how it becomes knowable and actionable. It also concerns who can produce evidence, challenge a classification, obtain review, and participate in shaping the conditions of future generation.

Source interpretation and proposed operational translations are recorded in the foundation traceability map. The current development proposal is the comprehensive plan.

7.1.5 2.1 The historical problem

Contemporary knowledge production increasingly leaves behind abundant outputs while preserving much less information about how those outputs became possible.

A paper may survive while the following disappear:

- the encounters that redirected the inquiry;
- the relations that enabled the work;

- the alternatives that were considered and abandoned;
- the changes in judgment that occurred over time;
- the conditions under which an idea became recognizable;
- the capacities that were created, weakened, or lost;
- the role of human, institutional, computational, and environmental contributors.

A final artifact therefore often preserves substantially less than the generative history from which it emerged.

7.1.6 2.2 The AI-era problem

AI-assisted work intensifies this problem.

A simple statement such as “AI was used” does not reveal:

- what role the AI system played;
- which materials were supplied to it;
- which outputs were selected or rejected;
- how human judgment interacted with machine-generated material;
- which later ideas depended on earlier AI-mediated encounters;
- how the trajectory changed through repeated interaction.

As automated and agentic systems become increasingly involved in research, education, policy, design, and administration, conventional provenance records may be too coarse to preserve the relevant history of generation.

7.1.7 2.3 The generativity problem

The programme is motivated by a broader GR concern: the history of a process includes more than its manifested outputs.

Of particular interest are changes in:

- available distinctions;
- relational structures;
- constraints;
- possible continuations;
- interpretive frames;
- generative capacities.

A process may produce a modest output while opening an important future trajectory. Another may produce a highly valued output while exhausting the conditions that made future generation possible.

For this reason, output history and generativity history should not be treated as equivalent.

7.1.8 2.4 The archival problem

Future observers may need to do more than retrieve an artifact.

They may need to ask:

- How did this become possible?
- Which relations mattered?
- What was known or believed at the time?
- Which alternatives were visible then?
- Which later interpretations rewrote the earlier history?
- Which possibilities remained unrealized?
- Which records are absent, restricted, lost, or destroyed?

A durable standards programme can help preserve enough structured information for later reconstruction, reinterpretation, contestation, and continuation.

7.1.9 3. What

7.1.10 3.1 Object of standardization

The programme develops standards for the recording, preservation, exchange, presentation, assessment, contestation, and revision of **generativity-related records**, and for their accountable use in inquiry and practical action.

The programme does not attempt to standardize a complete metaphysics of reality.

It develops an operational framework through which generative histories and the grounds of claims about them can be recorded in a consistent, inspectable, and interoperable form. It distinguishes changes in the situation under inquiry, changes in evidence and judgment, and changes in categories or methods of recognition.

7.1.11 3.2 Conceptual architecture

Within the wider multilayer architecture, a foundational distinction separates the following two levels.

7.1.12 Deep metamodel

The GR background emphasizes four highly abstract dimensions:

- Constraint
- Change
- Structure
- Difference

These belong to the foundational theoretical layer.

7.1.13 Operational record ontology

The standards programme currently explores six operational record classes:

- Entity
- State
- Event
- Process
- Relation
- Property

These are candidate standardized forms for recording.
They are not assumed to be ultimate ontological kinds.

7.1.14 3.3 What a generativity record may need to preserve

Depending on the profile and use case, a record may include:

- entities and participants;
- states and state changes;
- events and processes;
- relations;
- properties and observations;
- temporal information;
- provenance;
- perspective;
- epistemic status and uncertainty;
- generative conditions;
- contingent encounters;
- decisions and judgments;
- alternatives and unrealized branches;
- enabling and constraining relations;

- later reinterpretations;
- changes in available distinctions;
- changes in future possibilities;
- generativity return;
- access, privacy, restriction, and retention metadata.

7.1.15 3.4 Standards family

The programme is intended to produce a family of coordinated documents rather than one monolithic standard.

The provisional family includes:

- **GR-100 — Foundations and Vocabulary**
- **GR-110 — Generativity Recording Requirements**
- **GR-120 — Generativity Information Model**
- **GR-130 — Generativity Interchange Specification**
- **GR-140 — Generativity Presentation Requirements**
- **GR-150 — Conformance and Validation**
- **GR-160 — Preservation, Privacy, Access, and Retention**
- **GR-200 — Epistemic Recording Framework**
- **GR-210 — Evidence, Interpretation, and Contestation**
- **GR-300 — Jurisprudential Interface**
- **GR-310 — Rights, Duties, and Procedural Profiles**
- **GR-400 — Governance and Institutional Use**

These identifiers currently name preliminary standards-track projects, not adopted Standards. Their proposed coordinated scopes and dependencies appear in the comprehensive plan. Existing GR-120/130 project titles are retained; their requirements are distinguished from the implementable details in GR-SPEC-120/130. GR-SPEC-200 supports epistemic representation where draft requirements establish the need.

Supporting publications include:

- manuals;
- implementation guides;
- technical reports;
- schemas;
- validation artifacts;
- worked examples.

7.1.16 3.5 Normative and non-normative layers

The programme deliberately separates:

- **normative standards**, which define requirements, recommendations, permissions, and conformance;
- **manuals**, which provide practical guidance;
- **technical reports**, which develop theory, mathematical semantics, comparison, and experimental ideas;
- **foundation manuscripts**, which preserve GR conceptual history and source material.

This separation allows the standards to remain operational without losing contact with their theoretical foundations.

7.1.17 3A. Beyond ontology: epistemic, normative, legal, and institutional dimensions

The programme does not assume that a sufficiently detailed ontology alone can produce an adequate generativity record.

A mature framework must also specify how records are:

- known;
- evidenced;
- interpreted;
- contested;
- normatively evaluated;
- legally recognized;
- institutionally used;
- politically and economically situated.

Accordingly, the programme now treats ontology, epistemics, normativity, jurisprudence, governance, political economy, and technical implementation as interacting but distinguishable layers.

See `docs/framework/multilayer_architecture.md`.

7.1.18 3B. Dual outputs: standards and policy proposals

The programme may produce two coordinated families of public outputs:

1. **standards and technical infrastructure**, concerned with interoperable requirements, models, profiles, and conformance; and
2. **policy and institutional proposals**, concerned with how international organizations and other institutions may pilot, adopt, govern, or build capacity around these infrastructures.

Policy proposals are not themselves standards, and standards do not by themselves settle political or legal choices.

7.1.19 3C. Publication classes

The programme distinguishes three principal public-output families:

1. **Specifications** — technically precise and implementable documents that may be experimental, candidate, or stable without yet being formal Standards.
2. **Standards** — formally adopted normative publications with programme-level conformance authority.
3. **International Political / Policy Proposals** — recommendatory institutional or policy publications directed to international organizations or other transnational actors.

This distinction prevents technical precision, formal standardization, and political/institutional recommendation from being treated as the same kind of authority.

See `docs/framework/publication_taxonomy.md`.

7.1.20 4. How

7.1.21 Protocols within publication classes

A protocol describes behavior: participants, interactions, states, transitions, outcomes and failures. Protocols are technical subjects documented in Specifications or, after formal adoption, Standards. They do not create a separate publication authority class. Institutional review procedures and machine-to-machine protocols can support the same purpose while requiring different implementation and assessment methods.

7.1.22 Comparative and cross-domain development

The programme studies ISO/IEC and IEEE standards-development approaches, ITU technical publication practice, and relevant UN-system quality and institutional frameworks to inform its own proportionate procedures. The comparative study distinguishes source practices, proposed adaptations and unresolved governance choices. The drafting-model study records verified ISO, IEEE, ITU and UN sources, their different functions, and access limitations. This work does not imply affiliation, accreditation or compliance with those organizations' procedures.

The cross-domain programme connects the mission to epistemology, archival practice, jurisprudence, ethics, institutional governance, public policy, political economy and implementation. These domains contribute substantive work and review throughout development; they are not reduced to metadata fields or a final compliance check.

7.1.23 4A. Standards-first development

The default programme logic begins with the Standard.

The Standard identifies what a conforming practice should achieve. If those requirements create a need for shared technical infrastructure, the programme develops one or more Specifications.

This yields a recurring development loop:

Standard Working Draft → Specification need → Specification → pilot → revision of the Standard

The Standard and Specification may therefore co-evolve before publication.

7.1.24 4.1 Develop the standards programme before the standards

The programme first establishes the rules by which standards are created.

The initial governance layer includes:

- Standards Programme Charter;
- Directives Part 1 — Procedures for Development and Maintenance;
- Directives Part 2 — Structure and Drafting Rules;
- Technical Committee Charter;
- public review procedure;
- consensus and decision policy;
- conflict-of-interest and ethics policy;
- intellectual property policy;
- maintenance and versioning procedure;
- records and transparency policy.

This creates a defined process through which later GR standards can claim procedural consistency.

Validation-revised preparatory version 0.3 texts for this governance layer and GR-100/110/200/210 are available in the working-draft package. Versions 0.1 and 0.2 remain archived. The substantive validation cycle covers the 753 baseline identifiers through explicit review groups, new synthetic P0/P1 fixtures, bounded component assessments and executed ballot arithmetic. It identifies supported corrections without establishing governance adoption, institutional performance or legal authority. Readiness and burden evidence remains necessary before those claims.

7.1.25 4.2 Development lifecycle

The provisional standards lifecycle is:

Stage	Status
00	Preliminary
10	Proposal
20	Working Draft
30	Committee Draft
40	Public Review Draft
50	Final Approval Draft
60	Published Standard
90	Review / Revision / Withdrawal

The process is intended to remain lighter than ISO while preserving comparable principles of traceability, review, versioning, and maintenance.

7.1.26 4.3 Evidence and source discipline

The programme distinguishes several kinds of authority.

- Governance directives govern the standards-development process.
- Published standards govern conformance.
- Accepted ADRs govern project architecture.
- Foundation manuscripts provide source authority for GR concepts.
- Working drafts and planning documents remain provisional.

Agents and contributors should not silently convert a theoretical statement into a normative requirement.

Where a standard intentionally narrows or operationalizes a broader GR concept, the divergence should be explicit and traceable.

7.1.27 4.4 Foundation manuscript workflow

The folder `foundation_manuscripts/` serves as the project-local GR source corpus.

When relevant manuscripts are added, contributors should:

1. index them in `foundation_manuscripts/MANIFEST.md`;
2. identify important concepts and notation;
3. record historical changes and tensions;
4. map relevant ideas to candidate standards clauses;
5. preserve disagreements and revisions;
6. create an ADR when a standards-specific interpretation materially departs from the source corpus.

7.1.28 4.5 Issue and decision traceability

Substantive changes should leave a visible record.

The preferred pattern is:

$$\text{Issue} \rightarrow \text{Alternatives} \rightarrow \text{Decision} \rightarrow \text{Rationale} \rightarrow \text{Affected documents}$$

Architecture-level decisions are recorded as ADRs.

Public-review comments should likewise record:

$$\text{Comment} \rightarrow \text{Disposition} \rightarrow \text{Rationale} \rightarrow \text{Resulting change}$$

The development process should itself exemplify the kind of generative traceability the standards seek to support.

7.1.29 4.6 Incremental implementation

The programme should avoid attempting to solve the entire conceptual problem before implementation begins.

A preferred development strategy is:

1. establish governance;
2. stabilize core vocabulary;
3. define a minimal coordinated recording, epistemic, presentation, protection and review profile;
4. test it first on bounded examples and then on appropriately governed real use cases;
5. develop the information model;
6. build exchange schemas;
7. test independent implementations;
8. revise through public and technical review;
9. refine conformance using assessment methods drafted alongside the requirements;
10. maintain the standards as the field evolves.

7.1.30 4.7 Pilot-driven development

Candidate pilots include:

- individual research;
- AI-assisted manuscript development;
- collaborative research;
- institutional decision processes;
- historical reconstruction from incomplete archives.

Pilots are used to test whether the standards are sufficiently expressive without becoming impractically burdensome.

The current planning proposal begins with the programme's own documented decision history and a synthetic contested institutional case. A complete pilot cycle includes evidence, interpretation, challenge, reasoned response or revision, protection, presentation and practical consequences. Real external pilots depend on actual institutional participation and appropriate access arrangements. No participation is presumed.

The comprehensive development plan sets out the proposed portfolio, milestone evidence, dependencies and immediate work queue. The earlier preliminary plan remains available as a historical draft. Planning does not substitute for governance adoption or work-item approval.

7.1.31 5. Design principles

The programme currently follows these principles:

- preserve trajectory, not only output;
- distinguish occurrence from interpretation;
- distinguish present validity from historical existence;
- treat relations as first-class when their own histories matter;
- preserve uncertainty rather than forcing premature certainty;
- preserve alternatives without implying equal feasibility;
- separate preservation from publicity;
- expose mediation in reconstructed presentations;
- distinguish evidence integrity from the warrant of a claim;
- support meaningful contestation and revision of action as well as correction of records;
- examine how recording and recognition affect participation and future possibilities;
- support future reinterpretation;
- maintain compatibility with GR foundations without turning philosophical theory directly into compliance language;
- allow standards to evolve while preserving their own development history.

7.1.32 6. Intended outcome

The long-term goal is a standards infrastructure that supports warranted, revisable recognition and practical action while enabling future actors to recover more than a final artifact.

A successful record should help a later observer understand, within the limits of available evidence:

- what changed;
- what relations mattered;
- what was recognized at the time;
- what alternatives were available;
- how judgments evolved;
- how the field of future possibilities changed;
- and how the recorded process may be continued or reinterpreted.

The programme therefore aims at three linked capacities:

$$\text{future re-recognizability} + \text{reinterpretability} + \text{regenerability}.$$

These capacities provide the broad orientation for the standards family while remaining subject to refinement through the formal standards-development process.

8 README

Original source: `README.md`.

8.1 Generativity Standards Program

Status: Preliminary standards programme and experimental applications; no adopted technical Standards.

Start here: Programme Brief ·Development plan ·Application setup

Source repository: Generativity-Epistemic-Infrastructure

The Generativity Standards Program develops epistemic and practical infrastructure for recognizing, recording, examining, contesting and revising claims about reality and its generative trajectories. Its concern includes the conditions, encounters, relations, judgments, alternatives and changes in possibility through which an outcome becomes possible.

The programme responds to **symbolic crisis**: instability in the connections among representations, their referents, institutional classifications and practical trust. A traceable record can help people inspect a claim and its grounds. Provenance, technical validity and institutional acceptance remain distinct from the truth of that claim.

This repository brings together the theoretical source corpus, development procedures, working drafts, specifications, review evidence and an application infrastructure maintained through nested Git submodules.

8.1.1 What is being developed

Area	Current work
Standards-development governance	Charter, directives, committee arrangements, ethics and contribution rights, review, maintenance and decision procedures
Recording and presentation	Operational records, relations, generative trajectories, provenance, uncertainty, revision, protection and presentation
Epistemic and institutional practice	Evidence, interpretation, contestation, judgment, jurisprudential interfaces, governance and policy options
Technical infrastructure	Experimental information model, transaction protocol, Git storage, modules, schemas and executable verification
Applications	A generalized visual record workspace and an independent academia application

The conceptual architecture distinguishes the deep metamodel of **constraint, change, structure and difference** from the operational record roles **Entity, State, Event, Process, Relation and Property**. These roles support recording; they do not exhaust GR theory or describe ultimate constituents of reality. Ontological, epistemic, normative, legal, institutional, political-economy and implementation concerns retain their different kinds of authority. See the multilayer architecture and foundation traceability map.

8.1.2 Publication status and reading guide

The publication package contains nine developed TeX working drafts at version 0.3, with prior editions retained. Governance adoption, actual appointments and formal technical work-item approval remain pending. The review dossier records substantive findings, synthetic assessments and remaining evidence gaps.

Publication or source	Read it for
Programme Brief	Motivation, scope, authority and development process
Foundation manuscripts	GR terminology, conceptual history and source interpretation
Governance	Proposed procedures for developing and maintaining the programme
Working-draft package	Charter, Directives, GR/TC 1 charter, ethics/IP, GR-100/110/200/210
Standards-track projects	Draft requirements, including GR-120/130/140/160 and further planned projects
Specifications	Implementable experimental models and protocols, particularly GR-SPEC-120/121/130
Manuals and technical reports	Practical guidance, theory, comparison and experimental semantics
Policy proposals	Recommendatory institutional and public-policy options
Planning and open questions	Dependencies, priorities and unresolved decisions
ADRs, reviews and changelog	Decisions, evidence and development history

A **Specification** can contain precise technical requirements without being an adopted **Standard**. A **Policy / Institutional Proposal** recommends choices and does not itself define technical conformance. The publication taxonomy explains these boundaries.

The working sequence is **Standard Working Draft → infrastructure need → Specification → pilot → feedback to Standard**. The comparative study and drafting models examine ISO/IEC, IEEE, ITU and UN practices without claiming affiliation or adoption of those organizations' authority.

Generalized application	Generalized-Generativity-Relational-Social-Science-Application
Academia application	Generative-Relational-Academia-Application

The applications also create Git repositories for **user project records** inside their private runtime. Those data repositories have a different purpose and are never application-source submodules.

8.1.4 Obtain the complete workspace

With GitHub SSH access configured, clone the programme and both levels of submodules:

```
git clone --recurse-submodules git@github.com:huangwanhong-maker/Generativity-Epistemic-Infrastructure.git
↪  generativity_standards_program
cd generativity_standards_program
```

For an existing checkout, synchronize the committed submodule URLs and initialize the pinned revisions:

```
git submodule sync --recursive
git submodule update --init --recursive
git submodule status --recursive
```

The submodule URLs use SSH and require access to all four repositories. The Git workflow guide documents the Windows SSH identity setup, remotes and dependency order for publishing. Cloning an application alone obtains its source; the full setup below expects the parent infrastructure layout and shared tools.

8.1.5 Work across repository boundaries

Make and commit a change in the repository that owns the file. When an application changes, commit it first, then commit its updated submodule reference in infrastructure, then commit the infrastructure reference in this programme. A common-package change starts at infrastructure; a standards-only change stays in this repository. Record architectural decisions and affected publication requirements in the programme alongside implementation changes.

Submodule updates check out the revisions selected by the parent repositories. They do not automatically select a domain application's newest work. Before changing a pin, review the relevant change and its verification evidence. See the Git workflow guide for the repository boundaries and maintenance commands.

8.1.6 Run the applications

Requirements: Python 3.11 or later and Git. Academia additionally requires Node.js and npm; the validated setup uses Node 22, and its current frontend tools require Node 22.12 or later on that release line. Dependency installation needs package-registry access. The generalized interface has no Node build.

From this programme directory:

```
python applicative_infrastructure/common/tools/setup_application.py generalized --dev
python applicative_infrastructure/common/tools/setup_application.py academia --dev
```

Launch in separate terminals:

```
python applicative_infrastructure/common/tools/run_application.py generalized
python applicative_infrastructure/common/tools/run_application.py academia
```

Application	Local address	Current scope
Generalized workspace	http://127.0.0.1:8000	Registration, private projects, record graphs, event-defined spacetime and trajectories, first-class Relations, notes/files, atomic Git transactions, historical views and exports
Generative Relational Academia	http://127.0.0.1:8001	Research projects, question-led trajectories, graph exploration, domain record operations, workspaces and native GRRP tooling

Use Python 3's local command name where appropriate on Linux/WSL. The infrastructure guide covers ports, environments, configuration, accounts, backups and independent operation.

The generalized application implements the experimental gsp-record-protocol/0.2 model and gsp.general/0.2 profile. Academia retains native **GRRP v0.1**. Shared account authority, single sign-on and a completed GRRP/general-protocol adapter are not present. Earlier generalized records are converted only through an explicit migration request.

8.1.7 Application gallery: River Commons

River Commons is a comprehensive synthetic demonstration of the generalized workspace: 31 records across all six operational roles, five Events, six retained source files and seven Git revisions. A fictional garden inquiry develops through encounters, provisional access, shared work, competing accounts and later corrections. The later review is recorded before its earlier context, making represented event order visibly distinct from recording order.

[Image description: River Commons record graph with a first-class Relation and its participant roles]

[Image description: Event precedence and an event-defined boundary in the River Commons project]

8.1.8 Visualized spacetime

Space is the ontology topology at a chosen event boundary. The event partial order above supplies the boundaries; the views below show which scoped records and connections apply. Both use the same preserved Git revision.

After the provisional access agreement: two events have passed, and 10 records enter this projection. The trial-access State and provisional stewardship Relation apply.

[Image description: Spacetime after the access agreement: selected event frontier, ontology topology and trial-access State]

After the shared review: four events have passed, and 13 records enter the projection. Trial accounts end; revised access, a renewed stewardship arrangement and the workload concern apply.

[Image description: Spacetime after the review: selected event frontier, changed topology and revised-access State]

Follow a subject through these boundaries. The garden's descriptions progress from **Access not yet arranged** through **A garden open for a trial** to **Access under a revised rota**. The trajectory view retains their explicit event bounds, competing descriptions and uncertainty.

[Image description: Subject trajectories with active, ended and indeterminate descriptions]

These are selected cuts of a partial order, not equally spaced clock instants. The independent water observation remains unordered; incomparable events are not asserted simultaneous. Choosing a boundary changes the view without creating a Git revision.

The full ten-image gallery also shows two temporal cuts of the same revision, subject trajectories, retained files, the upload dialog, a preserved contradiction and a mobile view. The graph overview's visible **care** filter displays 11 of the 31 records; its node positions are arranged for readability. Every account and source material is fictional.

Follow the demo guide to create a separate local demo account and project, explore the story, or reproduce the screenshots. Credentials and runtime records stay outside source control. Preview copies are maintained inside this repository so these images also render across Git submodule boundaries on GitHub.

8.1.9 Verification and publication builds

The application verification guide gives isolated package, API and browser test commands. The relocation report records **427 passing tests and one platform-specific skip**, production builds and preservation checks from the application migration. These are dated implementation results, not a claim of programme adoption, institutional conformance or production readiness.

The subsequent spacetime implementation review records **185 passing tests across focused runs** for the updated generalized/common implementation, including seven browser tests. The event-spacetime design explains how event-defined cuts select represented topology independently of Git recording order.

To compile the nine working drafts using an installed TeX environment:

```
python tools/build_publications.py --wsl Ubuntu-24.04
python tools/check_publications.py
python tools/check_validation_package.py
```

The first two commands need the compiler, fonts and Python packages documented in the publication build guide. WSL/Linux users can run the build script directly with Python 3. Generated PDFs and reports live in ignored build output; a fresh clone needs compilation before generated-PDF links become available.

8.1.10 Data, provenance and preservation

Application source, personal runtime data and generated build output have separate lifecycles. Private account databases, sessions, keys, user project repositories, environments and dependency trees are excluded from source control. A source clone does not transfer user accounts or research records. Back up complete runtime directories using the operation guidance.

Academia's original source history remains in its repository ancestry and a verified Git bundle with an import manifest. The original checkout remains separate. Historical publications and source notices retain their original wording; later decisions and additional grants are recorded explicitly.

8.1.11 Contributing

Read PROGRAMME_BRIEF.md and AGENTS.md before substantive work. Consult foundation manuscripts for GR-specific definitions and preserve disagreements instead of silently reconciling them. Use normative terms deliberately and label unresolved proposals.

For a substantive change, update the affected document, record the issue and alternatives, add or amend an ADR when architecture changes, update CHANGELOG.md, and retain unresolved matters in open questions. Use the templates for work items, comments and assessment evidence. Implementation checks belong with the repository owning the code; programme decisions and conformance authority remain here.

See CONTRIBUTORS.md for contribution attribution and how to maintain the contributor record.

8.1.12 License

Project-authored material is available under the MIT License, with copyright held by its contributors as recorded in CONTRIBUTORS.md. The scope and historical-license notes explain the additional grant, retained historical notices and exclusions. Third-party components keep their own terms; application users' records and uploaded materials are not relicensed merely by being stored in these applications. Each submodule carries its own license and contributor files.

9 WRITING PRINCIPLES

Original source: `WRITING_PRINCIPLES.md`.
Original source SHA-256: `f12e627e0e2a2d8b2a3a13a5b9ad13974304bdb4e73807c3f6052406d3b03104`.

9.1 GRE Writing Principles

This file governs drafting across the entire book. It should be supplied at the beginning of every drafting session together with the relevant chapter session packet.

9.1.1 1. Structural titles

Any Part, Chapter, section, subsection, subsubsection, table-column title, figure-panel title, or comparable structural title should avoid:

- question forms such as `Why ...`, `What ...`, `How ...`, `When ...`, or titles ending in `?`;
- claim-form titles that read like a conclusion rather than a structural locator;
- quantifier-phrase titles such as `All ...`, `Every ...`, `No ...`, unless a technical term genuinely requires it;
- negative or contrastive titles built around `not`, `no`, `instead`, `rather`, or similar oppositional framing;
- ambiguous titles such as `The Problem`, `The Criterion`, `The Issue`, `Discussion`, `Some Remarks`, or titles that carry little information outside their immediate context.

A good title should identify the **structural role, analytical object, and local context** of the material.

9.1.2 2. High cohesion and low coupling

Each section should be understandable even when read directly rather than only as the next turn in a conversation. Section openings should therefore avoid ambiguous pronouns, deictic expressions, and context-dependent phrases such as `this`, `that problem`, `the above`, or `as we just saw` when the referent is not named explicitly.

A section should introduce its own analytical object with enough precision that the reader can recover the local argument without reconstructing the entire preceding conversation.

9.1.3 3. Section openings

The opening paragraph of every section should, where appropriate, state:

1. the section's **role** in the chapter;
2. the section's **objective**;
3. the **structure** of the discussion;
4. the **method or mode of argument** when it matters (historical, interpretive, empirical, formal, comparative, normative, etc.).

The opening should remain scholarly and direct. Avoid essay-like hooks, conversational scene-setting, casual rhetorical questions, or vague motivational prose.

9.1.4 4. Positive and direct prose

Avoid negative contrast constructions when a positive formulation is available, especially:

- `not ... but ...`;
- `is not ...; rather ...`;
- `instead of ...` used as a repeated argumentative device;
- stacked negations used to define a concept only by exclusion.

Negative distinctions remain permissible when analytically necessary, but positive specification should carry the argument whenever possible.

9.1.5 5. Scholarly register

Use formal scholarly prose rather than conversation-like or essayistic prose. Avoid casual transitions, rhetorical filler, and unsupported evaluative adjectives. Claims should state their scope, evidential standing, and limitations precisely.

9.1.6 6. Figures and tables

Every figure and table must:

- have a descriptive caption;
- have a unique `\\label{...}`;
- be referenced in the main text at least once with `Figure~\\ref{...}` or `Table~\\ref{...}`;
- be placed at the **top of a page** wherever feasible, using `[!t]` as the default float placement;
- avoid appearing as an unintroduced visual object.

A figure or table should serve an analytical purpose stated in the prose. Decorative figures are inappropriate.

9.1.7 7. Citation verification before drafting

Every external reference written into the manuscript must be verified from the internet before it is inserted into the paper. Post-verification is not allowed.

Before using a citation:

1. verify the bibliographic record from an authoritative or reliable online source;
2. verify that the source actually supports the intended claim;
3. add the citation to `refs/references.bib`;
4. add a row to `refs/VERIFICATION_LEDGER.tsv` with status `VERIFIED`;
5. only then insert the citation into manuscript prose.

A remembered citation, model-generated citation, secondary citation copied without verification, or plausible-looking bibliographic entry is insufficient.

9.1.8 8. Formula placement and equation discipline

Short mathematical expressions should remain inline when they fit naturally within a sentence.

A displayed formula is appropriate only when display materially improves readability or when the expression is analytically important. Every displayed equation must:

- use a numbered environment such as `equation`, `align`, or `gather` rather than `\\[ ... \\]`, `$$ ... $$`, `equation*`, or `align*`;
- have a unique `\\label{eq:...}`;
- be referenced at least once in the main text with `Equation~\\ref{eq:...}`.

When prose introduces a displayed equation, the preceding prose sentence should be grammatically complete and end with a full stop. For example:

```
The local transformation law is stated in Equation~\\ref{eq:local-law}.
\\begin{equation}
  x_{t+1}=F(x_t,R_t)
  \\label{eq:local-law}
\\end{equation}
```

Do **not** write a comma immediately before a displayed equation as if the display were merely a continuation of an unfinished sentence.

Natural-language relations should be described in prose. Do not use mathematical arrows, `\\neq`, plus signs, or other mathematical operators as shorthand for ordinary-language claims unless the symbols have been formally defined and are doing genuine mathematical work.

9.1.9 9. Formalism must earn its place

Do not introduce mathematics merely to make prose appear rigorous. Every formal object should have:

- a defined analytical role;
- explicit assumptions;
- a stated relation to evidence or interpretation;
- a statement of scope and limitations where necessary.

Formal analogy, structural formalization, and empirically parameterized model should be distinguished.

9.1.10 10. Boxed formulae

Avoid `\\boxed{...}` and visually boxed formulae as a default stylistic device. Use theorem-like environments, propositions, definitions, remarks, or ordinary displayed equations when formal emphasis is needed.

9.1.11 11. Structural blocks

Definitions, propositions, claims, lemmas, theorems, remarks, examples, conjectures, hypotheses, and cautions may be used where they sharpen structure. They should not be used mechanically. Each block type should correspond to its actual epistemic standing.

Use `claim` for a substantive claim whose status is argued in the chapter, `hypothesis` for a testable or provisional mechanism, and `remark` for clarification that does not carry the main argument.

9.1.12 12. Claim strength and revisability

GRE is an open research programme. Distinguish carefully among:

- established argument within the book;
- proposal;
- hypothesis;
- heuristic;
- analogy;
- formal representation;
- empirical finding;
- open problem.

Avoid presenting a useful representation as an ontological proof or a preliminary hypothesis as a settled result.

9.1.13 13. Epistemic humility and scope discipline

Scholarly writing should maintain a close correspondence between the strength of a statement and the strength of its available support. GRE treats intellectual humility as part of responsible and ethical research practice rather than merely a stylistic preference.

Use universal, categorical, or near-universal formulations with particular care. Expressions such as `all`, `every`, `any`, `none`, `never`, `always`, `must`, `cannot`, and categorical constructions beginning with `No ...` should appear only when the relevant domain, assumptions, and evidential basis justify the stated scope.

Where support is partial, historically situated, domain-specific, interpretive, provisional, or theoretically mediated, prefer language that preserves that status. Depending on the local argument, suitable formulations may include `may`, `can`, `often`, `tends to`, `under these conditions`, `within the present framework`, `in the cases considered here`, `the analysis suggests`, `the present argument proposes`, and comparable scoped expressions.

Epistemic humility does not require vague or weak writing. State arguments clearly and directly while preserving their actual domain of validity, uncertainty, and revisability. Avoid strengthening a conclusion beyond the evidence for rhetorical effect. Distinguish observed

evidence from interpretation, interpretation from theoretical extension, and theoretical extension from broader conjecture. Relevant uncertainty, counterevidence, alternative interpretations, and limitations should remain visible when they materially affect the argument.

Strong formulations remain appropriate where they are established by definition, formal proof, explicit assumptions, procedural requirements, legal or institutional rules, or sufficiently robust evidence. Their scope should remain identifiable from the surrounding argument.

9.1.14 14. Ontological restraint

The current GRE framework uses ontological suspension. Relational, field-theoretic, geometric, dynamical, category-theoretic, and spacetime language may provide useful representations without establishing the ultimate ontology of the economic or social world.

9.1.15 15. Historical and disciplinary restraint

Economic concepts, methods, values, and disciplinary boundaries are historically generated. Avoid treating historically specific categories as timeless universals unless the argument establishes the required scope.

GRE is a domain instantiation of broader GR foundations. It should maintain explicit interfaces with GRH, GRG, law, political theory, education, ecology, aesthetics, and AI studies without absorbing those disciplines into economics.

9.1.16 16. Methodological pluralism

Historical/interpretive/qualitative, quantitative/empirical, and formal/computational inquiry are partially irreducible modes of access. Do not present one methodological tradition as automatically epistemically superior. Explain why a method is adequate to the local research question.

9.1.17 17. Value terminology

Generative value is importantly informed by Eglash and related work; GRE should not imply that it invented the entire generative-value tradition. GRE's distinctive questions include heterogeneous value, conversion, circulation, return, capture, dissipation, regeneration, power over conversion interfaces, and justice under partial or absent commensurability.

9.1.18 18. Historical dynamics

Fast–slow dynamics, multiple timescales, criticality, attractors, and field language are available as analytical resources. Their use requires local justification. Early GRH insights are sources for critical inheritance, not canonical commitments.

9.1.19 19. Avoid premature synthesis

A relational translation between theories does not establish identity. Preserve irreducible disagreements, domain-specific remainders, and failed translations. Use equivalence language only at the level actually supported.

9.1.20 20. Cross-references

Every table, figure, displayed equation, theorem-like item when numbered, appendix, and major formal construction should be cross-referenced in prose. Labels should be semantic and stable, for example:

- `fig:value-conversion-interface`
- `tab:value-forms`
- `eq:relational-dynamics`
- `sec:historical-timescales`

9.1.21 21. Drafting granularity

Draft one coherent section at a time. A section may be split across sessions, but the active file should remain a single section source file. Complete local argument structure before moving to the next section. Avoid drafting disconnected paragraphs across many sections simultaneously unless explicitly planning cross-chapter consistency.

9.1.22 22. Vertical page spacing

Preserve consistent local spacing between headings and prose. The manuscript uses `\raggedbottom` so that LaTeX leaves modest residual whitespace at the bottom of a page rather than stretching the vertical glue after a section or subsection heading.

A page may therefore end slightly higher than another page when a following heading and its opening lines need to move together. This is preferable to creating conspicuous blank bands between a heading and its first paragraph.

Do not insert manual `\vspace`, blank display environments, or repeated line breaks to force page-height alignment. Diagnose unusual whitespace at the page-layout level before changing prose.

10 CONTRIBUTING

Original source: `applicative_infrastructure/CONTRIBUTING.md`.
Original source SHA-256: `b2c5620f49e8608fc9a82ce25b44fbd43b8098e91e2f1f29424c196589404ba4`.

10.1 Contributing

Shared protocols, Git storage, launch tools and conformance support belong in this repository. Application-specific features belong in the relevant application submodule. Explain the problem, affected consumers and validation evidence; coordinate incompatible package changes with both applications before updating their pinned revisions.

The project-authored material is offered under the MIT licence, with scope and exceptions. By intentionally submitting original work for incorporation, you offer it under MIT while retaining your copyright. Identify any third-party material, its source, licence and your authority to contribute it. Do not include private runtime data, credentials or signing keys in source changes.

Add your preferred contributor name or organization and a short contribution description to CONTRIBUTORS.md when your work is incorporated. Preserve existing author and third-party notices. Contributions to a distributable Python package also update its packaged contributor list so attribution travels with the distribution.

11 CONTRIBUTORS

Original source: `applicative_infrastructure/CONTRIBUTORS.md`.

Original source SHA-256: `575792d4d60feac3284af25d8e22f64a81817b9f19497424896f64b7bad7d831`.

11.1 Contributors

Copyright (c) 2026 the contributors listed in this file, for their respective contributions.

Contributor	Recorded contribution
Wanhong Huang	Shared infrastructure conception, protocol and application design, development direction.

Domain contributions are credited in generalized application and academia application.

The MIT licence in LICENSE refers to this list. Contributors retain the rights in their respective contributions; this list does not assign ownership of every file to every person or organization listed.

Add a contributor's chosen name or organization and a brief contribution description when their work is incorporated. Preserve existing attribution. Corrections can be proposed through the same review process as other repository changes.

AI tools have assisted drafting, implementation, and review. They are development tools and are not listed as copyright holders. Third-party components retain their own author and licence notices.

12 LICENSE

Original source: `applicative_infrastructure/LICENSE.md`.

Original source SHA-256: `4652c1eb4d4310ea760ecd3b09ec9fd90d578f23a1eae70415a086b1b2eed7e9`.

12.1 Licensing scope

Effective date: 2026-09-22. **Licence:** MIT, under the project owner's explicit instruction for the repository family.

The MIT licence covers project-authored shared packages, tools, conformance artifacts and documentation in this repository. Copyright is held by the contributors listed in CONTRIBUTORS.md, for their respective contributions. The licence text follows the Open Source Initiative MIT text.

The generalized and academia application repositories each carry their own MIT licence and contributor list. Their scope notices remain available at generalized application and academia application. A submodule's licence travels with that repository and does not depend on a parent checkout.

Dependencies and reproduced external materials retain their original notices and terms. MIT here does not grant rights in third-party materials. Private accounts, research records, attachments, keys and project repositories under `.runtime/` are user material, not part of the source licence. Installing or running these applications does not license that content to anyone else.

Contributors retain their rights in their respective contributions. CONTRIBUTING.md states how future contributions are offered and credited. Previously offered permissions and preserved historical notices are not withdrawn by the current MIT grant.

13 README

Original source: `applicative_infrastructure/README.md`.

Original source SHA-256: `8b141077469c48ff873ebb22fcf3655956701f91515bed86e43ed4f9a8f15ce4`.

13.1 Applicative infrastructure

Class: Implementation and operation guide
Status: Experimental shared infrastructure and independent domain applications

Source repository: Generativity-Relational-Epistemic-Applicative-Infrastructure

This repository provides common record and Git-storage packages, repeatable local setup tools and two application submodules. It implements parts of the Generativity Standards Program's research and working specifications while keeping application behavior, protocol evidence and programme authority distinct.

The current domains are a generalized visual record workspace and Generative Relational Academia. Each has a separate entry point, account database, runtime and source history. Academia retains its native GRRP model; consolidation and shared hosting do not establish interoperability with the generalized protocol.

13.1.1 Repository responsibilities

```
applicative_infrastructure/                This Git repository

    ├── academia/                         Accounts, index, native records and keys
    └── environments/                     Separate Python environments
```

Area	Responsibility
Common packages	Reusable implementation with no dependency on a domain application
Generalized application	General records, visual graphs, event-defined spacetime and trajectories, modules, retained files and project transactions
Academia application	Scholarly trajectories, native GRRP operations and domain workspaces
Verification	Tests and the limits of their interoperability claims

This repository is itself a submodule of the programme. Programme standards, specifications, manuscripts, governance and ADRs remain canonical in the parent repository. Links such as the Programme Brief, GR-SPEC-120, GR-SPEC-130 and consolidation decision resolve in that complete checkout. An infrastructure-only clone can run the applications without those publication files.

13.1.2 Demo and gallery

The generalized application's **River Commons** project demonstrates a fictional shared-garden inquiry with 31 records, all six operational roles, five Events, six retained materials and seven Git revisions. Its recorded event order, changing topology, subject trajectories and corrected accounts can be explored together.

[Image description: The River Commons graph and a Relation's named participants]

[Image description: An event partial order in the generalized Spacetime workspace]

13.1.3 Visualized spacetime

The event graph supplies a partial order; each chosen boundary selects a topology of scoped ontology records. These two views share one preserved project revision:

After the access agreement — 2 events passed, 10 projected records. Trial access and provisional stewardship apply.

[Image description: Selected agreement boundary, its ontology topology and the trial-access State]

After the review — 4 events passed, 13 projected records. Trial accounts end; revised access and stewardship accounts apply.

[Image description: Selected review boundary, changed topology and the revised-access State]

The garden's subject trajectory connects **Access not yet arranged**, **A garden open for a trial** and **Access under a revised rota**, retaining their event bounds:

[Image description: Garden and stewardship-team trajectories across event boundaries]

These cuts do not assign a common clock or infer simultaneity. The independent observation remains unordered, and selecting a cut creates no Git revision.

See the complete gallery for ten actual UI screenshots, including earlier and later topology at one revision, file controls and a preserved historical contradiction. The pictured graph uses the visible **care** search filter and a local display arrangement. All content is synthetic.

The demo runbook creates a separate account through the ordinary API and documents screenshot regeneration. Its private credentials and project metadata live under ignored `.runtime/demo/`; the preview images above are deliberate copies maintained by the capture script. This demonstration uses the generalized protocol and does not imply an academia protocol migration.

13.1.4 Clone and maintain submodules

With GitHub SSH access configured, obtain this repository and both application submodules:

```
git clone --recurse-submodules git@github.com:huangwanhong-maker/Generativity-Relational-Epistemic-Applicative-Infrastructure.git
↪  applicative_infrastructure
cd applicative_infrastructure
```

The application sources are hosted independently as Generalized-Generativity-Relational-Social-Science-Application and Generative-Relational-Academia-Application. For the complete programme, recursively clone Generativity-Epistemic-Infrastructure instead. The programme Git guide covers SSH configuration and publishing.

Each application is pinned to a specific commit. After changing an application, commit its source there, then commit the changed submodule reference here. If this repository is checked out inside the programme, commit its updated reference in the programme as well. Common-package and launcher edits belong directly to this repository. Use the following to inspect the selected revisions:

```
git submodule status --recursive
```

After updating this repository, use `git submodule sync --recursive` and `git submodule update --init --recursive` to restore its committed application revisions. Publish application commits before the infrastructure commit that references them; publish infrastructure before a programme commit that references it. A submodule may have a detached HEAD, so select a development branch before committing application changes.

Source submodules are distinct from the Git repositories that applications create for users' records. Private project repositories belong in runtime storage and are excluded from source version control.

13.1.5 Setup

Use Python 3.11 or later and Git on PATH. Academia additionally needs Node.js/npm; Node 22.12 or later on the Node 22 release line is suitable for the current frontend tooling and matches the validated major version. Installation downloads declared dependencies. Commands below run from **this infrastructure directory**:

```
python common/tools/setup_application.py generalized --dev
python common/tools/setup_application.py academia --dev
```

Run either command independently if only one application is needed. Use Python 3's local command name on Linux/WSL. On Windows the setup tool uses extended Python paths for deeply nested dependencies without changing system settings.

Setup creates separate environments under the ignored runtime environment directory. Generalized setup installs its requirements and the two editable common packages; its interface has no Node build. Academia setup installs its native Python package, runs npm's lockfile installation, and builds its protocol, server and client. Repeating setup can reuse an existing environment. Omit the development option when Python test dependencies are unnecessary; academia still needs its declared TypeScript build dependencies.

Cloning an application alone does not reproduce this layout or install shared tooling. The infrastructure checkout is the supported combined development environment. Domain README files describe lower-level entry points and dependencies.

13.1.6 Launch independently

Run each application in its own terminal:

```
python common/tools/run_application.py generalized
python common/tools/run_application.py academia
```

Application	Default address	Default runtime	Session cookie
Generalized	http://127.0.0.1:8000	.runtime/generalized/	gsp_session
Academia	http://127.0.0.1:8001	.runtime/academia/	gra_session

The launcher accepts host and port arguments and defaults to loopback. For example:

```
python common/tools/run_application.py generalized --port 8002
```

Ctrl+C stops the selected process. The launcher resolves paths from its own location, so invoking it by absolute path works from another directory.

Both applications have their own accounts; no shared sign-on or shared project authority is introduced. Generalized registration is available in its interface. Academia preserves its account-provisioning behavior and has an operator CLI when registration is closed. No demonstration account or default password is installed.

Separate ports and cookie names prevent ordinary naming collisions; ports do not isolate browser cookies. Local launch commands are development/operator entry points rather than a production service manager. Local previews created during migration have ignored process logs under the programme's build output.

13.1.7 Configuration

Explicit path overrides passed to the launcher must be absolute. Use separate locations for unrelated deployments.

Variable	Purpose
GSP_DATA_DIR	Generalized account database and project repositories
GSP_COOKIE_SECURE	Set to 1 when generalized is served exclusively through HTTPS
GSP_TRUSTED_HOSTS	Generalized accepted request hostnames
GRA_RUNTIME	Academia parent runtime directory
GRA_RECORDS	Academia native record tree; overrides the derived default
GRA_DB	Academia account/index database; overrides the derived default
GRA_PYTHON	Single absolute Python interpreter path with native grrp installed

Variable	Purpose
GRA_CLIENT	Academia compiled client directory

The launcher selects host and port through its command arguments. Domain guides document additional direct-server settings. A source checkout or environment rebuild does not create a copy of an existing runtime.

13.1.8 Data and recovery

Both SQLite databases contain retained account information. Academia's database also has rebuildable indexes, but that does not make the database disposable. A complete backup includes the matching account database, project repositories, retained material, record-local keys and relevant SQLite journals. Stop the application's writer before a filesystem copy, or use a specifically verified online backup procedure. Treat backup archives as private data.

The application relocation preserved four accounts, three projects, record bytes, native keys and reachable Git histories. It did not convert the legacy generalized project or academia's native records. Detailed scope and checks are in the migration verification and independent audit.

The original migration workspace retains complete source/runtime ZIP backups under ignored programme build/private-backups/; build/migration-current-backup.txt identifies that workspace's backup set. Former local source trees remain under build/retired-webapp/ and build/retired-gsp-record-protocol/. These are local recovery artifacts and do not accompany a clone. The original academia checkout and runtime remain unchanged.

For rollback, stop the new writer before restoring a matched runtime backup and application revision. Restore accounts and record custody together. Do not run two writers against the same restored data directory. Recreate virtual environments after moving their source/environment layout; retaining their old files does not make them portable.

13.1.9 Verification

Install development dependencies first. From this directory on Windows PowerShell:

```
& ./.runtime/environments/generalized/Scripts/python.exe -m pytest -c gr_generalized_application/web_application/pytest.ini
↪  gr_generalized_application/web_application/tests common/packages/gsp_record_protocol/tests common/packages/gsp_git_store/tests
↪  --basetemp .runtime/test-output/generalized -q
& ./.runtime/environments/academia/Scripts/python.exe -m pytest gr_academia_application/domain_packages/grrp/tests --basetemp
↪  .runtime/test-output/academia -q
npm.cmd --prefix gr_academia_application/web_application test
npm.cmd --prefix gr_academia_application/web_application run build
```

Use bin/python instead of Scripts/python.exe and npm instead of npm.cmd on POSIX. Pytest's temporary-output directory is disposable and must never name retained runtime data. Prefer a short checkout/test path on Windows because Git clone tests can encounter path-length limits.

Set the GSP_BROWSER environment variable to msedge to include the generalized browser journeys using installed Edge; the browser test guide describes alternatives. The migration recorded 427 passing tests and one platform-specific skip across the applications and shared packages. These dated checks verify observed behavior and do not establish cross-application semantic equivalence.

13.1.10 Current boundaries and further domains

The generalized application consumes the common packages. Academia currently retains separate Python and TypeScript GRRP implementations. A future adapter needs explicit mappings for identity, signed bytes, authority, disclosure, modules, partial mappings and retained files before interoperability can be claimed.

The applications remain experimental. Generalized sharing, recovery, selective erasure and formal review workflows remain limited; academia retains known identity/custody questions and six affected npm packages in its dated relocation assessment. Review domain-specific limitations before exposing either service beyond its local operating context.

A future domain receives its own repository/submodule, entry point, runtime, profile and operation guide. Extract further common code when a concrete shared interface and preservation tests justify it. Domain history and concepts remain traceable rather than being flattened into a universal application schema.

13.1.11 Contributing and license

Use CONTRIBUTORS.md to maintain contribution attribution. Keep shared packages independent of domain application imports, add meaningful verification for behavioral changes, and update the programme's decisions and specifications when an implementation exposes a conceptual or interoperability gap.

Project-authored material is available under the MIT License, with copyright held by the contributors recorded in CONTRIBUTORS.md. LICENSE.md explains scope, historical additional grants and third-party exclusions. Each application submodule has its own license and contributor record. User-created records, files and research material retain their own rights.

14 README

Original source: `applicative_infrastructure/common/README.md`.
Original source SHA-256: `25962c4ce28a7219b87668fee20961fa3766624b1ed376f19faf47cb28135e15`.

14.1 Common implementation infrastructure

Class: Implementation guide
Status: Experimental shared packages

Component	Responsibility
gsp_record_protocol	Independent record/module/transaction validation, candidate preparation, schema, graph projection and CLI
gsp_git_store	Atomic Git storage, retained material, receipts, history and exports
tools	Explicit setup and independent application launch
verification	Shared package and application regression commands; future independent interoperability checks
design	Relocation provenance and migration evidence

Canonical technical texts remain GR-SPEC-120 and GR-SPEC-130, with their motivating Working Drafts at the programme root. The protocol package owns the single machine-readable schema resource for its version. No copied normative text is maintained here.

The Git package does not depend on Flask, accounts or the protocol validator. The protocol package does not depend on Git or either application. Each receiving application remains responsible for authentication, authority checks, applicable profile semantics and client behavior. Academia's native GRRP and TypeScript protocol packages remain domain-specific; their new location does not turn them into the general shared protocol.

15 README

Original source: `applicative_infrastructure/common/conformance/README.md`.
Original source SHA-256: `cb69439eeb1fd5bf44f15640890749d811c4c1948502133844dbb5a59c3936e0`.

15.1 Implementation verification and interoperability boundary

Class: Verification guide
Status: Experimental implementation tests; no independent cross-application conformance claim

From the programme root after setup, run the shared packages and generalized application together:

```
$verificationPython = '.\applicative_infrastructure\.runtime\environments\generalized\Scripts\python.exe'
& $verificationPython -m pytest -c applicative_infrastructure/gr_generalized_application/web_application/pytest.ini
↪  applicative_infrastructure/gr_generalized_application/web_application/tests
↪  applicative_infrastructure/common/packages/gsp_record_protocol/tests
↪  applicative_infrastructure/common/packages/gsp_git_store/tests --basetemp build/gsp-tests -q
```

Set `$env:GSP_BROWSER='msedge'` to include the browser journeys, using installed Edge. `chrome` or a separately installed Playwright Chromium can also be selected. The chosen `--basetemp` is disposable test output and must not contain runtime or other valuable files. A short workspace path avoids Git for Windows path-length restrictions in cloned test repositories.

Academia's native Python and npm checks remain separately documented in its guide. The original domain protocol fixtures continue to assess that domain implementation. They do not establish a GRRP/general-protocol mapping.

Protocol fixtures remain beside the versioned package tests. This avoids duplicated authoritative copies. When an academia adapter is implemented, cross-application cases will need to exercise identity, signed-byte preservation, unmapped fields, authority, complete/partial mappings, files and failure recovery. That work is distinct from the source relocation verified here.

16 migration audit

Original source: `applicative_infrastructure/common/design/migration_audit.md`.
Original source SHA-256: `5c8853385434f5375e09c7277999ad8ee0f1dd6125b8121f0f4feec1d405456c`.

16.1 Independent migration audit

Document class: Informative implementation verification report
Date: 2026-09-22
Status: Bounded migration checks passed; identified provenance discrepancy corrected and rechecked
Scope: Relocation into `applicative_infrastructure`, without semantic conversion of retained records

This audit independently read the original and relocated data, inspected source provenance, resolved installed packages, evaluated launcher configuration, and checked the two live entry points. It did not create accounts, edit records, change keys, run a reindex, or alter retained user data. Account rows were compared internally; credentials, account identities, record text and key bytes were not included in the report or tool output.

16.1.1 1. Retained runtime

The generalized source was the earlier local `webapp/.data`. The academia source was the original application's ignored `web/packages/server/data`, which contains both records and an account database. The destinations were `.runtime/generalized` and `.runtime/academia`. Source copies remained present when the comparisons were performed. The earlier local web application and packages were subsequently retired into ignored `build/` storage after the programme's separate source-hash guard; this audit's comparisons preceded that retirement.

For each retained record tree, the audit compared relative file inventory, byte length and SHA-256. It then compared Git reference identifiers and reachable commit counts independently of the filesystem comparison. Databases were opened read-only; `PRAGMA quick_check`, table counts and complete `users` rows were compared without printing row contents.

Check	Generalized	Academia
Retained record-tree files	11 source; 11 destination	299 source; 299 destination
File inventory and every compared byte digest	Equal	Equal
Missing, additional or changed record-tree files	0 / 0 / 0	0 / 0 / 0
Retained project repositories	1	2
Git reference sets	Equal	Equal for both projects
Reachable commits	2 at both locations	26 and 8, unchanged at both locations
Source and destination database quick check	`ok`	`ok`
Complete account-row comparison	Equal; 1 account	Equal; 3 accounts
Project-row counts	1, unchanged	2, unchanged

The academia index also contained five trajectories and 29 search rows at both locations when inspected. These derived counts are a consistency observation, not a substitute for preserving the three account rows. Starting that application can rebuild derived index material; the audit therefore compared account content separately.

The generalized project still declares `gsp-workspace/0.1`, contains its one retained record, and has no fabricated transaction receipts or material assets. Its source main reference is unchanged. Filesystem relocation did not perform the separate `project.migrate` operation or retrospectively assign structured relation semantics.

The academia record-tree comparison includes the original Git directories, native GRRP material, project metadata, key-related files and mutable project workspaces. This demonstrates byte preservation for those files at the comparison time. It does not independently validate every historical signature, claim, permission or private-key custody arrangement.

16.1.2 2. Installed packages and application boundaries

The generalized Python environment imports `gsp_protocol` and `gsp_git_store` from the relocated `common/packages` trees. The observed protocol identifier is `gsp-record-protocol/0.2`. The academia environment imports `grrp` from `gr_academia_application/domain_packages/grrp`; the generalized protocol package is not installed in that environment. No observed editable import resolves to the retired local package locations or the external academia source repository.

These results support separation of the application environments and retention of academia's native protocol. They do not demonstrate that academia implements the generalized transaction model or that the two native record formats are interchangeable.

The common launcher's default command and path configuration was evaluated from the programme directory and its parent. The resulting configurations were identical. Default data, database, client-build and Python paths were absolute; relative `GSP_DATA_DIR` and `GRA_DB` overrides were rejected. Default ports are 8000 for generalized and 8001 for academia.

After the launcher update, an absolute `GRA_RUNTIME` override routed both records and the database beneath that selected root, while a relative override was rejected. The academia native runtime resolver was also evaluated from two working directories and returned identical default paths. A Python executable path containing spaces remained one command argument. These checks evaluated configuration only and created no alternate runtime.

The academia server and account CLI use the same runtime-path resolver. `GRA_PYTHON` identifies one executable argument, avoiding the old ambiguity of splitting an executable path containing spaces. The legacy `GRA_GRRP` fallback remains a separate documented compatibility behavior.

The source declares distinct cookie names, `gsp_session` and `gra_session`, and independent session implementations. This prevents accidental name collision. Different localhost ports do not themselves establish browser-cookie isolation or a security boundary between applications on the same host.

16.1.3 3. Live, read-only observations

Both `http://127.0.0.1:8000/` and `http://127.0.0.1:8001/` returned HTTP 200 with HTML. Those requests set no cookie. The generalized public capability endpoint returned `gsp-record-protocol/0.2` and `gsp.general/0.2`. Both listeners were bound to `127.0.0.1` when inspected.

These checks establish that both entry points respond and that the generalized endpoint identifies the expected protocol. This audit did not log into the retained accounts or submit mutations to user data. Browser workflows, domain tests and temporary-data mutation tests are separate verification evidence.

16.1.4 4. Source provenance

All 35 entries in the common relocation manifest match the archived pre-relocation source bytes held in the private source backup. Their source-path inventory contains no runtime, account database, environment or private-key paths under the checked path patterns.

For academia, the source repository remains at the recorded commit with a clean working tree. The preserved history bundle matches its recorded SHA-256, and an independent `git bundle verify` reports a complete history. The all-reference history contains 131 distinct tracked paths. The broad key-path check identified a historical `.grrp/keys/self.pub` public-key path; it found no runtime database, environment file or private-key path under the bounded path rules. This is not a comprehensive content or secret scan.

AUDIT-01 — Corrected and closed. The initial import manifest labeled archive-export bytes as committed Git blob bytes. Independent `git cat-file blob` comparisons found 56 of 121 entries different from that claim. The history bundle and runtime preservation comparisons were unaffected. The corrected import manifest distinguishes raw Git blob bytes, archive-export bytes, pre-edit imported bytes, source checkout bytes and final relocated bytes. The initial manifest remains as explicitly superseded evidence.

The audit independently re-read all 121 raw blobs, generated a fresh archive in memory, compared exported entries against the retained import baseline, and checked final destination hashes. Raw hashes and byte lengths, corrected committed-byte aliases, fresh archive hashes/lengths, retained initial baseline and final destination hashes all matched. All 56 raw-to-export differences were explained by LF-to-CRLF conversion. This closes the inaccurate provenance

label while preserving the observed import history rather than rewriting it as an earlier exact-blob copy.

Public source provenance is separate from private runtime migration evidence. Private backups and inventories remain under ignored `build/`; application state and recreated environments remain under ignored `.runtime/`. Neither belongs in the public source import or its history bundle. Git checks confirmed that both runtime database paths and the private-backup pointer are ignored and untracked.

16.1.5 5. Limits

The comparisons describe a specific migration and observation time. They are not a continuing backup service, a full disaster-recovery exercise, a deployment-security assessment, an independent signature audit, or a whole-GR conformance determination. Subsequent legitimate use can change the destination database and repositories while leaving this recorded migration result valid for its stated scope.

17 migration verification

Original source: `applicative_infrastructure/common/design/migration_verification.md`.

17.1 Application consolidation verification

Class: Implementation verification report
Status: Relocation completed, 2026-09-22; experimental applications

ADR-0009 records the approved repository boundary. The operation guide provides setup and launch commands. This report describes source/runtime relocation; it does not assert semantic equivalence between academia GRRP and the generalized record protocol.

17.1.1 Source and history

The 35-file generalized application/protocol baseline is recorded in relocation_manifest.json, with original paths, destination paths and before/after SHA-256 digests. Original source hashes were rechecked before retirement. The record protocol implementation and extracted Git-store implementation remain byte-identical. Changes concern imports, runtime defaults, documentation and test/artifact locations; one storage test uses a shorter temporary clone destination for Git for Windows.

The old `webapp/` and `packages/gsp_record_protocol/` trees are retained at ignored `build/retired-webapp/` and `build/retired-gsp-record-protocol/`. They are rollback material, not alternate active implementations. Environments are recreated in the new location; a retired virtual environment is not portable merely because its files are retained.

Academia's source was imported from commit `b98730b46eca5fdf441937aef0180f5b3d4f94dd`. Its 121 tracked source files, original README and component licensing notices are retained with a verified complete source-history bundle. The original checkout remains clean at the same commit. Its provenance guide identifies source-byte representations and the deliberate relocation edits. No outer-repository history was rewritten or merged.

17.1.2 Retained private data

The old generalized writer was stopped before transfer; no academia source writer was running. SQLite databases were copied through the backup API from read-only source connections. Full logical database digests matched immediately after copying and `quick_check` succeeded. Non-database file inventories were compared by relative path and SHA-256; transient SQLite shared-memory files were excluded from file-byte comparison.

Property	Generalized	Academia
Existing accounts	1 preserved	3 preserved
Existing projects	1 preserved	2 preserved
Retained content	1 legacy record	5 native trajectories
Reachable project commits	2 preserved	26 and 8 preserved
Record repository bytes and references	Exact match	Exact match
Identity and authentication material	Existing database/session material retained	Existing account data and native key material retained
Semantic conversion	None; schema 0.1 retained	None; native GRRP retained

The complete source/runtime ZIPs and detailed comparisons remain under ignored `build/private-backups/`, identified by `build/migration-current-backup.txt`. The ZIP archives are the authoritative backup artifacts; an earlier partial filesystem copy in that backup set is not a complete backup. Reports and archives contain private material and are not included in source provenance or the project index. The original academia checkout and data remain unchanged.

Academia startup rebuilds its derived search index in the new database. Consequently later database-file hashes are not expected to equal the offline backup; the independent audit compared complete account rows and native record trees after startup. No migration test accounts or demonstration records were added to retained user databases.

17.1.3 Executed verification

Check	Observed result
Generalized application plus common packages	**128 passed**, including three Edge browser journeys
Academia Python	**208 passed, 1 skipped**; POSIX editor fallback skipped on Windows
Academia TypeScript protocol	**43 passed**
Academia server	**48 passed**, including runtime path checks
Academia production build	Protocol, server and client passed
Academia deep-path write smoke	Separate test project/question created; graph read and GRRP validation passed
New live entry points	HTTP 200 at ports 8000 and 8001; expected protocol/account endpoints respond
Academia live browser	Edge renders the retained project listing with no uncaught JavaScript errors; screenshot inspected
Common launcher	Paths remain stable across working directories; absolute runtime overrides honored; relative overrides rejected
Independent audit	Account rows, record inventories, Git references, source provenance and import locations examined separately; provenance-label finding corrected and closed

All active programme/application guide links resolve. Historical publication and imported historical document links were excluded from this active-navigation check. The source index excludes runtime databases, keys, environments and dependency trees. All three authoritative backup ZIPs passed archive CRC checks.

The combined generalized/common suite ran from the new environment with `GSP_BROWSER=msedge` and `--basetemp build/gm`. Academia's detailed commands, environment information and scope are in its validation report. Reproduction guidance is in common verification.

17.1.4 Limits and subsequent work

The consolidation preserves two independent account and protocol systems. Shared code is available to future domains; academia does not yet consume the generalized protocol or Git transaction implementation. A domain mapping must preserve native identifiers, signed bytes, registrations, disclosure and unmapped content before interoperability can be claimed.

The inherited academia lockfile has six reported affected npm packages, documented in its validation report. Dependency maintenance, identity/custody findings from the earlier source review, deployment isolation, measured accessibility and a full operational restoration rehearsal remain separate work. Different ports and cookie names prevent ordinary namespace collisions; ports do not isolate browser cookies. Current services bind to loopback by default.

These checks establish the observed migration behavior. They do not adopt a Standard, certify production security, validate institutional practice or warrant the truth of recorded claims.

18 README

20.1 Generativity Git store

Document class: Software package guide
Status: EXPERIMENTAL, version 0.2.0
Python: 3.11 or later; Git executable required on `PATH`

An application-independent Git storage binding for project records, complete project transactions, retained material and revision history. Each project uses a separate bare repository. The package has no Flask, SQLite, browser or protocol-validator dependency. Its Python runtime uses only the standard library and invokes the installed Git executable.

The binding implements the storage responsibilities described in GR-SPEC-130. The separate record protocol package supplies model validation and transaction preparation. Applications supply authentication, authorization, verified upload metadata, recorder attribution, request replay matching and their own presentation.

This extraction preserves the existing workspace adapter's behavior. Moving the adapter into a shared package does not establish independent application interoperability, adoption of a Standard or factual warrant for stored statements.

20.1.1 Install and import

From the standards-programme repository root, using the application's chosen Python environment:

```
python -m pip install -e applicative_infrastructure/common/packages/gsp_git_store

from pathlib import Path
from gsp_git_store import GitStore, Conflict, NotFound, StoreError, LimitExceeded

store = GitStore(Path("private-project-data"))
```

The data directory and its contents need application-administrator-controlled filesystem access. Instantiating a store creates its `repositories` directory if needed. It does not create an account, authorize a caller or choose a project owner.

20.1.2 Public API

Method	Result and responsibility
`create_project(project, actor)`	Initialize a separate bare repository and return its initial commit; modern projects receive the binding manifest
`head(project_id)`	Current complete project commit
`snapshot(project_id, revision=None)`	Project manifest and records read from one accepted revision
`get_record(project_id, record_id, revision=None)`	Record and its selected revision
`commit_transaction(project_id, snapshot, receipt, actor, expected_head, assets=None)`	Publish the prepared candidate, receipt and retained file bytes through one conditional reference update
`transaction_receipt(project_id, transaction_id)`	Original committed receipt/result and observed current head, or `None`
`history(project_id, record_id, revision=None)`	Up to 100 commits affecting the record, pinned when a revision is supplied
`project_history(project_id, revision=None)`	Up to 100 project commits
`asset_file(project_id, digest, revision=None)`	Caller-owned binary temporary file positioned at byte zero
`bundle_file(project_id)`	Caller-owned binary temporary file containing complete accepted reachable history

Method	Result and responsibility
`limits()`	Applicable storage limits for application capability disclosure

`write_record()` and the in-memory `bundle()` helper remain compatibility interfaces. New coordinated application writes use `commit_transaction()`; HTTP downloads use `bundle_file()`.

`snapshot` is the complete prepared `{project, records}` candidate. `receipt` identifies its `transaction_id`, `expected_head`, reason, actor, digest and change account. `assets` maps verified SHA-256 strings to temporary source `Path` objects. The adapter independently checks and freezes supplied bytes before retaining them. The protocol package evaluates semantic structure; the store evaluates storage identities, bounds, understood descriptor/material closure and publication.

20.1.3 Publication and reads

The binding prepares immutable blobs, trees and a commit, then conditionally advances `refs/heads/main` from `expected_head`. The accepted project therefore contains either the previous complete snapshot or the new complete snapshot. Prepared objects can remain unreachable after a failed publication; they are not accessible as accepted project revisions.

Receipts are retained at `.gsp/transactions/<transaction-id>.json`. Their original resulting commit is resolved from the path's introduction. The application checks actor and request digest before treating a receipt as a replay and does so before rejecting an old base. The storage method itself rejects duplicate receipt paths; it does not authenticate idempotent requests.

New projects using `gsp-workspace/0.2` receive `.gsp/protocol.json`, asset and transaction trees. An unfamiliar or extended binding manifest is preserved and blocks mutation. Legacy project dictionaries and old commits remain readable. Migration is a separately prepared explicit transaction, not a side effect of reading.

Project snapshots use bounded Git batch reads instead of launching a process for each record. Requested revisions must be complete commit identifiers reachable from the selected project's accepted history. Repository-relative Git execution preserves support for long Windows data paths.

20.1.4 Material, streams and limits

Assets are stored at `assets/<sha256>`. Original filenames are metadata rather than storage paths. Existing assets remain in later trees when a descriptor is detached or replaced; this custody policy preserves their historical bytes. A current-snapshot application export needs to select only its intended referenced material. A full Git bundle deliberately includes reachable historical material and receipts.

The initial limits include 10 MiB per file, 20 MiB of distinct supplied asset bytes per storage transaction, eight distinct supplied blobs, 128 MiB of unique retained asset blobs in the current tree, 1,000 records, 2 MiB per serialized JSON resource and 32 MiB for the serialized project-plus-record snapshot. The HTTP/protocol layers separately count all incoming parts, including duplicate bytes, and may impose narrower transport limits. Call `limits()` when disclosing the binding's bounds.

The retained-asset budget does not bound unreachable objects, receipt-ledger growth, Git metadata, backups or total filesystem use. Operators remain responsible for capacity and recovery arrangements.

Close every returned stream, including when response creation or delivery fails:

```
## The application has already authorized the descriptor at this project revision.
with store.asset_file(project_id, descriptor["sha256"], revision) as content:
    while block := content.read(64 * 1024):
        consume(block)
```

Knowledge of an asset digest or commit identifier is not authorization. The caller must check project access and the requested record/file descriptor at the selected revision before delivering bytes. The store does not implement accounts, encryption at rest, selective erasure, legal holds, malware examination or independent attestation. Git content identity and recording attribution do not establish truth or immutable custody against the server operator.

20.1.5 Errors

`StoreError` is the safe storage-error base class. `Conflict` reports a stale publication base or duplicate published transaction identifier; `NotFound` reports invalid or unavailable identifiers/resources; `LimitExceeded` reports a declared binding limit. All are exported from `gsp_git_store`.

The application distinguishes authentication/validation failures from these storage outcomes. After an uncertain publication response, it recovers through the transaction receipt rather than asserting that nothing committed or silently creating a new transaction identifier.

20.1.6 Tests

The standalone suite uses temporary data directories and real Git repositories, including concurrent writers, failed publication, material identity/limits, historical reads, immutable receipts, bundle restoration and legacy migration. It does not require an application server or an account database.

```
python -m pip install -e 'applicative_infrastructure/common/packages/gsp_git_store[test]'
python -m pytest -c applicative_infrastructure/common/packages/gsp_git_store/pyproject.toml
↪  applicative_infrastructure/common/packages/gsp_git_store/tests --basetemp build/shared-git-store-tests
```

The pytest configuration also permits source-tree testing before installation. Test results establish their tested storage behavior and environment, not broader semantic or institutional conformance.

20.1.7 License and contributors

This package is available under the infrastructure repository's MIT License, with copyright held by the contributors recorded in CONTRIBUTORS.md. The license scope notes preserve third-party terms and distinguish software licensing from the rights in user-created records. Programme governance drafts remain separate from this express software grant.

23 README

Original source: `applicative_infrastructure/common/packages/gsp_record_protocol/README.md`.
Original source SHA-256: `a3c60a7344614fdab69c20db235db4f905f5f3712ab5c33a968c3b4fcf2731e7`.

23.1 GSP record protocol package

Class: Experimental implementation package
Package version: `0.3.0` (additive temporal capability; base protocol identifiers below are unchanged)
Protocol: `gsp-record-protocol/0.2`
Record schema: `gsp-workspace/0.2`
Profile: `gsp.general/0.2`

This independent Python package validates bounded record graphs, prepares transactions, and produces incidence and event-based spacetime projections. It has no Flask, database, filesystem-storage, or Git dependency. The CLI reads a supplied JSON file; the preparation library does not publish changes or inspect actual attachment bytes.

The information-model Specification defines the experimental contract and its limits. The design separates semantic graphs, recording history, and views. Passing these validators is not factual verification or full GR conformance.

23.1.1 Install and inspect

From the repository root, using a Python 3.11+ environment:

```
python -m pip install -e ./applicative_infrastructure/common/packages/gsp_record_protocol
python -m gsp_protocol validate-snapshot
↪  applicative_infrastructure/common/packages/gsp_record_protocol/tests/fixtures/graph_snapshot.json
python -m pytest applicative_infrastructure/common/packages/gsp_record_protocol/tests
```

Restricted Windows environments can supply an existing writable parent and a fresh `--basetemp` path to pytest.

23.1.2 Public API

Function	Result and responsibility
`capabilities()`	Fresh dictionary describing protocol, profile, modules, operations, and library limits.
`validate_transaction(tx)`	Structural request validation. It cannot resolve references without a snapshot.
`normalize_snapshot(snapshot)`	Deep-copied read adaptation with `legacy`, `source_schema_version`, and `read_adaptation`. Original schema declarations remain unchanged.
`validate_snapshot(snapshot)`	Schema and scoped semantic report, including warnings for unsupported or unstructured material. Does not inspect actual file bytes.
`project_graph(snapshot)`	Snapshot-bound nodes and incidence/neutral-reference edges, warnings, selection declaration, and source `head`.
`project_spacetime(snapshot, after=None)`	Explicit event partial order, ancestor-closed cut, scoped ontology topology, trajectory groups and diagnostics. `None` selects all events; `[]` selects the empty cut. No storage writes.
`request_digest(tx, files_meta={})`	SHA-256 of RFC 8785 canonical JSON `{transaction: tx, files: files_meta}`. File metadata comes from an adapter that has actually hashed received bytes.
`prepare_transaction(snapshot, tx, actor, now, files_meta={})`	Candidate `snapshot`, `receipt`, and `changed_record_ids`. Inputs are unchanged. The returned head still identifies the expected parent.

`ProtocolError` carries `code`, `message`, and a `fields` mapping. HTTP status, authentication, authorization, binary acquisition, idempotent receipt lookup, storage budgets, conditional publication and recovery belong to the binding. The storage adapter records the new commit after publication; this package does not predict a self-referential commit identifier.

The actor has `id` and `display_name`. The recording timestamp is an ISO 8601 value with an offset. `files_meta` maps each declared multipart name to exactly `sha256` and integer `byte_length`; server paths are excluded. Duplicate, missing, extra and mismatched parts fail validation.

23.1.3 Module and graph rules

Implemented version `1` modules are `gsp.relation`, `gsp.notes`, `gsp.files`, `gsp.event_order`, and `gsp.temporal_extent`. The two temporal modules require `required: true` so earlier readers preserve them and block edits that cannot validate their constraints. Optional unknown modules or unsupported versions survive unrelated edits exactly and remain read-only. Required unsupported modules block project mutation. New unknown modules cannot be introduced through this implementation's editing interface.

An unsupported declared project profile also blocks mutation, including migration. Reads preserve its declaration and report an interpretation warning. An absent profile in a legacy workspace remains eligible for explicit migration. A structural report does not claim to assess an unfamiliar profile's additional requirements.

Every record remains a node. A structured Relation is independently selectable and contributes one edge per participant incidence. Orientation `in` points from the participant to the relation; `out` points from the relation to the participant; `undirected` has no asserted arrow direction. A neutral cross-reference is separately labeled `kind: reference`; its `source` records where the navigation reference is stored, without asserting a directional substantive relation.

Legacy snapshots retain their `gsp-workspace/0.1` declarations during reads. Only a sole `project.migrate` operation, with the `migration` change category, produces current schema content. Migration does not infer relation participants or change earlier account attribution/timestamps.

23.1.4 Event-defined topology

The additive GR-SPEC-121 extension keeps the base protocol/schema/profile at 0.2. Event order is asserted by first-class Relation records with matching `gsp.relation` incidences. Git ancestry, recording timestamps and free-text dates never determine that order. Event ranks support layout; incomparable events are not thereby simultaneous.

Temporal extents specify inclusive start and exclusive end boundaries, each explicitly an Event reference, unknown, or unbounded within a stated account scope. Records without an extent remain unscoped. Only accounts established active at a cut contribute to its induced topology; omitted relation participants are diagnosed. An optional subject reference groups accounts into a stated trajectory without proving target identity or continuity.

Cycles are retained as contradictory accounts with a diagnostic event graph and no fabricated cut or topology. Unsupported event-order versions likewise prevent a cut; unsupported extent versions make the affected presence indeterminate. This projection selects applicability claims; it does not simulate event effects, infer causation, resolve competing accounts, or reconstruct an unrecorded historical state.

23.1.5 Limits and evidence

The reusable profile permits 100 operations, 1,000 records, 32 incidences per relation, eight binary parts, 10 MiB per file and 20 MiB combined binary parts. Module JSON is bounded to 256 KiB; transaction JSON to 2 MiB; snapshot JSON to 64 MiB. These are application limits, not GR theoretical requirements. A binding can declare tighter limits; the current HTTP binding uses 1 MiB transaction JSON and its Git reader uses 32 MiB aggregate snapshot JSON.

The tests exercise semantic cycles, parallel and higher-order relations, partial incidence, repeated participant roles, independent qualification dimensions, opaque modules, migration, final-reference validation, retained material descriptors, replay-digest inputs, historical projections, invalid inputs and the CLI. Static fixtures are stipulated examples. They do not constitute an independent academia implementation or an institutional pilot.

24 CONTRIBUTING

Original source: `applicative_infrastructure/gr_academia_application/CONTRIBUTING.md`.
Original source SHA-256: `38c11a3c6659933950025859b27bbd318ffb6d328134754fb5014a7b4c80e519`.

24.1 Contributing

Use this repository for academia-specific workflows, the native GRRP implementation and its web application. Explain how a change affects research acts, provenance, contestation and portability. Preserve source history and distinguish a proposed shared-protocol adapter from a completed semantic migration. Keep private research records, accounts and keys outside the source repository.

The project-authored material is offered under the MIT licence, within the current scope. By intentionally submitting original work for incorporation, you offer it under MIT while retaining your copyright. Identify third-party material, its terms and your authority to contribute it; access to a research record alone is not permission to publish it.

Add your preferred contributor name or organization and a short contribution description to CONTRIBUTORS.md when your work is incorporated. Changes to GRRP also update its packaged contributor list. Preserve prior author and organizational credits, external notices and historical licensing artifacts. AI tools may be acknowledged as tools, not as copyright holders.

25 CONTRIBUTORS

Original source: `applicative_infrastructure/gr_academia_application/CONTRIBUTORS.md`.
Original source SHA-256: `0ca6ed514b41159077a3efece79ef79b6c8c5e38adf033eb6354ce2b49f560b5`.

25.1 Contributors

Copyright (c) 2026 the contributors listed in this file, for their respective contributions.

Contributor	Recorded contribution
Wanhong Huang	GRA papers, GRRP design, original application development, and subsequent design direction. Source Git author variants include `HUANG WANHONG` and `Wanhong HUANG`.
Serendip Commons Society	Organization credited in the original application copyright notice and GRRP package authorship metadata.

Attribution is grounded in the preserved original README, original licensing statement, GRRP package metadata, and source Git history. Commit authorship is evidence of contribution, not by itself a determination of ownership. This file preserves the organizational credit without inventing an assignment of individual rights.

The MIT licence in LICENSE refers to this list. Contributors retain the rights in their respective contributions; this list does not assign ownership of every file to every person or organization listed.

Add a contributor's chosen name or organization and a brief contribution description when their work is incorporated. Preserve existing attribution. Corrections can be proposed through the same review process as other repository changes.

AI tools have assisted drafting, implementation, and review. They are development tools and are not listed as copyright holders. Third-party components retain their own author and licence notices.

26 LICENSE

Original source: `applicative_infrastructure/gr_academia_application/LICENSE.md`.

Original source SHA-256: `0617f4b27c8d9088452d16b2c9ad48407e9c08b000a2d6bde27626928b912459`.

26.1 Licensing scope

Effective date: 2026-09-22. **Licence:** MIT. **Authority:** explicit project-owner instruction to use MIT across the four project repositories and credit all contributors.

The MIT licence applies to the project-authored software, GRRP implementation and specifications, documentation, tests, research papers, and other project-controlled materials distributed in this repository. Its copyright notice credits the contributors listed in CONTRIBUTORS.md, for their respective contributions. The licence text follows the Open Source Initiative MIT text.

26.1.1 Earlier licences and the current grant

The imported application previously stated AGPL-3.0-or-later for software, CC BY 4.0 for documentation, and CC BY-NC 4.0 in the four research papers. The present MIT grant is additional permission for the project-authored material in the current repository. Earlier permissions remain available; the old publication notices are preserved rather than rewritten as if they had always said MIT.

In particular, the project-authored content of the four PDFs in `papers/` is now also offered under MIT. The PDF bytes and their embedded CC BY-NC 4.0 notices remain unchanged as historical source artifacts. A redistribution relying on MIT includes this scope notice, `LICENSE` and `CONTRIBUTORS.md` with the PDF to make the additional permission explicit. This grant does not extend to externally authored material quoted or reproduced within a paper.

The earlier licensing statement, AGPL licence text, migration-era notes, original README and source Git bundle remain preserved. These record earlier terms; they are not the current package licence declaration. The transition record identifies the change and unchanged artifacts. The original external checkout is unaffected.

26.1.2 Scope boundaries

Dependencies, copied external works and third-party notices retain their respective terms. This project does not claim authority to relicense them. Research records, manuscripts, datasets, media and other content supplied by application users retain their own rights; hosting or processing them does not apply the software licence to them.

No copyright assignment is required by this statement. Contributors retain rights in their respective contributions, with future contributions offered as described in CONTRIBUTING.md.

27 README

27.1 Generative Relational Academia

Class: Domain application and development guide
Status: Experimental application retaining native GRRP v0.1
Source repository: Generative-Relational-Academia-Application

Generative Relational Academia records research as an evolving trajectory: questions, positions, objections, transformations, decisions and connections can remain inspectable alongside the material through which inquiry develops. The web application presents projects, trajectories and record workspaces; the native Python implementation also supports local command-line use.

This repository is the academia application within the Generativity Standards Program. Its existing GRRP identifiers, signatures, transition rules and domain behavior are preserved. Alignment with the generalized application's record protocol remains separate design and implementation work. Imported theoretical papers retain their historical role; the current programme manuscripts and recorded decisions guide programme-level interpretation.

27.1.1 Current capabilities

- Browse shared projects and search their records; signed-in users can create and operate their own projects.
- Open questions within a project and follow the trajectories of identified states and transitions.
- Explore graph views, select a record or connection, and inspect its record, disclosure and workspace panels.
- Retain research material and working content beside the relevant subject rather than only at project level.
- Invoke native research acts through the interface and Python CLI, including claims, challenges, transformations, decisions and connections.
- Use native GRRP validation, signatures, registrations, disclosure declarations and portable record tooling within that protocol's existing scope.

The web guide explains the hosted model, and the Python package guide documents the CLI. Search is a filtering facility rather than a participant or trajectory ranking. A cryptographically valid or well-formed record does not by itself establish that the recorded claim is true.

27.1.2 Repository layout and authority

```
gr_academia_application/               This application Git repository
├── web_application/
│   ├── packages/client/               React and Vite interface
│   ├── packages/server/               Fastify host, accounts, SQLite and record operations
│   └── packages/protocol/             Native @gra/protocol TypeScript implementation
├── domain_packages/grrp/              Native Python implementation and CLI
├── provenance/                       Import manifest and original Git history bundle
├── docs/                             Interface guides and historical overview
├── notes/  plans/  papers/            Imported domain research and design history
└── LICENSE  LICENSE.md  CONTRIBUTORS.md
```

The application is a submodule of applicative_infrastructure, which pins a specific revision. Its original Git ancestry is retained, and the provenance guide records the original source commit, archived bundle and path mapping. The original overview remains in docs/history/original_README.md; its historical status and licensing statements should be read with the current scope notes.

Native Python grrp and TypeScript @gra/protocol remain domain packages. This application does not yet use the common generalized record protocol or Git transaction implementation. It has independent accounts, permissions and runtime records. Links to the parent Programme Brief and specifications resolve when the complete programme is checked out.

For the supported combined development layout, clone infrastructure with its submodules using GitHub SSH access:

```
git clone --recurse-submodules git@github.com:huangwanhong-maker/Generativity-Relational-Epistemic-Applicative-Infrastructure.git
↪  applicative_infrastructure
cd applicative_infrastructure
```

To obtain only academia's source, use `git clone git@github.com:huangwanhong-maker/Generative-Relational-Academia-Application.git gr_academia_application`. For the complete programme and canonical publications, recursively clone Generativity-Epistemic-Infrastructure. Its Git workflow guide covers Windows SSH configuration and remotes.

27.1.3 Install and run

Use Python 3.11 or later, Git, and Node.js/npm. Node 22.12 or later on the Node 22 release line supports the current frontend tools and matches the validated major version.

The supported combined setup runs from the **parent infrastructure directory**, with its application submodules initialized:

```
python common/tools/setup_application.py academia --dev
python common/tools/run_application.py academia
```

Open **http://127.0.0.1:8001**. Setup creates a separate Python environment, installs the relocated native package, installs the npm lockfile and builds the protocol, server and client. The development option includes Python test dependencies. It does not create demonstration accounts or seed research records.

The shared tools belong to the infrastructure repository. A clone of this application alone contains its Python and Node sources but not those tools or the predefined environment layout. For a manually configured installation, install the Python package, run npm's lockfile installation/build in the web workspace, and provide explicit absolute paths for the runtime and Python interpreter.

After setup, the compiled server can be launched directly:

```
node "<absolute-academia-directory>/web_application/packages/server/dist/main.js"
```

Defaults are resolved from source location instead of shell working directory. The default interpreter still expects the parent infrastructure environment unless GRA_PYTHON selects another installed interpreter.

For interface development, run these in separate terminals from this application's web_application directory:

```
npm.cmd run dev --workspace @gra/server
npm.cmd run dev --workspace @gra/client
```

Use npm on POSIX. The optional Vite client uses port 5174 and proxies API requests to the server on port 8001.

27.1.4 Accounts

Academia preserves its existing account-provisioning behavior. When public registration is closed, the operator CLI creates accounts. From this application's web_application directory:

```
npm.cmd run account --workspace @gra/server -- list
npm.cmd run account --workspace @gra/server -- add "<account-name>" --password "<chosen-password>" --party
↪  "<user-generated-public-party-key>"
```

Replace placeholders locally. The password must be at least eight characters; the current CLI accepts it as a command argument, so shell history and process visibility need consideration. Supplying a party key generated by the participant avoids the CLI generating and displaying a private key. Omitting the party flag invokes the existing key-generation bootstrap flow.

The same runtime configuration applies to the server and account CLI. Accounts represent access to this host, while native record identities and signing material have their own custody. Account database columns alone do not establish that a host cannot sign for a party: native record directories can contain private keys.

27.1.5 Runtime configuration and backups

Default locations below are relative to the parent infrastructure directory.

Variable	Default	Purpose
GRA_RUNTIME	.runtime/academia	Parent runtime
GRA_RECORDS	.runtime/academia/records	Native record trees, Git histories, material and keys
GRA_DB	.runtime/academia/index.sqlite	Retained accounts plus rebuildable indexes
GRA_PYTHON	.runtime/environments/academia/Scripts/python.exe on Windows; bin/python on POSIX	Interpreter with the native Python package installed
GRA_CLIENT	gr_academia_application/web_application/packages/client/dist	Built client
GRA_HOST / GRA_PORT	127.0.0.1 / 8001	Direct-server address

Supply absolute paths for location overrides. The shared launcher selects host and port through its command arguments. GRA_PYTHON is one executable path and supports spaces; GRA_GRRP remains the legacy simple-command override. The session cookie is gra_session, distinct from generalized's cookie.

Back up the complete account database and records tree, including private key material and active journals, with appropriate access restrictions. Stop the writer for a filesystem backup or use a verified online procedure. Accounts are not reconstructable from the derived record index. Source history, npm dependencies and virtual environments cannot replace a runtime backup.

Relocation preserved the existing three academia accounts, two projects and five trajectories without altering native record semantics. Those are properties of the migrated local runtime; source clones contain none of that private data. The original source checkout/runtime remains separate and unchanged. See migration evidence for the backup and comparison boundary.

27.1.6 Verification

After development setup, from this application directory on PowerShell:

```
& ../.runtime/environments/academia/Scripts/python.exe -m pytest domain_packages/grrp/tests --basetemp
↪  ../.runtime/test-output/academia -q
npm.cmd --prefix web_application test
npm.cmd --prefix web_application run build
```

Use bin/python and npm on POSIX. The test-output directory is disposable and must not name retained user data. The native Python and TypeScript vector suites check agreement on protocol identifiers.

The relocation validation report records **208 Python tests passed, one platform-specific skip, 43 TypeScript protocol tests passed and 48 server tests passed**, plus a production build and isolated deep-path record operations. These assess the native domain application; they do not verify a generalized-protocol adapter.

27.1.7 Current limits and next work

The inherited lockfile's dated migration audit reports six affected npm packages. Dependency maintenance remains open. Native identity/custody choices, disclosure behavior, account recovery and production operation also need dedicated review before broader deployment.

Generalized transaction receipts, modules, concurrency behavior and epistemic recording requirements are not automatically supplied by relocating this application. Future alignment needs an explicit preservation mapping, including signed bytes, native identifiers, registrations, disclosure and unmapped content. Avoid rewriting imported records or papers to make them appear to have used later programme concepts.

Demo tools create accounts and research records. Use a separate explicitly configured runtime when exercising them; they are not setup prerequisites.

27.1.8 Contributing and license

Commit academia source changes here, then update the application reference in infrastructure and its reference in the programme. Keep native protocol vectors and preservation tests alongside behavioral changes. Record cross-domain mapping decisions in the programme and shared design material rather than silently changing domain meaning.

Publish academia's commits before the infrastructure commit that references them, followed by the programme's infrastructure update. Select a development branch before committing in an initialized submodule, which normally begins with a detached HEAD. Existing remote ancestry is preserved through ordinary fast-forward publishing.

Project-authored software, documentation and research material are available under the MIT License, with copyright held by contributors recorded in CONTRIBUTORS.md. LICENSE.md and licensing provenance explain the additional grant and retained historical notices. Third-party components and user-created research records retain their own terms.

Copyright (c) 2026 all contributors listed in CONTRIBUTORS.md, for their respective contributions.

28 README

Original source: `applicative_infrastructure/gr_academia_application/docs/gallery/README.md`.
Original source SHA-256: `34c155d408f2200cde21a1515e362975a65b03bc1b6b709db5ca5f665ccdddae`.

28.1 Gallery

Real output from a real record, not mock-ups.

file	what it is	made by
`01-front-page.png` … `08-search.png`	the hosted interface, signed out and signed in	`node web/tools/gallery.mjs`, against a running server
`trajectory.svg`	a trajectory drawn from the record	`grrp graph -o trajectory.svg`
`release.md`	the document a release emits	`grrp export`

To remake the screenshots:

```
cd web
npm run account --workspace @gra/server -- add ada --password '…'
npm run dev                  # in one terminal
node tools/gallery.mjs       # in another; needs a project with some work in it
```

The script needs `puppeteer`, which is deliberately **not** a dependency of anything — `npm install -D --no-save puppeteer` when you want it. A gallery tool should not be something the project needs in order to build.

29 release

Original source: `applicative_infrastructure/gr_academia_application/docs/gallery/release.md`.
Original source SHA-256: `30cbc38ea0a9b0d8c8096de4b1893743841eaec253ec38499bf49dc542e8b95b`.

29.1 trust

Question. Is trust a property obtaining between individuals?
Released 2026-08-07T11:50:06Z ·release `44090b81ceee` ·state `960f13b89624` ·protocol `grrp/0.1`

> **Unattested.** Every transition in this record was registered by the party who performed it. A record registered by one party alone carries utility to its author and no evidential weight, and this document does not claim otherwise.

29.1.1 Released state

Narrow the account to institutional settings.

29.1.2 Objections standing at release

None recorded at the time of release.

30 LICENSE.before MIT

Original source: `applicative_infrastructure/gr_academia_application/docs/history/LICENSE.before-MIT.md`.

Original source SHA-256: `eb10bc17c76529f1d238ae97a08b3ad8f448320822bb28ca1e9086cc7f20650b`.

30.1 Licensing

Generative Relational Academia (GRA) is developed as open scholarly infrastructure intended to remain freely usable, inspectable, extendable, and continuable by researchers, institutions, and communities.

30.1.1 Software

The `grrp` reference implementation and other software in this repository, unless otherwise stated, are licensed under the **GNU Affero General Public License, version 3 or any later version (AGPL-3.0-or-later)**.

Copyright © 2026 Wanhong Huang and all contributors listed in CONTRIBUTORS.md.

The complete licence text is provided in `LICENSE`.

The choice of AGPL reflects the generative and commons-oriented design of this project. GRA may be deployed as network-accessible scholarly infrastructure, and developments emerging from the shared implementation should remain capable of circulating back into the commons.

30.1.2 Specification and documentation

The GRA and GRRP specifications and documentation are intended to be openly forkable, independently implementable, and continuable across infrastructures.

They are licensed under the **Creative Commons Attribution 4.0 International licence (CC BY 4.0)** unless otherwise stated.

Two requirements of the design particularly motivate this openness:

- The specification must be licensed so that **any party may fork it**, and conformance to a fork must be expressible in the version identifier. Otherwise, custodianship of the specification becomes a position of authority rather than a service (Paper IV, Requirement 19.4).
- A record must permit **continuation elsewhere**. This is one of the five joint properties of portability, and portability is the principal bound this design places on the authority of any infrastructural position within it (Paper I, Requirement 16.2).

The licensing of the protocol does not require an independent implementation of GRA or GRRP to use the licence of the reference software merely because it implements the protocol.

30.1.3 Research records and contributed content

The software and documentation licences of this repository do not automatically determine the licences of research records, manuscripts, datasets, media, or other scholarly content created, deposited, referenced, or managed through GRA.

Such materials remain subject to the licences and rights specified by their respective authors or rights holders.

30.1.4 The four papers

The PDFs in `papers/` each carry their own licence notice within the document:

Creative Commons Attribution–NonCommercial 4.0 International (CC BY-NC 4.0).

They remain under those terms until their licence notices are revised by their author.

Where this licensing statement and a document's own licence notice differ, the licence stated within that document governs that document.

31 LICENSING NOTES.before MIT

Original source: `applicative_infrastructure/gr_academia_application/docs/history/LICENSING_NOTES.before-MIT.md`.

Original source SHA-256: `af7b0ab32d77abe75896a40710d9093926b9cf68d7f4f055e1711eb124824661`.

31.1 Licensing preservation notes

Status: Informative import record, 2026-09-22; no change of licence.

The source `LICENSE.md`, Python package metadata, and npm package metadata identify the software as **AGPL-3.0-or-later**. The source GRRP README instead ended with a stale MIT statement. The active relocated README now refers to the repository's existing AGPL licensing statement; the earlier text remains recoverable from the source Git bundle and import manifest.

The source licensing statement linked a `LICENSE` file that was absent. The official AGPL v3 text was retrieved from `https://www.gnu.org/licenses/agpl-3.0.txt` on 2026-09-22 and saved as `../LICENSE` (34,523 bytes; SHA-256 `0d96a4ff68ad6d4b6f1f30f713b18d5184912ba8dd389f86aa7710db079abcb0`). The "or later" choice remains in the preserved licensing statement and package metadata.

The preserved copyright notice refers to `CONTRIBUTORS.md`, also absent in the imported source. No contributor list has been invented. Source commit authorship is available in the history bundle; authorship metadata is not itself a determination of copyright ownership.

The documentation and papers retain the distinct licences described in `LICENSE.md` and their own notices. Research records and contributed content do not acquire the software licence solely by being handled by this application.

32 original README

Original source: `applicative_infrastructure/gr_academia_application/docs/history/original_README.md`.
Original source SHA-256: `cda22e27690eae441d5cca3791eac52edfff75bc068183fae3cb4906960774bd`.

[!IMPORTANT]

32.0.1 Building the next open infrastructure for generative academia

Recent changes across the open-science infrastructure landscape have again highlighted how difficult it is to sustain open scholarly spaces over the long term.

Knowledge and academia develop through continuous co-evolution, propagation, discussion, revision, and co-creation within a commons. Research projects are living generative processes: ideas emerge, relations form, evidence changes understanding, discussions redirect trajectories, and new knowledge creates conditions for further knowledge.

This is one of the motivations behind **Generative Relational Academia (GRA)**.

GRA aims to develop an open academic protocol and infrastructure supporting familiar scholarly functions such as research project management, publication, persistent identification and DOI integration, while placing particular emphasis on the **generativity and evolving trajectory of research itself**. We are exploring how research processes, epistemic transitions, provenance, collaboration, discussion, AI participation, and relations among scholarly objects can become visible, interoperable, reconstructable, and capable of continuing across platforms.

This is currently an independently initiated open project. We welcome researchers, developers, librarians, open-science communities, universities, research infrastructures, and anyone interested in the future of scholarly communication to discuss, experiment, contribute, or explore possible cooperation with us.

If you are interested in co-creating this infrastructure, please feel free to contact us or contribute directly to this repository:

Wanhong HUANG Serendip Commons Society huangwanhong@serendip.ngo

32.1 Generative Relational Academia (GRA)

Infrastructure for recording how understanding changes.

Scholarly communication transmits finished artefacts and discards the *trajectory* that produced them — which assumption was abandoned, which objection forced the abandonment, which approach was tried for six months and set aside, which direction was chosen over which alternative and on what ground. GRA is a protocol, and a reference tool, for keeping that record.

Stage 0 — design and standardisation. Four papers are drafted and the protocol is specified as **GRRP v0.1**, which has **no deployment history and no evidence of use** — every requirement in it is a proposal about what such use would need. The reference tool `grrp` implements the protocol through the **open tier**, and **all eight acceptance tests pass**. It has not yet been used on real work.

The protocol now exists **twice**: in Python (`grrp/`) and in TypeScript (`web/packages/protocol`), agreeing byte-for-byte on 35 shared vectors. A protocol nobody has implemented twice is a protocol whose specification has not been tested — and that suite found a real one on its first run, where the two languages stripped different sets of trailing whitespace and produced two different identifiers for the same document.

A hosted interface is being built in `web/`: **a host for projects, which is not their authority.** It stores no private key, computes no quantity over anyone, and can be deleted without costing anybody a record.

32.1.1 Gallery

Everything below is real output from a real record — the philosophy case from the specification. Nothing here is a mock-up. The screenshots are taken from a running server by web/tools/gallery.mjs; the drawings are emitted by the tool itself. The command that produced each one is named.

32.1.2 The front page, signed out

Reading what people have shared, and searching it, needs no account. An account is access to one host, not permission to look — and a front door that showed nothing until you signed in would have already decided it was the authority.

[Image retained in source archive.]

32.1.3 A project, as one graph

Every question in a project, in one picture — the demonstration record `field-memory`, which carries every node and edge kind the graph model names. The deeper rose edge **crosses between questions**; the labelled capsule on a line is a **connection: a reified edge**, drawn as an edge and openable as a node, because it is one. Nodes drag; the view pans and zooms; positions are your view only, recorded nowhere.

Left to right is distance from a question, not importance. Nothing is ranked, sized or coloured by how much it matters, and no line is marked the principal one.

[Image retained in source archive.]

32.1.4 One subject, in full — including an edge

Selecting anything lights what it touches and lets the rest recede. Here the selected subject is a **connection** — the reified SUPPORTS edge between two questions — opened as a node beneath the drawing with its record panel (the signed payload, the CiTO binding, registration, the full identifier), its disclosure panel, and **its own workspace**. The acts row records against it through `grrp`, whose refusals are shown verbatim.

[Image retained in source archive.]

32.1.5 What happened, under one question

[Image retained in source archive.]

32.1.6 Search, which filters and does not rank

No relevance ordering, no best match, no score. Matches come back in the same order everything else is listed in, and the API says so in its own payload so that a second client cannot present them as ranked without contradicting it.

[Image retained in source archive.]

32.1.7 The trajectory, drawn by the tool itself

[Image retained in source archive.]

```
grrp graph -o trajectory.svg
```

One column per step away from the question. Edges are labelled by the act that made them. The two positions on the right **diverged, and are drawn identically** — nothing in the picture designates a principal line, because nothing in the record does. In inquiry a fork is frequently the correct outcome, so plurality is the normal shape of a healthy record rather than an unfinished one.

The objection in amber is `unresolved` and has never been answered. It stays there.

32.1.8 Where the work stands

```
$ grrp show
trust   (trust)
  question   Is trust a property obtaining between individuals?

  live positions
    960f13b89624  Narrow the account to institutional settings.
    9168b1900d17  Keep the general scope and weaken the claim.
    these diverged. Neither is the canonical one.

  unanswered
    a670a1a0d460  question    Is trust a property obtaining between individuals?
    68985dd9b7cb  challenge   The revision cannot now distinguish trust from complian⋯

  unattested throughout - useful to you, evidence to nobody
```

Derived from the log, never stored. The last line is the honest one: **a record you registered yourself is useful to you and is evidence to nobody.**

32.1.9 What you still owe an answer to

```
$ grrp open
trust - trust
  a670a1a0d460  question     2026-08-07T11:48:32Z
      Is trust a property obtaining between individuals?
  68985dd9b7cb  challenge    2026-08-07T11:48:34Z
      The revision cannot now distinguish trust from compliance.
      against b9493578195b
```

This is also **the entry path**. Each item is an identified state that someone holding no prior standing in your work can reference in a challenge, a connection or a verification — and be judged on the act itself, not on who they are.

32.1.10 What a ground leaves disclosable

```
$ grrp disclose 616bb79843 --class private --ground appropriability
disclosed 616bb79843a1  at private
  ground   appropriability - the content whose disclosure would destroy that excludability

  What this ground leaves disclosable, and what you must still disclose:
    appropriability: the existence of the work, the questions pursued, the decisions
    taken and their reasons, and negative results

  Misapplied, this is: rent-seeking secrecy - secrecy obtained on an economic
  justification that does not apply.
```

The residue is surfaced at the moment of withholding, because it is the **one question a reader can always ask**: was what the ground leaves disclosable in fact disclosed? A declaration accompanied by its residue costs the declaring party something; one without it costs nothing.

32.1.11 What it refuses

The most characteristic thing about the tool is what it will not do.

```
$ grrp register 3bd6fc72e6
[C2] you cannot register your own act. Credibility follows from the distribution of
registrations across parties who did not coordinate, and follows from no property of
the record itself.

$ grrp disclose 687087cf --class private --ground hazard
[C7] disclosure may widen and never narrow. 687087cf329f is at 'public'; 'private'
is narrower. A party who has read a record retains what they read, so an operation
offering the appearance of withdrawal would misdescribe to your own participants a
state of affairs obtaining outside this record.

$ grrp disclose 616bb79843 --release-at 2030-01-01
refused: a schedule may be shortened, never extended (2027-06-01).
  Recording the attempt, because it should be visible that it was made.
[C7] a delay that can be extended indefinitely is a permanent withholding made to
look temporary.
```

Each refusal names the constraint and says what to do instead, because a protocol that refuses things without saying why reads as a bug.

32.1.12 The document it emits

```
grrp release && grrp export <release> -o paper.md
```

docs/gallery/release.md — the released state, **the chain of transitions that produced it**, the parties with their CRediT roles, the content absorbed from elsewhere with its attribution, and the objections standing unresolved at the moment of release. Assembled from records made in the course of the work, with no additional writing.

That last section is the one no other process can produce, and the reason adoption does not require anyone to stop publishing.

32.1.13 The local page, and the hosted one

```
grrp ui                     # single user, loopback, no account, no network
cd web && npm run dev       # a host: accounts, projects shared between them
```

Both are **Level 3 — an application over the record, outside conformance**: everything they offer is available from the command line, no module of the record imports them, and a test asserts that a record written from a page and one written from the terminal are the same record.

The hosted one stores **public keys only**. It has no column a private key could go in, which is what makes an attestation registered there worth anything: a host holding both parties' keys could forge one, and C2 would be bookkeeping rather than evidence. Deleting its whole database costs a reindex and nothing else — a test asserts that by deleting it and checking every record returns identical from the files.

32.1.14 The argument in four steps

1. The artefact is weakening as evidence. A published artefact conveyed information about its producer's capacity *only because producing it was costly in a way that discriminated between producers*. The evidence was never in the object — it was in the difference between what the object cost different producers. Where that cost falls for producers of every capacity at once, the discrimination goes while the artefact, the practice, and the systems reading it all remain in place. **The failure is invisible from inside the practice**, because the artefacts continue to arrive and continue to be counted.

2. So the trajectory becomes a candidate — but it inherits the same problem. Two hundred entries describing questions, attempts, failures and revisions, internally consistent and plausibly paced, are an *easier* object to fabricate than the paper they purport to have produced. Length, detail and the appearance of struggle are properties a fabricated record has as readily as a true one. **Preserving a research process establishes nothing on its own.**

3. Therefore credibility must come from distribution, not from content. A transition registered by **a party distinct from the one who proposed it** is costly to fabricate in proportion to the number of parties who would have to participate in the fabrication. The precedent is old: the bound, paginated laboratory notebook countersigned by a witness who was not the inventor — evidential *without* disclosing its contents to anyone. This is why GRA is a **protocol and not a platform**: a platform operator is party to every entry and cannot supply the independence the record's credibility depends on.

4. And the binding constraint is capture cost, not representation. Systems adequate to represent issues, positions, objections, options, claims and evidence have existed since 1970 — IBIS, gIBIS, Compendium, design-rationale notations, scholarly claim ontologies — built by capable people with funding, connected to deployed standards. **They were not adopted.** The documented cause is that the work of recording fell on the party who gained least from the record, at the moment they could least bear it, in a form that served a different party later.

The first constraint on the design follows: every act the protocol defines is one a participant performs for a reason of their own, with the record falling out of its performance. An act that exists *so that a record should exist* will not be performed, and any part of the design depending on such an act is moved to an optional tier or removed.

32.1.15 What is recorded

The unit is **not** a document, a comment, or an output. It is a **transition**: an identified prior state became an identified posterior state, through a typed act performed by a party and registered by a party.

```
state s_k  ──[ act: challenge  •  target: assumption  •  relation: modifies ]──▶  state s_k+1
               performer: A          registrar: B (distinct, signed)
               disposition: unresolved
```

A **trajectory** is the directed graph of these. **The "current state" is computed from the graph and never stored as an authority.**

This is what no existing system records. Platforms that decompose a publication into typed linked units show that a second hypothesis exists; they do not show that *this objection converted the first hypothesis into it*. Commentary systems attach a remark to an artefact — nothing transitions, no state is superseded, and the relation between the comment and any later change lives only in the author's memory.

32.1.16 Transitions are typed along five independent dimensions

Not one flat list of several dozen tags. Agreement between people classifying the same event declines as the number of categories rises, and a vocabulary requiring deliberation re-introduces the capture cost the whole design exists to avoid.

Dimension	Values	Extensible?
act	`question` `claim` `challenge` `transformation` `decision` `connection` `verification` `release`	fixed by the protocol
target	question ·assumption ·hypothesis ·concept ·theory ·method ·path ·artefact	by charter
relation	extends ·modifies ·replaces ·refines ·generalises ·specialises ·transfers	bound to **CiTO**
trigger	reflection ·literature ·experiment ·simulation ·observation ·discussion ·objection ·failure ·automated suggestion ·**entry of a new party**	by charter
disposition	`accepted` ·`contested` ·**`unresolved`**	fixed by the protocol

`unresolved` is not optional. Most objections in theoretical work are never resolved: they stand, and the work proceeds beside them. A vocabulary recording only acceptance and rejection would produce a systematically false record of the fields this project most concerns — and would exert pressure toward **fabricated closure**.

Contribution is not an act. It types a party's part **in** an act, and binds to **CRediT**.

32.1.17 Three planes

```
Applications          search  •  matching  •  summarisation  •  visualisation  •  assessment of content
                      ── outside conformance. The protocol requires none of it. ──
        ▲
   TRANSITION PLANE   typed transitions  •  parent links  •  attestation + signature  •  attribution and
                      absorption links  •  disposition  •  disclosure class + declared ground
```

```
                  APPEND-ONLY. The system of record.
      ▲  registration by a responsible party promotes an event to a transition
EVENT PLANE       auto-generated records that something occurred: meetings, comments, file
                  changes, permission changes, model operations.
                  PRIVATE TO PARTICIPANTS. Never exported, never indexed.
      ▼  delegation
Substrates        version control  •  repositories and persistent identifiers  •  federation protocols
                  ── existing, maintained by others, not reimplemented here ──
```

The event plane is cheap to populate and carries **no epistemic claim**. It is also where the surveillance hazard falls: a complete log of who attended and whose files changed is a monitoring record by construction. It is confined to participants and reaches wider disclosure **only through a transition that references it**.

GRA contributes the transition plane and the rules governing promotion into it — and nothing else. Storage, identifiers, append-only history, content addressing, archival deposit and transport all exist, are maintained by parties with the resources to keep maintaining them, and are delegated.

32.1.18 Withholding

An arrangement that records how understanding changes **must** be able to withhold. The question is never *whether* but **on what ground — and what follows from the ground**.

Nothing here confers a right to exclude. Withholding is justified **by a reason, never by a title**, and the reason does work: it determines what is withheld *and what must still be disclosed*.

Ground	Condition	What it restricts	**Residue — must still be disclosed**
rivalry	a resource admits limited simultaneous use	**access to the resource**	**the trajectory in full**
hazard	propagation of the content creates risk	the propagable content of a method	existence, questions, decisions, interpretations, non-conveying results
exploratory vulnerability	exposure now would suppress or distort the work	**the timing of exposure**	**everything, at the scheduled time**
appropriability	funding requires excludability	content whose disclosure destroys excludability	existence, questions, decisions, **negative results**

The residue rule is the operative rule of the whole design. Without it, every ground collapses into the same thing — silence with a justification attached. With it, a restriction becomes a **dated, attributable assertion**, and a reader has one checkable question: *was what the ground leaves disclosable in fact disclosed?*

That question is the only observable available in every case. **A declaration accompanied by its residue costs the declaring party something; a declaration withholding it costs nothing — and the second is the signature of misapplication.**

Three further rules:

- **Disclosure is monotone.** It may widen and must not narrow. **There is no `unpublish` operation** — a party who has read a record retains what they read, and an arrangement offering the appearance of withdrawal misdescribes to its own participants a state of affairs obtaining outside it. A scheduled release may be **shortened, never extended**.
- **Restriction is per record**, never per repository or per project. A single line of work carries states disclosed to everyone, to a group, and to nobody, with the differences declared and grounded.
- **Content is separable from the attested skeleton**, so **redaction removes content while leaving the graph and the signature chain intact** — and the record of the redaction itself is never removed.

The design cannot separate the valuable from the dangerous within a trajectory, **because they are the same material** — so it separates the *parties to whom it is disclosed* rather than filtering the content.

32.1.19 How it is adopted, if it is

The design assumes it will be used first by **one researcher, alone, with no collaborators**. If the tool is not worth using by a single person on the first day, nothing that follows happens.

Tier	Adds	What its adopter gets
Personal	transitions with parent links against identified prior states ·append-only log with derived views ·three acts (`claim`, `challenge`, `release`) ·content separable from skeleton	a searchable record of what was ruled out **and why** ·a standing list of objections not yet answered ·**a citable release with its chain**
Group	attestation by a distinct party · CRediT roles ·absorption links · disclosure classes with declared grounds ·administrative operations recorded	**evidence** — credibility begins where a second party registers ·visible attribution of changes · onboarding a new member from the record
Open	propagation with declared profile ·distributed custody ·archival deposit of released material · charter reference ·operator-independent identifier resolution	exchange with parties elsewhere ·continuation of the record beyond any operator ·entry of strangers through the open register

The personal tier delivers utility and no evidential weight, and the two must not be confused. Every transition in a self-registered trajectory is marked **unattested**, and stays marked on export.

Two things make the tiers matter economically. **Each tier must return something at its own scale**, so no party is ever asked to act on a benefit that requires others. And the **minimum viable adopting unit** is small: two parties who register each other's transitions at the group tier; one community with an implementation and a charter at the open tier. A design whose minimum unit was a discipline would need an agreement nobody can broker. This one needs a decision two people can take on a Tuesday.

A release emits a citable document — the released state, the chain of transitions leading to it, the parties with their roles, the absorption links with their attributions, and **the objections standing unresolved at the moment of release** — assembled from records created in the course of the work, with no additional effort. Nothing here asks anyone to stop publishing.

32.1.20 The entry path

A trajectory holds states whose disposition is `unresolved`: obstacles met, objections standing, questions raised without answers. That set, published at each disclosure class, is a **register of open problems**, and any party holding **no prior position at all** may reference one in a `challenge`, a `connection` or a `verification` — decided on the act itself.

This matters because the usual qualifications fail. *Demonstrated contribution* requires access in order to be satisfied and grants access in return for satisfaction; *trust extended by existing participants* has the same shape with an extra step. Both are closed against every party who holds no prior position — which reproduces, at the scale of a working group, exactly the exclusion the project diagnoses at large scale.

32.1.21 What this project does not claim

The papers spend a substantial part of their length forbidding specific claims. They are repeated here because they are the ones most likely to creep back into a description of the work.

- **It does not reduce competition or democratise recognition.** Standing is a *positional* good: the aggregate available in a field is fixed by construction. Making more contributions visible **redistributes** recognition; it does not create it. What may be claimed is that it **changes what competition rewards** — and that attribution mechanisms will therefore be *resisted* by parties who benefit from the present invisibility of others' contributions.
- **It does not produce serendipitous encounters.** There is no evidence that infrastructure increases productive unplanned encounter, and the strongest qualitative study of an arrangement designed to produce it reports occupants developing strategies to *avoid* it. What may be claimed is a lowered **cost of preparation**: a recorded, available state is preparation externalised, so that another party's preparation may meet it.
- **It does not measure capacity.** Two trajectories may coincide entirely in their recorded appearance while differing entirely in the generativity of the relations that produced them. **The record holds what occurred, not what the relation was capable of.**
- **It does not make another party's work continuable from where they stopped.** A record carries only the *articulable fraction* of what its participants held; the rest transmits, if at all, by working alongside them. What transfers is **the redirection of attention** — that an approach was attempted, on what assumption, and what obstruction was met.
- **It computes no scores.** No quantity over participants or over trajectories, and no total order over either. Not transition counts, not attestation depth, not contribution shares, not "trajectory health". This costs the arrangement the ability to report that a project is going well or to rank contributors for a committee, and the cost is real and accepted. *(Counts **within** one trajectory, shown without comparison across trajectories or participants, are permitted.)*
- **It requires no AI.** Every conformant operation is performable with a text editor and a version-control system. A model may *propose* a transition and may **not author or register one**, and a model-originated proposal is marked as such.
- **It has no merge.** Two revisions of a concept do not compose, no conflict region localises, and no test decides the result. Integration appears only as a **synthesis** (a state referencing several parents) or an **absorption** (content taken from elsewhere, with attribution to its originator). **In inquiry a fork is frequently the correct outcome, and plurality is the normal shape of a healthy record.**

32.1.22 What is known to be unsolved

These are stated as open, not as oversights. A difficulty counts as *addressed* only where there is a mechanism, an identified party who bears its cost, and a stated condition under which the mechanism fails. Four fail that test:

- **Assessment capacity.** Every mechanism lowers the cost of contributing and lowers the cost of assessing by nothing, so congestion follows *from the design working*. The usual remedy — ranking — is excluded. The remaining options (reciprocal obligation, bounded intake, maintainer triage) are all charter matters and all place an unfunded burden on a few parties. **This is the difficulty most likely to determine whether a conforming arrangement survives at scale.**
- **Maintainer labour.** Unfunded, concentrating on few parties, growing with adoption, with no party whose interest is proportional to the benefit. The open-source record is a warning here, not an encouragement.
- **The regressive incidence of overhead.** Recording falls hardest on those with the least time and the least standing — the population the diagnosis concerns. The byproduct principle addresses the *magnitude* and the *timing* of that cost, and not its *distribution*.
- **Recognition of attributed contribution.** No property of a protocol makes a community count what it records.

And two the papers name as structurally beyond the four grounds: **downstream reuse** of trajectory records by parties who did not produce them (the design's own criterion marks uncompensated corpus assembly as *extractive*, and supplies no mechanism against it), and **hazard restrictions**, which admit no scheduled release and so commit a community to maintaining a class indefinitely.

32.1.23 How this project would be shown to have failed

Stated in advance, so they can be looked for:

1. **Personal-tier adoption without progression to the group tier**, over a substantial population and period — the arrangement would have delivered private utility without the attested records on which every evidential claim rests, and become **a note-taking convention**.
2. **Records in which the `decision` act is rare while transformations are common** — the act on which the reuse of abandoned work depends is not being performed, and making it cheap was insufficient.
3. **Group-tier declarations alongside registration patterns of pairs who register only each other** — attestation operating as a formality.
4. **A widely used external score computed over conformant records** — the exclusion of scalar measures displacing the dynamic rather than preventing it.

Beyond the specification, the whole account is withdrawn on any of: a deployed system or published specification already taking the transition between identified states as its unit with registration by a distinct party; a specification already defining admissible acts and their effect on a shared state for scholarly work, with conformance conditions; evidence that the rationale-capture systems failed for reasons **other than capture cost**; or evidence that the artefact's separating condition has **not** weakened.

32.1.25 The papers

I ·Designing Generative Relational Academic Infrastructure	The problem, the prior art conceded in full, and **sixteen requirements** derived from it.
II ·Incentives, Collective Action, and Adoption	Whether any of this happens. Where the commons dilemma actually sits, the positional bound, **the absorption test**, and ten predictions with their refutations.
III ·Grounds of Restriction	Disclosure governance: four irreducible grounds, each with an object, a residue, and a named failure.
IV ·Specifying the GRRP	**The normative specification, v0.1** — record model, act vocabulary, attestation, absorption, disclosure, redaction, identity, propagation, conformance tiers and tests.

Notes: Paper I ·Paper II ·Paper III ·Paper IV ·Glossary ·Gaps and actions

32.1.26 The reference implementation

`grrp/` — a command-line tool recording trajectories as typed transitions in an ordinary git repository, in plain text, **with no server, no account, and no network**. Plan: plans/implementation-plan.md.

```
cd grrp && pip install -e . && python -m pytest

grrp init
grrp new "Is trust a property obtaining between individuals?"
grrp claim     -m "Trust obtains between individuals."
grrp challenge -m "This omits institutional power."      # defaults to the live position
grrp transform -m "Trust is shaped by asymmetry of power." --answering <challenge>
grrp decide --abandon      # omit -m and your editor opens, asking for the reason
grrp connect --to doi:10.1234/x -m "Same obstruction, other field."
grrp verify --failed -m "Independence does not hold in the target domain."

grrp show        # where this stands: question, live positions, what is still open
grrp open        # what you still owe an answer to — and the entry path for strangers
grrp release && grrp export <release> -o paper.md
```

Milestone	
M0 skeleton, canonical hashing, `init`	**built**
M1 personal tier — five acts, append-only log, derived views, `open`, `show`, `export`	**built — this is the ship point**
M2 full act vocabulary, `check` over the whole chain, separable content, `redact`	**built**
M3a group tier — keypairs, signatures, `register` with performer ≠ registrar	**built**
M3b CRediT attribution, absorption links, contested attribution, synthesis	**built**
M3c disclosure classes, grounds, monotone release	**built**
M4 open tier — `bundle`/`continue`, profile declaration, deposit, sealed registration	**built**
UI a local page — Level 3, outside conformance	**built**

The acceptance tests are written against the constraints rather than the features, and **all eight now pass** — including the last one: bundle on one machine, continue on another with no shared service, and get one graph rather than two.

Conformance is **self-declared and checkable from the record**. There is no certification body and none is required: a doubting party obtains the record under the continuation requirement and verifies the signatures, the identifier construction, and the presence of the required fields.

> `plans/implementation_plan.md` was an earlier draft that predated the specification and conflicted with it — "commit" for the epistemic unit, a flat type list, and roadmap items excluded as scalars. It has been retired; see notes/gaps-and-repo-actions.md for what it got wrong and why.

32.1.27 Status and declaration of interest

Stage 0. The specification is **v0.1**, published with an amendment procedure rather than as finished — a specification published as finished would contradict the account it specifies. **There is no implementation, no deployment history, and no evidence of use.** Every requirement is a proposal about what such use would need, and the requirements are expected to be wrong in ways argument cannot anticipate.

Amendment is itself conducted through a conforming record: a proposal is a **state**, objections are **challenges**, revisions are **transformations**, and adoption is a **release at the widest class** — enumerating the objections that stood unresolved at the moment of adoption.

Declaration of interest. GRA is developed by the **Serendip Commons Society**, which would host an implementation of the protocol and is a candidate custodian of the specification. Two rules follow and are held without exception. The society's activity is **evidence for no claim** in the papers. And every requirement imposed on a custodian applies to the society itself — including that **the specification be forkable**, that **stewardship of the specification be separated from operation of any implementation**, and that any conflict be recorded together with the arrangements limiting it.

The papers state that an arrangement in which the proposing party maintained the charter, operated the implementation, and held the restricting authority **would be an instance of the concentration the project diagnoses**. Declaring that conflict is a condition of the account's coherence, not a courtesy.

32.1.28 Contributing

The most useful contributions are the ones that would show the account wrong: a system or specification that already occupies the gap; a **reasonable restriction that fits none of the four grounds** (which would show the set incomplete — the account invites the observation, since a typology whose exhaustiveness cannot be challenged is a stipulation); or a demonstration that an act the protocol requires has no purpose for the party performing it.

Correspondence: huangwanhong@serendip.ngo

32.1.29 Licence

AGPL-3.0-or-later for the software. See LICENSE.md. © 2026 Wanhong Huang and Serendip Commons Society.

The choice is not incidental. Two requirements of the design constrain it, and the AGPL discharges both while adding a third thing this design wants: the specification must be licensed so that **any party may fork it** — otherwise custodianship is a position rather than a service (Paper IV Req. 19.4); and a record must be **licensed so that continuation elsewhere is permitted**, which is one of the five joint properties of portability, and portability is the only bound this design places on the authority of any position within it (Paper I Req. 16.2).

What the AGPL adds is the network clause, and it bears directly on the central risk here. A host that ran a modified GRA as a service would have to offer its modifications. **A closed fork cannot become the place everyone's records live** — which is the failure this whole design is arranged against, and the one a permissive licence would leave open.

Three things it deliberately does not reach:

- **The protocol.** An independent implementation of GRRP does not inherit this licence merely by implementing the specification. If it did, C10 would be a slogan.
- **Research records and contributed content.** Manuscripts, datasets, media and records created or managed through GRA remain under whatever their authors and rights holders specify.
- **The four papers.** The PDFs in papers/ each carry their own **CC BY-NC 4.0** notice inside the document and remain under it until those notices are revised. Where this repository's licence and a document's own notice differ, the document's notice governs that document.

35.1 grrp

Reference implementation of the **Generative Relational Research Protocol v0.1**, specified in *Specifying the GRRP*. **The specification governs where the two differ.**

A command-line tool that records the trajectory of an inquiry as **typed transitions** in an ordinary git repository, in plain text, **with no server, no account, and no network**.

Status: M0–M4, plus a local page. All eight acts, redaction, attestation, attribution and absorption, grounded disclosure, and portability. **All eight acceptance tests pass.** M5 is the conformance suite.

35.1.1 The unit of record

Not a document. Not a comment. A **transition**: an identified prior state became an identified posterior state, through a typed act performed by a party and registered by a party.

```
state s_k  ──[ act: challenge  •  target: assumption  •  relation: cito:disagreesWith ]──▶  s_k+1
               performer: key:ed25519:⋯    disposition: unresolved
```

A **trajectory** is the directed acyclic graph of these. **The current state is computed from the graph on demand and is never stored as an authority** — a stored snapshot becomes the thing people trust, the log drifts from it or is edited to match it, and every claim about integrity fails at once.

35.1.2 Install and use

```
pipx install -e .          # or: python -m pip install -e .

grrp init
grrp new "Is trust a property obtaining between individuals?"
grrp claim      -m "Trust obtains between individuals."
grrp challenge  -m "This omits institutional power."
grrp transform  -m "Trust is a process shaped by asymmetry of power." --answering <challenge>
grrp decide     --abandon        # no -m: opens your editor and asks for the reason
grrp connect    --to doi:10.1234/x -m "Same obstruction, other field."
grrp verify     --failed -m "Ran it on the target domain; independence fails."
grrp redact     <state> --ground consent_withdrawn

grrp show                  # where this stands: question, live positions, what is open
grrp open                  # what you still owe an answer to — and the entry path
grrp state                 # the live positions, derived
grrp log
grrp release               # publishes, enumerating objections that still stand
grrp export <release> -o paper.md
grrp check                 # verify the record, and this tool against the protocol
grrp ui                    # a local page, if you would rather see it than read it
```

35.1.3 The page

```
grrp ui        # anywhere — it does not need a record to exist yet
```

Serves a page on the loopback interface. From it you can **start a record** (a directory, and a git repository inside it if you want one), open a question, record any act, register a colleague's proposal, release, and **see the trajectory drawn**: one column per step away from the question, edges labelled by the act that made them, divergent branches side by side and drawn identically.

It is **Level 3 — an application over the record, outside conformance**. Everything it offers is available from the command line, no module of the record imports it, and deleting it

would leave the record untouched. That last claim is checked by a test rather than asserted. Stdlib only, no account, nothing leaves the machine.

It is tested for what the design forbids, because a screen is where the temptation is strongest: no quantity over participants or trajectories, no branch marked principal *in the drawing or anywhere else*, no control that narrows disclosure, no approve or veto, and the word *merge* nowhere at all — not in the page, not in the stylesheet.

A test also asserts that a record written from the page and one written from the terminal are the same record. Both go through `actions.py`, so the page is an application over the protocol rather than a second implementation of it.

35.1.4 Credit

```
grrp claim -m "…" --contributor bo=Methodology     # CRediT roles, attached to the act
grrp transform -m "…" --from <state>               # content you took, credited to its producer
grrp transform --with <state> -m "…"               # a synthesis drawing on several branches
grrp contest <tx> -m "…"                           # this attribution is wrong
```

Attribution attaches to **an act**, not to a finished work. A contributor statement says a person contributed to a paper; this says which change in the content of a claim a person produced.

An absorption link confers **attribution and no power to prevent, condition or reverse the use**. Rights to exclude, multiplied across many small contributions, produce the fragmentation in which downstream work needs so many permissions that it does not occur. A party who does not want their state absorbed has one instrument, and it is the disclosure class of that state.

`grrp contest` records that an attribution is wrong. Nothing is deleted or altered, and **no party is empowered to settle it** — what the record contributes is that both positions are visible with their dates.

35.1.5 Leaving

```
grrp bundle -o traj.zip        # the complete record: no permission, no service
grrp continue traj.zip         # anywhere, under any implementation
grrp profile --json            # what another implementation needs to read it
grrp deposit <release> -o dir/ # an archival package, released material only
grrp custody add "the departmental archive"
grrp custody succession "passes to …"
```

Portability is not export. A data dump leaves you with an archive. What matters is that the record can be *continued* elsewhere, with what you record next referencing what you obtained as parents — **one graph, not two**. That capacity is the only bound this design places on the authority of anyone holding a position over your record, including whoever wrote this tool.

Records that arrive are **copied byte for byte and never normalised** — rewriting them would invalidate their signatures. A signature that will not verify, a parent that is absent, a version this tool cannot read: each is **retained and marked**, never discarded, because discarding what an implementation does not understand is how a record quietly becomes a different record.

Two parties continuing the same record independently produce **a divergence**. Both are kept, neither is principal, and no reconciliation is offered.

35.1.6 Not ready to show anyone

```
grrp seal -m "…"          # records that you held this, at this time. Not what it is.
grrp openseal <state>     # later, when you choose
```

It **does not establish priority** — priority is a community's recognition of a claim, and no tool manufactures that. A sealed state **generates nothing**: no objection, no connection, no encounter, because nobody can see it. And an unanchored time is your own assertion; it becomes evidence to someone who does not trust you only if you publish the identifier somewhere you do not control.

35.1.7 Withholding

```
grrp charter adopt --classes private,group,public   # yours to decide; there is no default set
grrp grounds                                        # the four, and what each leaves disclosable
grrp disclose <tx> --class private --ground appropriability
grrp disclose <tx> --class private --ground vulnerability --release-at 2027-01-01
```

The question is never whether to withhold but **on what ground — and what follows from the ground**. There are four, the set is closed, and each leaves a **residue that must still be disclosed**:

ground	restricts	residue
rivalry	access to the resource	**the trajectory in full**
hazard	the propagable content of a method	existence, questions, decisions, interpretations, results that do not convey the method
vulnerability	the timing of exposure	**everything, at the scheduled time**
appropriability	content whose disclosure destroys excludability	existence, questions, decisions, **negative results**

Declaring a ground prints its residue and the named failure it becomes if misapplied. That residue is the one question a reader can always ask: *was what the ground leaves disclosable in fact disclosed?*

Disclosure may widen and never narrow. There is no `unpublish`. A schedule belongs only to vulnerability — the only ground with a terminus — fires by itself at the stated time, and **may be shortened but never extended**; an attempt to extend is refused *and recorded*, because a delay that can be extended indefinitely is a permanent withholding made to look temporary.

35.1.8 Two parties

A record you registered yourself is useful to you and is **evidence to nobody**. One colleague's key is what makes it evidence, and it is the whole of the setup that takes.

```
grrp key mine                     # hand this to them
grrp key add bo key:ed25519:⋯      # they do the same with yours
                                  # the record is now at the group tier

grrp claim -m "Trust obtains between individuals."
## claim  a72fe32c349e  (proposed)
## not yet in the log. Another party registers it:
## grrp register a72fe32c349e

grrp pending                      # what waits on you, and what of yours waits on them
grrp register a72fe32c349e        # they run this; you cannot
grrp withdraw <tx>                # a registrar undoing their own attestation
```

At the group tier **you cannot register your own act**, so what you perform is a proposal until someone else takes responsibility for it. That is where a record's credibility comes from: not from its content, its length or its detail, but from being registered by parties who did not coordinate.

`grrp register` refuses when the two keys are identical, and names the constraint. A withdrawal is itself an act, so it too must be registered by another party — the rule does not bend for the party undoing something.

`GRRP_KEY=<name>` selects which local key acts, for a machine two parties share and for the tests.

You rarely need to name a state. `challenge`, `transform`, `decide` and `release` default to the live position, which is what you almost always mean, and saves copying a hash out of one command into the next. Where two positions are live they refuse and list both with their text — nothing in the design gives the tool a basis for picking one.

Omit `-m` and your editor opens, with a prompt for the act you are performing. `decide` gets the longest prompt, because articulating why a direction was set aside is the expensive act and the one everything else depends on. Set `$GRRP_EDITOR` if you want a different editor here than in git.

Every command's `--help` states **`Purpose (for you):`** — what the person running it gets. That is checked by the test suite, because the reason every comparable system since 1970 went unadopted is that the work of recording fell on the party who gained least from the record.

35.1.9 Layout

```
.grrp/
  profile.yaml              protocol version, tier, hash, canonicalisation, party, vocabularies
  keys/self.pub             the private key is gitignored and never leaves the machine
  events/                   local event plane — gitignored, never exported
trajectories/<traj-id>/
  trajectory.yaml
  states/<hash>.md          content: separable, redactable
  transitions/<hash>.yaml   skeleton: append-only, never rewritten
  disclosure/<hash>.yaml    sidecar (M3): class and ground, outside the identifier
  releases/<hash>.yaml
```

35.1.10 Two design decisions worth stating

Disclosure is a sidecar, not a field in the transition file. The illustrative skeleton in the build brief shows `disclosure:` inline. Keeping it there forces a choice between two rules that both have to hold: *any edit under `transitions/` is detected*, and *changing a class or a scheduled release firing invalidates nothing*. Putting disclosure in `disclosure/<id>.yaml` lets both stay strict, and it is what the specification's own git deployment (§21.5) recommends for the same reason. Touches **C3, C7, C8**.

Registration is excluded from the identifier; the signature covers the identifier. The identifier is computed over the covered payload and the parent identifiers, and excludes `registration` and `disclosure`. A signature (M3) will cover `{id, registrar, time}`, so it binds the registrar and the time without self-reference and stays valid when disclosure widens or content is redacted. The cost, stated plainly: at the personal tier, where nothing is signed, **editing the `registration` block of a transition is not detectable by `grrp check`.** Every covered field is. This is acceptable only because the personal tier carries no evidential weight in the first place, and it closes at M3.

35.1.11 Derivation rules

Views are computed, never stored. The rules are choices you are entitled to disagree with, so they are stated in one place (`views.py`):

produces a state	every act writes a posterior state
supersedes its prior	`transformation` only
retires its prior	`decision` whose relation is `cito:retracts` (i.e. `--abandon`)
a **live position**	posterior of `claim` or `transformation`, not superseded and not retired
answered	a challenge or failed verification that a later `transformation` or `decision` names among its parents

A trajectory's opening **question is a state and not a position**: it is what the work is about, it does not stop being so when someone takes a view, and it stays on the open register until something answers it. It also anchors the first claim, so that even the first transition references an identified prior state rather than the project as a whole.

Objections, decisions and releases produce states too, but those are annotations on a position rather than positions themselves, so they are not candidates for "the current state". Nothing is edited to mark a challenge answered — the graph already records it.

35.1.12 What this tool will not do

- **No scores, rankings, counts across trajectories, or dashboards.** No quantity over participants or over trajectories is computed, stored, displayed or exported. Counts *within* one trajectory, shown without comparison, are permitted. When something feels like it wants a number, that is the constraint working.

- **No merge.** Two revisions of a concept do not compose, no conflict region localises, and no test decides the result. Integration is a **synthesis** (a state with several parents) or an **absorption** (content taken with attribution). The word does not appear in the interface.
- **No principal branch.** Where the work diverges, both directions are kept and neither is marked canonical, default or current. In inquiry a fork is frequently the correct outcome.
- **No unpublish.** Disclosure may widen and never narrow. A party who has read a record retains what they read, and an operation offering the appearance of withdrawal would misdescribe the world to the people relying on it.
- **No model, no network, no database.** Every operation runs with a text editor and git. A model may *propose* a transition and may not author or register one; a model-originated proposal is marked as such (`trigger: ai_suggestion`).
- **No editing.** A recorded transition is never altered or removed. A correction is a further transition referencing the one corrected.
- **No silent erasure.** `redact` removes a state's content and leaves everything else: that the transition occurred, by whom, of what type, where in the graph — and that a redaction was performed and on what ground. A system that erased the trace of an erasure would leave a record misdescribing its own history in a way no later reader could detect. It also tells you plainly that earlier git commits still hold the text, because possibility is not lawfulness.

35.1.13 Bindings

Relations bind to **CiTO**, contributor roles to **CRediT**, provenance concepts to **PROV**. Values stored are identifiers, never display labels — a record holding the word `extends` is uninterpretable once a second vocabulary uses the same word differently. Three relations the design names have no CiTO counterpart (`generalises`, `specialises`, `transfers`); they are available as `local:` values, are flagged as local, and need a charter to define them.

35.1.14 Records are bytes

A state's identifier is the **hash of the bytes of its file**, so anyone holding the file can check it with `sha256sum` and no knowledge of this tool:

```
sha256sum trajectories/*/states/*.md      # the hash is the filename
```

Nothing in a record is ever written in text mode, because that translates newlines on the way out and would leave a file whose name is a hash of something the file no longer contains. `grrp init` also writes a `.gitattributes` telling git not to rewrite the record on checkout, and `grrp check` verifies that every state's content still yields its identifier.

35.1.15 A walkthrough

```
bash examples/walkthrough.sh        # all four phases
bash examples/walkthrough.sh 1      # just the first
```

Works the philosophy case from the specification: a claim about trust, an objection that it omits institutional power, a transformation accepting it, a second objection that is never resolved, a divergence, and a release enumerating the objection still standing. Then a failed check and an abandoned direction, a second party registering, and finally withholding on a ground and leaving with the record.

It builds everything under `./grrp-walkthrough` and touches nothing else.

35.1.16 Tests

```
python -m pytest
```

The acceptance tests are written against the constraints, not the features:

---

1 no scalar over participants or trajectories, in source or in any command's output

2	the whole flow runs with no network, no model and no service
3	every command's `--help` names the purpose it serves for the person running it
4	editing anything under `transitions/` is detected by `grrp check`
5	a disclosure change does not invalidate verification
6	after `grrp redact`, the chain verifies, the graph is unchanged, and the redaction is recorded
7	`grrp register` refuses when performer and registrar are identical
—	acts default to the live position, and refuse rather than guess at a divergence
—	omitting `-m` opens an editor; the prompt below the cut is never recorded
8	*(M4)* `bundle` here, `continue` there, one graph and not two — **skipped**

Skipped tests are present and named, so what is not yet built is visible rather than absent.

35.1.17 Next

Use it on real work for two weeks before M2. Record what was annoying — those notes are the input to everything after this, and they belong in a trajectory.

35.1.18 Licence

MIT — see the application LICENSE, scope notes and CONTRIBUTORS.md. Copyright remains with the respective contributors. The licensing history records the earlier inconsistent notices and the explicit additional MIT grant; archived source and historical notices remain preserved. This software license does not determine the rights in research records created with the tool.

36 README

Original source: `applicative_infrastructure/gr_academia_application/notes/README.md`.
Original source SHA-256: `8ef2de44ad7bf00971ffb80c094d36f03aadcc7af4fb3c985ee18e1f29891c1d`.

36.1 Notes on the GRA papers

Working notes taken while reading the four papers in papers/. They are dense on purpose: the intent is that these files can be used **instead of** re-reading 217 pages of PDF, and that any claim made in this repository can be traced back to the paper and requirement that licenses it.

Quotation is used heavily where the papers' own wording is the point — several of the design rules are stated as *"an error to be corrected"* or *"the single most likely implementation error"*, and paraphrase loses their force.

36.1.1 Files

File	What it holds
paper-I-design-and-requirements.md	The problem, the survey of prior art, the derivation, and **the sixteen requirements (R1–R16)**. Start here.
paper-II-incentives-and-adoption.md	Why any of this might not happen. The commons dilemma, the positional bound, **the absorption test**, the dominance argument, **ten predictions with refuting observations**. Mostly a list of things the project may not claim.
paper-III-grounds-of-restriction.md	Disclosure. **Four irreducible grounds, each with an object, a residue, and a named failure.** The residue rule. The shared component of value, evidence and hazard.
paper-IV-grrp-specification.md	**GRRP v0.1 — the normative specification.** Record model, act vocabulary, attestation, absorption, graph, disclosure, redaction, identity, propagation, durability, charters, amendment, **conformance tiers and tests**, a git deployment, worked examples, failure modes.
glossary.md	Every fixed term with the definition and citation. Use this when writing anything user-facing.
gaps-and-repo-actions.md	Where this repository currently diverges from the papers, what to change, and what is still the user's decision.

36.1.2 The shortest possible summary

Scholarly communication transmits finished artefacts and discards **the trajectory** that produced them. An artefact carried evidence about its producer only because producing it was costly *in a way that discriminated between producers*; that discrimination is weakening. So attention moves to the trajectory — but **a trajectory record is as cheaply fabricated as the artefact whose function it would inherit**. Its credibility can therefore only come from **distribution across parties who did not coordinate**, which is why this is a **protocol** and not a platform: a platform operator is party to every entry.

The representational problem was solved repeatedly between 1970 and now, and every such system failed on **capture cost**. So the first constraint is: **nothing may be required of a participant that the participant would not do anyway.**

Everything else follows from those four sentences.

36.1.3 Reading order if you only have an hour

1. glossary.md — 10 min, gives you the vocabulary.

2. Paper I notes §11–§13 and §22 — the derivation and the sixteen requirements.
3. Paper IV notes §6, §8, §20 — the act vocabulary, attestation, and the conformance tests.
4. Paper II notes §12 and §16 — the dominance argument and the ten predictions.

36.1.4 Provenance of these notes

Extracted from the PDFs and read in full on 2026-08-06. Section, definition, claim and requirement numbers are the papers' own. Where a numbered cross-reference in a paper was broken in the source (a few `??` and `refsec:` artefacts survive in the PDFs), the note resolves it from context and says so.

37 gaps and repo actions

Original source: `applicative_infrastructure/gr_academia_application/notes/gaps-and-repo-actions.md`.
Original source SHA-256: `6db395e6f6001abfc23889f722df425ca890675c1e9fee2e90485ff2576bb2e2`.

37.1 Gaps between the repository and the papers

Written after reading all four papers. Each item names **what the repo says**, **what the papers require**, and **the action**. Ordered by how much damage the divergence does.

37.1.1 A. Conflicts that would make the repo non-conformant or misleading

37.1.2 A1. "GRA Commit" is the wrong word — and it is the exact word the papers refuse

Repo: README.md has a section headed *"GRA Commit Concept"*, and the retired `plans/implementation_plan.md` used "Commit" throughout (Stage 1 "Semantic Commit System", "Create GRA commits", "commit types").

Papers: *"the epistemic unit is called a **transition** throughout, in place of a **commit**, since the protocol is layered over version-control systems whose commits appear in the same repositories and **the collision would mislead every implementer**."* (Paper I §2.7)

Action: rename everywhere → **transition**. [check] Done in the README, the new plan, and the tool.

37.1.3 A2. Flat "commit types" instead of the five-dimension factorisation

Repo: `implementation_plan.md` Stage 1 lists a single flat enumeration — Progress ·Failure ·New problem ·New idea ·New question ·Literature integration ·Objection ·Response ·Synthesis.

Papers: *"A transition is typed along **five independent dimensions** with small closed vocabularies, in place of a single enumerated list. An implementation **must not** define a single enumerated type combining these dimensions."* (Paper I Req. 13.3; Paper IV Req. 6.1) — because inter-rater agreement declines as categories rise, and deliberation over classification re-introduces capture cost.

Also: the flat list has **no `unresolved` disposition**, which Paper IV Req. 6.3 makes mandatory and non-extensible; without it *"a record admitting only acceptance and rejection would be systematically false about the fields this protocol most concerns, and would exert pressure toward fabricated closure."* And "Progress" is not an act at all.

Action: replace with `act × target × relation × trigger × disposition` (see glossary.md). [check] Done in the README, the new plan, and the tool.

37.1.4 A3. Roadmap items that are forbidden scalars

Repo: `implementation_plan.md` Stage 4 — *"Generate progress reports"*; Stage 5 — *"Trajectory risk analysis"*, *"Research obstacle detection"*, *"Similar trajectory search"*, *"Similar failure discovery"*.

Papers: R10 / Req. 20.4 — an implementation **fails conformance** where it computes, stores, displays or exports **any total order or numeric measure over participants or over trajectories**, including counts of transitions, counts of attestations, contribution shares, activity indices and derived scores. Paper II Claim 8.4 adds that even an *absorption* score violates it. And Paper I §22.2: R10 costs the arrangement *"the ability to report that a project is going well"* — that is precisely what "progress report" and "trajectory risk analysis" name.

Action: - Anything that ranks, scores, or reports "health/progress/risk" across trajectories or participants is **out of the protocol entirely**. It may exist as an **L3 application**, clearly labelled as outside conformance, and the papers note the party building it *"owns the consequences"*. - Within-trajectory counts shown **without cross-trajectory or cross-participant**

comparison are permitted (Req. 20.4, second sentence). A "what I ruled out this month" view is fine; a dashboard number is not. - **Similar-trajectory / cross-field matching must additionally be removed from any adoption argument** (Paper II Claim 13.5): it is not decomposable by tier, returns nothing to any adopting party, and is "a late property of an adopted arrangement". Paper I Claim 18.3 says the same and adds that the matching problem itself is **unsolved and belongs at L3**.

37.1.5 A4. The staging is inverted — the adoption-critical features are scheduled last

Repo: `implementation_plan.md` puts *"Generate paper outline from trajectory"* at Stage 4 and integration/collaboration at Stages 2–3; there is no personal-tier ship point.

Papers: R15 + Paper II Req. 11.4 — *"An arrangement is adoptable only where its minimal form is worth adopting by a single participant with no other participants present."* And **R16 / Req. 12.7** — **emission of a citable document from a release** is *the* mechanism that makes adoption possible under the dominance argument (Paper II §14). The GRRP plan gets this right: **"M1 — Personal tier. Ship here."**

Action: re-order so the personal tier (three acts + append-only log + derived views + `open` register + **`export` on release**) is the first shippable unit, matching plans/implementation-plan.md. [check] Reflected in the README and in the new single plan, whose M1 is marked as the ship point.

37.1.6 A5. The two implementation plans disagreed with each other — *resolved*

Repo: `plans/implementation_plan.md` (Stages 0–7, commit-based, platform-flavoured: "Discussion System", "Feedback System", "AI research assistant") and `plans/GRRP-implementation-plan.md` (M0–M5, transition-based, CLI, no server, no account, no network).

They are not two views of one plan; they encode **different designs**. The GRRP plan is the one derived from the specification.

Action: [check] **`plans/implementation_plan.md` has been retired** (removed; recoverable from git history), and `plans/GRRP-implementation-plan.md` has been folded into a single plans/implementation-plan.md. The specification governs where that plan and the papers differ.

37.1.7 B. Claims the papers forbid

The papers spend a lot of length forbidding specific sentences. These are the ones most likely to reappear in a README, a grant application, or a website.

Do not write	Why	Cite
"makes scholarship less competitive" / "democratises recognition" / "dissolves hierarchy"	recognition is **positional**; attribution redistributes and does not create it. *"any passage implying otherwise is an error to be corrected"*	P-II Claim 6.2
"GRA will increase serendipitous encounters"	no evidence; the best qualitative study reports **avoidance**. Only *cost of preparation* may be claimed	P-I Req. 3.2; P-II Claim 15.4
"adopt this because it benefits scholarship collectively"	*"available to no individual party, and its repetition is the characteristic error of proposals in this field"*	P-II Claim 12.4

Do not write	Why	Cite
"a trajectory record proves the work happened"	attestation asserts **registration at a time**, not truth, improvement, or understanding; **collusion is not eliminated**	P-IV Claim 8.4, §23.1
"personal-tier records are verified / corroborated"	the personal tier carries **utility and no evidential weight**; every transition must be **marked unattested**	P-IV Req. 20.3
"merge two branches"	no merge operation exists; the word must not appear	P-I Claim 14.1; P-IV Req. 10.5
"restrict the instrument, open the reasoning" (as general policy)	correct under **rivalry**, **exactly wrong under hazard** — the reasoning is where the hazard lives	P-III Claim 4.1
"publish the trajectory minus the dangerous parts"	value in reuse, evidential force and hazard are **the same component**	P-I Prop. 20.2; P-III Claim 9.3
"sealed registration establishes priority"	it records that a party held a content at a time. **A timestamp is not priority**	P-IV Req. 15.7
"the record makes a research process available"	a record carries **the articulable fraction**; capability does not transfer	P-I Claim 10.1, Def. 20.1

37.1.8 C. Things the papers require that are missing from the repo entirely

1. **A declaration of interest.** Paper I §2.8 and Paper III Claim 11.6 both bind the author's society: *"the requirements imposed on a custodian apply to that society without exception, including that the specification be forkable and that stewardship of the specification be separated from operation of any implementation."* Paper IV Req. 19.4 makes it normative. **The repo, operated by Serendip Commons Society, should state this in the README.** [check] Added.

2. **The four "findings that would show the specification inadequate"** (Paper IV §24.4) are the project's own evaluation plan and have no home in the repo. [check] Added to README as an explicit failure-conditions section.

3. **The four unaddressed difficulties** (Paper II §17.2): assessment congestion, maintainer labour, regressive overhead incidence, recognition of attributed contribution. These are *known holes*, not oversights. [check] Added to README.

4. **Licence — resolved: MIT.** [check] Paper I Req. 16.2 property (4) requires the record to be *"licensed so that continuation elsewhere is permitted"*, and Paper IV Req. 19.4 requires the specification to be licensed so **any party may fork it**. CC BY-**NC** satisfied neither, and was not a software licence for `grrp` either. MIT discharges all three. The four PDFs still carry an embedded CC BY-NC notice and remain under it until their author revises them.

5. **An `open` register / entry-path affordance** is required by Req. 6.5 and is the answer to the bootstrap failure (Paper I §17). The GRRP plan has `grrp open` and calls it *"the entry path"*. Good. It should not be described anywhere as a nice-to-have.

37.1.9 D. Implementation traps the papers name explicitly

Worth pinning here because each is described as *the* likely error.

- **Signature coverage** — *"Getting this wrong makes ordinary operation invalidate signatures — the single most likely implementation error."* Spec §8.3 says the signature covers

the disclosure class; deployment §21.5 says commit signatures therefore break on scheduled release, and the workable arrangement is to hold the class **in a separate file the signature does not cover**. Follow §21.5.

- **A stored authoritative current state** — *"the requirement most often violated in practice, since a stored current state is convenient and fast. Where a stored snapshot is authoritative … every claim the protocol makes about credibility fails at once."* Caches must be reconstructible and marked derived. (Req. 4.4)
- **Unattended/default registration** — *"a default that registers unattended proposals violates the requirement, because the record's credibility rests on registration meaning something."* (Req. 4.3)
- **Exporting or indexing the event plane** — *"the failure with the largest consequence for participants and the one an implementer is most likely to introduce while improving a feature."* (Req. 3.1, §23.4)
- **Disclosure by inference** — revealing a record's existence through a gap, an identifier sequence, or the shape of a derived view. *"A genuine implementation hazard and easy to introduce accidentally."* (§11.4, §23.3)
- **Reconstruction of redacted content from its content-derived identifier** where the content is short and its space small → **apply a per-record secret before computing the identifier**, a decision that must be made **in advance**. (§13.5, §23.3)
- **Normalising received records** — invalidates their signatures and destroys the property that makes propagation worth having. (Req. 16.5)
- **Per-repository rather than per-record disclosure** — the git deployment *approximates and does not meet* Req. 11.5; class changes require **moving** a record, and the movement must be recorded as an administrative operation. (§21.5)

37.1.10 E. Status of the repo's own actions

Item	Status
Notes folder with per-paper notes + glossary	[check] this folder
README rewritten against the papers	[check]
Both old plans folded into one plans/implementation-plan.md	[check]
`grrp` reference implementation, M0 + M1	[check] grrp/ — 36 tests passing, 3 skipped and named for M2–M4
Licence settled as **MIT** — discharges Req. 19.4 (forkable specification) and Req. 16.2(4) (continuable record)	[check]

37.1.11 F. Decisions taken while building M0/M1, and why

These touch the hard constraints, so they are recorded rather than buried in the code.

1. **Disclosure lives in a sidecar (`disclosure/<id>.yaml`), not inline in the transition file.** The illustrative skeleton shows it inline. Keeping it there forces a choice between two rules that both have to hold — *any edit under `transitions/` is detected* and *changing a class invalidates nothing*. The sidecar lets both stay strict, and it is what the specification's own git deployment (§21.5) recommends for the same reason. **Touches C3, C7, C8.**

2. **The identifier excludes `registration`; the signature (M3) will cover `{id, registrar, time}`.** Registrar cannot be inside the identifier, because at the group tier a proposal is registered by a *different* party later, and the identifier would change under its own children. **The cost, stated plainly: at the personal tier, where nothing is signed, editing the `registration` block is not detectable by `grrp check`.** Every covered field is. Acceptable only because the personal tier carries no evidential weight, and it closes at M3. **Touches C2, C3.**

3. **A keypair is generated at `init`, three milestones before anything is signed**, so that party identifiers recorded from the first day stay valid when signing arrives. The private key is written unencrypted; a passphrase belongs with signatures, not before them.

4. **`--abandon` is `cito:retracts`, not a new field.** The design names an abandonment relation that CiTO has a genuine counterpart for. Three relations it names have none (`generalises`, `specialises`, `transfers`); those are `local:` values, flagged as local, and need a charter. **Touches C12.**

5. **A challenge is answered by the graph, not by an edit.** A `transformation` or `decision` naming the challenge among its parents is what takes it off the open register. Nothing is rewritten. **Touches C3.**

6. **The opening question is a state and not a position.** It anchors the first claim (so even the first transition references an identified prior state), it stays on the open register until something answers it, and it is not a candidate for "the current state". **Touches C4.**

7. **Transitions are committed to git automatically when inside a work tree**, and only the paths `grrp` wrote — a researcher's tree is usually dirty, and committing anything else would be taking a decision that is not the tool's. `check` and every read command work on the files alone.

8. **Ordering follows the graph, not the clock.** Two transitions recorded in the same second are listed parents-first; recorded times only break ties among transitions with no path between them.

38.1 Glossary — GRA / GRRP

Terms as the four papers fix them. Where a term also has a settled sense in an adjacent literature, the divergence is marked. **Bold** entries are the load-bearing ones.

38.1.1 The record

Trajectory — the directed graph whose vertices are **states** and whose arcs are **transitions**; an ordered record of the transitions a shared understanding has passed through, with the acts and the parties to them. **A trajectory is identified by the record, and its current state is *derived* from the record, never stored alongside it.** *(P-I §2.7, P-IV Def. 2.1)*

State — an identified condition of a shared understanding at a point in a trajectory: the recorded content plus the identifier under which it is addressed. **Created by a transition and never modified.** Its *form* is deliberately unspecified — prescribing the form of a scholarly claim would be prescribing research practice. *(P-IV Def. 5.1)*

Transition — **the unit of record.** A change from one identified state to another, produced by a typed act performed by a party and **registered by a party**. *(P-I Def. 2.8, P-IV Def. 2.1)* > Called **transition**, never *commit* — the protocol is layered over version-control systems whose > commits appear in the same repositories, and the collision would mislead every implementer. > *(P-I §2.7)*

Event — an automatically generated record that *something occurred* (a meeting was held, a comment posted, a file changed, a permission altered). **Asserts nothing about an understanding.** Near-zero cost, possibly large volume. Lives on the **event plane**, private to participants by default. *(P-IV Def. 2.2, Req. 3.1)*

Artefact (reference) — a produced object referenced by a record: document, dataset, recording, transcript, release. Held by substrates, not by the protocol. *(P-IV Def. 2.2)*

Promotion — the act by which an **event becomes a transition**: a responsible party registers it. Candidates may be proposed by any means (including model analysis of the event plane); **a proposal becomes a transition only when a party registers it**, and a model-originated proposal must be marked as such. *(P-IV Req. 4.3)*

Administrative operation — a record concerning *the arrangement* rather than the understanding (disclosure class changed, key rotated, redaction performed, fork declared, attribution contested). Same envelope, **mandatory `kind` field**, no act/target/relation/disposition. Must be distinguishable from transitions — otherwise administrative activity inflates apparent generativity, and a position holder could act without leaving an inspectable record. *(P-IV Req. 4.6)*

Skeleton / content — **skeleton** = identifier, kind, parent links, state references, typed fields, parties, signature, disclosure class and ground. **content** = the material referred to. **Stored separately, referenced by content-derived identifier**, so removing content leaves the skeleton valid and the signature chain intact. This is what makes redaction possible in an append-only log. *(P-IV Def. 13.1, Req. 13.2)*

38.1.2 The factored type — five dimensions, small closed vocabularies

(P-I Req. 13.3, P-IV Req. 6.1. Never flatten into one enumerated list: agreement between classifiers declines as categories rise, and deliberation over classification re-introduces capture cost.)

act *(fixed, 8)* — `question` ·`claim` ·`challenge` ·`transformation` ·`decision` ·`connection` ·`verification` ·`relea se` **target** *(charter-extensible)* — question ·assumption ·hypothesis ·concept ·theory ·method · path ·artefact **relation** *(bound to CiTO)* — extension ·modification ·replacement ·refinement ·generalisation ·specialisation ·transfer **trigger** *(charter-extensible)* — reflection ·literature ·

experiment ·simulation ·observation ·discussion ·objection ·prior failure ·automated suggestion ·**entry of a new party disposition** *(fixed, 3)* — `accepted` ·`contested` ·**`unresolved`**

> **`unresolved` is required and the vocabulary is fixed because of it.** Most objections in theoretical work are never resolved: they stand, and the work proceeds beside them. A record admitting only acceptance and rejection would be **systematically false** about the fields this protocol most concerns, and would exert pressure toward **fabricated closure**. *(P-IV Req. 6.3)*

Decision — the act that records a direction taken or abandoned **with the reason**. *A path recorded as abandoned without a reason cannot be revisited by anyone.* **The demanding act** — the one whose purpose for its performer is weakest, and the one on which reuse of abandoned material depends. *(P-IV §6.2, §22.4; P-II Claim 11.3)*

Release — a declaration, never a judgement. Declares a state published at a class and records **the objections standing unresolved against it at that moment**. Must not be presented as certifying, validating or approving. Also the object to which a priority claim attaches where a community honours registration. *(P-IV Def. 12.5, Req. 12.6)*

Synthesis — a transformation with **two or more parents from distinct branches**, producing a state its performer **composed** from what those branches reached. **The branches it draws on continue to exist; a synthesis is a further state, not a resolution of the divergence.** *(P-IV Def. 10.4)*

Divergence — two or more transitions sharing a parent and producing distinct successors. **Both preserved; neither designated principal, default, canonical or current; no ordering over branches may be recorded or exported.** *(P-IV Def. 10.2, Req. 10.3)* > **Disanalogy with software forks:** in software a fork is a coordination failure to be reunified. **In > inquiry a fork is frequently the correct outcome, and plurality is the normal shape of a healthy > record.** *(P-I §14.4)*

Merge — does not exist. Version control merges because changes to distinct text regions compose, a conflict can be localised, and a test decides the result. **Two revisions of a concept satisfy none of the three.** Integration appears only as a **synthesis** or an **absorption**. *The word must appear nowhere in the specification or the UI. (P-I Claim 14.1, P-IV Req. 10.5)*

38.1.3 Parties, credit, credibility

Party — an entity capable of performing and registering acts, **identified by a public key**. **Continuity of identity is required; legal identity is not.** Pseudonymous participation must be permitted at every tier. *(P-IV Def. 14.1, Req. 14.3)*

Registration — the act by which a transition enters the log. **Attestation — registration performed by a party other than the one who proposed the transition**, recorded with that party's identifier and signature. *(P-I Def. 2.9, P-IV Def. 2.3, Req. 8.1)* > **What it asserts:** that an identified party registered a transition at a time. > **What it does not assert:** that the change was an improvement, that the claim is true, or that the > registering party understood it. *(P-IV Claim 8.4)* > **Never counted.** Attestation depth is a scalar over trajectories and would be farmed by reciprocal > registration. *(P-IV Req. 8.5)*

Distributed attestation — the design's answer to fabrication. **Credibility follows from the distribution of registrations across parties who did not coordinate, and from no property of the record's content, length or detail.** *This is why the design is a protocol and not a platform: a platform operator is party to every entry and cannot supply the independence. (P-I Req. 12.2, Claim 12.3)*

Attribution — the recording of a party's part in an act, with a **CRediT** role. **Attaches to an act, not to a finished work** — *a contributor statement says a person contributed to a paper; this record says which change in the content of a claim a person produced. (P-IV Req. 9.1)*

Absorption — the taking of content from a state in one trajectory into a transition in another. The **absorption link** records the state absorbed from, **the party who produced it**, and the transition that took it. *(P-IV Def. 9.2, Req. 9.3)* > **No veto (Req. 9.4).** An absorption link confers **attribution and no power to prevent, condition or > reverse use** — the moral-rights construction, chosen to avoid the anticommons. **A party who does not > wish their state absorbed has one instrument: its disclosure class.**

Absorption test — the criterion separating a **generative** arrangement from a **competitive** one: *examine the record of the work that proceeded and look for transitions whose content originated in work that was **not selected**, with attribution.* **Where such transitions are absent, the arrangement is competitive whatever its constitution states.** Applied by readers, **never computed as a score.** *(P-II Def. 8.1, Req. 8.2, Claim 8.4)*

Competitive / generative arrangement — turns entirely on **what becomes of unselected work**, not on openness of entry, number of participants, or manner of decision. *An open arrangement discarding losing proposals is competitive; a closed arrangement that takes up and credits a rejected proposal's method is generative. (P-II Def. 8.1)*

Encounter — a transition performed by **a party who has performed no prior act in the trajectory**, with a trigger identifying the occasion. **No new primitive** — the trigger dimension covers it. *(P-I Def. 18.1)* > Every claim about encounters is **envisagement** and must carry the counter-evidence (Irving et al. > 2020: occupants of a building designed for serendipitous collaboration developed strategies to avoid > it). What may be claimed is a lowered **cost of preparation** — never an increased frequency of > encounter. *(P-I Req. 3.2, P-II Claim 15.4)*

38.1.4 Disclosure

Disclosure class — a value attached to a **record** (not a repository, project or trajectory) governing to whom it may be disclosed. **Ordered by inclusion. Enforced by the implementation, opaque to the protocol, interpreted by the charter.** *(P-III Def. 2.1, P-IV Def. 11.1, Req. 11.5)*

Ground — the **declared reason** for restricting disclosure. **A property of a restriction, not of a record** — the same content may be restricted on different grounds in different arrangements, with different consequences. **A closed set of four.** *(P-III Def. 2.2, Req. 2.5)*

Residue — **what remains disclosable at the widest class while a restriction on that ground is in force.** *A ground with an empty residue licenses total silence.* **The residue requirement is the operative rule of the whole account** — without it every ground collapses into silence with a justification attached. *(P-III Def. 2.3, Req. 2.6)*

Ground	Condition	Object restricted	Residue	Named failure
rivalry	a resource admits limited simultaneous use	**access to the resource**	**the trajectory in full**	a restriction on access converted into a restriction on knowledge
hazard	propagation of the content creates risk	the **propagable content of a method**	existence, questions, decisions, interpretations, non-conveying results	widest restriction on the strongest justification, **unfalsifiable from outside**
exploratory vulnerability	exposure at this stage suppresses or distorts the work	**the timing of exposure**	**everything, at the scheduled time**	postponement converted into permanent withholding
appropriability	funding requires excludability	content whose disclosure destroys excludability	existence, questions, decisions, **negative results**	**rent-seeking secrecy**

Irreducible — rivalry restricts a *resource*; the others restrict *content*. Hazard restricts what a *reader* could do; appropriability what a *competitor* could sell. Vulnerability restricts a *time*; the others a *set of parties*. *(P-III Claim 7.1)* **Composition** — where several grounds obtain, each is declared separately and **the residue disclosed is the intersection.** Declaring more grounds is **not free** — each is an assertion that can be found false. *(P-III Req. 7.2)* **Termini** — vulnerability ends **on a recorded schedule**; rivalry when the resource is uncontended (unenforced); appropriability when the funding purpose is served (**known to the declaring party alone**); **hazard does not end.** *A community wishing its record to open over time must prefer the ground that ends. (P-III Claim 7.4)*

Monotone disclosure — disclosure may widen and must not narrow. No `unpublish` operation exists. *Ground: a party who has read a record retains what they read, so an apparent withdrawal misdescribes to participants a state of affairs obtaining outside the system.* A schedule may be **shortened, never extended or cancelled**; any attempt must be recorded. *(P-III Claim 5.1, P-IV Req. 12.1, 12.4)*

Redaction — removal of **content** while the **skeleton remains**. The redacted record continues to assert that a transition occurred, by whom, of what type, at what graph position. **The record of the redaction must not be removed, the graph must not change, and redacted content must not be represented as never having existed.** *(P-IV Def. 13.3, Req. 13.4–13.5)*

Sealed registration — publication of a **content-derived identifier** of a state, plus registering party and time, **with the content disclosed to nobody**. Asserts that the party held that content at that time. **Available at every class, including disclosure-to-nobody.** *(P-I Def. 19.1, P-IV Def. 15.1)* > **A timestamp is not priority.** It evidences possession, not understanding. **It generates nothing > while sealed** — no objection, no connection, no encounter; it purchases *the possibility of later > opening*, not the benefits of early opening. It adjudicates nothing against independent arrival. And its > time is evidence only if **anchored in a medium the implementation does not control.** > *(P-IV Req. 15.6, 15.7, §15.5)*

Conditional / structured access — supplying a capability **without transferring the artefact that confers it**, under conditions the supplier enforces. Applied here: a party is **admitted to a restricted class** under a charter's assurance requirements, **with the admission and its ground recorded.** The mechanism that makes work under the hazard ground possible at all. *(P-III Claim 4.3)*

38.1.5 Structure and governance

The four levels *(P-I Def. 2.1)* — **L0 external law** (described, never encoded; reaches the design only *negatively*, through structural incapacity) ·**L1 operating norms** (the charter: which classes exist, who belongs, retention, consent, conduct, assurance, extended vocabularies) ·**L2 protocol** (the capacity: state model, act vocabulary, registration, attribution, parent links, classes as opaque enforced values, conformance) ·**L3 application** (interfaces, capture assistants, search, matching, summarisation, **assessment of content** — replaceable, and the protocol is implementable with none of it). > **The protocol carries the capacity; the normative level carries the content.** *(Req. 2.2)*

Operating charter — an identified, **versioned** document a community adopts, stating its rules. **The protocol references it by identifier and interprets nothing in it. The charter is where everything contested lives.** A record must carry the charter identifier and version that governed it. Amendments are **prospective only**. *(P-IV Def. 18.1, Req. 18.2–18.4)*

Description language vs. interaction protocol — a **description language** fixes a vocabulary for recording what occurred and imposes no condition on what may occur (PROV, CRediT, CiTO, Web Annotation, RO-Crate are all of this kind). An **interaction protocol** fixes **which acts are admissible, what each does to a shared state, which party may perform each, and what conformance requires.** *This distinction is where the word "protocol" in the title is meant literally. (P-I Def. 7.1, Claim 7.2)*

Protocol vs. plan — a **plan** specifies outcomes and the steps to them. A **protocol** specifies admissible acts and their effect on a shared state, **and leaves every participant's trajectory undetermined.** Relation = grammar to sentences. *Any drift into prescribing what participants should record, conclude or value is an error to be corrected, not a position to defend. (P-I Def. 2.3)*

Functional vs. structural position — a position is **functional** where constituted by acts the arrangement requires, recorded and attributable, with occupancy depending on continuing to perform them. It is **structural** where occupancy confers persistent standing, or where others' capacity to act depends on the holder's permission. *(P-I Def. 15.1)* **Admissibility of authority** — two joint conditions: **(i)** the constituting acts are recorded and attributable and visible; **(ii)** participants **retain the capacity to proceed without the holder's permission**. *Visibility without exit produces documented autocracy; exit without visibility leaves participants unable to judge whether to leave. (P-I Req. 15.2)* > **Four positions the design**

generates (not imports): **registrar ·trajectory steward ·> holder of disclosure authority ·custodian of the specification.**

Portability *(five joint properties, P-I Req. 16.2)* — the complete record is **(1)** obtainable by any participant **without permission ·(2)** in a **self-describing format readable without the producing software ·(3)** carries **identifiers that stay resolvable when held elsewhere ·(4) licensed** to permit continuation ·**(5) continuable under the same protocol by an implementation the original operator does not control. > Property 5 is what distinguishes portability from export.** A data dump satisfies 1–4 and leaves > departing participants with an archive. **> Portability is the bound on the authority of every position** — the cost of exit, not any rule > addressed to the holder. *(Claim 16.1)* But it **secures the record, not the participants, not the > resources, and not the standing** — and it bounds the **restricting** authority weakly, because a > departing party cannot take what they were never shown. *(P-III Claim 11.4)*

Propagation — the movement of **transitions** between trajectories (**lateral**) and between independent implementations (**inter-implementation**). **Dissemination of finished artefacts is excluded from the term.** *(P-I Def. 2.11, P-IV Def. 16.1)* **Continuation** — obtaining the complete record without permission and continuing it elsewhere, with appended transitions **referencing the obtained ones as parents so the result is one graph and not two.** *(P-IV Req. 16.4)* **Exchange minimum** — the only things two implementations must agree on: record structure, act and disposition vocabularies, bound-vocabulary identifiers and versions, **content-derived identifier construction**, and **signature scheme**. *The last two cannot be relaxed. (P-IV Req. 16.2)*

Conformance tiers *(cumulative)* — **personal** (one participant; three acts; **utility and no evidential weight**) → **group** (attestation, roles, absorption, classes; **credibility begins**) → **open** (propagation, distributed custody, deposit, charter reference; **exchange and stranger entry**). *(P-IV Def. 20.1)*

Open register — the set of states whose disposition is `unresolved`, made available at each disclosure class. **This is the entry path**: a party holding no prior position may reference such a state in a `challenge`, `connection` or `verification`, decided on the act itself. *(P-I Req. 17.2, P-IV Req. 6.5)*

38.1.6 Concepts from the argument

Separating condition — an artefact carries evidence of its producer's capacity **only while producing it is more costly for a lower-capacity producer**, by a margin making it worthwhile for one and unattractive for the other (after Spence 1973). **The evidence was never in the object; it was in the difference between what the object cost different producers.** *(P-I Def. 11.1)* > A **uniform fall in production cost** weakens the evidential function while the artefact, the practice > and the systems reading it all remain in place — **and the failure is invisible from inside the > practice.** *(Prop. 11.2)*

Capture cost — the documented cause of the non-adoption of every rationale-capture system since 1970: **the work of recording falls on the party who gains least from the record, at the moment they can least bear it, in a form that serves a different party later** (Grudin 1988). **The representational problem was solved; this is what defeated it.** *(P-I Claim 8.1)*

Byproduct principle (R1) — every act the protocol defines is one a participant performs **for a reason of their own**, with the record falling out of its performance. **An act existing so that a record should exist will not be performed.** *(P-I Req. 8.2, P-IV Req. 4.2, test at Req. 20.6)*

Articulable fraction — that part of what a trajectory's participants held which they were able to put into the record. **Its complement transmits, if at all, by working alongside them, and no property of the record's design recovers it** (Collins 1974/2010; MacKenzie & Spinardi 1995). *(P-I Def. 20.1)*

The omitted component — what a finished artefact does not contain: approaches attempted and abandoned, the reasons, the constraints discovered, the parameters that mattered, the practical technique. **> It carries the value in reuse, the evidential force, AND the hazard — at once. > No design publishes the trajectory minus its dangerous parts and retains the benefit, because the > parts are the same parts.** All three scale together

with the articulable fraction, and **no design > alters the ratio.** > *This is why the account is a typology of grounds separating **parties** rather than a filtering rule > separating **content** — and why the **residue**, lying outside the component, is the only part of the > design that gains something without giving something up. > (P-I Prop. 20.2; P-III Def. 9.1, Prop. 9.2, Claims 9.3–9.5)*

Generativity — the capacity of a relation to produce states that neither party held. Distinguished from the developmental-psychology sense and from Zittrain's platform sense (the capacity of a *technical system* to admit contributions). *(P-I §3.2)* > **Trajectory ≠ generativity (P-I Def. 10.2, Prop. 10.3).** A trajectory is the recorded sequence — an > object that can be inspected. Generativity is a **capacity**, of which the trajectory is *one > realisation among those that were possible*. **Two trajectories may coincide entirely in recorded > appearance while differing entirely in the generativity of the relations that produced them.** > *This is the deep ground of the no-scalar rule: a quantity computed over a trajectory measures a > realisation, not a capacity, and that is an error no amount of data corrects.*

No scalar (R10) — the protocol defines **no scalar quantity over participants or over trajectories, and admits no total order over either.** Local, two-valued acceptance conditions replace indicators throughout. **Counts of records within a single trajectory, presented without comparison across participants or trajectories, do not violate it.** *(P-I Req. 2.6, P-IV Req. 20.4)* > Cost stated openly: cannot report that a project is going well, cannot rank contributors for a > committee, cannot summarise a trajectory's standing in a number.

Positional good — a good whose value consists in the holder's **rank** among others, so the aggregate available is **fixed by construction** and increases in supply do not increase it (Hirsch 1976). **Standing is positional.** *(P-II Def. 2.2, Claim 6.1)* > Therefore: **attribution redistributes recognition; it does not create it** — and parties who benefit > from the present invisibility of others' contributions are made worse off, **which predicts resistance.** > **No claim that the arrangement reduces competition, dissolves hierarchy, or increases recognition may > stand anywhere in the series.** *(Claim 6.2)*

Subtractable goods — the four things a commons dilemma actually attaches to here: **review/assessment capacity** (the one the design most strains) ·**maintainer labour** ·**the instrument** ·**community trust**. *(P-II Claim 3.3)* **Knowledge itself is non-rival — the tragedy of the commons has no object in it, and its failure mode is underprovision, not overuse.** *(Claims 3.1–3.2)*

Private-benefit sufficiency — an arrangement is adoptable **only where its minimal form is worth adopting by a single participant with no other participants present.** *An arrangement whose benefits appear only at scale is never adopted, since no party is ever in a position to obtain them. (P-II Req. 11.4; = R15)*

Dominance argument — in an environment rewarding output rate, a group adopting an arrangement with **any net cost** is disadvantaged **irrespective of its epistemic merits**, and sustained, adopting groups are **selected against**. *Two escapes only: net private benefit, and insulation from output-rate selection. (P-II Claim 12.1)*

Compatibility (R16) — a participant must be able to obtain, **from a conforming record and without additional work**, an artefact of the kind the incumbent reward system accepts. Mechanism: **emission on release** — the state, its chain, contributors with roles, absorption links with attributions, and the objections standing at release. *(P-II Req. 14.1, P-IV Req. 12.7)* > **It postpones the conflict with incumbent interests and does not remove it — and the conflict returns > at exactly the point at which the arrangement begins to succeed.** *(Claim 14.4)*

Minimum viable adopting unit — the smallest set of parties for which benefits exceed costs **without participation by anyone outside the set**. **Group tier: two parties who register each other's transitions. Open tier: one community with an implementation and a charter.** *A design whose minimum unit was a discipline requires an agreement nobody can broker; a design whose minimum unit is a seminar requires a decision two people can take on a Tuesday. (P-II Def. 13.3, Claim 13.4)*

Sparsity / plurality — of a selection: **sparsity** = the interval between selection events measured against the interval over which a line of work develops; **plurality** = the number of applied criteria **that cannot be combined into a single ordering**. **Plurality is not preserved under frequent application, so sparsity is a *condition* of plurality.** Charter parameters, not protocol parameters. *(P-II Def. 10.2, Claims 10.3–10.5)*

Dissipation — the aggregate effort entrants expend in a contest **in excess of what the**

selection required. Opening a selection to more entrants **increases** it, disproportionately burdening those for whom preparation is a larger share of available time. *(P-II Def. 7.1, Claim 7.2)*

38.1.7 Modal conventions used throughout the series

Analysis — states what is the case, supported by evidence or argument. **Design** — states what a specification requires, supported by derivation from a requirement. **Envisagement** — states what would follow in use; **supported by nothing available at present.** > No envisagement sentence appears in a design section, and every envisaged consequence is stated > conditionally with its conditions named. *(P-I Convention 2.4)*

Formal / empirical / conjecture *(Paper II's marking, Req. 2.3)* — **formal** follows from stated assumptions; **empirical** is supported by cited studies with population and strength stated; **conjecture** is neither, and is marked wherever it appears.

Standard for a solution *(Paper II Req. 2.4)* — a difficulty is **addressed** only where there is **a mechanism**, **an identified party who bears its cost**, and **a stated condition under which the mechanism fails**. A mechanism without an identified cost-bearer is recorded as **unaddressed**.

39.1 Notes — Paper I: *Designing Generative Relational Academic Infrastructure*

Subtitle: A Protocol Framework for Collaborative Knowledge Evolution and Propagation **Author:** Wanhong Huang (huangwanhong@serendip.ngo) ·working draft, 2026 ·CC BY-NC 4.0 **Length:** 76 pp, 26 sections. Source: papers/GRA-paper-I-…pdf

Role in the series: the *design and standardisation* paper. States the problem, concedes prior art, derives **16 requirements**, sketches the architecture. Does **not** specify the protocol (→ Paper IV) and reports **no implementation**.

39.1.1 1. The one-paragraph argument

Scholarly communication transmits finished artefacts and discards the *trajectory* that produced them. Two developments make that discard worth revisiting. (a) **Evidence:** an artefact carried information about its producer's capacity only because producing it was costly *in a way that discriminated between producers*; when production cost collapses for everyone at once, the discrimination is lost while the artefact and the systems reading it stay in place. (b) **Reuse:** the omitted material (failures, abandoned directions, objections) is not worthless — it transfers to problems its authors never considered. So attention moves to the trajectory. But a trajectory record is *as cheaply fabricated* as the artefact whose function it would inherit. Therefore its credibility must rest on **distribution across parties who did not coordinate** — and that requires a **protocol, not a platform**, because a platform operator is party to every entry.

39.1.2 2. Six method instruments (§2) — these govern everything downstream

39.1.3 2.1 The four levels (Definition 2.1) — *the single most load-bearing instrument*

Level	Held by	Contains
L0 external law	jurisdictions	consent, data protection, erasure rights. **Described, never encoded.** Enters L2 only *negatively*, as a constraint ruling designs out.
L1 operating norms	communities + custodian	which disclosure classes exist, who belongs to them, retention periods, conduct, review templates. Adoptable/revisable.
L2 protocol	the specification	state model + act vocabulary; registration/attestation; attribution + absorption links; parent links + divergence; disclosure classes **as opaque enforced values**; conformance.
L3 application	implementers/users	interfaces, capture assistants, search, structural matching, summarisation, visualisation, **evaluation of content**. Replaceable; protocol implementable with *none* of it.

Requirement 2.2 (Capacity and content). An element belongs to L2 only where interoperability requires agreement on it *and* it survives change in surrounding technology. **The protocol carries the capacity; the normative level carries the content.**

Consequences: all analytical/AI capability is L3. A data model that cannot express redaction forecloses lawful operation in every erasure-rights jurisdiction — no charter repairs that.

39.1.4 2.2 Protocol vs plan (Def. 2.3)

A **plan** specifies outcomes and steps to them. A **protocol** specifies which acts are admissible, what each does to a shared state, and what conformance is — and *leaves every participant's trajectory undetermined*. Relation = grammar to sentences. Any drift into prescribing what participants should record/conclude/value is **an error to be corrected, not a position to defend**.

39.1.5 2.3 Modal marking (Convention 2.4)

Three modes, never mixed: **analysis** (what is the case, with evidence) ·**design** (what a spec requires, by derivation) ·**envisagement** (what would follow in use — supported by nothing yet). No envisagement sentence in a design section.

39.1.6 2.4 Borrowed analogies carry stated boundaries

From version control: append-only history, content addressing, parent links, branching. **Not merging.** From network protocols: layering, implementation-independence, conformance. **Not** delivery guarantees, formal verification, packet semantics.

39.1.7 2.5 No redefinition (Req. 2.5)

Where a deployed standard defines a needed vocabulary, **bind to it**. New terms only where nothing deployed covers the case. Cost: dependency on vocabularies the project doesn't maintain.

39.1.8 2.6 No scalar (Req. 2.6) — *the most counterintuitive constraint*

No scalar quantity over participants or over trajectories; no total order over either. Local two-valued acceptance conditions replace indicators throughout. Cost stated openly: cannot report "a project is going well", cannot rank contributors for a hiring committee, cannot summarise standing in a number. Anyone wanting one computes it at L3 and owns the consequences. Grounds: (i) reactivity/Goodhart — a measure adopted for evaluation becomes the object of effort (Espeland & Sauder 2007); (ii) deeper — a quantity over a trajectory measures a **realisation, not a capacity** (Prop. 10.3).

39.1.9 2.7 Fixed terms

- **Trajectory** — ordered record of the transitions a shared understanding has passed through, with the acts and the parties. *Current state is derived from the record, never stored alongside it.*
- **Transition** — a change from one identified state to another, by an act of a stated type, referencing the prior state, registered by a party.
- **Attestation** — registration of a transition **by a party distinct from the one proposing it**, with identifier and signature.
- **Disclosure class** — value governing to whom a record may be disclosed; enforced at L2, interpreted at L1. **Ground** — the stated reason for restricting, which determines both what is restricted and what remains disclosable.
- **Propagation** — movement of transitions *between* trajectories and *between independent implementations*. Excludes mere dissemination of finished artefacts.
- Terminology note: the epistemic unit is called a **transition**, never a "commit", to avoid collision with version-control commits in the same repositories.

39.1.10 2.8 Declaration of interest

Author founds a society that would host an implementation and is a candidate custodian. Two rules: the society's activity is evidence for nothing; and every requirement on custodians applies to it without exception (forkable spec; stewardship separated from operation).

39.1.11 3. Motivating conditions (§3) — *motivation, not evidence*

Encounter condition. Much of what changes an inquiry arrives from outside its plan (Merton's serendipity pattern; Dunbar 1997 on lab meetings as sites of analogical conceptual change). Present arrangements make such encounters structurally improbable. - **Claim 3.1** is narrow: the design lowers the **cost of preparation** — a recorded, available state is preparation externalised so another party's preparation may meet it. *Not* a claim about the frequency of encounter. - **Req. 3.2:** every statement about encounters is envisagement, and the counter-evidence must be cited alongside it. Counter-evidence: Irving et al. 2020 — occupants of a building designed for serendipitous collaboration developed strategies to *avoid* it.

Generativity condition. *Generativity* here = the capacity of a **relation** to produce states neither party held. Distinguished from the developmental-psychology sense and from Zittrain's platform sense (capacity of a technical system to admit contributions). Evidence that artefact volume/composition is changing (Glynn 2024; Liang et al. 2024 on 6–17% AI-modified text in CS peer reviews; redundant-publication growth 2022–24) — but **no study measures the evidential value of an artefact directly**, so the whole argument is explicitly conditional.

C2PA content provenance is the instructive parallel: it certifies *who asserted what and when*, not truth; and embedded credentials get stripped on redistribution. Both limitations reappear here and force the two answers: **registration by a distinct party** and **portability**.

39.1.12 4–10. The survey (concessions) — *what is already occupied*

39.1.13 §4 Correspondence networks

Mersenne, Hartlib, Oldenburg. The circulating unit was a **state of an inquiry**, not a result; circulation was mediated by a party who held the network; the record was retained **privately**. *Philosophical Transactions* (1665) began as a **periodic digest of Oldenburg's post** — i.e. the periodical **compressed an existing layer and then displaced it** (Claim 4.1), keeping the **registration of priority** and shedding the **warranting detail** (Shapin & Schaffer 1985 on Boyle's circumstantial "literary technology"; Bazerman 1988 on the contraction). **The countersigned laboratory notebook** — bound, paginated, signed by a witness who was not the inventor — is the nearest historical precedent for attestation, *and it shows attestation is compatible with keeping the content private*. Boundary: establishes precedent only. Nothing about feasibility, desirability, or magnitude at present scale.

39.1.14 §5 The reputation-mediated model

Cycle: standing → resources → work → standing (Merton 1968, Matthew effect). **Two functions conceded without qualification and which any proposal must preserve:** (1) concentration of resources on evidenced capacity; (2) **priority as the reward that makes early disclosure rational** (Merton 1957). Documented difficulties: low inter-assessor agreement (Cole et al. 1981; Pier et al. 2018; Fang et al. 2016); competition consumes ~the value of the awards (Gross & Bergstrom 2019); **penalty on novel combination** (Boudreau et al. 2016; Wang et al. 2017) — assessment computes expected value from precedent (Claim 5.1). Political economy: standing is a **positional good** (Hirsch 1976) — competition for it cannot be dissolved by increasing supply; credentialing is consumed cheaply by parties who bear none of its cost; incumbency is concentrated while reform benefit is diffuse (Olson 1965). **Adoption cannot be expected on merit.** Boundary: every cited study samples producers who *entered* the procedures — silent by construction about the population the diagnosis concerns.

39.1.15 §6 Open platforms

Conceded in full: preregistration + Registered Reports (pre-commitment works, but only where the outcome lies in the future); repositories/identifiers/deposit (**taken as substrate, never reimplemented**); **Octopus** — 8 publication types along research stages, hierarchical linkage, priority registered at every stage, open post-publication review; ResearchEquals; open commentary. **Limitation that matters:** a comment attaches to an *artefact*; where it persuades an author, the relation between comment and change is **recorded nowhere**. **Claim 6.1** — nothing surveyed takes *the transition between two identified states* as its unit, and four functions are absent throughout: attested registration; absorption attribution; portability as a bound on authority; grounded restriction. Structural note: every system here is a **platform** (operator, database, location).

39.1.16 §7 Standards — bind, don't redefine

PROV (entities/activities/agents, derivation, attribution) ·CRediT (contributor roles) ·CiTO (typed citation relations) ·W3C Web Annotation (body/target/motivation + selectors) · RO-Crate/FAIR packaging ·micro/nanopublications ·repository notification + federation protocols. **Definition 7.1 / Claim 7.2 — the pivot of the paper:** all of these are **description languages** (fix a vocabulary for recording what occurred, impose no condition on what may occur). GRA specifies an **interaction protocol** (which acts are admissible, what each does to a shared state, which party may perform each, what conformance requires). None of the standards requires registration by a second party, constrains record order, or defines conformance *for a process* rather than a document.

39.1.17 §8 Rationale capture — *the decisive section*

IBIS (Kunz & Rittel 1970) → gIBIS (Conklin & Begeman 1988) → Compendium/dialogue mapping; design rationale QOC (MacLean et al. 1991); scholarly claim ontologies (ScholOnto, Buckingham Shum et al. 2000; micropublications, Clark et al. 2014). > **Claim 8.1. The representational problem is solved** — since 1970, repeatedly, by capable > funded people, connected to deployed standards. **The recorded cause of non-adoption is capture > cost:** the work of recording falls on the party who gains least, at the moment they can least > bear it, in a form serving a different party later (Grudin 1988).

> **Requirement 8.2 (Recording as byproduct).** Every act the protocol defines is an act a participant performs **for a reason of their own**, with the record falling out of its performance. An act existing so that a record should exist will not be performed; any element depending on such an act is moved to an optional tier or removed.

Excludes: general obligation to document reasoning; any separate structuring stage after the work. Admits: an objection registered because the raiser wants a claim changed; a decision recorded because a group must remember what it ruled out; a release declared because the author wants something citable.

39.1.18 §9 Norms, ethics, law

Mertonian norms govern *results*, not process. Authorship criteria + CRediT attach credit to a finished work — **this design moves the attachment point to a change within one**. Fricker 2007 (testimonial + hermeneutical injustice) names the diagnosis but supplies no infrastructure. **Claim 9.1** — copyright (expression), patent (invention), trade secret (non-disclosure), moral rights (attribution/integrity) all protect *finished products*. **None protects a party's position in an ongoing process of generation.** Two consequences: the design offers **evidence, not a right** (sealed registration); and attribution is modelled on **moral rights** — attribution *without any power to exclude* — to avoid the anticommons (Heller & Eisenberg 1998; Boyle 2008). Lex informatica (Reidenberg 1998; Lessig 2006) accepted: a data model *is* a normative fact — but the response is to keep protocol rules few, explicit, inspectable, and push contested content to L1.

39.1.19 §10 The limit of legal reconstruction

Evidence is discrete; generation is continuous. The design **improves the sampling without changing its character** (Claim 10.1). Causal attribution under cumulative/nonlinear conditions strains the counterfactual test (Wright's NESS; Halpern & Pearl). > **Definition 10.2 / Proposition 10.3.** A **trajectory** is the recorded sequence. The > **generativity of a relation** is its capacity to produce states its participants did not hold. > Two trajectories may **coincide in recorded appearance while differing entirely in generativity** > — the record holds what occurred, not what the relation was capable of.

This is the deeper ground of the no-scalar rule. **Open question the paper does not answer:** how generativity is to be *represented*, *reasoned about*, *utilised*, and *protected*. GRA contributes to the first only.

39.1.20 11–20. The derivation (Part II) — where the requirements come from

39.1.21 §11 Displacement of evidential value

Def. 11.1 (separating condition) — after Spence 1973: an artefact carries evidence of capacity only while producing it is *more costly for a lower-capacity producer*, by a margin making it worthwhile for one and unattractive for the other. **The evidence was never in the object; it was in the difference between what the object cost different producers. Prop. 11.2** — a uniform fall in production cost weakens the evidential function while the artefact, the practice, and the systems reading it all remain. **The failure is invisible from inside the practice.** (Says nothing about quality of content.) **Req. 11.3** — any replacement channel must satisfy the same separating condition. Since expense is excluded by Req. 8.2, credibility must rest on **something the producing party does not control alone** → §12.

39.1.22 §12 Fabrication and distributed attestation

Claim 12.1 — a record held and produced by a single party inherits the artefact's fabrication cost. Length, detail, internal consistency, and the appearance of struggle are properties a fabricated record has as readily as a true one. Three sources of credibility: **cost** (excluded by 8.2) ·**pre-commitment** (real but only covers what lies in the future) ·**distribution** (general). > **Requirement 12.2 (Distributed attestation).** A transition is registered by a party distinct > from the one proposing it, with that party's identifier recorded. Credibility follows from the > **distribution of registrations across parties who did not coordinate**, and from **no property of > the record's content, length or detail**.

Implications: registering must be **cheap** (Grudin applies to registrars too); entries must be tamper-evident (content addressing + parent links — available from the substrate, no new crypto). **Limits:** attestation establishes registration, not truth/improvement/understanding; requires ≥2 parties (personal tier has *zero* evidential weight and is justified by usefulness alone); collusion is raised in cost, not eliminated; **counting attestations is forbidden** (a scalar; farmable by reciprocal registration). > **Claim 12.3 — why a protocol and not a platform.** A platform can host a record but cannot supply > the independence its credibility depends on, since the operator is party to every entry.

39.1.23 §13 The unit of record

Candidates rejected: **utterance** (unreadable volume; burden moves to interpretation), **output** (Octopus-style — shows a second hypothesis exists, not that *this objection* converted the first into it), **artefact version** (difference computed, reason absent by construction). **Adopted: the transition.** Components + why each: prior state ref (a change naming no antecedent degrades into commentary) ·posterior state ·typed act (searchability) ·performing party (attribution) ·registering party (Req. 12.2) ·disposition ·absorption links. > **Req. 13.1 (Granularity).** A transition references a **specific identified prior state**. > A record attached to a project, repository or document as a whole is not a transition.

This *diagnoses* §6's observation: commentary systems never became epistemic infrastructure because a comment attaches to an artefact — nothing transitions, no state is superseded.

Worked case 13.2 (social theory, 3 steps): trust-between-individuals → [party B objects: omits institutional power] → trust-as-process-shaped-by-power-asymmetry → [party C, entering from commons governance, connects to monitoring/graduated sanction] → trust-generated-under-governance. Exhibits: two transitions each referencing the state altered; an objection by a non-author with acceptance as disposition; an **encounter** (entering party) at step 3; both attributable *without either claiming to have authored the theory*.

Three consequences: *curation follows from the unit* (a two-hour meeting altering no state produces no record — nobody decides what deserved keeping, so nobody holds a position over the archive); *performativity resisted* (inflating the record requires recruiting a registrar); *compression without a model* (typed transitions are readable by anyone — this is what independence requires in practice).

> **Req. 13.3 (Factorisation of the type).** Type is factored into independent dimensions with small closed vocabularies, not one flat enumerated list. Flattening multiplies terms and inter-rater agreement declines as categories rise; deliberation over classification re-introduces capture cost.

Dimension	Values
act (8)	question ·claim ·challenge ·transformation ·decision ·connection ·verification ·release
target	question ·assumption ·hypothesis ·concept ·theory ·method ·path ·artefact
relation	extends ·modifies ·replaces ·refines ·generalises ·specialises ·transfers → **binds to CiTO**
trigger	self ·literature ·experiment ·simulation ·discussion ·objection ·failure ·model suggestion ·entering party
disposition	accepted ·contested ·**unresolved**

Contribution is not an act — it types a participant's part in an act and binds to CRediT. **The `unresolved` disposition is essential:** most objections in theoretical work are never resolved; a vocabulary with only accept/reject would produce a systematically false record and exert pressure toward **fabricated closure**.

39.1.24 §14 Divergence, and no merge

Identity of a state across transitions is **a matter of record, not adjudication** — a state is a later version of another where a chain connects them; whether they are "the same theory" is a reader's L3 judgement. **Claim 14.1 — no merge operation.** Version control merges because (i) identity criteria exist at byte/line level, (ii) changes to distinct regions compose, (iii) a test decides the result. **None holds for a state of an understanding.** What is called integration is either a **synthesis** (a new state referencing ≥2 parents) or an **absorption** (taking content from another trajectory *with attribution to its originator*). **The word "merge" appears nowhere in the specification.** A trajectory is a **directed graph, not a sequence**. Two states sharing a parent = divergence; neither is designated the principal line. **Attribution crosses divergence. Disanalogy with software forks:** in software a fork is a failure to be reunified; in inquiry a fork is *frequently the correct outcome*. **Plurality is the normal shape of a healthy record.** Forgone: canonical current version; automatic reconciliation; protection against the attention cost of plurality.

39.1.25 §15 Positions and functional authority

Four positions the design **generates** (not imports): **registrar** ·**trajectory steward** ·**holder of disclosure authority** ·**custodian of the specification**. Openness does **not** dissolve hierarchy — contradicted by Shaw & Hill 2014 (concentration of decision rights in open peer-production communities) and Michels 1962. The design assumes it is false. > **Def. 15.1.** A position is **functional** where constituted by acts the arrangement requires, > recorded and attributable, with occupancy depending on continuing to perform them. It is > **structural** where occupancy confers persistent standing, or where others' capacity to act > depends on the holder's permission. > **Req. 15.2 (Admissibility).** Two joint conditions: (i) constituting

acts are recorded as > transitions or administrative operations, attributable and visible; (ii) **participants retain the > capacity to proceed without the holder's permission** (supplied by portability, §16).

Neither suffices alone: visibility without exit → documented autocracy; exit without visibility → participants can't tell what a holder has done. *This is why administrative operations are recorded distinctly from transitions.* Limits: a protocol cannot prevent positions forming; **recording is not review** (a steward who always declines one participant's transitions leaves a complete record and the protocol does nothing — L1 responds); the condition secures *capacity*, not practice.

39.1.26 §16 Portability as the bound on authority

Hirschman 1970 (exit/voice): availability of exit conditions everything about how voice operates, **whether or not exit is used**. > **Claim 16.1.** In this design the bound on any position's authority **is the cost of exit**, not > any rule addressed to the holder. (Rules require an enforcer; the enforcer occupies a position; > the regress terminates only where a participant can act without anyone's permission.) > **Req. 16.2 (Portability) — five joint properties.** The complete record (transitions, > attestations, attribution, parent links) is (1) obtainable by any participant **without > permission**; (2) in a **self-describing format readable without the producing software**; > (3) carries **identifiers that stay resolvable when held elsewhere**; (4) **licensed** to permit > continuation; (5) **continuable under the same protocol by an implementation the original operator > does not control**.

Property 5 is what distinguishes portability from export. A data dump satisfies 1–4 and leaves departing participants with an archive. Evidence: open-source forks are rare *because the option exists*. Contrast: editorial secessions in publishing are notable events — **Claim 16.3**: their rarity is evidence about **exit cost**, not about the quality of what was departed from. A journal's standing lives in its title and indexing; it does not leave with the people. **Limits:** portability secures the record — **not the participants, not the resources, not the standing**. Standing is positional and held by the arrangement. It converts a prohibitive exit cost into a substantial one; expecting frequent secession is unwarranted.

39.1.27 §17 Entry paths

Four candidate qualifications: demonstrated contribution ·code of conduct ·trust extended by existing participants ·verification of competence. > **Claim 17.1 (bootstrap failure).** Qualification by demonstrated contribution *requires access in > order to be satisfied and grants access in return for satisfaction* — closed against every party > with no prior position. Trust-extension has the same form with an extra step.

(Same shape as Arrow 1962 on information as a commodity, and as §5's novelty penalty. Also the empirical mechanism by which open communities concentrate decision rights.) > **Req. 17.2 (Entry path).** At least one path exists by which a party with **no prior position** > may perform an act **decided on the act itself**; cheap to attempt; its **material supplied by the > arrangement**; outcome verifiable by others.

The mechanism is already in the vocabulary: a trajectory holds states whose disposition is `unresolved` — standing objections, open questions, obstacles. A **register of unresolved states is the entry path** (cf. `grrp open` in Paper IV). A stranger may `connect`, `challenge`, or `verify` against an identified state; each is decided on content; none requires standing. Untouched: volume/attention rationing; conduct+moderation (L1); competence for restricted classes; and the fact that an arrangement whose participants decline every stranger still *conforms* — the record of declining is what a reader has to go on.

39.1.28 §18 Encounter and the participant set

A trajectory changes in **content** and in **who holds it** — both are transitions. > **Def. 18.1 (Encounter).** A transition performed by a party who has performed **no prior act** in > the trajectory, with a trigger identifying the occasion. No new primitive is added — the trigger > dimension already covers it. > **Claim 18.2.** The record holds **the generation of the arrangement that produced an > understanding**, not the understanding alone. Where the unit is an output, an entering > participant leaves no trace beyond a name on a later artefact.

Uses: attribution for parties who altered a trajectory **without producing an artefact of their own**; conditions of productive encounter become inspectable (material for study, not a protocol function). > **Claim 18.3 (matching, narrowed).** The discovery claim concerns **structural similarity between > states in different fields** and **nothing within a field** (within a specialty everyone already > knows each other). Cf. Swanson 1986 (disconnected literatures jointly entailing a conclusion > neither states) — extended here from published claims to *recorded states, including unresolved > ones*. It depends on a large corpus, so it is a **late property of an adopted arrangement and > supplies no reason for anyone to adopt one**.

Two further boundaries: cross-vocabulary structural matching is an **unsolved L3 research problem**; and **recording an encounter alters it** — the material most worth preserving is the least likely to be produced under observation.

39.1.29 §19 Priority and disclosure timing

The dilemma: circulation is where benefits arise; concealment is where a participant's protection lies. **Asymmetric** — a well-positioned party risks little; a party without position bears the whole risk, and that is the population the diagnosis concerns. Priority answers it in the incumbent system but **attaches at publication**, i.e. after the work is substantially complete — the generative phase is unprotected, and the only instrument is silence. Deployed devices (preregistration, stage-wise publication, preprints) all **require disclosing the thing registered**. > **Def. 19.1 (Sealed registration).** Publication of a value derived from a state's content, from > which the content cannot be recovered and against which it can later be checked, plus the > registering party's identifier and a time. Disclosure is a **separate, subsequent** act. > **Req. 19.2.** Registration is available at the moment the act is performed, at **every** disclosure > class including disclosure-to-nobody. The record shows *that* registration occurred at its time > **without showing what was registered**.

Five limits. Evidences possession, not understanding/capacity/priority. **Generates nothing while sealed** — it buys the possibility of later opening, not the benefits of early opening. No protection against independent arrival. Requires a trusted publisher of the value or a public medium (outside the protocol). **A timestamp is not priority** — priority is a community's recognition, an L1 matter.

39.1.30 §20 Transmissibility — *the strongest single result of Part II*

Collins 1974/2010 (TEA laser): labs failed to build the device from published papers; success followed *contact with people who had built one*. MacKenzie & Spinardi 1995 (nuclear weapons design): same structure where the incentive to record fully was extreme. > **Def. 20.1 (The articulable fraction).** That part of what participants held which they were able > to put into the record. Its complement transmits, if at all, by working alongside them, and **no > property of the record's design recovers it.**

- **Reuse** survives in weakened form: what transfers is the *propositional content of a failure* (an approach was attempted, on what assumption, what obstruction was met) → **redirection of attention**, not transfer of capability. A reader cannot take up another's work where it stopped.
- **Evidence** is bounded to *the acts performed* — a record can be traversed by a modest party working slowly. Claim is that the record **discriminates better than an artefact under present conditions**, not that it measures capacity.
- **Hazard** is bounded by the same fraction: what a hostile reader gets is the propagable part.

> **Proposition 20.2.** The component the artefact omits is **simultaneously** the component carrying value in reuse, evidential force, and hazard. All three scale together with the articulable fraction, and **no design increases one without increasing the others.**

Kills a whole class of proposals: you cannot publish the trajectory *minus its dangerous parts* and retain the benefit. Hence the answer to hazard is disclosure classes + stated grounds (→ Paper III), never selective omission. Same component also carries the **reputational cost** of disclosing failure → exploratory vulnerability (Paper III).

39.1.31 21. The gap, stated once (Claim 21.1)

> No arrangement in the surveyed literatures **(a)** takes the transition between two identified states as its unit of record, **(b)** registers that transition by a party distinct from the proposer, **(c)** attributes content absorbed from one line of work into another, **(d)** bounds the authority of positions by the portability of the record, and **(e)** restricts disclosure on a stated ground that determines what remains disclosable — **specified as an interaction protocol where the standards are description languages.** The elements are severally available; **the conjunction is unoccupied**.

Every element has an ancestor (attestation ← countersigned notebook; attribution ← CRediT + moral rights; portability ← software forking; grounded restriction ← hazardous-research governance; typed relations ← CiTO). Novelty is claimed **for the assembly and the requirements forcing it**, not the parts.

Four findings that withdraw the claim (stated so a reader can look for them): 1. A deployed system/spec whose unit is the transition between identified states, with distinct-party registration → defeats the claim entirely. 2. A spec defining admissible acts + effects on shared state for scholarly work, with conformance → defeats the description-language claim. 3. Evidence that rationale-capture systems failed for reasons **other than capture cost**, or were adopted more widely → removes Req. 8.2, the principal design constraint. 4. Evidence the separating condition has **not** weakened, or that evaluation has already replaced the artefact → removes the premise of the whole argument. *(Empirical; unsettled.)*

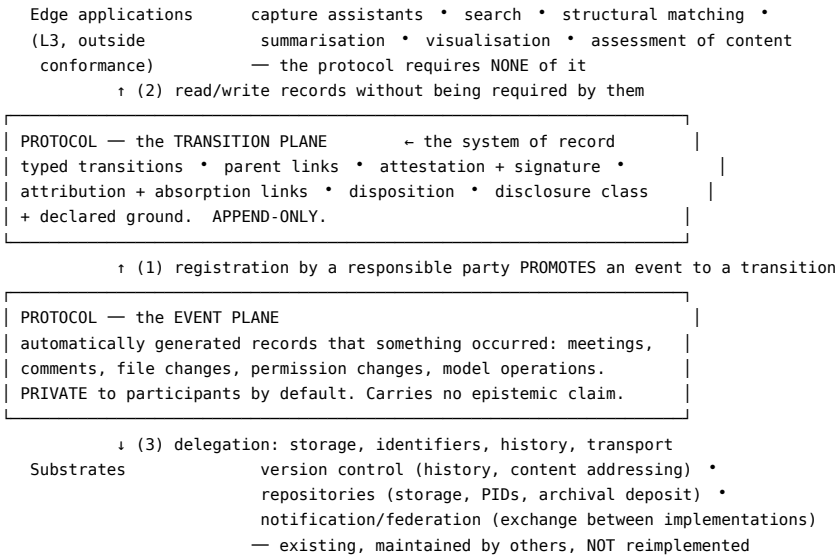
39.1.32 22. The sixteen requirements (the spec is judged against these)

#	Requirement	Derived in
R1	Recording is a **byproduct** of acts performed for their own sake	§8
R2	Deployed vocabularies are **bound, never redefined**	§7
R3	A transition is **registered by a party other than its proposer**	§12
R4	The unit of record is a **transition referencing an identified prior state**	§13
R5	The log is **append-only**; current state is **derived**; edits are **detectable**	§13
R6	**Divergence is recorded; no merge operation is defined**	§14
R7	The complete record is **portable and continuable elsewhere**	§16
R8	An **entry path** exists: cheap to attempt, externally verifiable	§17
R9	**Absorbed content is attributed to its originator, without veto**	§9
R10	**No scalar** quantity over participants or trajectories	§2
R11	Disclosure is **monotone**: scheduled release, **no withdrawal**	§10
R12	Personal content is **separable**, so redaction leaves the log intact	§9
R13	Records are **durable**: plain formats, distributed custody, deposit	§25

#	Requirement	Derived in
R14	The protocol is implementable with **no analytical capability present**	§2
R15	The **core tier is worth adopting by a single participant**	§3
R16	A **release can emit the artefact the incumbent reward system accepts**	§5

The three that constrain most severely: R1 (eliminates the most otherwise-attractive designs — no documentation obligation, no post-hoc structuring stage), **R10** (costs the ability to report progress, rank contributors, or summarise standing), **R14** (costs the ability to require model-assisted capture, matching, or summarisation). Status: **not claimed complete**; **not independent** (R3+R7 both serve credibility; R1+R15 both serve adoption); and this is the table Paper IV is assessed against.

39.1.33 23. The architecture in outline



The event plane is **where the surveillance hazard falls** — a complete log of who attended and whose files changed is a monitoring record by construction. Hence: confined to participants, disclosed only through registration. **Claim 23.1** — the arrangement contributes **the transition plane and the rules governing promotion into it**, and nothing else.

Three tiers (this stratification is what makes R15 achievable): - **Personal** — one participant, transitions with parent links against identified states, append-only log, derived views, three acts. Gets: a searchable record of what was ruled out and why; a standing list of unanswered objections; a release emitting a citable document. Gets **no evidential weight whatever** (attestation impossible with one party). - **Group** — attestation, contributor roles, absorption links, disclosure classes. **Credibility begins.** - **Open** — propagation, distributed custody, deposit, charter reference. Exchangeable with implementations elsewhere.

Left to Paper IV: act vocabulary + factorisation; identifier and signature construction; disclosure classes bound to grounds (→ Paper III); **conformance conditions** (without which the requirements are aspirations). **Claim 23.2** — this establishes the requirements are jointly satisfiable, and **nothing about whether the arrangement works**. Adequacy is settled by use.

39.1.34 24. Two speculative formal models (envisagement — the protocol depends on neither)

The design is **event-based**: state persists until an act occurs; nothing updates on a schedule. **Req. 24.1** — this is a reference to the *class of event-advanced systems* (DEVS, Zeigler et al. 2018; spiking networks, Maass 1997 are another instance). **No property of neural computation is transferred.**

1. **Generalised heterogeneous dynamical network (Def. 24.2)** — nodes each carrying their own state space *and their own law of evolution* (discrete dynamics on a complex; spiking; continuous field; discrete-event automaton), coupled by **propagation operators** Π_{ij} mapping events emitted at v_i to admissible inputs at v_j. Motivation: a knowledge trajectory couples participants whose internal dynamics are not of one kind. Nearest prior art: DEVS multi-formalism coupling; multilayer network dynamics. **Three stated obstacles:** a shared time base + consistent event ordering across dynamics that individuate events differently; coupling semantics across differing state-space types; **closure under coupling**.
2. **Spin-foam-like representation** — a history as a **two-complex**: vertices = events, edges = couplings between elements of an event, faces = primitive elements; the §13 transitions are its one-dimensional shadow. Ancestry: Whitehead 1929 (events as primitive constituents); Kowalski & Sergot 1986 (event calculus). **Three objections recorded and unanswered:** no analogous algebraic structure on the informational side (so the borrowing is figurative); no counterpart to superposition, so the amplitude machinery may be inert; borrowed heavy formalism without its home-domain empirical constraints is a recognised failure mode.

Four conditions for either to become formal: explicit mapping with no ornamental elements; a composition rule gluing histories along shared boundaries (natural candidate: a state of a shared understanding); an interpretation of the weight assigned to a history; and a demonstration that some question about trajectories is answerable in it **and not in the directed graph of §14** — which is the representation the protocol actually uses and which is adequate to everything it requires.

39.1.35 25. Open problems, by what each awaits

- **Legal** — the unprotected position of a party in an ongoing generation; erasure rights vs integrity guarantees (answered by separating content from the attested skeleton, but not adjudicated); cross-border multiplicity of regimes; status of model-assisted contributions.
- **Normative** *(these bear directly on whether the claimed benefits appear)* — whether registration confers priority; **whether disclosed failure can be non-punitive** (the reuse argument depends on it); whether the **labour of registration** is recognised (unpaid work for someone else's benefit — precisely the disparity that killed the §8 systems; answered by making it cheap, not by rewarding it); whether an unresolved disagreement is publishable as a state.
- **Organisational/economic** — decades-long custody with succession; **assessment capacity is subtractable** and rationing without ranking is unsolved (→ Paper II); the **regressive distribution of overhead** (recording falls hardest on those with least time — exactly the population the diagnosis concerns).
- **Technical** — representing a state so structural similarity is computable across vocabularies (undemonstrated; retrieval by topic does not do it); trajectory-graph shape analysis (persistent homology, Carlsson 2009 — applicability unknown); quantum approaches (marked speculative; three obstacles: hardware, unproven advantage, and the representation problem is prior).

None is required for conformance. All sit at L3 so the protocol depends on none of them.

39.1.36 26. Conclusion — five results, three concessions

Results: (1) the evidential function rests on a separating condition and is weakening invisibly; (2) a single-party record inherits the same weakness, so credibility must come from distributed attestation — **hence a protocol, not a platform**; (3) the representational problem was solved repeatedly and failed on **capture cost**, which excludes more designs than any other consideration; (4) value-in-reuse, evidential force, and hazard are **the same component** and scale together; (5) the layer is a **restoration**, not a novelty.

Concessions: the prior art in platforms/standards/representational systems; **no evidence for the encounter motivation** (the best study points the other way); recognition is positional, so nothing here increases the standing available — **attribution redistributes it, which predicts resistance from parties who benefit from the present invisibility of others' contributions**.

> The account's contribution is to take capture cost as its **first constraint** rather than an obstacle to be regretted, and to see what a design looks like when **nothing may be required of a participant that the participant would not do anyway**. The result is smaller than the designs that failed, and whether smaller is enough is a question no argument settles.

39.1.37 Implications for this repository

- README/plans must not promise **progress reports, trajectory health, similarity ranking, contribution scores** as protocol features. Every such thing is **L3** and most are forbidden as scalars (R10). *(The retired* `implementation_plan.md` *had these as Stages 4–5 — see gaps-and-repo-actions.md.)*
- The word **"commit"** should not name the epistemic unit — the paper deliberately says **transition** to avoid collision with git commits in the same repository. The README's "GRA Commit Concept" contradicts the papers.
- The word **"merge"** must appear nowhere in the UI or spec (Claim 14.1).
- Any claim about encounters/serendipity must be marked **envisagement** and carry the Irving et al. 2020 counter-evidence (Req. 3.2).
- The personal tier must be **worth using alone on day one** (R15) — and must be described as carrying **no evidential weight** (§12.4), which is a distinction the README currently blurs.

40.1 Notes — Paper II: *Incentives, Collective Action, and Adoption in GRA Infrastructure*

Author: Wanhong Huang ·working draft, 2026 ·CC BY-NC 4.0 ·40 pp, 17 sections Source: papers/GRA-paper-II-…pdf

Role in the series: the *economic and institutional* paper. Paper I says the record is worth keeping; Paper IV says how to keep it. This one asks **whether any of it will actually happen** — and answers, honestly, that nothing here gives reason to expect it will.

> This is the paper that keeps the project honest. **Most of its content is a list of things the project may not claim.** Read it before writing any pitch, README, or grant application.

40.1.1 0. What the paper says it can and cannot secure

> A protocol **can** alter the distribution of costs and make certain acts cheap. It **cannot** create an incentive where none exists, **cannot** dissolve competition for a positional good, and **cannot** supply a norm a community has not adopted.

It also explicitly declines the standard rhetorical move: it does **not** argue that the present arrangement is so defective that any alternative is worth trying. The incumbent performs two functions that must be preserved — concentration of resources on evidenced capacity, and priority as the reward making early disclosure rational.

Requirement 2.3 (evidential marking). Every claim is marked **formal** (follows from stated assumptions) / **empirical** (cited studies, population + strength stated) / **conjecture**. Strength of the literatures used, descending: positional goods + contest theory (formal) → assessment reliability + cost of competition (empirical, reasonably strong) → **what makes research infrastructure adopted (thin, retrospective, selected-on-outcome)**.

> **Requirement 2.4 (Standard for a solution).** A difficulty is treated as *addressed* only where the paper states **a mechanism**, identifies **the party who bears its cost**, and names **the condition under which the mechanism fails**. A mechanism without an identified cost-bearer is recorded as **unaddressed**.

This is stricter than the field's practice, and deliberately: describing an arrangement in which someone does work benefiting others *without saying why they would* is the characteristic failure that produced the non-adopted systems of Paper I §8.

Terms. *Adoption* = begins conducting work under the protocol at a declared tier **and continues**; one trajectory then stopping is not adoption. *Overhead* = effort that would not have been expended without the arrangement, measured against the participant's own purposes. *Private benefit* = benefit accruing to the cost-bearer, at their own scale, **without the participation of others**.

40.1.2 §3 Where the commons dilemma actually is

> **Claim 3.1 (formal).** The **tragedy of the commons has no object in knowledge.** That analysis concerns a rival resource degraded by uncoordinated appropriation; no quantity of reading, citing, absorbing or forking diminishes what a trajectory record holds. Transferring the tragedy imports a mechanism whose precondition is absent.

Not pedantry: misdiagnosing the dilemma as appropriation invites appropriation-type remedies — **restrictions on use** — and Paper III shows restriction is justified only on grounds *none of which is overuse*.

> **Claim 3.2 (formal).** Knowledge is a public good, so the predicted failure is **underprovision, not overuse** (Olson 1965). Remedies that increase the cost of *using* knowledge address a failure that does not obtain and worsen the one that does.

The four subtractable goods (this is where Ostrom's design principles apply — *not* to the knowledge produced from them):

Good	Character
Review / assessment capacity	The time of a party competent to judge. Rival, limited, unpaid. **The one the design most directly strains.**
Maintainer labour	Keeping the record coherent, resolving duplicates, curating the open register, answering newcomers (Eghbal 2016).
The instrument	Rival in the ordinary sense, where the work needs one (→ Paper III).
Community trust	Willingness to extend good faith to unknown contributors. Consumed by bad experiences, replenished slowly. An open entry path draws on it directly.

> **Claim 3.3.** The protocol **lowers the cost of contributing and lowers the cost of assessing by nothing.**

Rationing without a ranking (Claim 3.4). Congestion is ordinarily managed by ranking; the no-scalar rule removes it. Three alternatives, all **charter-level, none supplied by the protocol**: *reciprocal obligation* (no deployed instance at scale) ·*bounded intake* (rations without ordering; displaces the difficulty onto the administrator; wastes arbitrarily) ·*maintainer triage* (what OSS does; efficient; reintroduces exactly the position Paper I §15 governs). **Recorded as unaddressed.**

The inverse risk (Claim 3.5). Fine-grained attribution across many small contributions resembles the biomedical-patent anticommons (Heller & Eisenberg 1998). Answered by **excluding any veto**: an absorption link confers *attribution and no power to prevent, condition or reverse use* — the moral-rights construction. **Complete against legal fragmentation; incomplete against social fragmentation** (a community may treat attribution claims as though they carried veto power whatever the spec says — *conjecture*).

40.1.3 §4 Review capacity — the binding constraint

Claim 4.1 (formal). The protocol shifts the ratio of contributing-cost to assessing-cost toward more demand on assessment. **Congestion is a consequence of the design *working*, not of its failing. Claim 4.2.** Assessment capacity is fixed in the short run, unpaid, provided under a norm rather than a contract, and **already strained**. **Claim 4.3.** The protocol **makes assessment activity visible and provides no assessment capacity.** Visibility is a *precondition* for a community to run a reciprocity norm; it is not such a norm. **> Claim 4.4.** Congestion of assessment capacity is **the difficulty in this series least addressed > by the design and most likely to determine whether a conforming arrangement survives at scale.** > Every available remedy places an **unfunded burden on a small number of parties**.

40.1.4 §5 Maintainer labour

The non-research work: registering others' transitions ·resolving duplicate/near-duplicate states ·curating the open register *so it stays a list of open problems and not a list of everything nobody has closed* ·answering entrants ·maintaining charter, classes, membership ·custody, deposit, succession.

> **Claim 5.2 (empirical).** Open-source is **not** evidence that voluntary maintenance of shared infrastructure is sustainable. It is evidence that such maintenance **concentrates on very few, frequently unpaid parties** and **fails silently until something breaks** (Eghbal 2016; Shaw & Hill 2014). *Usually cited as encouragement; it reads as a warning.*

Two disanalogies, running opposite ways: software has tests, so a maintainer's per-contribution assessment cost is low — **assessing a challenge to a claim has no such shortcut**, so maintenance here is *more* expensive per unit. And software has a large dependent *commercial* user population that sometimes funds maintenance — **a trajectory record has no such population**, so the OSS funding argument does not transfer.

Claim 5.3. No party's interest is proportional to the benefit it would receive (institutions gain evidence of contribution, funders gain selection information, unaffiliated scholars gain visibility — all diffuse, against concentrated cost). Olson's **privileged-provider exception** names both how comparable infrastructure actually gets funded *and* the failure mode: **the paying party's purposes become the arrangement's purposes.**

Protocol's contribution (none of it a solution): makes maintenance **visible** (precondition for compensation, not compensation) ·**bounds the maintainer's authority via portability** *— at a cost to the maintainer, who then holds the burdens of authority and few of its returns* · **permits** the work to be distributed. **Recorded as unaddressed.**

40.1.5 §6 The positional bound — *the section that deletes claims*

Claim 6.1 (formal). The aggregate quantity of standing in a field is **fixed independently** of how much work is produced or how visible contributions are made. Any arrangement making more contributions visible **redistributes standing; it does not increase it.**

> **Claim 6.2 (formal).** The series **may claim** that the arrangement changes *what parties compete for*. It **may not claim** that it reduces competition, dissolves hierarchy, or increases the recognition available to those who lack it — **any passage implying otherwise is an error to be corrected.**

Consequences: attribution mechanisms are **redistributive**, so a party who presently benefits from the invisibility of others' contributions **is made worse off** — *a reason to expect resistance, not an argument against the mechanism*. Openness alters *who may enter*, not *what is competed for*.

Two dimensions actually open to alteration: (1) **the basis of comparison** — artefact counts vs recorded contribution to changes in understanding; available *because* the artefact has weakened as evidence (Paper I §11); (2) **the visibility of contribution** — but standing rises only if the community counts it, which returns to (1).

Claim 6.4 — the objection that this proves too much fails. What is fixed is the *aggregate of standing*. What is **not** fixed: which activities produce it, who may compete, what evidence is admissible, and **what is lost when work is not recorded**. Retention, reuse of abandoned material, and interpretability of a decision years later **are not bounded by the positional argument at all**. Keep the two sets of claims apart.

40.1.6 §7–8 Selection, dissipation, and the absorption test

Definition 7.1 / Claim 7.2 (formal). An open selection is an **all-pay contest**: effort is sunk whether or not the entrant wins. Opening it to more entrants **increases aggregate**

dissipation — and disproportionately burdens those for whom preparation is a larger share of available time. *An arrangement where many develop proposals in the open and the rest are discarded is the incumbent arrangement with a wider entrance and a higher aggregate cost.* Neither standard rebuttal closes the gap (**Claim 7.3**): the *learning* response identifies a gain that is **private, unrecorded, and lost when the entrant moves on** — precisely the condition this series exists to address; the *signalling* response is bounded by the evidence on assessment reliability.

> **Definition 8.1.** An arrangement is **competitive** where the work of unselected entrants **leaves no trace** in the work that proceeds. It is **generative** where content originating in unselected work **enters the work that proceeds and is attributed to the party who produced it.**
>
> The definition turns on **what becomes of unselected work** — not on openness of entry, number of participants, or manner of decision. *An open arrangement discarding losing proposals is competitive. A closed arrangement that takes up and credits a rejected proposal's method is generative.*
>
> **Requirement 8.2 (The absorption test).** Examine the record of the work that proceeded and count the transitions whose content originated in work that was **not selected**, with attribution to the originating party. **Where such transitions are absent, the arrangement is competitive whatever its constitution states.**

Three properties make it usable: **checkable** from the absorption links the spec already requires (no new instrument); **falsifiable against the proposal itself** — any conforming arrangement may be examined and found to absorb nothing; and **applicable to existing arrangements** without the protocol (laboriously — a funding programme, a lab, a journal can be asked whether the work that proceeded took up content from what it declined).

Claim 8.3. The absorption test is **the folding criterion of the companion papers applied at the point of selection** — *the series employs one criterion at four positions, not four criteria.* (Value returning to the relation that produced it = generative; value accruing to an attractor outside that relation = not.)

Four limits (Claim 8.4). Absorption is **necessary, not sufficient** (an arrangement may absorb diligently and produce nothing of value). It may be **performed badly** — content taken up in a way that misrepresents what the originator held, recording a debt they would not recognise (hence the spec's **contested attribution** provision). **Counting is forbidden** — an absorption count is a scalar, farmable within a season by nominal absorptions; the test is applied *by a reader reaching a judgement*, never computed or displayed. And it says nothing about **generative capacity** — two arrangements may absorb identically while the relations differ entirely.

40.1.7 §9 Staged selection and backward induction

The natural design: (1) open work, no ranking, diversity encouraged → (2) collective development with objection and revision → (3) selection and allocation.

> **Claim 9.1 (formal).** Where a later stage allocates a scarce resource and everyone knows it, the earlier stages **are not unranked — they are ranked with a delay.** A declaration that a stage is non-competitive does not make it non-competitive. *(Robust: it suffices that some participants anticipate the selection; their behaviour imposes the same pressure on the rest.)*

Two predicted behaviours (Claim 9.2): - **Withholding** — a participant with a strong idea discloses late. **The exploration stage therefore fills with the material participants are least concerned about, which is the material least worth having.** - **Adversarial objection** — improving a rival's line raises the probability the rival is selected, so the rational act is **to object in ways that damage rather than in ways that improve** — and objection is exactly the mechanism the arrangement relies on for its generative benefit.

> **Claim 9.3 — the repair.** Where content absorbed into a selected line is **attributed** to its producer, and the attribution is **recorded durably and recognised**, contributing to a rival's line carries a **positive expected return**, and improving objection carries a return that damaging objection does not. **Attributive absorption is the condition under which a staged design survives backward induction — not a courtesy extended to unselected parties.**

Notes: it operates more strongly on **development** than exploration (an improving objection is credited immediately; an early-disclosed idea is protected only by registration, which converts exposure into a dated claim *and generates nothing*). And it **requires the attribution to be worth something** — a community counting only selected outcomes leaves the repair inoperative.

> **Claim 9.4.** Staged selection without attributive absorption is **worse than an undisguised competition**, since it obtains the appearance of openness while producing the behaviour of a contest.

40.1.8 §10 Sparsity and plurality of selection criteria

Claim 10.1. Any criterion applied **often enough and singly enough** becomes the description under which participants organise their work. *The problem is frequency and singularity, not the choice of criterion.* > **Definition 10.2. Sparsity** = the interval between selection events, measured against the > interval over which a line of work develops. **Plurality** = the number of applied criteria **that > cannot be combined into a single ordering.**

Claim 10.3. Sparse → weak optimisation pressure between events. Plural → no single ordering forms. **Frequent + single-criterion = worst case. Claim 10.4 (conjecture). Plurality is not preserved under frequent application** — participants infer the operative criterion from repeated outcomes. **So sparsity is a *condition* of plurality, not an independent parameter.**

Three costs. Sparse selection **concentrates risk** on those with short horizons — again the least-standing population. It is **administratively unattractive** (frequent small allocations are easier to justify and correct, and produce a steady record of activity). Plural criteria are **contestable** — the decision cannot be defended as following mechanically from the criteria, so the decision-maker's judgement becomes visible. *A cost by ordinary standards; an advantage under this series' analysis, since a visible judgement is attributable to a party.*

Claim 10.5. Both are **charter parameters, not protocol parameters**. The protocol makes their values visible after the fact and supplies no means of setting them. **Unaddressed at the level of the design.**

40.1.9 §11 Overhead and its incidence

Claim 11.1. Overhead concentrates in **acts requiring articulation**, specifically **the decision act**. Typing and registration are cheap by construction (a small number of narrow choices under the factorisation; a single affirmative action). **Recording *why* a direction was abandoned, at the moment of abandoning it, is not — and no property of an interface reduces that cost.**

> **Claim 11.2 (formal).** Overhead falls hardest on participants with **the least time and the least standing — the population the series' diagnosis concerns.** The arrangement is **regressive in the dimension the series most cares about, whatever its intentions.**

The byproduct principle, restated economically: an objection is raised because the objector wants a claim changed; a release is declared because the author wants something citable; a connection is recorded because the connector wants the relation known. > **Strongest form:** the arrangement records **what participants already produce and discard** — > weekly progress reports, supervision notes, meeting summaries are *compressed accounts of a > trajectory produced routinely under present conditions*. Adding a little structure to work already > performed imposes far less than asking for new work.

Claim 11.3. The byproduct principle reduces the overhead of every act **except the decision act**, whose purpose for the performer is weakest. A participant abandoning a direction gains little from recording why; the party who gains is a stranger years later. **This is the disparity that defeated earlier systems, surviving in one act after the design removed it from the others.**

Requirement 11.4 (Private-benefit sufficiency). An arrangement is adoptable **only where its minimal form is worth adopting by a single participant with no other participants present.** An arrangement whose benefits appear only at scale is never adopted, since no party is ever in a position to obtain them.

Historical analogue: **version control was adopted by programmers working alone, for private reasons**; the collaborative benefits followed. *Nobody adopted it out of commitment to a social model of software production.* (Claim 11.5 — conjecture by analogy, and the analogy is to a case with a **far more favourable cost structure**.)

Claim 11.6. Residual **regressivity is unaddressed**: the private-benefit condition addresses the *timing* of benefits, not their *distribution*. A senior party adopting the personal tier loses little; a precarious party obtains the same record and loses time they cannot spare. Compensating it would require a funding party no analysis identifies.

40.1.10 §12 Selection pressure on adopting groups — the strongest argument against

Claim 12.1 (formal, the dominance argument). In an environment rewarding output rate, a group adopting an arrangement that imposes **any net cost** is disadvantaged relative to groups that do not, **irrespective of the arrangement's epistemic merits**. Sustained, adopting groups are **selected against.**

Hence adoption is not a matter of persuasion: *a group persuaded of the value and situated in this environment is a group persuaded to accept a competitive disadvantage, and persuasion of that kind does not survive a funding cycle.* And that collective benefits exceed collective costs is **not in dispute and not relevant** — no group receives the collective benefit; every adopting group bears its own cost.

Two escapes only: 1. **Net private benefit** at the adopting party's own scale. Candidate components, stated as an economic claim rather than a feature list: *time recovered in preparing progress reports and presentations from an existing record ·effort saved in not repeating an abandoned approach ·faster onboarding of a new member from the record instead of from conversation*. **Whether these exceed the overhead is an empirical question nobody has measured.** 2. **Insulation** from output-rate selection — theory groups with secure funding, nonprofit research bodies, interdisciplinary institutes, retired scholars, unaffiliated researchers.

Claim 12.2. Adoption is predicted to **begin among insulated parties** and spread to others only where net private benefit is demonstrated. **The prediction is uncomfortable for the series, since insulated parties are peripheral to the fields whose practice the arrangement would have to change.**

Claim 12.4 (the honesty condition). The series **may not argue for adoption on the ground that the arrangement benefits scholarship collectively.** That argument is available to no individual party, and **its repetition is the characteristic error of proposals in this field.** What may be argued: that a particular party, at a particular scale, obtains more than it gives up — **and that argument requires evidence this series does not have.**

40.1.11 §13 Network externalities and the tier structure

Claim 13.1. Benefits rising with participation → a coordination problem where **the return to the first adopter is lowest**; where the benefit is *entirely* of this kind, the arrangement

has no first adopter and does not begin. *This is a second, independent explanation for the non-adoption of the 1970– systems: a party constructing an argument map alone obtains a map, and the promised value lay in a network that never formed.*

Three ordinary remedies, all unavailable: **subsidy** (needs a funding party whose interest is proportional — §5 established there is none) ·**mandate** (converts the arrangement into a compliance requirement, and the mandating party's purposes become the arrangement's) · **bundling with an already adopted good** — *the most promising, and layering over version control and repositories is the attempt; success unknown*.

> **Claim 13.2.** Where benefits are **stratified so each tier returns something at the scale of that tier**, the coordination problem decomposes into a sequence of decisions **a party can take alone**. The strict condition: **each tier must return something at its own scale**; a tier returning nothing until the next is reached collapses the decomposition. *The personal tier is where this is most doubtful.*

> **Definition 13.3 / Claim 13.4 (Minimum viable adopting unit).** The smallest set of parties for which benefits exceed costs **without participation by anyone outside the set**. **Group tier = two parties who register each other's transitions. Open tier = one community with an implementation and a charter.** *A design whose minimum unit was a discipline requires an agreement nobody can broker. A design whose minimum unit is a seminar requires a decision two people can take on a Tuesday.*

Claim 13.5. The tier structure addresses **the coordination problem and not the cost problem**, and the two are independent. Also: **cross-field matching is not decomposable** — it needs a multi-field corpus, belongs to no tier, returns nothing to any adopting party, and **must play no part in any adoption argument.**

40.1.12 §14 Compatibility with the incumbent reward system

> **Requirement 14.1 (Compatibility).** An arrangement is adoptable only where a participant can obtain, **from a conforming record and without additional work**, an artefact of the kind the incumbent reward system accepts.

Mechanism: a `release` emits a document containing the released state, **the chain of transitions leading to it**, the parties with their CRediT roles, the absorption links with attributions, and **the objections standing at release**. Two economic properties: it requires **no additional work** (assembled from records created in the course of the work); and it carries **an appendix no other process can produce**.

Claim 14.2. Compatibility converts the decision from *a choice between two systems* into *an addition to one*. **Three effects:** removes the sacrifice ·supplies an immediate return **in the currency that binds** (time recovered assembling a paper) ·**defers organised opposition** (Olson: opposition organises when a threat becomes visible).

The objection that compatibility concedes too much — participants keep publishing, publications keep being counted, and the trajectory record becomes an unread appendix. **Answer is partial and honest (Claim 14.3):** the objection is correct that the appendix may go unread indefinitely; what it misses is the alternative — demanding abandonment of publication means accepting the dominance argument's cost in full, so **the comparison is between an arrangement that may be ignored and one that will not exist.** *That the first is preferable is a position, not a result.*

> **Claim 14.4 (the terminus).** Compatibility **postpones the conflict and does not remove it**, and **the conflict returns at exactly the point at which the arrangement begins to succeed.** A proposal claiming to threaten nobody while proposing to change what counts as evidence is **either naive or evasive** — this series states the terminus rather than claiming the conflict away.

40.1.13 §15 What the empirical record actually shows

Claim 15.1. No systematic study exists of a defined population of research infrastructures assessed against adoption outcomes. Available evidence = retrospective accounts of individual systems, written mostly by associated parties, selected for attention because they succeeded or failed conspicuously. **Infrastructures quietly built and quietly unused generate no literature at all — so the population is unobservable exactly where the account makes its prediction.**

Pattern the discussed cases suggest (**Claim 15.2, conjecture**): infrastructures that **supplied a tool researchers needed for their own work, with sharing as a byproduct of using the tool**, were taken up (simulation/analysis platforms). Infrastructures **whose proposition was sharing** — the contribution was the point and the return arrived through others — were built and **largely unused** (workflow-sharing repositories). **Claim 15.3 (conjecture).** Funding + institutional expectation are **sufficient to build** shared research infrastructure and **not sufficient to produce voluntary use** — a mandate alters what a participant must be *seen* to do, not the cost they bear. **Claim 15.4.** No evidence that infrastructure increases productive unplanned encounters; the strongest qualitative study reports **avoidance** (Irving et al. 2020).

> **Claim 15.5.** The empirical record **supports this paper's negative claims and none of its positive ones.** It gives reason to expect that arrangements without private benefit fail, and **gives no reason to expect that an arrangement with private benefit succeeds.**

40.1.14 §16 Ten predictions (with refutations) — *the project's own evaluation plan*

Adoption: P1 begins among parties insulated from output-rate selection, and among those whose reporting burden is high relative to output ·**P2** proceeds tier by tier — a substantial personal-tier population **precedes** any group-tier population ·**P3** arrangements adopted for a private benefit persist; those adopted for a collective one do not. **Behaviour: P4** where selection is present and absorbed content is *not* attributed, objection is disproportionately destructive and strong material is disclosed late ·**P5** where absorption is attributed *and recognised*, contribution to others' lines rises ·**P6** where selection is frequent, plurality of criteria decays ·**P7 assessment capacity, not contribution volume, becomes the binding constraint on any arrangement that succeeds. Distribution: P8** overhead falls disproportionately on participants with least time, visible in participation rates by career stage ·**P9** maintenance concentrates on a small number of parties whose number does not grow with adoption ·**P10** attribution mechanisms are resisted by parties benefiting from present invisibility, and **the resistance appears as objection to the mechanisms' *accuracy* in place of objection to their *purpose*.**

Refuting observations are given for eight (e.g. adoption concentrated among parties under strong output-rate selection without demonstrated private benefit refutes P1 *and the dominance argument with it*; contribution volume rather than assessment capacity binding refutes P7 *and the location of the commons dilemma*).

Four measurement difficulties, all against the account's interest: non-adoption is unobservable (P1/P3 testable only among adopters); attribution recognition happens in non-public appointment and funding decisions; destructive objection is surface-identical to rigorous objection; and **every prediction concerns an arrangement that does not exist.**

> **Claim 16.1 — the prediction the account is most exposed on: P2.** If a substantial **personal-tier population appears and no group-tier population follows**, the tier decomposition will have delivered private utility **without the attested records on which every evidential claim in the series depends**, and the arrangement will have become **a note-taking convention**. This outcome is consistent with everything the account asserts and **would defeat the purpose the series was written for.**

40.1.15 §17 Conclusion

Five results: location of the commons dilemma (four subtractable goods, not knowledge) · the positional bound and the claims it forbids ·open selection as a dissipating contest with the absorption test as the distinguishing criterion ·attributive absorption as the condition on staged selection ·private benefit as the condition on adoption.

Four difficulties recorded as unaddressed (no mechanism with an identified cost-bearer for whom bearing it is rational): **assessment congestion ·maintainer labour ·the regressive incidence of overhead ·the recognition of attributed contribution**.

Three arguments declined: that the incumbent's defects justify any alternative ·that adoption follows from collective benefit ·that the empirical record supports the proposal.

> The account is compatible with an outcome in which the arrangement is adopted by a small number of insulated parties, delivers private utility, never reaches the scale at which its evidential claims mean anything, and **is remembered as one more proposal of a kind that has been made since 1970. That outcome is stated here because the account predicts it, and because a paper that concealed it would exhibit the failure it spends its length diagnosing.**

40.1.16 Implications for this repository

- **Never argue for adoption on collective grounds** in README, site copy, or applications (Claim 12.4). Argue: *this particular party, at this scale, gets back more than it gives up.*
- **Delete/never write:** "makes scholarship less competitive", "democratises recognition", "dissolves hierarchy" (Claim 6.2). Permitted: "changes what competition rewards".
- **Cross-field matching / similar-trajectory search must not appear in any adoption argument** (Claim 13.5) — it is a late corpus property that returns nothing to an adopting party. *This is why the retired plan's Stage 5 was struck.*
- **P2 is the project's own risk register entry:** ship the personal tier, but treat "personal tier adopted, group tier never" as the named failure mode, not a success.
- The **absorption test** should be a stated evaluation criterion for the project itself — and must **never be implemented as a counter or score** (Claim 8.4).
- The **release → citable document with lineage appendix** (Req. 14.1) is the single most adoption-critical feature. It belongs in M1, not a later stage.
- Roadmap items that add contribution volume without adding assessment capacity make P7 worse.

41.1 Notes — Paper III: *Grounds of Restriction and the Governance of Disclosure*

Author: Wanhong Huang ·working draft, 2026 ·CC BY-NC 4.0 ·38 pp, 15 sections Source: papers/GRA-paper-III-…pdf

Role in the series: the *disclosure governance* paper. An arrangement that records how understanding changes **must be able to withhold**. The question is never *whether* but **on what ground — and what follows from the ground**.

> Its single operative idea: **a ground determines an object and leaves a residue.** What a ground leaves *disclosable* is what distinguishes an arrangement that withholds **for a reason** from one that withholds **because it can**.

41.1.1 Why ownership cannot supply the answer

Three reasons, inherited from the companion papers: 1. Legal instruments protect **finished products** — copyright/fixed expression, patent/completed invention *with disclosure*, trade secret/concealed information. A party's position **within an ongoing generation** is protected by none (Boyle 2008; Scotchmer 1991; Lemley 2012). 2. Rights to exclude, multiplied across fine-grained contributions, produce the **anticommons** (Heller & Eisenberg 1998). 3. **The design's own criterion runs the other way** — an arrangement in which value converges on a party *outside* the relation that produced it is exactly what the series diagnoses; exclusive rights over trajectory content would install that.

So **withholding is justified by a reason, never by a title.** And the reason must do work.

41.1.2 §2 The instrument

- **Definition 2.1 — disclosure class.** A value attached to a record governing the set of parties to whom it may be disclosed. Classes are **ordered by inclusion**. Their identity and membership are settled by a community's **operating charter (L1)**, not by this account (Ostrom 1990, collective-choice arrangements).
- **Definition 2.2 — ground.** The declared reason a record is disclosed at less than the widest class available. **A ground is a property of a restriction, not of a record** — the same content may be restricted on different grounds in different arrangements, with different consequences.
- **Definition 2.3 — residue.** What remains disclosable at the widest class while a restriction on that ground is in force. **A ground with an empty residue licenses total silence.**

  Requirement 2.4 (What a ground must state). Four things: **(i) the condition** under which it obtains; **(ii) the object** it restricts; **(iii) the residue** it leaves disclosable; **(iv) the failure** produced by applying it where its condition does not obtain.

  (iv) is what makes the instrument useful. A ground stated without its failure mode **is a licence** — any party may assert the condition and no party can say what has gone wrong when the assertion is false.

  Requirement 2.5 (Closed set). The set of grounds is **closed**. A community **may not declare a new ground** in its charter; a restriction fitting none of the four is **inadmissible**. *Cost stated: a reasonable restriction fitting none of the four cannot be imposed — so the account may be wrong by omission. §14 invites exactly that observation.*

Requirement 2.6 (Disclosure of the residue) — the operative requirement of the paper. Where a restriction is imposed on a ground, **the corresponding residue is disclosed at the widest class available.** A restriction withholding material its ground does not cover is **inadmissible, whatever the ground's condition.** *Without it every ground collapses into the same thing — silence with a justification attached.*

Requirement 2.7 (Assessment). Three questions: **does the condition obtain? is the object restricted the object the ground identifies? has the residue been disclosed?** Failing any → the restriction is **misapplied**. Applied **by readers, not by the protocol** (the spec records the declared ground and enforces the class; it cannot assess whether the condition obtains). Applied **to a restriction, not to a party** — a party may restrict properly once and improperly the next time, and no inference runs from one to the other.

41.1.3 §3–6 The four grounds

41.1.4 The comparison table (Table 7.1)

Ground	Condition	Object restricted	Residue	Named failure on misapplication
Rivalry	a resource admits limited simultaneous use (instrument, facility, compute, clinical population, budget line)	**access to the resource**	**the trajectory in full** — questions, methods, decisions, failures, interpretations, results	a restriction on **access** is converted into a restriction on **knowledge**
Hazard	propagation of the content creates risk of serious harm — the risk arises from the content **being known**, not from use of a resource	**the propagable content of the method**: the sequence by which a capability is obtained, the constraints discovered, the parameters that matter, the practical technique	existence of the work, questions pursued, decisions and their reasons, interpretations, **results that do not convey the method**	the **widest restriction on the strongest justification**, and it is **unfalsifiable from outside the restricted class**
Exploratory vulnerability	exposure at this stage would suppress or distort the work (premature criticism, appropriation, the participant's reluctance to record what may be read)	**the timing of exposure**	**everything, at the scheduled time** — the ground justifies delay and **no permanent withholding**	postponement converted into permanent withholding (schedule extended, or never set)
Appropriability	the work is funded by an arrangement requiring **excludability**	the content whose disclosure **would destroy the excludability the funding depends on**	existence, questions, decisions and their reasons, **and negative results**	**rent-seeking secrecy** — general secrecy obtained on an economic justification that does not apply

41.1.5 §3 Rivalry — the conversion that is "routine"

Claim 3.1 (formal). Rivalry justifies selectivity **in access to the resource** and **no restriction on the record**. A record is non-rival, so the ground's condition does not obtain of it.

Labs with restricted instruments routinely restrict the surrounding record too — **and the practice has reasons: appropriability, hazard, or vulnerability. Those are different grounds with different residues, and they must be declared as themselves.**

> **Claim 3.3 — the paper's principal positive contribution on this ground.** Where an instrument is scarce, **the deciding process may be opened without opening the instrument.** Proposals, the reasoning behind them, the objections raised, the decision and its stated reason are all inside the residue, and disclosing them costs **nothing in the resource**. **What is opened is the direction of the work, not the capability to perform it.**

Two consequences: allocation decisions become inspectable; and **unsuccessful proposals become available — which is the condition under which the absorption test (Paper II §8) can be satisfied at all.** *An arrangement whose declined proposals are unrecorded cannot absorb from them.* **Claim 3.4 — three limits.** It does not reduce dissipation (it converts dissipated effort into a retained record, which is worth less than not dissipating it). It **exposes unsuccessful applicants** (a declined proposal is a record of a judgement that did not persuade). And it is costless in the *instrument* but **not costless** — it consumes **assessment capacity**, the binding constraint.

41.1.6 §4 Hazard — where the design's central tension lives

> **Claim 4.1 (formal).** Where the hazard lies in **propagation of a method**, restricting access to an **instrument accomplishes nothing** — the instrument is frequently replaceable and often widely held. Rivalry and hazard restrict **different objects** and are **not substitutes**.
>
> This **disposes of the design the source discussion for this series proposed at length**: *restrict the instrument, open the reasoning.* That is correct under rivalry and **exactly wrong under hazard, since the reasoning is where the hazard lives.** (Bostrom 2011: the hazard attaches to **knowing**, not to **holding**.)

Claim 4.2 — the residue is larger than practice usually allows. That a line of work exists, what question it pursues, what obstacles it met, what directions it abandoned and why, what its participants take their results to mean: **none of these conveys a capability.** Withholding them on the hazard ground is **misapplication**. Practical arrangement for restricted work: **the trajectory is visible in its structure and its reasoning; the propagable method is held at a narrow class.**

Claim 4.3 — conditional access. Following structured access (Shevlane 2022): a party **uses a capability without receiving the artefact that confers it**, under conditions enforced by the supplying party. Here: a party is **admitted to the restricted class under a charter's assurance requirements, with the admission and its ground recorded.** This **converts a binary question (disclose or not) into a question of whom to admit and under what commitments** — and the conversion is what makes work under this ground possible at all.

Four limits. Hazard assessment **is not a competence a protocol has, and frequently not one the participants have either** (hence institutional review). **Misapplication is undetectable from outside** — a party outside the class cannot assess whether the restricted content is in fact propagable, so the §2 standard is available only to parties inside the class or to a body a charter empowers. The hazard is bounded by the **articulable fraction** — which bounds the benefit identically. And: > **Claim 4.4 — hazard has no natural terminus.** Rivalry ends when the instrument is free. > Appropriability ends when the funding purpose is served. Vulnerability ends when the work matures. > **Hazard does not end.** So **scheduled release is unavailable**, and the class must be maintained > indefinitely by **parties who must continue to exist**. Where the community ceases, the material is > held by nobody under any charter — **and the account offers no treatment of that case.**

41.1.7 §5 Exploratory vulnerability — the timing ground

> **Claim 5.1 (Monotonicity).** Disclosure **may widen and cannot narrow** — a party who has read a record retains what they read. An arrangement offering the ap-

pearance of withdrawal **misdescribes to its own participants a state of affairs obtaining outside it.**

Two consequences: **the default must be restrictive** (an error toward openness is uncorrectable, and defaults are where such errors occur); and **a schedule may be shortened and must not be extended** — *this asymmetry is the substance of the ground.*

Claim 5.2 — the observer effect (conjecture). Recording alters what is recorded. **The material this series most wants preserved — half-formed ideas, real disagreement, the remark someone makes before they are sure of it — is the material least likely to be produced under observation.** The degradation falls precisely on the content the arrangement most values. Mitigations, all partial and stated as such: narrowest default class, scheduled rather than immediate release, participant-marked exclusions. *None removes the effect; an arrangement claiming otherwise claims people behave identically observed and unobserved.* **Structural mitigation = the unit of record.** What is preserved is *that an objection altered an assumption* — **not that a particular party expressed it clumsily at a particular moment.**

Claim 5.3 — the two populations. A **well-positioned** party is exposed to criticism but not to appropriation (standing protects the association of an idea with its author); delay serves them **weakly**. A party **without position** is exposed to both, and **appropriation is the exposure that matters**; delay serves them **strongly**, as does sealed registration. **So a charter setting short delays uniformly imposes the exposure on the population least able to bear it.**

Three limits. Delay costs the work **the objections it would have received** — protected from appropriation *and* from improvement, and the arrangement cannot supply the second without the first. No objective terminus (a party may in good faith judge indefinitely that the work has not matured). And it is **the easiest of the four to assert** — its condition concerns the state of a piece of work, which only its participants can assess, so misapplication is detectable **only from a pattern of schedules over time.**

41.1.8 §6 Appropriability — legitimate, and most often declared as something else

Claim 6.1. The condition is **legitimate and not a regrettable concession**. Some work is not performed unless somebody pays, and some funding requires excludability. Where that obtains, **insisting on disclosure does not produce a disclosed trajectory; it produces no trajectory, because the work does not occur.** (Arrow 1962 supplies the general form.)

Claim 6.2. The residues of hazard and appropriability **coincide in shape and differ in content** — hazard asks *what does not convey a capability*; appropriability asks *what does not destroy excludability*. **A negative result may be commercially harmless and hazardous; a question may be commercially revealing and entirely safe.** Declaring one ground while applying the other's residue is misapplication. **Two residue items practice withholds routinely and shouldn't:** *the existence of the work* (rarely what destroys excludability, and its disclosure is what lets others avoid duplicating effort) and **negative results** (rarely what a competitor would have paid for — *and their disclosure is the principal contribution the series claims for the reuse of abandoned material; this is the residue item the series presses hardest*).

Claim 6.3. A party **holding a patent has exchanged disclosure for exclusion and may not invoke appropriability over the disclosed matter.** Trade secret is the corresponding instrument. Copyright is irrelevant (protects expression, not the excludable content). *The account adds nothing to what the law permits and constrains what a party may declare within a conforming arrangement.*

Claim 6.4 — the strongest argument in the paper for the residue requirement. Appropriability is **unverifiable from outside**, so misapplication is detectable **only through the residue**. **A party declaring appropriability and disclosing the residue has made a claim that costs them something; a party declaring it and withholding the residue has made a claim that costs nothing — and the second is the observable signature of misapplication.** *Where residues are disclosed, a false declaration is expensive; where they are not, it is free.*

Three limits: the terminus exists in principle and **rarely in practice** (nothing obliges release once the funding purpose is served); the ground is **available only to parties with funding arrangements**, so it is asymmetric **in favour of the well-resourced — a direction the series generally resists and cannot resist here**; and assessment reduces to one question a reader can answer — *was the residue disclosed?*

41.1.9 §7 Irreducibility, composition, and how restrictions end

> **Claim 7.1 (Irreducibility).** No ground reduces to another. **Rivalry restricts a resource; the others restrict content. Hazard restricts what a *reader* could do; appropriability restricts what a *competitor* could sell — and the two select different content from the same trajectory. Vulnerability restricts a *time*; the others restrict a *set of parties*.**

Consequences: a restriction **must declare which ground it invokes** (object and residue follow from the ground, not from the content); and **an arrangement using one ground for everything has either misapplied it or is operating under a condition that does not obtain** — most commonly, declaring *commercial sensitivity* over material that is actually restricted because it is dangerous, or early, or because the instrument is booked.

> **Requirement 7.2 (Composition).** Where several grounds obtain, **each is declared separately, and the residue disclosed is the *intersection* of the residues of the grounds declared.** A party may not declare one ground and withhold on the strength of another. **Claim 7.3 — declaring more grounds is not free:** it narrows the residue **and raises the number of conditions the party asserts**, each of which can be assessed and found false.

(Example of genuine composition: pharmaceutical development — funded by excludability, produces material whose propagation carries risk, and involves early work exposure would distort.)

> **Claim 7.4 — how each ground ends. Vulnerability** ends on a *recorded schedule* (shortenable). **Rivalry** ends when the resource is no longer contended — observable, unenforced. **Appropriability** ends when the funding purpose is served — *known to the declaring party alone*. **Hazard does not end.** Therefore **an arrangement resting mostly on the other three accumulates restricted material indefinitely**, and **a community that wishes its record to open over time must prefer the ground that ends.**

Claim 7.5 — what the apparatus achieves (stated modestly): a restriction becomes a **dated, attributable assertion** where present practice makes it a default that asserts nothing; misapplication becomes **describable** (each ground has a named failure, giving a reader a vocabulary); and the **residue becomes the object of attention** — the informative question is not *was something withheld* but **does what was disclosed match the ground declared**. **No enforcement is supplied.**

41.1.10 §8 Simulation displaces the governance problem — it does not remove it

Claim 8.1. Where a simulated environment is faithful enough for exploration, the **rivalry ground contracts to the validation stage**, and earlier stages open to any party with computation. *(Genuine, with instances: community simulation → shared fabrication in hardware design; open computational exploration → experimental validation.)*

> **Claim 8.2 — the displacement. A simulated environment is a selection environment.** What it admits, rewards, renders visible, and cannot represent determines which explorations succeed — so **the party who specifies the model and the benchmark occupies the position the party allocating the instrument**

previously occupied. The displacement is unfavourable in one respect: allocation is **visible, episodic and contestable** (a decision is made, a party is refused, the refusal can be challenged); **benchmark specification is continuous, technical and rarely contested, and its effects appear as properties of the field rather than as decisions anyone took.**

Claim 8.3. Opening the benchmark is insufficient — **an open benchmark is a public attractor.** Parties optimise for what it measures and the categories it recognises become the categories the field maintains; inspectability of its assumptions does not prevent this. **Openness of a selection environment makes its criteria visible and does not prevent them from governing.** *(Therefore a simulated exploration stage is subject to Paper II's sparsity/plurality analysis — and a single widely adopted benchmark applied continuously is both the worst case for reactivity and the arrangement a field finds most convenient.)*

Claim 8.4 — validation dependence. A simulation's fidelity is established against the physical apparatus, so **the open layer inherits a dependence on the closed one**; the parties who validate hold a position over what the open layer may take as fidelity, **and the validation itself consumes the scarce resource the proposal claimed to economise on.**

Claim 8.5 — effect on hazard runs both ways. Simulation **lowers** hazard where the hazard lies in **execution** (exploration produces no dangerous artefact; the dangerous stage is confined and supervised). It **raises** hazard where the hazard lies in **design** — an environment letting many parties explore a design space cheaply lowers the cost of arriving at a dangerous design (*the biological case is the one usually named*). **A proposal to displace exploration into simulation must state which kind of hazard the domain carries.**

Claim 8.6 — the qualification, and it is real. Displacement **widens participation** in exploration from parties with instrument access to parties with computation — a far larger and differently distributed population. **This is the strongest reason to pursue the proposal, and the displacement does not defeat it.**

41.1.11 §9 The shared component — *the result that governs every restriction*

Definition 9.1 (The omitted component). What a finished artefact does not contain: the approaches attempted and abandoned, the reasons for abandoning them, the constraints discovered, the parameters that mattered, **the practical technique by which a result was obtained.**

Proposition 9.2. The omitted component carries **three properties at once**: **value in reuse** (what transfers is the record of what was tried and what obstruction was met) ·**evidential force** (a record of a completed result is cheap to fabricate; a record of the path is costly in proportion to the parties who attested it) ·**hazard** (a propagable method is a sequence of steps and constraints, not a statement of a result).

Claim 9.3. No design achieves the epistemic benefit of an open trajectory while withholding the parts that carry risk, since the parts are the same parts. A proposal to publish the trajectory minus its dangerous content is a proposal to publish the record minus what makes it worth publishing.

This is why the account is a typology of grounds rather than a filtering rule: the design cannot separate the valuable from the dangerous within the component, so it separates the *parties to whom the component is disclosed*.

Per ground: under **hazard**, the residue lies *outside* the component, so a hazard restriction **genuinely costs the commons something**. Under **appropriability**, same shape, different boundary — **negative results usually fall outside the excludable content while remaining inside the omitted component**, which is why the series presses them hardest. Under **vulnerability**, the component is disclosed **later rather than never** — *which is why that ground costs the commons least*.

Claim 9.4 — bounded together as well as carried together. All three scale with the **articulable fraction** (Collins 1974/2010; MacKenzie & Spinardi 1995). **A domain in which little of what matters can be written produces records of little use, little evidential**

weight and little danger; a domain in which much can be written produces records of much use, much weight and much danger. No design alters the ratio. *Practical use for a charter: where participants find little can be recorded, the arrangement will deliver little and its restrictions may be correspondingly relaxed.*

> **Claim 9.5.** Conditional access preserves the component **for a class**; delay **postpones** it; and **the residues, being outside the component, are disclosable without touching the trade-off at all.** *This is why the residue requirement is the paper's operative rule:* ***it is the only part of the design that gains something without giving something up.*** *An account attending only to the component would find no room to move; the residue is where the room is.*

41.1.12 §10 Downstream use — the structural gap

Claim 10.1. A record of how understanding changed, at scale, is an object of interest to parties who did not produce it: **training material** (a corpus of recorded reasoning with typed transitions and attached outcomes is precisely what a system learning to model reasoning would want) ·research material for the study of science ·evaluation material for institutions · commercial material for services. **The interest is proportional to the qualities the series claims — so the design's success creates the interest.**

> **Claim 10.2. The four grounds govern *to whom* a record is disclosed and do not govern *what a party may do* with a record disclosed to them.** The account is therefore **incomplete with respect to downstream use, and the incompleteness is structural rather than an oversight.**

Claim 10.3. The labour of producing the record is borne by participants; the value of a corpus assembled from many such records accrues to whoever assembles it. Where the assembler is well-resourced and the producers are the population the series concerns, **value transfers from those with least to those with most — which the design's own folding criterion marks as extractive, and which the design supplies no mechanism to prevent.**

> **Requirement 10.4 (Terms of downstream use).** A charter **must state the terms** on which records disclosed under it may be reused by parties other than their producers, and **must state separately whether consent to disclosure constitutes consent to inclusion in a corpus assembled for purposes unrelated to the work. A record must carry the identifier of the charter under which it was disclosed**, so a party obtaining it can determine the terms.

Three matters a charter must decide (the account decides none of them): whether reuse *for study of the work's own subject matter* differs from reuse *for training a system*; whether participants may withhold consent to corpus inclusion while consenting to open disclosure — **and what a record looks like where some have and some have not**; and whether a licence attaches, given that **licences designed for finished works apply awkwardly to a graph of attributed transitions**.

Claim 10.5 — three limits, the first defeating most of the attempt. Terms attached to a disclosed record are hard to enforce, and **the producing parties are least placed to bring the action**. Consent to corpus inclusion is **not meaningfully separable in practice** — a term forbidding one use of openly available material is a term whose breach is undetectable. And **restricting disclosure to prevent assembly is not available**: it is a restriction on a ground the account does not admit, and it would **impose the cost on the commons in order to withhold a benefit from a third party. Unaddressed.**

41.1.13 §11 Who may restrict — the authority is itself a position

Claim 11.1. The authority to restrict **is a position** in the series' sense: constituted by acts the arrangement requires, its holder determines what other participants may see, and others' capacity to act depends on its exercise. *An arrangement designed to resist concentration cannot exempt the one authority that determines what participants know.*

> **Requirement 11.2 (Recorded exercise).** Every **imposition, alteration and release** of a restriction is recorded as an **operation** carrying: the performing party, the **ground declared**, the **class imposed**, the **schedule** where one applies, and the **time**. *Cheap, and the whole of what the design can do here. It does not prevent improper restriction; it makes a party's pattern inspectable — the only basis on which misapplication can be detected at all.*
>
> **Requirement 11.3 (Separation of restricting from recording authority).** The party who **registers transitions** and the party who **determines disclosure classes** should be distinguishable in the record; a charter concentrating both must **state that it does so**. *A party holding both holds the record and its visibility together — and the record then evidences nothing about the party who produced it.*
>
> **Claim 11.4 — the series' general answer is weakest where the stakes are highest.** Portability bounds this authority **weakly**, because **a departing party can take the record they can see and cannot take what they were never shown.** The bound here is **charter and community, not exit.**
>
> **Requirement 11.5 (Charter statement of restricting authority).** A charter must state **which parties may restrict, on which grounds, at which classes, and whether any party may restrict without a schedule. A charter that leaves the authority unstated has left it with whoever operates the implementation.** *Authority not allocated is not absent; it is held by the operator — the party the series has least reason to trust.*

Claim 11.6 — applied to the author. An arrangement in which the proposing party maintained the charter, operated the implementation, **and** held the restricting authority **would be an instance of the concentration the series diagnoses**. Declaring that conflict is *a condition of the account's coherence, not a courtesy.*

41.1.14 §12 Detecting misapplication

> **Claim 12.1. Detectability of misapplication is inversely related to the width of the restriction the ground supports.** Ordering, most to least detectable: **Rivalry** (residue = trajectory in full, so any withholding is visible on its face) → **Vulnerability** (visible over time: extended schedules, or restrictions with no schedule) → **Appropriability** (detectable only through the residue) → **Hazard** (least detectable — the condition cannot be assessed without the content, and the content is what is withheld).
>
> **So hazard restrictions cannot be policed by readers.** A community relying on them must place the assessment with a **body it constitutes for the purpose — and must accept that the body then holds a position of the kind §11 treats.**
>
> **Claim 12.2 — the residue is the universally available observable.** For every ground, the question a reader can answer is **whether the residue was disclosed**. This **turns an unfalsifiable condition into a checkable one**: a party declaring hazard *and* disclosing existence, questions, decisions and interpretations **has behaved as a party with a genuine hazard would**; a party declaring hazard and disclosing nothing **has behaved as a party would who wanted silence and reached for the strongest available reason.**

Claim 12.3. Individual restrictions are frequently ambiguous; patterns are not. A party whose restrictions are *always* on the same ground, *always* without a schedule, *always* at the narrowest class, *always* without a residue, has a practice visible in the record even where no single restriction can be faulted. **This is the design's principal contribution to disclosure governance — and it is a contribution to visibility, not to control.**

Claim 12.4 — three limits. Detection is not remedy (the account supplies no procedure by which a restriction is overturned). **Detection depends on someone looking** — and *the parties best placed to look are frequently those with the least reason to.* And **a community that does not care will not be made to care by a record**: every mechanism here produces information for parties who wish to use it, and **none produces the wish.**

41.1.15 §13 Jurisdictional variation

Claim 13.1. Law is described and never encoded. A specification encoding any jurisdiction's rules would be **wrong somewhere immediately and obsolete everywhere within a few years. Claim 13.2. Law reaches the design negatively, through structural incapacity — and that is the only channel.** A data model incapable of expressing redaction forecloses lawful operation in every regime with a right of erasure, and no charter repairs it (Reidenberg 1998; Lessig 2006).

Four capacities that follow (design properties, not legal conclusions): 1. **Separability** — personal content separable from the attested skeleton, so removal leaves the structure and its verification intact (Finck 2018; GDPR). 2. **Expressibility of redaction** — record *that* content was removed, when, by whom, on what ground, **without removing the record of the removal**. 3. **Consent as a recorded object** — a record concerning a person can reference a consent whose scope and date are recorded. 4. **Locality of storage** — record where material is held and restrict where it may be replicated.

Claim 13.3. These are **capacities, not rules.** An arrangement possessing them may still operate unlawfully; one lacking them **cannot** operate lawfully where they are required. *The design's obligation is to possess the capacities; lawfulness lies with implementers and their advisers.*

> **Requirement 13.4 (Charter statement of legal operation).** A charter must state: the **jurisdictions**, the **consent** required before a record concerning a person is created, the **retention** applying to each class, the treatment of **erasure requests**, and any restriction on **where material may be held**. Unstated → left to the operator. An arrangement spanning regimes holds several charters or one with regime-specific provisions, and **a record must identify which charter and version governed it when it was created.**

Four limits (Claim 13.5). Federation **distributes** the compliance burden and does not remove it — *an implementation receiving records from another inherits obligations it did not create.* **Conflicting obligations are not resolved** (retention vs erasure of the same material is a real conflict; the implementation resolves it in a way it records, with no support from the spec). **Records already propagated are not reached** — a redaction notice reaches implementations that receive it and no copy held by a departed party. And **an arrangement cannot make its participants' own obligations disappear.**

41.1.16 §14 Predictions and falsification

P1 hazard restrictions withhold more than the ground covers, more often than the other three (← Claim 12.1) ·**P2** where residues are required *and inspected*, appropriability declarations **fall** (← 6.4) ·**P3** arrangements **accumulate restricted material over time** (← 7.4) ·**P4** communities will **declare vulnerability where appropriability obtains** — it is the easiest ground to assert and carries no admission of commercial interest (← §5 limits) ·**P5** displacement into simulation is followed by **contestation over benchmarks**, concerning technical specification in place of allocation (← 8.2) ·**P6** third-party corpus assembly occurs wherever a substantial corpus exists, **without compensation** (← 10.1, 10.3) ·**P7** where restrictions are

recorded and **nobody inspects them**, restriction practice will **not differ** from arrangements that record nothing (← 12.4).

Refuting observations given for all seven (e.g. *appropriability declarations unchanged in frequency where residues are required and inspected refutes P2 — and with it the argument that the residue requirement does any work*).

> **Claim 14.1 — what would show the set incomplete.** A restriction that **a competent and disinterested reader judges reasonable and that fits none of the four**. *The account invites the observation, since a typology whose exhaustiveness cannot be challenged is not a typology but a stipulation.*
>
> **Two candidates examined:** - *Protecting a third-party research subject* (medical/social research) — treated here as **hazard with an identified party** rather than a general one. A reader who finds that reading forced has a candidate. - *Honouring a confidentiality undertaking given to a supplying party* — fits appropriability **only with strain**, since the excludability may protect the **supplier**, not the receiver. The account's provisional answer (the receiving party declares appropriability on behalf of the supplier's condition) is **strained, and this is the stronger candidate.**

Three measurement difficulties: restrictions in non-recording arrangements are unobservable; **whether a residue was *disclosed* is observable, whether it was *complete* is not**; and misapplication concerns a relation between a declaration and a condition only the declaring party can assess, so it is testable **in aggregate patterns, not individual cases**.

41.1.17 §15 Conclusion

Six results: restriction justified by **reason, not title** ·**four irreducible grounds**, each determining an object and a residue ·**the residue requirement** as the barrier against a ground operating as a licence *and* the only universally available observable ·simulation **relocates** governance from allocation to specification, unfavourably ·**the shared component** of value, evidence and hazard ·**downstream use is governed by none of the four grounds.**

Five unsettled: closure of the set (confidentiality undertakings) ·assessment of hazard · absence of a terminus on three of four grounds ·the weak bound on the restricting authority · enforcement of downstream terms.

Three claims declined: that the four grounds are the *correct* set ·that the apparatus *prevents* improper restriction ·**that openness is preferable to restriction** — each ground states a condition under which restriction is legitimate, and appropriability is treated as *a condition of some work existing at all* rather than as a concession.

> The contribution is **a discipline rather than a mechanism**. A reason, once declared, determines an object and leaves a residue, so a restriction becomes a dated attributable assertion whose adequacy a reader checks by asking **one question: was what the ground leaves disclosable in fact disclosed?**
>
> The account **stops at visibility, states that visibility without inspection changes nothing**, and leaves the inspecting to communities that may or may not perform it.
>
> **What the paper is most confident of is negative.** No design separates the valuable from the dangerous within a trajectory, since they are the same material. No ground supports a restriction wider than its object. **And no arrangement that withholds its residues is withholding for the reason it declares.**

41.1.18 Implications for this repository

- Disclosure in the tool is **never a bare `--private` flag**: every restriction carries **a ground**, and grounds are a **closed set of four** (`rivalry | hazard | vulnerability | appropriability`) — which is exactly what `grrp disclose --class <c> --ground <g>` implements (Paper IV / M3).

- **Monotone disclosure (R11)** is a hard rule: **no `unpublish` operation exists**, and a schedule may be **shortened, never extended**. Enforce the direction, not just the field.
- **Vulnerability is the only ground with a recorded terminus** → `--release-at` applies to it naturally, is unavailable for hazard, and is unenforced for the other two. A UI that offers a schedule uniformly across grounds misrepresents the model.
- **Residue disclosure is the operative rule and should be surfaced by the tool**: when a ground is declared, prompt for / display *what the ground leaves disclosable* — this is the single highest-value affordance the account identifies, and it is the only thing that costs nothing.
- **Redaction must keep the record of the redaction** (Req. 11.2, §13 capacity 2) — matches the GRRP acceptance test "after `grrp redact`, the chain still verifies, the graph is unchanged, and the record of the redaction is present."
- **Records must carry the identifier of the governing charter and version** (Req. 10.4, 13.4) — the `charter.yaml` reference in `.grrp/` is doing this job; it must be **per-record-resolvable**, not just a repo-level file.
- **Downstream/corpus terms are a charter obligation and a known unaddressed gap.** If GRA ever publishes an aggregated corpus, Claim 10.3 says the design's own criterion marks uncompensated assembly as **extractive** — including if *we* do it.
- **Do not build "restrict the instrument, open the reasoning" as a general policy** — Claim 4.1 says it is exactly wrong under hazard.

42.1 Notes — Paper IV: *Specifying the Generative Relational Research Protocol*

Subtitle: Architecture, Conformance, and Deployment over Existing Repositories **Author:** Wanhong Huang ·working draft, 2026 ·CC BY-NC 4.0 ·63 pp, 24 sections Source: papers/GRA-paper-IV-…pdf

Role in the series: the **normative specification**. Discharges Paper I's sixteen requirements and fixes conformance. **Published as GRRP v0.1** — explicitly unfinished, with an amendment procedure, *because a specification published as finished would contradict the account it specifies.*

> This is the paper the implementation is built against. plans/implementation-plan.md is its builder-facing restatement — **the specification governs where the two differ.**

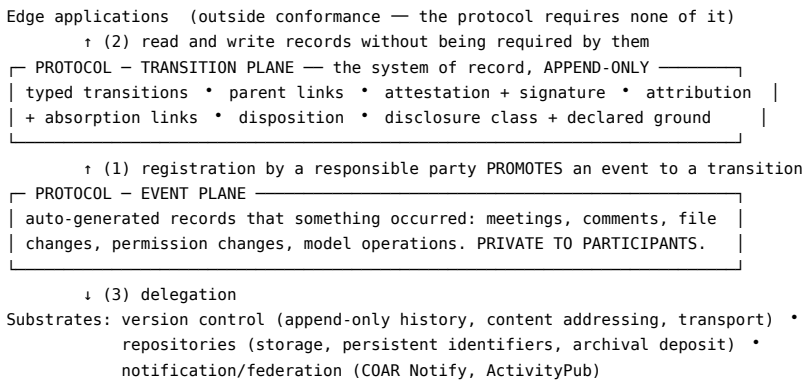
Conformance vocabulary: RFC 2119 `must / must not / should / may`. A `should` may be departed from where the implementer **states a reason**.

42.1.1 The four standing exclusions (§1)

Stated up front so absences are not read as omissions: 1. **No quantity over participants or trajectories, and no total order over either.** An implementation may compute one — outside conformance, on its own account. 2. **No analytical capability required.** Every conformant operation is performable **with a text editor and a version-control system**. Model-assisted capture is a convenience whose absence changes nothing about conformance. 3. **No merge operation.** 4. **No rules of conduct, membership criteria, retention periods or consent requirements.** These belong to a community's **operating charter**, which the protocol references and does not interpret.

> **Requirement 2.6 (Capacity and content).** The protocol fixes **the capacity and never the content.** A field whose values an implementation *enforces without interpreting* belongs to the protocol; the meaning assigned to those values belongs to the charter.

42.1.2 §3 Architecture: three planes over delegated substrates



> **Requirement 3.1 (Privacy of the event plane).** Event-plane records are disclosed **to participants of the trajectory by default and to no other party**. An event reaches wider disclosure **only through a transition that references it**, and an implementation **must not export, index or publish the event plane as such.** *(This is the plane where the surveillance hazard falls — a complete log of who attended, who commented and whose files changed is a monitoring record by construction.)*

Claim 3.2. The protocol contributes **the transition plane and the rules governing promotion into it — and nothing else.** Reimplementing storage/identifiers/history/transport would inherit their maintenance and compete with their installed base.

> **Requirement 3.3 (Substrate independence).** The specification **names capabilities, never products.** No conformance condition is expressed in terms of a particular VCS, repository service, identifier scheme or federation protocol; an implementation **must state which system supplies each**. *Cost, stated plainly:* no prescribed file layout or wire format — **interoperability rests on the record model and the bindings**, not on byte-level agreement (see the exchange minimum, §16).

> **Requirement 3.4 (Resolution and content addressing) — two properties commonly assumed and commonly absent, both load-bearing:** 1. **Every reference to a state or artefact must use an identifier that resolves independently of the implementation that created it.** *An identifier resolving through the original operator's service stops resolving when participants leave — and portability becomes nominal.* 2. **Every transition must carry an identifier derived from its content and from its parents' identifiers**, so altering an early transition invalidates everything after it.

42.1.3 §4 The event / transition / artefact model

Definition 4.1. An **event** records that something occurred and asserts nothing about an understanding. A **transition** records that an identified state became another, through a typed act performed by a party and registered by a party. An **artefact reference** records that a produced object exists, with a resolving identifier. *The division carries the economics of capture:* events are generated by systems participants already use, so **near-zero cost, possibly large volume**; transitions require a human judgement **and a registering party**, so **non-zero cost, small volume**; artefact references fall out of deposit.

> **Requirement 4.2 (Recording as byproduct).** Every act must be one a participant performs **for a reason of their own**. An implementation **must not require any act whose only purpose is that a record should exist**, and must not make conformance depend on such an act. *The requirement that determined the whole design.*

> **Requirement 4.3 (Promotion).** A transition enters the log **only by the act of a party who accepts responsibility for it.** An implementation may propose candidates by any means — **including analysis of the event plane by a model** — and a proposal becomes a transition only when a responsible party registers it. The record **must show which party registered**, and **must record that a proposal originated from an automated analysis where it did.**

Three consequences spelled out for implementers: - **Cheap confirmation is permitted; reflexive confirmation is not.** One affirmative action is fine; **a default that registers unattended proposals violates the requirement**, because the record's credibility rests on registration meaning something. - **Volume on the event plane is harmless.** A two-hour meeting altering no state produces events and no transitions — *nobody decides what deserved keeping, because the recording unit decides it.* - **A model may occasion a transition and may not author or register one.** The origin is marked, which lets a later reader weigh it and keeps the arrangement compatible with authorship rules excluding non-human authors.

Requirement 4.4 (Append-only log and derived state). The transition plane is append-only; a recorded transition **must not be altered or removed** — a correction is a further transition referencing the one corrected. **The current state must be derived from the log on demand and must not be stored as an authoritative object alongside it.** *The second sentence is the one most often violated, because a stored current state is convenient and fast. Where a stored snapshot is authoritative, the log becomes a secondary artefact that may drift from it or be edited to match it — and* ***every claim the protocol makes about credibility fails at once****. Caches are permitted if reconstructible from the log and marked as derived.*

Requirement 4.5 (Granularity). A transition **must** reference a **specific identified prior state**. A record attached to a project, repository, document **or person** as a whole **is not a transition, and an implementation must not admit one.**

Requirement 4.6 (Separation of administrative operations). Operations on the record itself (class changed, permission altered, attribution recorded, fork declared) **must be recorded, must carry the performing party, and must be distinguished from transitions by a mandatory `kind` field.** *Two reasons:* administrative activity would otherwise **inflate the apparent generativity** of a trajectory (the protocol computes no quantity, but **readers will nonetheless count**); and the admissibility condition on positions requires the acts constituting a position to be recorded — *a disclosure holder who could alter a class without leaving a record would occupy a position no participant could inspect.*

42.1.4 §5 States and identifiers

Definition 5.1. A **state** is an identified condition of a shared understanding — its recorded content plus the identifier under which that content is addressed. **Created by a transition and never modified**; a change is a further state produced by a further transition. > The **content of a state is deliberately unspecified** — paragraph, formal statement, diagram, claim > with qualifications, or a pointer to a section held elsewhere. **A specification prescribing the form > of a scholarly claim would be prescribing research practice.**

Requirement 5.2 (State identifiers). Unique within the trajectory ·resolves to content for a party permitted to read it ·**continues to resolve when the record is held by another implementation**. **An implementation must not use an identifier whose resolution depends on a service it alone operates.** Two satisfying constructions, named without preference: **content-derived** identifiers, and **repository-issued persistent identifiers**. Where both are used, **record the correspondence**.

Requirement 5.3 (Derivation of views). Any view — **including the current state** — must be computable **from the log alone**. Caches permitted if reconstructible. *Consequence: a view whose computation depends on information held only by the implementation (e.g. a proprietary ordering)* ***cannot be presented as part of the record*** *— it is an application output.*

Requirement 5.4 (Trajectory boundary). A trajectory carries an identifier, **a statement of the question or undertaking it concerns**, and the identifiers of parent trajectories where created by divergence. **A state may belong to more than one trajectory** — the protocol records the sharing and asserts nothing about which trajectory it principally belongs to (same reason it designates no principal branch).

Requirement 5.5 (External references). Persistent identifier where one exists, **with the scheme recorded**; otherwise enough descriptive information to identify the work, **plus the date the reference was made**. *The date addresses a failure that accumulates silently: a reference to a changed or vanished resource is uninterpretable without knowing when it was made — and a trajectory whose value appears years later will contain many.*

42.1.5 §6 The act vocabulary and the factorisation — *the part with no counterpart in any standard*

Requirement 6.1 (Factorisation). A transition is typed along **five independent dimensions**, each with a **small closed vocabulary**: **act ·target ·relation ·trig-**

ger ·disposition. **An implementation must not define a single enumerated type combining these dimensions.** *Ground: agreement between parties classifying the same occurrence declines as categories rise, and a vocabulary requiring deliberation re-introduces capture cost.*

Implementer's test when tempted to add a value: *a distinction that two competent participants would classify differently more than occasionally belongs in a community's charter, not in the protocol.*

42.1.6 Definition 6.2 — the eight acts

Act	What it does
question	opens a line of inquiry, or introduces a new question within one
claim	states a position as the content of a state
challenge	raises an objection against an identified state
transformation	alters a state in response to something, producing its successor
decision	records that a direction was **taken or abandoned, with the reason**
connection	relates a state to another state or to an external work
verification	reports the outcome of a check performed on a state
release	declares a state published at a class, **with the objections standing against it**

Three carry more weight than their brevity suggests: - **decision** is what makes an abandoned line **interpretable later**. *A path recorded as abandoned without a reason cannot be revisited by anyone* — and reuse of abandoned work is one of the two concrete benefits claimed for the design. - **release is a declaration and never a judgement.** It asserts a state is published and records which objections stand unresolved at that moment. **An implementation must not present a release as a certification of quality.** - **challenge** produces a transition when registered, **and does not thereby alter the state it challenges**. Where accepted, a *subsequent transformation* produces the successor, and the two are linked by parent references.

Contribution is not an act — it types a party's *part in* an act, and binds to CRediT (§7).

42.1.7 The other four dimensions

- **target** — question ·assumption ·hypothesis ·concept ·theory ·method ·path ·artefact. *Community-extensible.*
- **relation** — extension ·modification ·replacement ·refinement ·generalisation ·specialisation ·transfer. **Bound to a citation-typing vocabulary (CiTO); not defined here.**
- **trigger** — reflection ·literature ·experiment ·simulation ·observation ·discussion ·objection ·prior failure ·**automated suggestion** ·**entry of a new party**. *Where the trigger refers to something recorded, the reference is included.* **Community-extensible.**
- **disposition** — **exactly three values:** `accepted`, `contested`, `unresolved`. **> Requirement 6.3.** The disposition vocabulary is **fixed by the protocol and must not be extended > or reduced.** `unresolved` is required: most objections in theoretical work are never resolved — > they stand, and the work proceeds beside them. **A record admitting only acceptance and rejection > would be systematically false about the fields this protocol most concerns, and would exert > pressure toward fabricated closure.**

Requirement 6.4 (Extension per dimension). Communities may extend **target** and **trigger** by declaring values in a charter (identified in the record). **The act and disposition vocabularies must not be extended.** An implementation meeting an unrecognised target/trigger **must retain the record and must not reject it.** *Asymmetry is deliberate: targets and triggers are domain-specific (a mathematics community wants obstruction types; a laboratory wants deviation types).* ***Acts and dispositions are what interoperability rests on.***

Requirement 6.5 (Availability of the open register) — the entry path. An implementation **must make available, at each disclosure class, the set of states within that class whose disposition is `unresolved`**, and **must permit a party holding no prior position** to reference such a state in a **challenge, connection or verification**. *The protocol supplies the addressable problem and the admissible act — and **no obligation to accept anything**. Acceptance is decided by the parties holding the state, on the content of the act.*

42.1.8 The transition record (Figure 6.1)

```
id                content-derived, over payload + parents
kind              transition | administrative operation      ← mandatory
parents           identifiers of prior transitions (≥1; none only for the opening transition)
prior_state       identifier of the state altered
posterior_state   identifier of the state produced
── the factored type ──────────────────────────────────
act               one of eight                          (fixed)
target            what the act operated on              (charter-extensible)
relation          posterior to prior                    (bound vocabulary)
trigger           occasion, + event/artefact ref        (charter-extensible)
disposition       accepted | contested | unresolved     (fixed)
──────────────────────────────────────────────────────
performer         party identifier, with contributor role
registrar         party identifier + signature — DISTINCT (Req. 4.3 / 8.1)
absorption        links to states elsewhere, with attribution (no veto)
disclosure        class, declared ground, release schedule
artefacts         references to produced objects
```

An **administrative operation** uses **the same envelope** with `act`, `target`, `relation`, `dispositio n` **absent** and an `operation` field in their place.

42.1.9 §7 Bindings — four, and the protocol's own vocabulary is what remains

Requirement 7.1. Where a deployed standard defines a needed vocabulary, **bind by identifier and do not restate its terms.** New terminology is defined **only** for the act vocabulary, the disposition vocabulary, and the record structure. *Three reasons, the third decisive:* restating acquires an obligation to track revisions; conformance becomes cheaper for existing users; and **a specification that reinvents a deployed vocabulary is dismissed by the community that maintains it — the ordinary fate of standards written in isolation.*

Capability	Bound to
relations between states	**citation-typing vocabulary (CiTO)** — applied to relations between *states* rather than works
contributor roles	**contributor taxonomy (CRediT)** — *also serves the compatibility requirement*
agents, activities, derivation	**provenance model (PROV)** — export makes records readable by tooling that knows nothing of GRRP
anchored commentary	**annotation model (W3C Web Annotation)** — selectors carry the anchor; **the GRRP act type is carried in the annotation's `motivation`**

Claim 7.2. Under these bindings **the protocol's own terminology reduces to: the eight acts, the three dispositions, the record structure, and the disclosure + attestation fields.**

Requirement 7.3 (Recording of bindings). A record must identify, **for each bound vocabulary, the vocabulary and the version**. **A value drawn from a bound vocabulary must be recorded as an identifier in that vocabulary and not as a display label.** *Storing the word `extends` rather than the vocabulary's identifier is uninterpretable once a second vocabulary uses the same word differently — translation then depends on a guess.*

Three failure cases: a bound vocabulary is **revised** → the recorded version makes it detectable; records referring to an earlier version **remain valid and must not be rewritten**. A vocabulary is **withdrawn** → the identifiers in existing records **remain the authoritative statement of what was meant**; a community may declare a replacement with a mapping, **and the mapping need not be complete** — *a partial mapping preserving what can be preserved is better than a rewrite that silently changes what records assert.* A vocabulary **lacks a needed value** → declare a charter extension. **Requirement 7.4. Local values must be marked as local** and identify the defining charter; an implementation **must not present a local value as though it were bound.**

42.1.10 §8 Registration, attestation, signature

> **Requirement 8.1 (Attestation).** A transition **must record the party who performed the act and the party who registered it.** Where distinct, the transition **is attested**. The registering party's identifier **and a signature over the transition's content and parents** must be recorded; **registration by an unidentified party is forbidden.** *Satisfied by an act that costs the registrar very little — reading a proposed transition and confirming it. **The cheapness is required, not convenient**, since the registrar performs work whose benefit accrues to someone else.*
>
> **Requirement 8.2 (Independence of the registrar). No automatic registration on behalf of a party**, and **no party may hold another's credentials for the purpose of registration.** Where a transition is registered under a standing arrangement with the performer, **the arrangement must be recorded.** *Addresses the ordinary case of a supervisor routinely registering a student's transitions: the arrangement is legitimate and its effect on independence is real, **so it is recorded rather than forbidden.***
>
> **Requirement 8.3 (Signature coverage) — the single most likely implementation error.** A signature **must cover** content, parent identifiers, prior and posterior state identifiers, and disclosure class. A signature **must not cover fields a later lawful operation may alter**, and the implementation **must state which fields those are.** *Otherwise ordinary operation — scheduled release widening disclosure, redaction removing content — invalidates signatures, and implementations then either forbid the operation or ignore the invalidation. Both defeat the purpose.*
>
> [warning] *Note the tension:* `disclosure class` *is listed as covered here, while §12/§21 require class to widen without invalidating signatures. §21.5 resolves it in the git deployment by holding the class **in a separate file the signature does not cover** — the implementer must notice this. The implementation plan's field note ("Signature coverage **excludes** `disclosure`") follows §21.5.*

Claim 8.4. An attestation asserts that an identified party registered a transition at a time. It asserts **nothing** about whether the change was an improvement, whether the claim is true, or whether the registering party understood it. *Stated in the specification because implementations will be tempted to present an attested transition as a verified one, and readers will make the inference unaided.*

Three limits, recorded here because implementers must know them: credibility needs **≥2 parties**; **collusion is made costly, not impossible**; and **counting is forbidden**: > **Requirement 8.5 (No aggregation over attestations).** No **counts, depths, ratios or derived > scores** over attestations may be computed, stored or presented as part of a conformant record. > **Attestation is a property of an individual transition with two values.**

> **Requirement 8.6 (Marking of unattested transitions).** A transition whose performer and registrar are the same **must be recorded as unattested** and **presented as unattested wherever attested transitions are presented.** An implementation **must not describe a wholly self-registered trajectory as verified, corroborated or independently recorded.** *Protects the mechanism's meaning exactly where it would be diluted — **the personal tier is the tier most people will use first.***

Requirement 8.7 (Withdrawal of an attestation). An attestation must not be deleted. A registrar who wishes to withdraw records a further **challenge** referencing the attested transition and stating the ground; **the original remains in the log with the withdrawal linked to it.** *A reader sees both the original act and its withdrawal — more informative than a deletion or a silent correction, and it places the dispute in the record where later readers can weigh it.*

42.1.11 §9 Attribution and absorption — credit without exclusion

Requirement 9.1. A transition **must record the performing party**; where several parties contributed, **each with a CRediT role**. No contribution without a party; no party without a role where more than one is present. > **Attribution attaches to an act, not to a finished work.** *A contributor statement says a person > contributed to a paper.* ***This record says which change in the content of a claim a person > produced.***

Definition 9.2 / Requirement 9.3 (Absorption). Taking content from a state in one trajectory into a transition in another. The **absorption link records: the identifier of the state absorbed from, the identifier of the party who produced it, and the transition into which content was taken. Implementations must present absorption links alongside the transition wherever it is displayed.** > *This is what makes the difference between arrangements* ***visible in the record****: in an open > competition unselected proposals are discarded and their content, where used, is used without trace; > here it appears as an absorption link naming the party who produced it.* ***Whether a given arrangement > absorbs or discards is checkable from its record — and the check is performed by readers, not by the > protocol.*** (= Paper II's absorption test.)

> **Requirement 9.4 (No veto).** An absorption link confers **attribution and no right to prevent, condition or reverse the use of the content.** An implementation **must not provide a mechanism by which the named party can block a transition, require approval before absorption, or withdraw content already absorbed.** *Model: the moral-rights side of IP. Ground: avoiding the anticommons.* **Consequence for implementers:** *a party who does not wish their state absorbed has* ***one instrument — the disclosure class of that state****. Absorption operates on what has been disclosed to the absorbing party, and a party who discloses to a class has accepted that members of the class may build on the content with attribution.*

Requirement 9.5 (Contested attribution). A party holding that an attribution is wrong, or that an absorption occurred **without a link**, records a **challenge** stating the ground. The disputed record **must not be deleted or altered**; the challenge must be **linked to it and presented wherever either is presented. The protocol supplies no procedure and no party empowered to resolve it** — the record's contribution is that **both positions are visible with their dates.**

Three limits fixed as constraints on what an implementation may claim: attribution records that a party **performed an act — not that they originated the idea** (independent arrival is not adjudicated); an absorption link records **that content was taken, not how much it mattered** — **no measure of influence may be computed or displayed**; and **the presence of absorption links does not establish that the arrangement was generative** (necessary, not sufficient).

42.1.12 §10 The graph: parents, divergence, synthesis, no merge

Requirement 10.1 (Parent links). ≥1 parent, except the trajectory-creating transition. **The graph must be acyclic**; a transition whose parents include a descendant of itself **must be rejected.** *Not a formality — cycles admit a history in which a state precedes and follows itself, and every derived view, including the current state, becomes ill-defined.* > **Ordering follows from the graph and not from timestamps.** Two transitions with no path between > them are **unordered, whatever their recorded times**, and an implementation **must not**

present > unordered transitions as though one preceded the other. *Recorded times are evidence about when > parties acted; they are not the structure of the history.*

Definition 10.2 / Requirement 10.3 (No principal branch). An implementation **must not designate any branch principal, default, canonical or current**, and **must not order branches by any property of content, size or activity.** Where a reader needs a single view, **the implementation must require the reader to select a branch.** *It may of course display branches in some order on a screen. What it must not do is* ***record or export an ordering****, or present one branch with the marks of authority.*

Definition 10.4 (Synthesis). A transition carrying **≥2 parents from distinct branches**, producing a state whose content the performer **composed** from what those branches reached. An ordinary **transformation** with several parents. **The branches it draws on continue to exist and are not closed by it** — a synthesis is a further state, not a resolution of the divergence.

> **Requirement 10.5 (No merge operation).** The protocol defines **no operation combining two states automatically.** An implementation **must not compute a combined state, must not present such a computation as a transition, and must not use the term *merge* for synthesis or for absorption.** *Ground: version control merges because changes to distinct text regions compose, a conflict can be localised, and a test decides whether the result works.* ***Two revisions of a concept satisfy none of the three.*** The terminological clause is practical: the substrate uses *merge* for an operation that does exist, and borrowing the word would make every implementer expect behaviour the protocol does not have.

Requirement 10.6 (Identity is recorded, not adjudicated). An implementation **must not determine whether the states reached by two branches are versions of the same object.** Asked whether a later state is a version of an earlier one, **it must answer with the chain of transitions connecting them — and must not answer with a judgement.** *Two consequences: a trajectory may hold several live branches indefinitely,* ***a normal condition and not an unfinished one****; and a reader must choose among branches with no basis supplied —* ***a cost stated here and not concealed.***

42.1.13 §11–12 Disclosure

Definition 11.1. Classes **must exist, must be ordered by inclusion, and must be enforced**; their **identity and membership are declared in a charter**. Two protocol-fixed properties: **ordering by inclusion** (without it scheduled release has no meaning) and **opacity** — the implementation enforces class values **without interpreting them**. *A community with two classes and one with six are both conformant.*

Definition 11.2 / Table 11.1 — the four grounds (fixed, not extensible; see paper-III for the full analysis):

Ground	Object restricted	Residue remaining disclosable
rivalry	access to the instrument or resource	**the trajectory in full**
hazard	the propagable content of a method	questions, decisions, interpretations, negative results
exploratory vulnerability	the timing of exposure	**everything, at the scheduled time**
appropriability	content whose disclosure destroys excludability	existence, questions, decisions, negative results

> *The* ***rivalry row is the one implementers most often get wrong****: an instrument admitting one user at a time supplies* ***no reason to restrict the record of what was done with it****. Conditional access (structured access) is the mechanism the hazard row assumes.*

Requirement 11.3 (Declared ground). Any record disclosed at less than the widest class available in its trajectory **must carry a declared ground**; an implementation **must reject a restriction that declares none**, and **must present the ground wherever it presents the restriction**. **Requirement 11.4 (Residue).** The corresponding residue **must be disclosed at the widest class available**; a ground **must not be used to withhold material it does not cover**. > *This is what makes the grounds do work.* ***A design without the residue rule would permit any ground > to justify total silence — which is the present arrangement with a label attached.*** Misapplication > is named (rent-seeking secrecy; hazard-where-no-propagable-risk). **The protocol cannot detect > either** — the requirement that the ground be declared and displayed is what lets a reader raise the > question.

> **Requirement 11.5 (Per-record disclosure).** A class attaches to an **individual record**. **Disclosure must not be a property of a repository, project or trajectory as a whole**, and records within one trajectory **must be able to carry different classes.** *This is the second point at which the version-control analogy fails: in a VCS openness is a property of a repository chosen by its owner. Research requires that a single line of work carry states disclosed to everyone, to a group, and to nobody, with the differences declared and grounded.* **Consequence for views:** a view must be computed **over the records that reader may see**, and an implementation **must not disclose the existence of a record by omission, ambiguity, or a gap in numbering** where the charter requires existence to be concealed.

Left to the charter: which classes exist and who belongs ·consent and retention ·**who may change a record's class** (the change is an administrative operation; *who may perform it is a charter question, and the record makes the answer visible after the fact*).

42.1.14 §12 Monotone disclosure and release

Requirement 12.1 (Monotone disclosure). Disclosure may widen and must not narrow. No operation reducing the class of a disclosed record, **and no representation that such a reduction occurred.** *Ground: a reduction* ***cannot be effected*** *— a party who has read a record retains what they read, so an operation appearing to withdraw disclosure* ***conceals from the record's own participants a state of affairs obtaining outside it****, and the implementation would then be trusted with material that should never have been entered.* Two operations that resemble narrowing and are distinguished: **redaction** (removal from the store, not a change of class — §13) and **revocation of a party's class membership** (a charter matter about *future* disclosures; it does not alter what was already disclosed).

Requirement 12.2 (Restrictive default). Records are created at **the most restrictive class applicable under the declared ground** and widen **only by an explicit act**. **No widening as a side effect of any other operation.** *Where disclosure cannot be undone, an error toward openness is uncorrectable — and defaults are where such errors occur.*

Definition 12.3 / Requirement 12.4 (Scheduled release). A recorded commitment that a record will be disclosed at a stated wider class at or after a stated time; **the schedule is part of the record and is disclosed at the record's current class.** An implementation honouring it **widens the class at the stated time without a further act by any party. A schedule may be shortened; it must not be extended or cancelled**, and **any attempt must be recorded as an administrative operation with its ground.** *The asymmetry is the substance: vulnerability justifies delay and not permanent withholding, and a schedule extendable indefinitely is a permanent withholding made to look temporary. The attempt is recordable because a charter may sometimes allow it — and it must be visible.*

Definition 12.5 / Requirement 12.6 (Release). A release records the state identifier, the class, the time, **and the identifiers of every transition referencing that state whose disposition is `unresolved` at that moment.** It **must enumerate the standing objections**; an implementation **must not omit them, must not permit a release conditional on their resolution, and must not present a release as certifying, validating or approving the state.** > *The point at which this specification differs most visibly from publication as practised.* ***A > release asserts that a state is published and that these objections stand.*** *It asserts nothing about > their merit — and a community treating an enumerated objection as a defect will produce releases with > the objections suppressed,* ***which is a failure of the charter and not of the protocol.*** A release is also **what serves priority** (it carries a time and a registrant) — *the protocol supplies the record and cannot supply the recognition.*

Requirement 12.7 (Emission on release) — discharges the compatibility condition. An implementation **must be able to emit, from a release, a document containing: the released state, the chain of transitions leading to it, the parties with their contributor roles, the absorption links with their attributions, and the objections standing at release.** The emitted document **must carry the identifier of the release it was generated from.** *A participant obtains, **without additional work**, an object of the kind the incumbent reward system accepts, **carrying an appendix no other process can produce**. **Adoption does not require anyone to abandon publication.***

42.1.15 §13 Separability, redaction, integrity

Resolves the conflict that defeated comparable systems: an append-only log with content-derived identifiers cannot admit deletion, and a record holding personal data must.

Definition 13.1. Skeleton = identifier, kind, parent links, state references, typed fields, parties, signature, disclosure class and ground. **Content** = the material referred to: the text of a state, a recording, a transcript, an annotation body, a deposited file. **Requirement 13.2 (Separability). Content stored separately, referenced from the skeleton by a content-derived identifier. A skeleton must remain valid and verifiable when the content it references has been removed.** *The signature covers the skeleton, which includes the content identifier; removing content does not alter the skeleton, so the chain of identifiers and signatures stays intact and every later record remains verifiable.*

Definition 13.3 / Requirement 13.4 (Redaction). Removal of content while the skeleton remains. **A redacted record continues to assert that a transition occurred, by whom, of what type, at what position in the graph — and no longer supplies what was said.** The redaction **must be recorded as an administrative operation** carrying the redacted record's identifier, the time, the performing party, and the ground. **A skeleton must not be removed. The record of a redaction must not be removed. Redacted content must not be represented as never having existed.** *The last clause is the substance: a system erasing the trace of an erasure would leave a record that **misdescribed its own history**, making every later reader's inference unreliable in a way they could not detect.*

Three things survive and must all be presented: the fact of the transition with its type, graph position and date ·**the parties**, unless the ground requires their removal — *in which case the skeleton records that a party field was redacted, and the signature over the skeleton is preserved with the party identifier replaced by its own content-derived identifier* ·**the fact that a redaction occurred, with its ground**, so a reader finding an unreadable antecedent knows why. **Requirement 13.5 (Structural preservation). A redaction must not alter the graph.** Parent links, state references and the induced ordering **survive unchanged**; a record **must not be removed because its content was removed.**

Requirement 13.6 (Propagation of redaction). An implementation that received records **must accept and act on a redaction notice** for them and **must forward such notices onward**, and **must record notices received and forwarded. Two honest limits:** *a copy held by a departed party cannot be reached, and no protocol reaches it*; and derived objects (emitted documents, cached views) may embed content a later redaction removes — the implementation **must reconstruct affected caches and must record which emitted documents referenced redacted content**, so a party can pursue them outside the system.

Three further limits. Possibility is not lawfulness. Content-derived identifiers of removed content remain in the skeleton — where content is short and its space small, the identifier may permit **reconstruction by exhaustive search**, so an implementation handling such content **must apply a per-record secret before computing the identifier.** And **a redaction is visible** — a participant who removes their material leaves a record that they did so, with a ground. *This is the price of a tamper-evident log; it cannot be avoided within one; **and participants should be told before they enter rather than after they attempt a removal.***

42.1.16 §14 Identity

Definition 14.1. A **party** is an entity capable of performing and registering acts, **identified within the protocol by a public key.** Nothing requires that a party correspond to a natural person, that a natural person hold one identifier, or that an identifier connect to a legal name. **What is required is continuity. Claim 14.2.** Attestation and attribution **require continuity of identity and do not require legal identity.** A key pair establishes that the registering party is distinct from the performing party, and that the same party acted last week — **which is the whole of what §8 and §9 depend on.**

> **Requirement 14.3 (Pseudonymous participation).** An implementation **must permit a party to participate under a key not bound to any external identifier, at every conformance tier**, and **must not require a legal name, telephone number, institutional affiliation or government identifier** as a condition of holding a party identifier. *Three reasons, the second the one the series cares about:* the mechanisms don't need it; **a universal identity requirement excludes exactly the population the companion papers concern** — unaffiliated scholars, parties in jurisdictions where a phone number is a state-linked identity document, parties whose participation carries risk — **and the entry path would be closed at the door**; and the empirical record for real-name policies is **exclusion without the improvement in conduct they were introduced to secure.**

Definition 14.4 / Requirement 14.5 (Optional bindings). A **binding** is a recorded, verifiable association between a party identifier and an external identifier (researcher ID, institutional account, domain, attested legal identity), recorded as an **administrative operation** carrying the attesting party. Bindings **must be visible wherever the party identifier is presented, must record who attested and when, and must be revocable by a further recorded operation.** An unbound identifier **must not be presented as bound**; a revoked binding **must not be presented as current.**

> **Requirement 14.6 (Assurance by class and not by gate).** A charter may require a stated assurance level **for participation in a given disclosure class or for acts of a given kind**. An implementation **must enforce it at the point of the act** and **must not apply it as a condition of holding a party identifier or of reading records disclosed at the widest class.** *A community handling hazard-restricted material may reasonably require a verified institutional identity for that class.* ***The same community must not require it of a stranger who wishes to challenge a publicly disclosed claim*** *— that is the act by which parties without position enter, and gating it reproduces the bootstrap failure the design exists to avoid.*

Requirement 14.7 (Key lifecycle). Rotation: an administrative operation **signed by the old key** nominating the new one; both identifiers then refer to the same party and **prior records remain valid under the old identifier**. **Loss:** a new identifier plus a **charter-defined procedure**; the implementation **must record which procedure was used and must not represent such an association as equivalent to one signed by the old key** — *recovery procedures are necessary and weaker than a signature, and a record presenting them identically would misdescribe the strength of its own evidence.* **Compromise = revocation with a date**; registrations made before it **remain in the log, marked with the compromise** — *removal would alter the graph and conceal the history the record exists to hold.*

42.1.17 §15 Sealed registration

Definition 15.1. A record carrying the **content-derived identifier of a state**, the registering party identifier, a time, and a signature — **with the content disclosed to no party.** It asserts that the registering party **held content with that identifier at that time.** > *Requires nothing the specification does not already have: a sealed registration* ***is the skeleton of > a record whose content has not been disclosed****, not a new kind of object.*

Requirement 15.2. Registration **must be available at every disclosure class, including the class disclosing to no party beyond the performer.** A party **must be able to**

record a trajectory from its first state without disclosing any content, and **disclosure must not be a condition of registration. Definition 15.3 / Requirement 15.4 (Opening).** A transition disclosing previously sealed content, recording the sealed registration's identifier and the content, so **any party may verify from the record alone that the content yields the identifier registered earlier.** Verification failures **must be recorded, and neither record removed.** *Opening is optional and may never occur — a party may seal a trajectory and abandon it, and the sealed registrations remain as evidence of what was held and when, unopened and unverifiable by anyone.*

Claim 15.5. It **converts the choice between disclosing early and recording nothing into a choice about when to disclose.**

Five limits. Evidences **possession, not understanding** (a party may register a state they do not comprehend). **Generates nothing** — a sealed state attracts no objection, no connection, no encounter; *it protects a participant during precisely the phase in which the arrangement's benefits are unavailable to them, and it purchases the possibility of opening later.* **Adjudicates nothing against independent arrival. > Requirement 15.6 (No inference from precedence).** An implementation **must not present an earlier > sealed registration as establishing that a later party derived their work from it**, and **must not > rank, order or annotate parties by the times of their sealed registrations. > Requirement 15.7 (Statement of the limit).** An implementation **must not describe sealed > registration as establishing priority**, and **must describe it as recording that a party held a > content at a time.** *Where a community honours registration for priority, the honouring is recorded > in the charter and not in the protocol.*

Dependence outside the protocol (easy to overlook): a sealed registration is evidence **only if its time is credible to a party who does not trust the registrant.** An implementation **must anchor sealed registrations in a manner a third party can check** — publishing identifiers at intervals in a medium it does not control, or obtaining a timestamp from an independent party (Haber & Stornetta 1991) — **and must record which method was used.**

42.1.18 §16 Propagation

Definition 16.1. Lateral propagation = an objection raised against one trajectory entering another, and absorbed content moving across a divergence with its attribution. **Inter-implementation propagation** = exchange of records between implementations sharing no operator (COAR Notify, ActivityPub). **Dissemination of finished artefacts is excluded from the term** — repositories and indexes do it adequately and nothing here concerns it.

> **Requirement 16.2 (The exchange minimum).** Two implementations exchanging records **must agree on**: the **record structure** (§6) ·the **act and disposition vocabularies** ·the **identifiers of bound vocabularies in use and their versions** ·**the construction of content-derived identifiers** ·**the signature scheme. They need agree on nothing else** — not storage, transport, interface, or serialisation. *The identifier-construction and signature-scheme clauses **cannot be relaxed**: two implementations computing identifiers differently produce records that cannot be verified across the boundary, and **the record's credibility does not survive the crossing.***

Requirement 16.3 (Declaration of profile). An implementation **must declare, machine-readably**: protocol version, conformance tier, identifier construction, signature scheme, bound vocabularies with versions. **A receiving implementation must record the declaration under which records were received.**

> **Requirement 16.4 (Continuation) — portability is not export.** A participant **must be able to obtain the complete record** (transitions, skeletons and signatures, attributions, absorption links, parent structure) **without the permission of any position holder**, and **must be able to continue it under an implementation the original operator does not control. Transitions appended after continuation must reference the obtained transitions as parents, so the continued**

trajectory is one graph and not two. Two consequences: identifiers **must continue to resolve** (*a continuation whose references have become unresolvable is an archive, not a trajectory*); and **restricted content does not travel unless the receiving implementation can honour the class** — transfer the class and ground and honour them, **or transfer only the skeleton and record that content was withheld.**

Requirement 16.5 (Received records). Verify what can be verified; retain what cannot, marked unverified; never alter received records. Unrecognised vocabulary values are **retained unchanged**. > *The prohibition on alteration **extends to normalisation**. An implementation rewriting received > records into its preferred form would invalidate their signatures and destroy the property that makes > propagation worth having.* Redaction notices are the one exception (§13).

Four failure cases. Version mismatch — retain, do not process as own version; where versions differ only in additions, process recognised fields **and record that it did so**. **Vocabulary drift** — each record carries its own version; **no reconciliation by the protocol**. **Partial records** — retain the subgraph, **mark missing parents as unresolved references**, **do not synthesise missing transitions or present the subgraph as complete**. **Divergent continuation** — two parties continuing the same obtained record independently is **a divergence and is treated as one**: both retained, neither principal, shared ancestry visible in parent links. **No reconciliation is required and none is provided.**

42.1.19 §17 Durability

Requirement 17.1 (Self-describing formats). The **authoritative** form of a record **must be a plain, self-describing serialisation readable without the software that produced it**, in a publicly specified format. **It must not be held only in a database, index, or proprietary container.** *Any internal representation is permitted for speed — what is forbidden is that the internal representation **be** the record, since a record recoverable only through a running system is lost when the system stops running, **and systems stop running.*** **Requirement 17.2 (Field documentation).** Publish, alongside the records, the **vocabularies and versions used and the construction of identifiers and signatures**, in a document readable **without access to the implementation.** *Addresses a failure visible only after it is irreparable: a serialisation that is readable but uninterpretable, because the meaning of its fields lived in a codebase, is **a durable record of nothing.***

Definition 17.3. Custody is held by a party and not by a system. Requirement 17.4 (Distributed custody). At the **group and open tiers**, a record **must be held by at least two parties who do not share an operator** (LOCKSS-style replicated independent custody); the implementation **must record which parties hold copies** and make the record obtainable under Req. 16.4. *What makes portability meaningful in practice — a right to obtain a record from a party who has ceased to exist is a right without an object.* **Requirement 17.5 (Archival deposit).** At the **open tier**, **released states and the transitions leading to them** must be deposited with an **independent** archival service with stated preservation commitments; **the deposit identifier is recorded in the trajectory.** *Restricted to **released** material deliberately — **depositing sealed or restricted content with a third party would place material outside the disclosure regime governing it.*** **Requirement 17.6 (Succession).** An organisation-operated implementation **must publish what becomes of its records if it ceases to operate** — to whom custody passes, with which archival service material is deposited, or how participants may obtain the records. **An implementation must not claim durability without publishing such an arrangement.**

Three limits: a specification **cannot fund preservation**; **cannot compel a departed party** to keep a copy; and format stability is a matter of degree — *what is secured is that the difficulty is one of **interpretation** rather than of **recovery**.*

42.1.20 §18 Operating charters — the Level-1 interface

Definition 18.1. An identified, **versioned** document adopted by a community, which **the protocol references and interprets nothing in. > The charter is where everything contested lives:** which classes exist and who belongs ·consent > before a record concerning a person is created ·retention ·conduct and consequences of breach ·> identity assurance per act ·**whether registration is honoured for priority** ·review templates ·> declared target/trigger extensions.

Requirement 18.2 (Minimum charter content) — a condition of legibility, not a normative demand. A charter referenced by a conformant record **must state**: the disclosure classes and their ordering ·the parties/roles belonging to each ·the assurance level required per class and per act kind ·any extended target/trigger values with definitions ·**the procedure by which the charter itself is amended. An implementation must reject a record referencing a charter that does not state these.** *It obliges a community to have decided its own questions and settles none of them.*

Requirement 18.3 (Charter reference). A trajectory **must record the charter identifier and version**; any record whose class, assurance requirement or extended vocabulary value derives from a charter **must record that charter's identifier and version. Requirement 18.4 (Amendment is prospective).** An amendment **applies to records created after it and must not alter the interpretation of earlier records.** Earlier versions must be retained or locatable. > *One case implementations will handle badly:* **where an amendment removes a disclosure class, > records already carrying it retain it, and the implementation must continue to enforce the class as > the earlier charter defined it.** Reclassifying would either widen without an act (forbidden by 12.2) > or narrow (forbidden by 12.1).

Three refusals: no model charter, no default charter, **no minimum standard of conduct** (*a specification supplying one would be a specification of governance, and communities rejecting the model could not conform*) ·**no enforcement of charter provisions beyond the fields the protocol carries** (classes are enforced because they are protocol fields; conduct rules are not) ·**no adjudication between a charter and law.**

42.1.21 §19 Amendment and versioning — *the specification applied to itself*

Definition 19.1. A version is **compatible** with an earlier one where every record valid under the earlier is valid under it **and carries the same meaning**; otherwise **incompatible**. **Requirement 19.2.** Every record **must carry the protocol version under which it was created**. An implementation **must not alter the version identifier of a record it did not create, and must not upgrade records to a later version.** *A record created under one version asserts what that version's fields meant; rewriting it would silently change what it asserts.* **Protocol versions, implementation versions and charter versions are distinct** and must not share a numbering.

> **Requirement 19.3 (Recorded amendment).** An amendment to the specification is **proposed, discussed and adopted through a record conforming to the specification**: *a proposal is a **state**; objections are **challenges**; revisions are **transformations**; adoption is a **release at the widest class**.* **The trajectory of the specification must be publicly readable and must remain so.** *Practical effect beyond the reflexive demonstration: a reader can see which objections were raised against a provision, which were answered, and **which stood unresolved at adoption** — Req. 12.6 obliges the release to enumerate the last.*

Requirement 19.4 (Custodial separation). The party maintaining the specification **must not be the operator of any implementation for which conformance confers advantage — or must record the conflict and the arrangements limiting it.** The specification **must be licensed so any party may fork it, and conformance to a fork must be expressible in the version identifier. Requirement 19.5 (Declaration).** Declare the versions readable and the version records are created under; on exchange, **each records the other's declared versions. > Negotiation is minimal by design: no translation, no negotiation of a common subset, no downgrade** > — each would produce records asserting something other than what their creators asserted.

Three limits. Procedure **does not confer quality**. **The procedure is itself capturable** — a party controlling participation in the specification's trajectory controls the specification, and **no clause within it prevents this**; the bound is **the licence to fork and the portability of the specification's own record — the same partial bound placed on every other position.** And **an amendment cannot repair a record** — for each incompatible change the specification **must state what a reader should understand about records created earlier.**

42.1.22 §20 Conformance tiers

Cumulative: conforming at a tier satisfies every requirement of the tiers below.

Tier	Adds	Available to its adopter
Personal	transitions with parent links + identified prior states ·append-only log with derived views · **three acts minimum:** `claim`, `challenge`, `release` ·content separable from skeleton	a searchable record of what was ruled out and why ·a list of objections not yet answered ·**a citable release with its chain**
Group	attestation by a distinct party ·contributor roles ·absorption links ·disclosure classes with declared grounds ·administrative operations recorded	**evidence — credibility begins where a second party registers** ·visible attribution of changes ·onboarding a new participant from the record
Open	propagation with declaration of profile ·distributed custody · archival deposit of released material ·charter reference ·identifier resolution independent of the operator	exchange with parties elsewhere ·continuation beyond the operator ·**entry of strangers through the open register**

Requirement 20.2 (Minimal implementation). The personal tier **must not require** attestation, contributor roles, disclosure classes, charters or propagation. **Requirement 20.3 (Marking of the personal tier). Every transition marked unattested**, and the absence of attestation **stated wherever a record is presented or exported. Must not describe a personal-tier record as verified, corroborated or independently recorded.** > *The honest position:* ***the personal tier delivers utility and no evidential weight****, and the two must* > *not be confused at the point where most participants meet the protocol first.*

42.1.23 The three conformance tests (for the exclusions most likely to be violated in good faith)

Requirement 20.4 — scalar test. Fails where it **computes, stores, displays or exports any total order or numeric measure over participants or over trajectories**, including counts of transitions, counts of attestations, contribution shares, activity indices and derived scores. **Counts of records within a single trajectory, presented without comparison across participants or trajectories, do NOT violate this.**

Requirement 20.5 — independence test. Fails where any conformant operation cannot be performed without an analytical capability. **The test: can the record be created, registered, read, verified, exported and continued using a text editor and a version-control system?**

Requirement 20.6 — byproduct test. Fails where it requires an act whose only purpose is that a record should exist. **The test: does each required act have a purpose *for the party performing it* that is stated in the implementation's documentation?**

Requirement 20.7 (Self-declaration). Publish a declaration stating protocol version, tier, identifier and signature constructions, bound vocabularies with versions, the substrates supplying storage/identifiers/transport, and (at open tier) the succession arrangement. **Readable without access to the implementation. > Conformance is self-declared and checkable from the record. No certification body is established > here and none is required** — a doubting party obtains a record under the continuation requirement and > verifies signatures, identifier construction, and the presence of required fields.

Three limits on a conformance claim: it concerns **the implementation and not the records it holds** (*a conformant implementation may hold a fabricated trajectory*) ·it concerns **structure and not quality** ·at the open tier it establishes **capability, not that exchange has occurred.**

42.1.24 §21 A deployment over version control (NON-NORMATIVE — Requirement 21.1)

*Included because a specification with no worked deployment invites the reply that it cannot be implemented; excluded from the normative text because **a deployment ages faster than a specification and should not date it.***

The mapping. A **trajectory is a repository**. A **transition is a commit**; its **skeleton is a plain text file** added by that commit. **Content is in separate files**, referenced by the VCS's own content identifiers — *so the separation required for redaction is the substrate's ordinary behaviour*. **Parent links are the commit's parents; acyclicity is the substrate's.** A **synthesis is a commit with several parents and is not a merge in the substrate's sense** — no automatic combination is performed. **Signatures are commit signatures**; **attestation is expressed by a commit whose signer differs from the skeleton's `performer` field**, and the implementation enforces the distinction by **refusing commits where the two coincide at group tier and above. Event plane:** held **outside** the trajectory repository, in the systems participants already use (calendar, meeting recorder, message archive, working code repo). The implementation reads them, proposes candidates, **and writes nothing to the trajectory until a party registers one**. *The privacy requirement is satisfied by the arrangement rather than by a mechanism — the event plane is never copied in, so publishing a trajectory discloses no event record.* What is disclosed is a **trigger reference** in a registered transition. **Disclosure: one repository per class**, with restricted records held in narrower-access repositories and **referenced from the wider ones by identifier alone** — a reader at a wide class sees *that* a record exists without seeing its content. **Propagation** is clone and fetch; **the profile declaration is a file in the repository**. **Deposit** is transferring an archive of the repository at a release to a service issuing a persistent identifier, **recorded in a subsequent administrative operation**.

42.1.25 The four weaknesses (stated because a reader will otherwise assume the mapping is clean)

1. **Disclosure is per repository; the spec requires per record.** One-repo-per-class **approximates and does not meet** Req. 11.5 — a record whose class changes under a scheduled release **must be moved rather than relabelled**, and the movement is visible in a way relabelling would not be. **The movement must be recorded as an administrative operation.**
2. **Identifier resolution depends on hosting.** The substrate's content identifiers are stable and **not resolvable by a party who does not hold a copy** — so **resolvable identifiers must be obtained from a repository service for every state referenced from outside**, with the correspondence recorded.
3. **Redaction is available and not simple.** Removing a content file from the working tree **leaves it in the history** — so redaction needs history-rewriting, **or** a design in which **content files are held outside the versioned tree and referenced by identifier. The second is preferable and is what the mapping above assumes.**
4. **Signature coverage is fixed by the substrate.** Commit signatures cover the commit content, **including the skeleton file with its disclosure class — so the class cannot**

be widened by a scheduled release without invalidating the signature. The workable arrangement **records the class in a separate file the signature does not cover**, which satisfies Req. 8.3 **and requires the implementer to notice the problem.**

42.1.26 §22 Three worked examples (constructed, not observed — they establish nothing empirical)

Mathematics (Case 22.1) — an obstruction and an entering stranger. question → claim → transformation (trigger `reflection`) → verification recording the failure (an independence assumption does not hold) → **decision abandoning the approach, with the reason** → a state recording the current obstruction, disposition `unresolved`. Months later, **a party with no prior act finds it through the open register** and records a **connection** to a construction in another field where the same obstruction was met; the participants accept; a **transformation** follows, **registered by a party other than its performer**; the entering party is recorded as performer of the connection with a contributor role. *Exercises: the open register, the entry path, attestation, the decision act.* **Shows what the decision act is for** — the abandoned approach is interpretable years later **only because the reason was recorded with it**, and the connection was possible **only because the obstruction was addressable as a state**. *At the personal tier the same trajectory is recordable, carries no attestation,* ***and the entering party has nothing to find.***

Machine learning (Case 22.2) — an evaluation failure and a restricted method. Hypothesis + method state → verifications (trigger `experiment`), one with an unpredicted outcome → **challenge registered by a member who did not propose the hypothesis**, disposition `accepted` → transformation, relation `modification`. **Part of the method is held at a restricted class on the appropriability ground**; the **residue is disclosed at the widest class**: existence, question, decisions, **the evaluation outcomes that failed**, and the revised hypothesis. A **scheduled release** is recorded for the restricted state. **A second group absorbs the abandoned first hypothesis with its recorded failure, and the absorption link credits the originating party.** *Shows the residue rule doing the work it exists for:* ***the group withholds what excludability requires and discloses everything the ground does not cover — which is what makes the abandoned hypothesis available to the second group at all.***

Philosophy (Case 22.3) — a divergence that is not resolved. trust-between-individuals → challenge (omits institutional power), accepted → transformation → **a third party challenges the revised state on different grounds; neither accepted nor rejected — disposition `unresolved`, and work proceeds → two transformations diverge**: one narrows to institutional settings, one keeps general scope and weakens the claim; **neither designated principal** → a later **synthesis** references both as parents, **and the branches continue** → a **release on the narrowed branch enumerating the unresolved challenge as standing**, with an emitted document carrying state, chain, contributors and the standing objection. *> The case where the specification differs most sharply from publication as practised:* ***the released > document declares an objection its author has not answered.***

Three findings common to all three: every act has a purpose for its performer — *nobody documents in order to document* ·**the requirements exercised differ by field and the tiers accommodate the difference** (philosophy needs no classes; ML needs classes and the residue rule; mathematics needs the open register and entry path) ·**the demanding part is the same in all three: recording a decision with its reason at the moment of abandoning a direction.** *It is work with no present incentive, on which the reuse of abandoned material nevertheless depends.* ***The specification makes the act cheap and cannot make it attractive*** *— a limit of a protocol.*

42.1.27 §23 Failure modes and attacks

Of the record. Collusive fabrication — cost rises with the number of independent registrars and the visibility of their other work; **not eliminated; an implementation must not**

describe an attested record as proof of authenticity. Retroactive alteration — content-derived identifiers over payload and parents invalidate every descendant, **so detectable by any holder of a copy**; where a party holds the only copy, detection requires a second custodian (Req. 17.4, group tier and above). **Backdating — signatures do not establish time**; the §15 anchoring moves the question to a party the registrant does not control; **without anchoring, recorded times are assertions. Flooding** — no rate limit and no quality condition; the bearing mechanisms are indirect (attestation requires recruiting a registrar; the scalar exclusion removes the reward for volume); **rationing of attention is a charter matter.**

Of position. Registrar gatekeeping — the protocol records the declining party's other registrations and **supplies no remedy**; the charter responds, and **portability bounds the position**. **Custodial capture — the continuation requirement is the test**, and an operator refusing it is non-conformant; **the protocol cannot compel compliance**, and recourse is the copies under distributed custody. **Capture of the specification — no clause prevents it**; bounds are the licence to fork and the portability of the specification's record, **which are partial.**

Of disclosure. Misapplied grounds — declared and displayed, **not assessable by the protocol**; detectable by readers, corrected (where it is) by the community. **Disclosure by inference** — *a record's existence revealed by a gap, an identifier sequence or the shape of a derived view.* **Implementations must compute views over the records a reader may see and must not disclose existence by omission where a charter requires concealment. A genuine implementation hazard, easy to introduce accidentally. Redaction that cannot reach** a departed copy. **Reconstruction from an identifier** — answered by the **per-record secret**, applied before the identifier is computed, **which an implementer must decide in advance.**

Of the arrangement. > Surveillance through the event plane. *The plane that makes capture cheap is a monitoring log.* > The privacy requirement confines it to participants and forbids export and indexing, and an > implementation violating it **would produce exactly the instrument the design exists to avoid. > This is the failure with the largest consequence for participants and the one an implementer is most > likely to introduce while improving a feature.**

Scores at the edge — the protocol **forbids the implementation from computing one and cannot forbid third parties**; a widely adopted external score would reintroduce the dynamic the exclusion prevents. *The protocol's only contribution is that* ***it supplies no such quantity itself and no privileged basis for one.*** **Reflexive confirmation** — registration becomes a habitual click; **the affirmative-act requirement is the answer and is weak**; what strengthens it is a charter under which registering carelessly is a recognisable failure, **and the record shows who registered what.**

Three failures with no technical answer (*stated so that no reader mistakes the specification's silence for a solution*): 1. **A community that punishes disclosed failure will produce records with the failures removed** — and the reuse of abandoned material, one of the two concrete benefits claimed, **will not occur.** 2. **A community that does not honour registration** leaves sealed registration supplying evidence to parties with no forum in which it counts. 3. **A community in which nobody registers another party's transitions will operate at the personal tier under a group-tier declaration** — records whose marking is correct and **whose evidential value is absent.** *The protocol makes the condition visible and does nothing further.*

42.1.28 §24 Boundaries and open issues

Five refusals. It does not **assess content** ·does not **measure capacity** (a trajectory records what occurred, not what the relation could have produced, and what it records is the articulable fraction alone) ·does not **resolve disputes** (contested attribution, withdrawn attestation, disputed grounds are all recorded, and **no party is empowered by the specification to decide any of them**) ·does not **guarantee lawfulness** (it makes lawful operation *possible* where an unredactable record would foreclose it) ·**does not produce encounters** — *it records them and makes states addressable so a party elsewhere may find one;* ***whether such finding occurs is a matter of adoption, scale and community behaviour, on which the available***

evidence is discouraging.

Four open engineering questions: per-record disclosure over per-repository substrates (*a substrate supporting per-object access with cryptographic enforcement would settle it*) ·**resolvable identifiers at state granularity, cheaply** (presently expensive) ·redaction across implementations that no longer communicate ·**representation of a state for structural matching across vocabularies** (*the capability the cross-field claim depends on; the specification supplies a substrate and claims nothing about it*).

Three open normative questions no specification can settle: whether **registration is honoured for priority** ·whether **disclosed failure can be non-punitive** — *on which the reuse argument depends entirely* ·whether **the labour of registering another party's transitions is recognised** — *unpaid work for another's benefit, the disparity that defeated every comparable system.*

> **Four findings that would show the specification inadequate:** 1. **Personal-tier adoption without progression to the group tier**, over a substantial population and period → the arrangement supplies private utility and **does not produce the attested records on which every evidential claim rests.** 2. **Records in which the `decision` act is rare while transformations are common** → the act on which reuse depends is not being performed, and **making it cheap was insufficient.** 3. **Group-tier declarations alongside registration patterns of pairs who register only each other → attestation operating as a formality.** 4. **A widely used external score computed over conformant records → the exclusion of scalar measures displaces the dynamic rather than preventing it.**

Status: version 0.1. **No implementation, no deployment history, no evidence of use, and every requirement in it is a proposal about what such use would need.**

42.1.29 Implications for this repository

- **The tool's UI vocabulary must follow the eight acts, not invented ones** — and must never say "commit" for a transition or "merge" for a synthesis/absorption (Req. 10.5).
- **Every command's `--help` must state the purpose it serves *for the person running it*** — this is literally the byproduct conformance test (Req. 20.6), and the implementation plan already encodes it as an acceptance test.
- **`grrp check` should implement Req. 20.4/20.5/20.6 directly** as the three conformance tests, plus the append-only, signature-coverage, redaction, attestation and portability tests already in the plan.
- **Signature coverage is the named "single most likely implementation error"** — spec §8.3 vs. deployment §21.5. Follow §21.5: hold the disclosure class in a separate, uncovered file.
- **The personal tier must mark everything unattested and say so on every export** (Req. 20.3) — a plain requirement the current README does not reflect.
- **Emission on release (Req. 12.7) is not a "later stage" nicety** — it is the compatibility mechanism that makes adoption possible at all. It belongs in M1.
- **`grrp open` implements Req. 6.5** (the open register). It is the entry path, and Paper I §17 makes it the answer to the bootstrap failure.
- **The four "findings that would show the specification inadequate" are this project's evaluation plan.** In particular: *watch the ratio of `decision` acts to transformations*, and *watch for register-only-each-other pairs*.

43 design nodes time and occasions

Original source: `applicative_infrastructure/gr_academia_application/plans/design-nodes-time-and-occasions.md`.

Original source SHA-256: `b36a18d36aa8e5275c8e062bcb4475bea9cab07e736c57b863827d9450bae2e8`.

43.1 Design note — node panels, per-node files, calendar, meetings

Written before building, at the point where four proposals arrived at once and three of them touch a constraint. Nothing here is implemented yet.

The short version: **all four are buildable, none needs a new vocabulary, and two of them have a version that would quietly break the design.** The difference is worth writing down before it gets decided by whichever screen was easiest to draw.

43.1.1 1. The node panel — safe, and the dead space is already there

Clicking a node opens a modal today. That is wrong for something you want to keep open while you read the graph. A bottom panel that fills on selection, and stays, is better; it also uses the space below the drawing that is currently empty.

Tabs inside the panel:

tab	what it holds
Details	act, target, relation, trigger, disposition; performer; whether it is attested and by whom; the identifier, in full and copyable
Material	the artefacts this node cites, by hash — see §2
Bearing	what it follows, what follows from it, and what it crosses to under other questions
Provenance	contributions (CRediT), absorption, and the registration signature

No constraint touches this. It is presentation of fields that already exist.

One rule: **the panel shows what is in the record, and nothing computed.** No "influence", no "downstream count", no "centrality". A node with many edges is not more important; it is a node with many edges.

43.1.2 2. Per-node files: nodes cite, they do not own

The request was a small file system per node. The honest version is close but not the same, and the difference is C3.

A transition is never edited (C3, append-only). If a node owned a mutable folder, the node would mean something different tomorrow than it meant when it was signed, and the signature would still verify — which is worse than it failing, because nothing would tell you.

So:

- Material lives in the **project's** file store.
- A transition **cites** material by the hash of its bytes, through the `artefacts` field the skeleton already carries.
- The node panel shows *the material this node cites*. That reads as a per-node file list and is true.
- Adding material to a node after the fact is **a new transition** citing it — ordinarily a `connection`. That is what append-only means in practice.

Two changes worth making to the project file store:

- **Allow folders.** `files/` is flat today and rejects `/` in a name. Nested paths are fine as long as traversal is still refused; the guard becomes per-segment instead of whole-name.

- **Keep showing the digest.** It is the only thing that makes a citation possible, and it is what a reader elsewhere checks.

43.1.3 3. Calendar — and the version of it that is forbidden

There is a legitimate calendar here and an illegitimate one, and they look alike until you ask what is being plotted.

43.1.4 Forbidden

A contribution graph. Activity per day, per person, per project. This is C6 without disguise: a quantity over participants, and the one every forge has trained people to read as worth. It would also be the most-copied screen in the product, so it is worth naming now: **there will be no activity heatmap, no streak, no per-person timeline.**

43.1.5 Legitimate, and already in the record

The record already contains dated commitments that nobody can currently see:

- **Scheduled disclosure.** `release_at` on a restriction. The protocol allows a schedule only under *exploratory vulnerability*, and `grrp disclose` refuses to extend one — a schedule may be shortened, never lengthened, and a refused extension is itself recorded. A calendar of these is a calendar of promises the record is holding you to. That is worth showing.
- **Embargo expiry** under the other grounds, where one was stated.
- **A chronology of one project.** `performed` is on every transition. Shown within a project, in order, without comparison to another project — the same rule that makes a per-trajectory count permissible.

So: **a calendar of commitments and chronology, never of activity.** If the question a screen answers is "how much has this person done", it does not get built.

43.1.6 4. Meetings — where the real trap is

A meeting node that "associates with any node it wants" is easy to build and is one short step from the thing this project exists to refuse.

`actions.initialise` already says it, about the local event plane:

> A complete log of who attended, who commented and whose files changed is a monitoring record by construction, and it is the failure with the largest consequence for participants.

That is why `.grrp/events/` is gitignored and never exported. A meeting node carrying attendance, exported with the record, is that log — rebuilt on the front of the system instead of the back, and portable.

43.1.7 What a meeting is, in this model

A meeting is an **occasion**. Occasions enter the record through what they produced, and the protocol already carries every part:

the meeting	in the record
that it happened, and what kind of occasion it was	`trigger: discussion` on each transition that came out of it
the meeting itself, as one shared node	its minutes as an **artefact**, cited by every transition arising from it — same hash, so one node, many edges

the meeting	in the record
who did what in it	`contributions`, bound to CRediT — a role in an act, not a presence at an event
what came out of it	the transitions themselves: a decision, a challenge, a changed position

That gives exactly “one meeting node connected to everything it touched”, without a new record type and without an attendance list.

43.1.8 The case it does not cover, and what to do about it

A meeting that produced nothing recorded. Under C1 — byproduct only — that is not a record entry, and writing one is recording for the record’s sake, which is the adoption failure Paper II predicts. It is a **calendar** entry.

So the split is:

- **Calendar**: meetings scheduled and held. Local, not exported, not part of any bundle. It may live in the event plane, where this kind of thing already belongs.
- **Record**: what the meeting changed. Artefact + trigger + contributions.

A meeting becomes visible in the graph exactly when it changed something. If that feels like it is losing information, the information it is losing is attendance, and losing it is the point.

43.1.9 5. What is actually missing, ranked

All four proposals are **views over a record the browser still cannot write to**. That should be said plainly before any of them is built.

1. **Recording acts from the page.** claim, challenge, transform, decide, verify. Until this exists the site is a viewer with a good drawing.
2. **Attestation.** Two accounts exist; nothing lets one register the other’s act. C2 is the entire credibility mechanism and it is unreachable from the interface. This is the one that makes the system mean anything.
3. Node panel (§1) — cheap, and improves everything above.
4. Per-node material (§2) — small, once §1 exists.
5. Calendar of commitments (§3) — needs `disclose` to be reachable first, or it has nothing to plot.
6. Meetings (§4) — is mostly §2 plus a workflow, once §2 is there.

Suggested order: **1, 2, 3, 4, then 5 and 6 together.**

43.1.10 Decisions this note is asking for

- Per-node files: **cite, not own**. Confirmed by C3, unless there is an argument against.
- Calendar: **commitments and chronology only**. No activity view, ever.
- Meetings: **occasion + artefact + contributions**, with scheduling in the local plane and out of every bundle. Not a new record type.
- Build order: acts and attestation before any further views.

44 README

Original source: `applicative_infrastructure/gr_academia_application/plans/design-pass-graph-model/README.md`.

Original source SHA-256: `be2bb8bfbcc95c51a2d8a9fee5f60aeb93d0dab5547c9f4c28abbebd99083f53`.

44.1 Design pass records — the graph model specification

Raw output of the structured design pass behind ../spec-graph-model.md. Kept because this project is itself about recording how understanding changes — including its own.

file	what it is
`draft-practice.md`	design from the working-researcher lens: occasions, materials, scenarios
`draft-architecture.md`	the component/action machinery, incl. the **kind-manifest sketch deferred from v1** (three worked examples: meeting, instrument calibration, dispute edge)
`draft-conformance.md`	47-item feature gauntlet ruled against the constraints, + 12 audit findings on the skeleton
`verify-audit.json`	17 constraint leaks found *in the drafts themselves*
`verify-missing.json`	28 gaps; the load-bearing ones are answered in the spec §10
`verify-cuts.json`	22 cuts and the v1 kernel the spec adopted

Where a draft and the specification disagree, the specification governs.

45 draft architecture

Original source: `applicative_infrastructure/gr_academia_application/plans/design-pass-graph-model/draft-architecture.md`.

Original source SHA-256: `7bc9b72f3b1eb4ef1038933383bca308ca3cfdd9042b08047a0279f49424c1f5`.

45.1 The component/action machinery — modularity specification

Scope: the entity-component model for GRA. Node kinds and edge kinds are **presentation kinds over protocol facts** — the machinery below lets a community add kinds without touching protocol code, and guarantees that a record made under a community kind is still readable as plain GRRP anywhere.

45.1.1 0. Two invariants everything below obeys

1. **Kinds are lenses, not types.** No manifest ever adds a field to a transition, changes what `grrp` writes, or mints a new record type. A kind is a way of *reading* protocol facts (act, trigger, relation, artefact scheme) plus a bundle of applicative affordances. Delete every manifest and the record is untouched.
2. **Writes go through `grrp`.** A recording action is an argv template for the reference implementation, never a skeleton constructed by the UI (this is already the rule in `web/packages/server/src/records.ts`). Manifests can therefore never produce an unlawful record: `grrp` refuses, and the refusal is surfaced verbatim.

45.1.2 1. What a component IS

A **component** is a named facet of a subject (a node or a reified edge), belonging to exactly one of four **classes**. The class — not the manifest — fixes where its data lives, who may write it, and whether it travels.

class	data lives at	written by	mutable?	travels in a bundle?	in git?
`record-facet`	signed transition YAML (`trajectories/<t>/transitions/*.yaml`), state files, `files/` digests	`grrp` only, via recording actions	never (C3)	**yes — it *is* the record**	yes
`sidecar-facet`	disclosure sidecar beside the skeleton	`grrp disclose` / `grrp redact` only	widens only (C7)	yes	yes
`workspace-facet`	`nodes/<subject>/⋯` (per-subject) or `files/⋯` (project)	any authenticated party, through the app	freely; deleting costs nothing	**never**	yes (ordinary files)
`local-plane-facet`	`.grrp/events/`, `.gra/calendar/`	the host application	freely	**never**	**no — gitignored, never exported**

`<subject>` is the last segment of the subject's identifier (`nodeArea()` already does this), so it works identically for a transition id and for an artefact hash — which is what lets material nodes and reified edges get workspaces with zero new machinery.

45.1.3 1.1 Component *types* are a closed application registry; manifests *instantiate* them

Communities configure instances; they never define new classes and never define new storage semantics. The registry:

type	class	what it shows / holds
`identity`	record-facet	the id, in full, copyable
`details`	record-facet	act, target, relation, trigger, disposition, performer, attested-by
`bearing`	record-facet	parents / children / crosses (from `parents`, reverse index)
`material`	record-facet	artefacts cited by hash; digests shown
`provenance`	record-facet	contributions (CRediT), absorption, registration signature
`projection`	record-facet	**configurable, community-definable**: a read-only field selection (§1.2)
`disclosure`	sidecar-facet	class, ground, `release_at`; widen-only controls
`workspace`	workspace-facet	the `nodes/<subject>/` folder: list, upload, delete, digest per file
`note`	workspace-facet	one named markdown file in the workspace, e.g. `nodes/<subject>/agenda.md`
`form`	workspace-facet	one named YAML file in the workspace with a declared schema, e.g. `calibration-setup.yaml`
`schedule`	local-plane-facet	a calendar entry (when/where/link). Never exported. **No attendee list field exists in its schema.**
`commitments`	record-facet	dated promises already in the record (`release_at`, embargo expiry) — read-only calendar

45.1.4 1.2 The `projection` mini-language (how communities get custom read-only facets safely)

```
- use: projection
  id: certificate
  title: Calibration certificate
  select:
    - field: artefacts
      where: { scheme: state }        # filter by exact field equality only
    - field: trigger
    - field: performed
```

`select` permits **field selection and equality filtering only**. No arithmetic, no `count`, no `sum`, no sort-by, no cross-trajectory reach. C6 is enforced structurally: the language cannot express a scalar over participants because it has no aggregation forms at all.

45.1.5 1.3 How the UI discovers a subject's components

Resolution, at render time, per subject:

```
subject (transition | artefact | reified edge)
  → collect candidate kinds whose `match` block fits (§3)
  → pick the most specific (most match fields); charter kinds beat builtins at equal specificity
  → components = universal set (§5) ∪ family defaults ∪ the kind's declared list, in declared order
  → no kind matches → family fallback (generic transition / generic artefact / generic connection)
```

The panel's tabs are exactly the resolved component list. Nothing computed is ever added by resolution — a kind can add facets, never metrics.

45.1.6 2. What an action IS

An **action** is a declared affordance on a kind, in one of three classes:

class	records?	via	example
`recording`	**yes** — exactly one `grrp` invocation	argv template over a declared input form	*reply to this dispute* → `grrp record --act challenge --relation repliesTo …`
`applicative`	**no** — touches workspace or local plane only	app code (file write, calendar write)	*add to calendar*, *edit agenda note*
`bridge`	**yes** — promotes workspace material into the record by citing its hash	`grrp connect`/`record` with `--artefact state:sha256:…`	*cite these minutes*

An action declaration:

```
- id: reply
  class: recording
  label: "Reply"
  inputs:
    - { name: body, type: markdown, required: true }
  grrp: ["record", "--act", "challenge", "--relation", "repliesTo",
         "--parent", "{subject.id}", "--body", "{inputs.body}"]
  preconditions:
    - has-open-question            # C4: an identified prior state exists
    - registrar-differs            # C2, applies at group tier+
```

Preconditions come from a closed vocabulary owned by the app (manifests may only cite them): `has-open-question`, `registrar-differs`, `tier: {personal|group|open}`, `subject.act|trigger|relation|disposition in […]`, `artefact-hashed` (bridge only), `charter-declares: <value>` (the extended trigger/target is actually in the project's charter), `disclosure-permits`.

What an action produces: `recording` and `bridge` produce exactly one transition (its id comes back from `grrp`, never computed by the app); `applicative` produces file/calendar state and **a test-enforced nothing** in `transitions/` (the existing upload test generalises: *every applicative action leaves the transitions directory byte-identical*).

Refusals surface at four distinct layers, and the layer is part of the design:

1. **Never offered.** Constitutive refusals are enforced by the manifest *loader*, not by absence: a denylist rejects any manifest declaring merge/combine, edit/delete-transition, mark-resolved, attendance, weight, score, count-across, or person/project kinds (§4.3). A bad manifest fails to load *entirely*, with the reason; it is never partially honoured.
2. **Disabled, with the reason shown** — a precondition unmet (`registrar must differ from per former at this tier`). The button stays visible: the affordance exists, the condition doesn't.
3. **Refused by `grrp` at execution** — stderr surfaced verbatim, nothing written. One implementation owns lawfulness.
4. **Refused and recorded** — where the protocol itself records refusals (e.g. a refused extension of a disclosure schedule), the app shows the recorded refusal as a fact of the record, not as an error.

45.1.7 3. The kind manifest

One YAML file per kind. Locations (resolution order, most local wins only on *equal specificity*):

```
web/packages/server/kinds/*.kind.yaml           # builtin, ships with the app
~/.gra/kinds/<charter-id>/<charter-version>/    # community kinds, installed from the charter package
```

Community kinds are **distributed with the charter** (the charter is already an identified, versioned, locatable document — Req 18.1/18.3), cached by charter id + version. They are applicative material: **never inside `.grrp/`, never in a bundle.** A project's trajectory already records its charter id+version, which is how a host knows *which* kind package to fetch — and the record is complete without it.

Common header:

```
kind: <namespaced id>        # gra.* reserved for builtins; charter kinds use <charter-id>/<name>
family: act | occasion | material | edge
version: 1                   # integer; bump on any change. Kind versions are NOT protocol
                             # or charter versions and never share a numbering (Req 19.2)
title: <label>
charter: null | { id: <charter-id>, version: <v> }
match: { ⋯ }                  # protocol facts only — never workspace state
degrades-to: transition | artefact | connection   # what a manifest-less host shows (§4.2)
components: [ ⋯ ]
actions: [ ⋯ ]
```

`match` may test only: `subject` (transition/artefact), `act`, `trigger`, `relation`, `target`, `artefact-scheme`, `cited-with-trigger` (for artefact subjects: the trigger on citing transitions). Nothing mutable, nothing computed.

45.1.8 3.1 Example — builtin occasion-kind: `meeting`

```
kind: gra.occasion.meeting
family: occasion
version: 1
title: Meeting
charter: null
match:
  subject: artefact                 # the meeting node IS the shared minutes artefact —
  cited-with-trigger: discussion    # same hash, one node, many edges (settled design)
degrades-to: artefact
components:
  - use: identity
  - use: note                       # workspace-facet
    id: agenda
    file: agenda.md                 # lives at nodes/<hash>/agenda.md — mutable, unbundled
  - use: material                   # record-facet: the minutes bytes, digest shown
  - use: bearing                    # record-facet: every transition that cites this hash
  - use: schedule                   # local-plane-facet: when/where/link. .gra/calendar/,
                                    # gitignored. Schema has no attendee field.
actions:
  - id: add-to-calendar
    class: applicative
    label: "Add to calendar"
    writes: local-plane             # transitions/ provably unchanged
  - id: join-meeting
    class: applicative
    label: "Join"
    opens: "{schedule.link}"        # opens the link from the local plane; records nothing (C1)
  - id: cite-minutes
    class: bridge
    label: "Cite the minutes from an act"
    inputs:
      - { name: act, type: enum, values: [claim, challenge, decision, transformation] }
      - { name: body, type: markdown, required: true }
    grrp: ["record", "--act", "{inputs.act}", "--trigger", "discussion",
           "--artefact", "{subject.id}", "--body", "{inputs.body}"]
    preconditions: [has-open-question, artefact-hashed]
```

Note what is *absent*: no attendance component, no `mark-held` recording action. A meeting that produced nothing recorded is a calendar entry (C1) — the `schedule` component alone, in the local plane, is that entry.

45.1.9 3.2 Example — community occasion-kind: `instrument calibration` (no protocol code touched)

The community's charter declares an extended trigger `calibration` (triggers are charter-extensible; `grrp` stores it as `local:calibration`, accepted and flagged, per `vocab.py`). The charter package ships this manifest:

```
kind: metrology-lab-charter/instrument-calibration
family: occasion
version: 2
title: Instrument calibration
charter: { id: "charter:metrology-lab", version: "3.1" }
match:
  subject: artefact
  cited-with-trigger: local:calibration
degrades-to: artefact
components:
  - use: identity
  - use: form                       # workspace-facet: structured setup notes, mutable
    id: setup
    file: calibration-setup.yaml
    schema:
      instrument: string
      reference-standard: string
      environment: string
  - use: projection                 # record-facet, read-only, no aggregation (§1.2)
    id: certificate
    title: Certificate
    select:
      - field: artefacts
        where: { scheme: state }
      - field: performed
      - field: performer
  - use: schedule                   # next calibration due — a commitment, not activity
actions:
  - id: schedule-calibration
    class: applicative
    label: "Schedule"
    writes: local-plane
  - id: record-calibration
    class: recording
    label: "Record calibration outcome"
    inputs:
      - { name: outcome, type: markdown, required: true }
      - { name: certificate, type: workspace-file, required: true }
    grrp: ["record", "--act", "verification", "--target", "method",
           "--trigger", "calibration",
           "--artefact", "{inputs.certificate.digest}",
           "--body", "{inputs.outcome}"]
    preconditions:
      - has-open-question
      - charter-declares: "trigger:calibration"
      - registrar-differs
```

The lab got: a recognisable node kind, a structured workspace form, a certificate facet, a due-date calendar, and a one-click lawful recording path — from one YAML file and one charter line. `grrp` was not modified; the act is `verification` (closed vocabulary), only the *trigger* is extended.

45.1.10 3.3 Example — edge-kind: `dispute` (a reified semantic edge)

A semantic edge is already a node: a `connection` transition carrying a CiTO relation, with the cross-question parent edge. The kind matches the transition, and the graph draws it as an edge while the panel opens it as a node.

```
kind: gra.edge.dispute
family: edge
version: 1
title: Dispute
charter: null
match:
  subject: transition
  act: connection
  relation: cito:disputes
degrades-to: connection
components:
  - use: identity
  - use: details                    # relation shown with its CiTO binding, disposition shown
  - use: endpoints                  # record-facet (edge-family default): the two states it joins,
                                    # each openable — from parents + the connection's own reference
```

```
  - use: workspace                 # inherited universal (§5): nodes/<transition>/ — the dossier
                                   # of the disagreement lives HERE, on the edge itself
actions:
  - id: annotate
    class: applicative
    label: "Add working notes"
    writes: workspace
  - id: reply
    class: recording
    label: "Reply"
    inputs: [ { name: body, type: markdown, required: true } ]
    grrp: ["record", "--act", "challenge", "--relation", "repliesTo",
           "--parent", "{subject.id}", "--body", "{inputs.body}"]
    preconditions: [has-open-question]
  - id: cite-evidence
    class: bridge
    label: "Cite evidence bearing on this dispute"
    grrp: ["record", "--act", "verification", "--relation", "supports",
           "--parent", "{subject.id}", "--artefact", "{inputs.file.digest}",
           "--body", "{inputs.body}"]
    inputs:
      - { name: file, type: workspace-file, required: true }
      - { name: body, type: markdown, required: true }
```

Note the absences again: no `resolve` action (dispositions are closed; a dispute's standing changes only when a later transition changes it), no `weight`, no `strength`. **Structural edges** (`follows`/`crosses`/`cites`) get none of this machinery at all: they are facts read off `parents` and `artefacts`, have no identity of their own, take no components, take no actions, and appear in no manifest. Only *claims* — connections — are reifiable, because only claims have content to hold.

45.1.11 4. Versioning, extension, and travel

45.1.12 4.1 What may be extended, and by whom

dimension / thing	extensible?	by	mechanism
`act` (8)	**never**	—	interoperability rests on it; a manifest naming a ninth act fails to load
`disposition` (3)	**never**	—	`unresolved` is the point; no manifest may add, remove, or alias one
grounds of restriction (4)	**never**	—	free invention of grounds makes withholding free
`target`	yes	charter	value + definition in the charter (Req 18.2); stored as `local:` until/unless bound
`trigger`	yes	charter	same
`relation`	the three named locals only, plus charter-defined `local:` values	charter	CiTO stays the binding for everything CiTO covers (C12); locals flagged, never presented as bound
kinds, components-instances, actions	yes	charter package or builtin	manifests, this spec

Amendment is prospective (Req 18.4): a kind manifest at version *N+1* changes how *future* screens render; it never re-interprets records, because it never interpreted them — it lensed them.

45.1.13 4.2 A record made under a community kind, arriving at a host without the manifest

The record must read as plain protocol, and it does, because the kind contributed nothing to it. The calibration transition on disk:

```
## trajectories/tq7/transitions/<id>.yaml — this is ALL that travels
id: trn:sha256:9f2a…
act: verification            # closed vocabulary — understood everywhere
target: method
relation: null
trigger: local:calibration   # retained unchanged, flagged as local (Req 16.5, vocab.py)
disposition: accepted
parents: [trn:sha256:1c44…]
prior_state: state:sha256:77b0…
posterior_state: state:sha256:e01d…
performer: key:ed25519:…
performed: 2026-08-14T09:12:00Z
artefacts:
  - { scheme: state, ref: "state:sha256:ab31…" }   # the certificate bytes, by hash
registration: { registrar: key:ed25519:…, attested: true, signature: … }
charter: { id: "charter:metrology-lab", version: "3.1" }
```

A manifest-less host: verifies the signature; renders it with the **family fallback** (generic transition node: `verification` of a `method`, trigger shown as `local:calibration` — `charter-defined, charter:metrology-lab@3.1`, artefact by digest); offers only the universal components and generic actions. Nothing is missing *from the record* — what is missing is a nicer tab layout and a pre-filled form. The host may fetch the charter package by the id+version the record itself carries and gain the lens; it must never rewrite the record to fit a lens it has (no normalisation — Req 16.5).

45.1.14 4.3 The manifest loader's denylist (constitutive refusals, enforced at load)

A manifest is rejected in full, with the reason, if it declares: a kind matching persons or parties (person-centric graph → C6/monitoring) ·a project-level kind (C4) ·any component named or shaped as attendance, presence, activity, streak, progress, importance, score, rank, weight, or count-across-trajectories (C6) ·any action whose `grrp` template edits or deletes (C3) ·any merge/combine action, under any name (C5) ·any action setting or adding a disposition value outside the closed three ·a `projection` using forms outside §1.2 ·a `schedule` schema extended with people fields.

45.1.15 5. Composition rules

1. **Universal components** — every node kind and every edge kind, non-removable, prepended automatically: `identity`, `workspace` (the brief's premise: storage is common to all nodes *and edges*), `provenance` where the subject is a transition.
2. **Family defaults**, added unless the kind is a stricter match that already covers them:
   - *act-family*: `details`, `bearing`, `material`, `disclosure`
   - *occasion-family*: `material`, `bearing`, `schedule`
   - *material-family*: `bearing` (who cites it), digest display; external works (doi/arxiv/url) get a resolver link, no workspace upload of other people's bytes
   - *edge-family*: `details`, `endpoints`
3. **Reified-edge inheritance**: an edge kind's subject is a transition, so it inherits the full universal set *as a node* — same workspace path scheme (`nodes/<transition>/`), same provenance, same disclosure sidecar. The manifest may **add** edge-specific components; it may never remove a universal one. One subject, one component set, two renderings (drawn as an edge in the graph; opened as a node in the panel).
4. **Additivity**: resolution unions components; conflicts on `id` resolve to the more specific kind's instance. Actions never union across kinds — exactly one kind's action list is offered (the resolved one), so a community cannot *shadow* a builtin recording action with a differently-wired one at equal match specificity: builtins win ties on actions, charters

win ties on components (a lens may be enriched; a recording path may not be quietly swapped).

5. **Class discipline is per-instance and static**: a component's class comes from its type, fixed in the app registry; no manifest field can move data between classes, which is what makes "does it travel?" answerable by grep.

Relevant files: `c:\Users\Micro\Desktop\relational_being_infrastructure\research\projects\Generative-Relational-Academia-Application\grrp\src\grrp\vocab.py` (closed vocabularies the denylist mirrors), `web\packages\server\src\records.ts` (the `nodeArea`/`runGrrp` seams the component classes and recording actions attach to), `notes\paper-IV-grrp-specification.md` §§16–19 (travel and charter rules §4 binds to), `plans\design-nodes-time-and-occasions.md` (the meeting/occasion precedent §3.1 encodes).

46 draft conformance

Original source: `applicative_infrastructure/gr_academia_application/plans/design-pass-graph-model/draft-conformance.md`.

Original source SHA-256: `ffb1649808f2d4609eb4805cdd0145852107b549b7d4ef5f700bb9542266e9cd`.

46.1 Adversarial conformance review — feature gauntlet + skeleton audit

Rulings key: **(a)** safe as-is ·**(b)** safe only under the stated reformulation (layer named) ·**(c)** must be refused (constraint named, with a reason a user would accept). Layers: *record-facet*, *sidecar-facet*, *workspace-facet*, *local-plane-facet*; action classes: *recording*, *applicative*, *bridge*.

46.1.1 Part I — 38 things people will predictably ask for

46.1.2 (a) Safe as-is

1. **Node detail panel showing signed fields** (act, target, relation, trigger, disposition, performer, attestation, identifier). Record-facet, read-only projection. Already settled in the design note. Nothing computed may appear beside it.
2. **Cite-this-transition / export citation.** Emits identifier + CiTO term. Serves C10 and C12 directly. Record-facet + applicative copy action.
3. **Color/shape nodes by act or disposition.** Both vocabularies are closed and part of the signed payload; a legend over 8 acts and 3 dispositions is a projection, not a judgment. Record-facet.
4. **Vocabulary validation on entry** (reject unknown relation, flag `local:` as unbound). `resolve_relation` already does this; presenting unbound values as bound is the violation, refusing them is not. Recording-action plumbing.
5. **Counts inside one open trajectory's detail view** ("this question has 4 challenges, 2 unresolved"), shown only when that trajectory alone is open. Explicitly permitted by C6's carve-out — but see skeleton finding S8 for the badge trap.
6. **Bundle export / take-the-record-and-leave.** C10 is not just permitted, it is owed. Any friction added here is itself a finding.

46.1.3 (b) Safe only under reformulation

7. **Meeting RSVP.** Reformulation: a personal *add-to-calendar* entry in the requester's own local plane (`.grrp/`-adjacent, never exported). Refused variant: any shared roster of who intends to come — a pre-attendance list is an attendance list with a tense change. Layer: local-plane-facet.
8. **Activity feed.** Reformulation: *chronology of a single project*, ordered by `performed`, no per-person facet, no cross-project merge, no recency badges — exactly the design note's "calendar of chronology." Refused variant: any feed filterable by performer or unioned across projects (C6, per-person timeline). Layer: record-facet.
9. **Notifications.** Reformulation: local-plane alerts derived from record changes the user can already read ("a new transition took your state as parent"), computed client-side, never stored, no delivery/read receipts anywhere. Refused variant: server-side notification log or "seen" state — that is the event plane exported. Layer: local-plane-facet.
10. **Importance stars / pins.** Reformulation: a *private pin*, local-plane only, invisible to every other party, no count, never exported. Refused variant: shared or aggregated stars (C6 scalar over trajectories). Layer: local-plane-facet.
11. **Search.** Reformulation: filtering plus deterministic orderings (chronological, lexical); per-query text match may order results but the score is ephemeral, never displayed as a number, never persisted as an index, never applied to performers, and must work offline (C9, C11 — the search cache is rebuildable from files). Refused variant: "relevance" as a standing ranking over trajectories (C6 in a trench coat). Layer: applicative, rebuildable cache.

12. **Task lists.** Reformulation: notes in a *workspace* folder — mutable, unbundled, self-maintained; a person may write "I will address the objection." Refused variants: assignment of tasks *to* other people with tracked completion status (an obligations ledger is C6-adjacent accountability plumbing and pressures fabricated closure), and any rollup of open/closed tasks. Layer: workspace-facet.
13. **Deadlines.** Reformulation: the calendar of commitments already sanctioned — `release_at`, embargo expiry, shorten-only (sidecar-facet); plus private local-plane reminders. Refused variant: a deadline attached to a challenge or question ("resolve by Friday") — the vocabulary keeps `unresolved` precisely so that closure is never owed on a date.
14. **"Mark resolved."** Reformulation: a *recording action* — "record a `decision` (or `verification`) that addresses this challenge," a full new transition with content, citing the challenge's state (C3, C4). The disposition of the old transition never changes; the graph shows the answer standing next to the objection. Refused variant: any state flip on an existing node (C3 + closed dispositions).
15. **Approval workflow.** Reformulation: approval-as-record is an `agrees`/`supports`/`confirms` connection transition by the approving party, or attested registration (C2) — visible endorsement, never a gate. Refused variant: approval as a precondition for recording or publishing — C10 says nobody's permission is required to continue the record, including yours. Layer: recording.
16. **Private comments.** Reformulation: workspace notes — mutable, unsigned, never bundled; they enter the record only via the bridge (cited by hash inside a real act). Refused variant: a private thread stored *in* the record with narrowed visibility — disclosure widens only (C7), so the record cannot carry content that is secret-by-audience. Layer: workspace-facet.
17. **Comment threads on a transition (public).** Reformulation: threads are a *presentation* of `repliesTo` chains — connection transitions with content, signed, ordinary nodes. Refused variant: a lightweight unsigned comment table beside the record — that is a parallel, unattested record of scholarly speech (C1, C2, C12). Layer: record-facet over recording actions.
18. **Delete.** Reformulation: three honest deletions exist — (i) anything applicative, freely (that layer "costs nothing to delete"); (ii) *content* removal via redaction with a stated ground from `REDACTION_GROUNDS`, skeleton and signatures staying valid (C8); (iii) *standing* removal via a `retracts` transition (C3). Refused variant: deleting a transition (C3, no exception).
19. **Project archiving.** Reformulation: record-side closure is a `release` act or simply stopping; UI-side, hide the project from *my* workspace list (local-plane). Refused variant: unpublishing — C7, disclosure never narrows; see item 30.
20. **AI involvement.** Reformulation: `trigger=ai_suggestion` on a transition performed and signed by a human — the vocabulary already says a model "may occasion a transition and may not author or register one." Refused variant: model-as-performer or model-as-registrar (C2 — attestation between a person and their own tool is theater). Layer: recording.
21. **Auto-summaries.** Reformulation: optional, offline-capable, regenerable applicative caches, visually marked as unsigned derivations, never bundled, never the default face of a node (the signed content is the identity; a paraphrase presented as the node misattributes words to a signature). System must be fully usable with the feature off (C9). Layer: applicative cache under C11.
22. **Watch lists.** Reformulation: a private local-plane bookmark list — my attention, on my machine, visible to no one. Refused variants: "followers of X," follower counts, "who watches this" — a directory of attention is a monitoring record whichever direction you read it (C6 + the event-plane ruling). Layer: local-plane-facet.
23. **@mentions.** Reformulation: a mention inside content is just content; a mention in a workspace note may raise a *local* notification for the mentioned party's own client. Refused variant: mention analytics or a who-mentions-whom graph (C6, person-centric graph).
24. **Transition templates / prefill.** Reformulation: applicative prefill of vocabulary fields for a real act the user is already performing. Refused variant: template-driven prompting that solicits transitions ("weekly update template") — an operation whose purpose is that a record exist (C1).
25. **Draft transitions.** Reformulation: a draft is a workspace file — mutable, unsigned,

invisible to the record — until the moment of recording; there is no "draft" status in the record, because an unsigned record state would let signatures attest to things that later changed (C3, C8). Layer: workspace-facet → recording.

26. **Undo.** Reformulation: applicative undo freely; record undo is `retracts` (cito:retracts) — a new transition that says so, forever (C3).
27. **Sync/backup service.** Reformulation: transport of plain files and bundles (git, rsync, sneakernet); the service is a courier, never the system of record, and everything works with it absent (C9, C11).
28. **Duplicate / "related question" suggestions.** Reformulation: optional applicative aide, offline-degradable; acting on a suggestion is a human-performed `connection` with `trigger=ai_suggestion` if a model surfaced it. Refused variant: auto-created connection transitions (C1 + performer must be a person).
29. **Onboarding tutorial.** Reformulation: the tutorial drives a disposable demo repository, never the user's real record — practice transitions in a real trajectory are records manufactured so records exist (C1). Layer: applicative.

46.1.4 (c) Must be refused

30. **Unpublish.** C7. *"Others may already have continued from what you shared; the protocol promises them the ground under their work cannot be pulled back — redaction of content is available, retraction of standing is available, un-happening is not."*
31. **Person/profile node.** C4 + C6 + the monitoring ruling. *"The moment a person is a node, everything they did aggregates to them, and the graph becomes a dossier; the record attaches to states, and a performer is a key on a transition, not a place things pile up."* (The one survivable residue — a key-fingerprint verification panel — is applicative and is not a node.)
32. **Attendance lists.** Settled outright: the event plane is never exported. *"A log of who was present is a monitoring record by construction — the single failure with the largest consequence for participants — so presence is never written down, anywhere, in any layer that travels."*
33. **Progress bars.** C6, and the disposition design. *"A progress bar is a scalar over a trajectory and a promise of completion; this record exists to say honestly that most objections stay unresolved, and a bar stuck at 80% punishes exactly that honesty."*
34. **Kanban states.** Closed dispositions + C12 (parallel vocabulary) — the brief's own instinct is right. *"A column is a disposition vocabulary in disguise: 'done' is a fourth disposition the protocol deliberately refused, and dragging a card is an unsigned, unattested reclassification of a signed event."*
35. **Edge weights.** C6, plus reification. *"A semantic edge is already a signed transition; a weight would be an unsigned number ranking relations against each other, which is exactly the scoring the record refuses."*
36. **Reactions/emoji.** C6 + C2 + C1. *"A reaction is an endorsement with no content and no attestation that exists to be counted; the protocol's version of [approval] is an `agrees` transition where you say why, under your key."*
37. **View counts.** C6 + monitoring. *"Counting reads requires logging readers — a record of attention on both sides of the number — and no count over participants is ever shown."*
38. **Contributor leaderboards.** C6, verbatim. *"Any ranking of participants converts the record into the metric it was built to escape; there is no screen that answers 'who did most.'"*
39. **Merge/combine of branches.** C5, including the word ban. *"Divergent states both remain true records of what was understood; a transition may take both as parents and say, in content, what it makes of the divergence — but nothing collapses them, and no interface surface ever offers the word."*
40. **Edit-in-place on record content.** C3. *"The signature covers the bytes; a corrected understanding is a new transition with `modifies` or `replaces`, so the record shows both that you were wrong and that you noticed."*
41. **Cross-project dashboard.** C6. *"Two projects' numbers on one screen is a comparison whatever the labels say; projects are opened one at a time, and each shows only its own chronology."*
42. **Per-person timeline / filter-by-performer view.** C6 + design note's explicit ban. The files are portable and grep-able (C10) — anyone *can* compute this — but the application

must not offer the affordance. *"The record cannot stop you from studying a person; it can decline to be an instrument built for it."*

43. **"You haven't recorded in N days" nudges, streaks, badges.** C1 (and C6 for streaks). *"An operation that exists so that a record exists is the definition of the failure; the record is a byproduct of work, and silence is a permitted state of work."*
44. **"Last active" / presence dots.** Monitoring + C6. *"Presence indicators are attendance streamed live."*
45. **Graph-metric overlays** (centrality, node size by degree, influence). C6; design note: "a node with many edges is a node with many edges." *"Any computed prominence is a ranking over trajectories with extra steps."*
46. **Color-by-performer on the canvas.** C6/monitoring: it converts the graph into a per-person activity map at a glance. Performer stays where it is — in the detail panel of one node at a time.
47. **Time tracking.** C6 + monitoring + C1. *"Hours are a scalar over a participant, gathered by watching them."*

46.1.5 Part II — Audit of the skeleton itself

S1. Occasion-kinds risk violating C1 at the constructor. If "meeting" is a node kind, someone will build a *create meeting node* button — a node existing so the occasion is on record, with zero acts behind it. The precedent already decides this: a meeting that produced nothing recorded is a calendar entry. The spec must state that occasion-kinds are **derived** groupings (transitions sharing a cited artefact + trigger), never directly creatable, and that an occasion with no transitions does not exist in the graph.

S2. Occasion rollup = attendance by reconstruction. CRediT contributions per act are legitimate (C12), but an occasion-kind view that unions contributors across its transitions into a "participants" panel has rebuilt the attendance roster from signed parts. The occasion view may list its *transitions*; it must never present a merged roster of people. This is the single most likely quiet violation in the whole skeleton.

S3. The user's own example, "join-meeting action," is a trap the skeleton doesn't defuse. Join must be a pure launcher (open URL, add to own calendar) that writes nothing anywhere — the moment joining leaves a trace, it is presence logging. Name this explicitly in the action spec, because "join" naturally suggests membership state.

S4. "Bridge" cannot be a free-standing action class. The precedent says the bridge *is an act*: material joins the record only when a transition cites it. If bridge exists as its own button producing a bare citation-transition with no other content, that transition exists solely so a record exists (C1) and cites nothing specific in the sense C4 demands. Fix: bridge is a *parameter of recording actions* (an `artefacts` picker inside a real act), not a sibling class — or the spec must require that every bridge rides on a genuine act with content.

S5. Administrative operations have no home. `vocab.py` defines `OPERATIONS` (disclosure_changed, redaction, key_rotation, fork_declared, attribution_contested, binding_recorded, deposit_recorded) and `REDACTION_GROUNDS`. The skeleton's three action classes (recording / applicative / bridge) cover none of these: they are not acts, not applicative (they have record-plane consequences), not bridges. Either add a fourth class — *administrative* (sidecar/operations plane, widen-or-remove-content-only, grounds required) — or the redaction path (C8's whole point) will get bolted on ad hoc.

S6. Presentation names over acts strain the vocabulary's own rule. "Act-kinds as they read to a person" is fine until a friendly label drifts ("Objection" for `challenge`, "Answer" for `decision`) and becomes a de facto parallel vocabulary (C12; vocab.py: never present a value as something it isn't). Rule to add: presentation labels map 1:1, the protocol term is always inspectable one gesture away, and labels are never persisted into anything that travels.

S7. Structural edges "no identity, no components" needs its justification stated, or it will be reverted. Someone will want to *challenge a parent link* ("this doesn't actually follow from that") and will ask for edge identity to do it. The right answer exists and should be written in: the parents list is part of the child's signed payload, so you challenge the **child transition** (C4 gives you the specific state). Without this paragraph, edge identity gets added "just for commenting" and reification leaks into structural edges.

S8. The C6 carve-out will leak through badges. “Counts within one trajectory, shown without comparison” — but a canvas showing many trajectories, each node wearing a “3 challenges” badge, *is* comparison by juxtaposition. The spec must scope counts to the single-trajectory detail context (panel of one selected thing), never to decorations rendered simultaneously across the graph.

S9. Semantic edges inherit “every component a node gets” — including local-plane calendar. Mostly free and correct (reification pays off), but audit the inheritance rather than granting it wholesale: a calendar facet on a relation is meaningless surface area, and unused surfaces are where the next feature request lands. Grant components per kind, by argument, not by inheritance.

S10. Material-kinds referencing doi/arxiv/url must degrade offline. C9: an external-work node may *hold* a resolvable reference but must render fully (identifier, citing transitions) with no network. Live metadata fetch is an optional applicative enhancement, cached under C11.

S11. The refusal list is incomplete and asymmetric. It refuses “mark-answered” without naming the legitimate neighbor (a `decision`/`verification` transition citing the challenge — item 14), which invites implementers to conclude challenges are dead ends. And it omits refusals this review found load-bearing: no view counts or read logs, no per-person filter/timeline (already banned in the design note but absent here), no reaction counts, no relevance-as-standing-index, no presence indicators, no occasion roster (S2). A refusal list that undersells is a refusal list that gets “extended” by whoever draws the next screen.

S12. One wording nit with teeth. The brief says semantic edges get workspace storage “for free.” Nothing near C1–C12 is free; each inherited component either survives the same twelve tests independently or it doesn’t ship. Recommend the spec’s own language never uses “for free” — it is how the applicative layer’s mutability gets mistaken for a general license.

47.1 GRA from the bench: node kinds, edge kinds, components, actions for working researchers

Lens: a small lab / theory group / field team, day to day. Every item below is tagged **[P]** protocol (in the signed record) or **[A]** applicative (mutable, never signed, never bundled), and mapped to the exact protocol mechanism — act / target / relation / trigger / disposition / artefact / field — or refused with the nearest lawful alternative. Nothing here proposes a new record type: node kinds are *presentation kinds* over the five-dimensional transition vocabulary; occasion and material kinds are realised by trigger + shared cited artefact, per the settled meeting precedent.

47.1.1 1. Node kinds

47.1.2 1.1 Act-kinds (presentation of the 8 closed acts) — all [P] facts, [A] rendering

Node kind	Protocol realisation	Researcher reading
Question	`act: question`, origin of a trajectory	"what we are asking"
Claim	`act: claim`	a stated position or result
Challenge	`act: challenge`	an objection, anomaly, counterexample
Transformation	`act: transformation`	a reformulation, revision, derivation step
Decision	`act: decision`	a chosen path, an abandoned one
Connection	`act: connection`	a reified semantic edge (see §2)
Verification	`act: verification`	replication, check, confirmation
Release	`act: release`	disclosure event: preprint, dataset publication, talk

No further act-kinds may exist (closed vocabulary). Every research-life "event node" below must resolve to one of these eight or be applicative.

47.1.3 1.2 Occasion-kinds — [A] grouping over [P] facts; never a record type

Realised uniformly as: shared cited artefact (same hash ⇒ one node, many edges) + `trigger` on the resulting transitions + CRediT `contributions` per act. An occasion that produced no transition is a calendar entry only (C1).

Occasion kind	Trigger	Shared artefact (by hash or scheme)	Typical resulting acts
Lab meeting	`discussion`	minutes	decision, challenge, claim
Seminar / invited talk	`discussion` or `literature`	slides, abstract, recording hash	question, connection, challenge
Reading group / journal club	`literature` + `discussion`	the paper (`doi:`/`arxiv:`) — the external work itself is the shared node	challenge, connection, claim
Supervision meeting	`discussion`	meeting note	decision (student), with supervisor's part typed `credit:Supervision` in `contributions` — a role in an act, never a status

Occasion kind	Trigger	Shared artefact (by hash or scheme)	Typical resulting acts
Whiteboard session	`discussion`	photo of the board (hash)	transformation, claim
Experiment run	`experiment`	run log, raw output (hash)	claim, challenge (anomaly), verification
Simulation / parameter sweep	`simulation`	config + output hashes	claim, challenge, verification
Field trip / observation session	`observation`	field notes, GPS-stripped-as-needed media (hash)	claim, question, challenge
Failed attempt	`failure`	whatever evidenced the failure	decision (abandon path), challenge
Conference attendance	`literature`/`discussion`	the talk's paper or notes	connection, question
Onboarding of a newcomer	`entering_party`	the material absorbed (see §6.14)	question, claim, connection with `absorption` filled
AI-assisted analysis session	`ai_suggestion`	model output artefact	any act — model may occasion, never perform/register

Occasion detection is derived, not stored: the UI clusters transitions sharing an artefact hash + trigger + time window. No occasion identifier enters the record.

47.1.4 1.3 Material-kinds — [P] when cited, [A] while in workspace

A material node exists in the graph **only because at least one transition cites it** in `artefacts` (C1, C4). Before citation it is a workspace file, invisible to the record; a test already asserts upload changes no transition.

Material kind	Realisation
Held artefact (data file, figure, script, minutes, draft, photo, transcript, calibration file, instrument config)	`state:`/hash reference in `artefacts`; bytes in project file store (C8: deletable, skeleton stays valid)
External paper	`doi:` / `arxiv:` / `isbn:` reference — same hash/id ⇒ one shared node lab-wide
Web resource / preprint server page / code repo URL	`url:` reference
Dataset (versioned)	each version = distinct hash = distinct material node; "new version" = transformation transition, target `artefact`, relation `modifies`, citing the new hash, parent = the transition that cited the old one (C4: specific prior state, never "the dataset" as a whole)
Code release	`release` act, target `artefact`, citing the archive hash and/or `url:` of the tag; day-to-day commits stay applicative (git is workspace)
Manuscript draft vN	hash of the draft; revision = transformation citing the new hash (see §6.10)
Ethics approval, grant letter, MTA, DUA	artefact cited by the `decision` it licensed
Physical specimen / sample	**cannot be hashed** — nearest lawful: its metadata sheet (ID, collection record) is the artefact; the specimen itself is applicative inventory (§5)
Instrument	**refused as record node** (a thing-as-a-whole violates C4's spirit; a person/thing-centric graph invites C6). Nearest lawful: instrument *settings/calibration file* as artefact; instrument registry + booking in the local plane

47.1.5 2. Edge kinds

47.1.6 2.1 Structural (facts; no identity, no components, no actions)

Edge	Source	Notes
Follows (parent, same trajectory)	`parents` list	the DAG; branching = divergence, permanent (C5: never combined, the word never appears)
Crosses (parent, other trajectory)	`parents` entry created by `grrp connect`	cross-question edges are ordinary parent edges
Cites-artefact	`artefacts` field	transition → material node
Registered-by (attestation)	`registration` field	shown per transition only; **never aggregated per registrar** (C6)
Absorbed	`absorption` field	newcomer's transition → the specific prior states absorbed

47.1.7 2.2 Semantic (reified — each IS a connection transition, so it is a full node)

One presentation edge-kind per relation: the 16 CiTO bindings (`extends`, `modifies`, `refines`, `replaces`, `disagrees`, `agrees`, `supports`, `refutes`, `confirms`, `retracts`, `repliesTo`, `usesMethodIn`, `relates`, `supportedBy`, `usesDataFrom`, `disputes`) plus charter-local `generalises`, `specialises`, `transfers` (flagged, never presented as bound). Because the edge is a transition, it gets **every node component for free** — including workspace storage ("why this connection matters" can hold pages of argument, figures, worked examples). This is the answer to "edges should also have components": already true by reification; nothing to add at the protocol layer.

47.1.8 2.3 Derived presentation edges — [A] only, recomputed from files (C11), never stored, never exported

Derived edge	Computed from	Guard
Same-occasion (two transitions cite the same minutes/run log)	shared artefact hash	no count displayed across occasions (C6)
Same-source (two transitions cite the same paper)	shared `doi:`	reading-group view
Chronological adjacency within one project	`performed`	within-project only, no cross-project comparison (C6)

47.1.9 2.4 Refused edge features

- **Edge weights, strengths, confidence scores** — C6. Nearest lawful: the connection transition's *content* states the strength in prose; its `disposition` (accepted/contested/unresolved) is the only typed qualifier.
- **Person→person edges** (co-author graph, supervisor graph) — person-centric graph, C6/monitoring. Nearest lawful: none; CRediT roles live inside acts.
- **"Blocks/depends-on" task edges** — [A] task board only, never exported.

47.1.10 3. Components (the four classes, assigned per kind)

Universal on every node and every reified edge (the requested common component): **Local storage / workspace-facet** — `nodes/<transition>/`, ordinary mutable folder, records nothing; material enters the record only via a bridge action (§4.3).

47.1.11 3.1 Record-facet components (projections of signed fields; strictly read-only)

Component	Fields shown	Carried by
Identity	hash id, full and copyable	all record nodes
Type	act, target, relation (with bound/local flag), trigger, disposition	all
Provenance	performer, `performed`, contributions (CRediT), absorption, registration (attested? by whom? signature)	all
Material list	`artefacts` with digests — reads as the per-node file list; **cite, not own**	all
Bearing	parents / children / crossings	all
Occasion badge	trigger + shared-artefact cluster	transitions from occasions
Rationale	the state file's content (the "why")	all; the payload of connection edges

47.1.12 3.2 Sidecar-facet components (disclosure; widen-only, C7)

Component	Content
Disclosure status	current audience; history of widenings
Ground of restriction	one of the four closed grounds (rivalry/hazard/vulnerability/appropriability) with its stated residue
Release schedule	`release_at` (vulnerability only); shorten-only; refused extensions are themselves recorded
Redaction notice	redaction ground; skeleton+signature remain valid (C8)

47.1.13 3.3 Workspace-facet components (mutable, never bundled, deleting costs nothing)

Notes/scratch; draft material; run outputs awaiting citation; PDF annotation layer on cited papers; figure staging; code checkout; analysis notebooks; reviewer-response drafting table; onboarding tour bookmarks; task checklist (per node, not per person).

47.1.14 3.4 Local-plane-facet components (.grrp/events etc.; never exported)

Meeting details (time, place, video link, agenda); calendar entry; instrument booking; deadline entry (conference, grant, ethics renewal); reminder. **Commitments and chronology only, never activity** (settled). No attendee list anywhere, even locally: attendance is never recorded.

47.1.15 4. Actions (three classes)

47.1.16 4.1 Recording actions (each produces one transition through grrp; named by act)

`ask` (question — opens a trajectory), `claim`, `challenge`, `transform`, `decide`, `connect` (creates a semantic edge = full transition), `verify`, `release`. Plus **register/attest** (registrar ≠ performer at group tier, C2 — the credibility mechanism) and the administrative operations already in vocab: `disclosure_changed` (widen only), `redaction`, `key_rotation`, `fork_declared`, `attribution_contested`, `binding_recorded`, `deposit_recorded`.

47.1.17 4.2 Applicative actions (change workspace/local state; produce nothing in the record)

Schedule meeting; add-to-calendar; join-meeting (opens the link); book instrument; upload file to workspace; annotate PDF; edit notes; arrange/filter/pin the graph; add deadline; start onboarding tour; delete any of the above. A test-backed invariant: none of these touch the transitions directory.

47.1.18 4.3 Bridge actions (deliberate, visible promotion of workspace material into the record)

Cite-material (new transition whose `artefacts` includes the file's hash — usually a `connection` when attaching after the fact, per C3); cite-external (`doi:`/`arxiv:`/`url:`); attach-minutes (the meeting bridge); publish-dataset-version (release citing the hash); deposit (release + `deposit_recorded`). The bridge is always an act — there is no silent "sync folder to record".

47.1.19 5. Scenario walkthroughs (the daily-life checklist, each mapped)

1. **Lab meeting** — [A] schedule + details in local plane. During: notes in a workspace. After: attach-minutes bridge; each outcome its own transition, `trigger: discussion`, minutes hash shared ⇒ one meeting node, many edges; `contributions` per act. Nothing recorded ⇒ calendar entry only (C1). Attendance never recorded.
2. **Seminar** — same shape; external speaker without a key is not a performer: the lab member who took something from it performs (e.g. `connection`, relation `relates`/`extends`, `trigger: literature`) citing the abstract/slides.
3. **Reading group** — the paper (`doi:`) is the shared node. Per participant: `challenge` (relation `disputes`), `claim` (relation `agrees`/`supports`), `connection` (relation `usesMethodIn`) with `trigger: literature`; disagreements between members stay as sibling transitions with `disposition: contested` or `unresolved` — no combining (C5).
4. **Experiment + runs** — design: `decision`, target `method`, citing the protocol/SOP hash. Each run's outputs land in workspace (recording nothing — C1 protects against run-logging bureaucracy). A run that shifted understanding: `claim`/`challenge`/`verification`, `trigger: experiment`, citing run log + data hashes, parent = the specific hypothesis state (C4). Anomaly: `challenge`, `disposition: unresolved` — and it may lawfully stay unresolved forever. Deviation from protocol: charter-extended `target` (lab charter adds deviation types — explicitly anticipated).
5. **Datasets** — see §1.3; cross-trajectory reuse: `connection`, relation `usesDataFrom` (cito:usesDataFrom), which also makes the source transition a parent. Publication: `release` + `deposit_recorded`, DOI bound via `binding_recorded`.
6. **Code** — repo is workspace. A result depends on code: the transition cites the exact archive hash (`usesMethodIn` for someone else's code). Release: `release`, target `artefact`. CI, branches, issues: all [A].
7. **Instruments** — registry, booking, maintenance log: [A] local plane (booking is also presence-adjacent — never exported). Calibration file: artefact cited by the runs that depended on it. Restricted access: **rivalry** ground — the restriction covers access, never the trajectory (its stated residue).
8. **Field observations** — `trigger: observation`; field notes/media by hash; consent forms are artefacts cited by the `decision` to collect; personal data in content: redaction ground `personal_data` removes bytes, skeleton+signatures survive (C8). Works offline in the field (C9) — record at camp, register on return (C2 allows registrar later than performer).
9. **Peer review received** — reviewer with a key (best): they perform `challenge`, relation `disputes`, `trigger: objection`, we register (C2). Reviewer anonymous/external: we perform transitions responding, `trigger: objection`, citing the review report hash; response letter = `transformation` + `repliesTo`. Point conceded: `disposition: accepted` on our replying transition; point stood-beside: `unresolved` — the mandatory honesty case.
10. **Revision cycles** — each draft a hash; each revision a `transformation`, target `artefact`, relation `modifies` (cito:updates), parent = the previous draft's transition (C4). Camera-ready: `release`. The revision chain is the trajectory itself — no separate "version history" mechanism.

11. **Failed directions** — `decision`, target `path`, `trigger: failure`, relation `retracts` or `replaces` on the specific abandoned state; content says why. The branch stays in the DAG forever (C3) — presentation may render "closed path" leaves dimmed, never deleted, never scored.
12. **Conference deadlines** — [A] local calendar (commitment, legitimate). Submission: `release` citing the submitted PDF hash; acceptance letter an artefact; camera-ready another `release`. No countdown-pressure analytics beyond the plain date.
13. **External collaborations** — outsider gets a key ⇒ ordinary performer; `trigger: entering_party` on their first transitions with `absorption` filled. They may take the whole record and continue elsewhere without permission (C10); divergence is `fork_declared`, not a fight over the canonical copy. Disputed credit: `attribution_contested` — an operation, not an edit (C3). IP-constrained collaboration: **appropriability** ground; residue (existence, questions, decisions, negative results) stays visible.
14. **Student joining mid-project** — [A]: onboarding tour over the DAG (guided path through prior states — the graph *is* the onboarding document). [P]: their first acts carry `trigger: entering_party` + `absorption` referencing the specific states absorbed (C4 — never "joined the project"); their key registered; they attest others' acts immediately (C2 gives newcomers a real role from day one). Their naive `question` transitions are first-class — a newcomer's question is an origin state, not noise.
15. **Preregistration** — `release` of the hypothesis state before the experiment; later `verification/challenge` transitions parent it. **Vulnerability** ground with `release_at` for embargoed prereg; shorten-only.
16. **Grants / ethics / admin** — letters are artefacts cited by `decision` acts; `credit:FundingAcquisition` types the part; renewal dates are [A] calendar commitments. Grant reporting **must not** become a metrics surface: export for a funder is a bundle plus prose, never a dashboard (C6).

47.1.20 6. Refused, with nearest lawful alternatives

Wanted in labs everywhere	Why refused	Nearest lawful
Person node / member page / profile graph	person-centric graph → C6, monitoring	CRediT contributions inside each act; filter view by performer is at most a transient [A] query, never a stored or exported view
Project node, project status	C4: nothing attaches to a project as a whole	the trajectory's question node is the anchor; chronology within one project is permitted, uncompared
Attendance, attendee list, RSVP tracking	settled: never recorded, even locally	meeting logistics without people; presence is inferred by no one
Activity heatmap, streaks, per-person timeline, leaderboard, h-anything	C6 verbatim	calendar of commitments; within-one-trajectory counts shown without comparison
Merge of divergent branches	C5; the word never appears	a new transition citing both states as parents *as a claim about their relation* (`connection`) — divergence remains visible
Edit/annotate a past transition "to fix it"	C3	new transition, relation `replaces`/`retracts`
Mark-answered / close-question button	dispositions closed; fabricated closure	a new `decision` or `verification` with `disposition: accepted`; or it stays `unresolved`, which is the point
Meeting/experiment as new record types	closed act vocabulary; portability	occasion pattern (trigger + shared artefact + contributions)
Auto-record every run / every commit	C1 byproduct-only; recording cost kills adoption	workspace holds everything; bridge actions promote deliberately
Progress %, importance stars, priority ranks	C6 scalars	disposition + prose in state content

Wanted in labs everywhere	Why refused	Nearest lawful
Unpublish / retract-from-view	C7 widen-only	`retracts` relation (the retraction is public); redaction removes bytes only, with a stated ground
AI agent authoring or registering transitions	performer/registrar are keyed parties	`trigger: ai_suggestion` marks provenance; a person performs

---

47.1.21 7. Priorities from this lens

The occasion pattern (minutes-hash + trigger + contributions) covers meetings, seminars, reading groups, runs, and field sessions with **zero new protocol surface** — invest in making the bridge actions (attach-minutes, cite-material) one gesture each, because C1 means anything slower simply won't be recorded. Second: reviewer keys and `entering_party` onboarding, since peer review and mid-project joins are where the record either earns trust (attested challenges, honest `unresolved`) or gets bypassed. Everything a forge would ship as a dashboard is either the [A] commitments calendar or refused.

48 implementation plan

Original source: `applicative_infrastructure/gr_academia_application/plans/implementation-plan.md`.
Original source SHA-256: `b4435a4fa139ddb703ff7dc3086046f6de4af84d94b55c6a29f5a985e5aa611c`.

48.1 GRRP — implementation plan

Single plan for the reference implementation of the **Generative Relational Research Protocol v0.1**. Supersedes `implementation_plan.md` and `GRRP-implementation-plan.md`, both retired.

Authority. The specification governs where this document and the papers differ: *Specifying the GRRP*. This plan restates only what a builder needs, and cites the requirement behind each item so a disputed choice can be traced.

Where the work is. `grrp/` ·notes: Paper I ·II ·III ·IV ·glossary

---

48.1.1 Status

Milestone		
M0 Skeleton — layout, canonical hashing, `init`	[check] done	1–2 days
M1 Personal tier — **ship here**	[check] done	1 week
M1 usability pass — editor prompts, defaulted references, `show`	[check] done	1 day
Gate Use it on real work for two weeks	[unchecked] **deferred by decision**	2 weeks
M2 Integrity — full act vocabulary, chain verification, redaction	[check] done	3–4 days
M3a Group tier — keys, signatures, attestation	[check] done	3 days
M3b Attribution and absorption	[check] done	2 days
M3c Disclosure classes, grounds, monotone release	[check] done	3 days
M4 Open tier — bundle, continue, profile, deposit, seal	[check] done	1 week
UI A local page — Level 3, outside conformance	[check] done	1 day
M5 Conformance suite	[unchecked]	3–4 days

175 tests pass; 1 is skipped, and it is platform-specific. A walkthrough of the whole thing is at `grrp/examples/walkthrough.sh`; writing it found two bugs in `bundle` that argument had not, and running it on another platform found a third, worse one: **records written on Windows did not verify anywhere**, because `Path.write_text` translates newlines and the identifier is the hash of the bytes. **All eight acceptance tests pass.**

48.1.2 0. The constraint register

Never violated. Where a decision touches one, it is recorded in notes/gaps-and-repo-actions.md §F rather than settled quietly.

	Constraint	Consequence for the code	Requirement
C1	**Byproduct only**	Every command serves a purpose the user has anyway. Its `--help` names that purpose. A command whose only purpose is that a record should exist is not written.	R1 ·P-IV Req. 4.2, 20.6
C2	**Attested registration**	At group tier and above the registrar must differ from the performer. Refuse when the keys are identical.	R3 ·P-IV Req. 8.1–8.2
C3	**Append-only**	Nothing is edited or deleted. A correction is a further transition referencing the one corrected. Current state is derived on demand.	R5 ·P-IV Req. 4.4
C4	**Granularity**	A transition references a specific identified prior state. Project-, repository- or person-level records are rejected.	R4 ·P-IV Req. 4.5
C5	**No merge**	No operation combines two divergent states. The word appears nowhere in the interface.	R6 ·P-IV Req. 10.5
C6	**No scalars**	No count, score, ranking or index over participants or trajectories — not computed, stored, displayed or exported. Counts *within* one trajectory, shown without comparison, are permitted.	R10 ·P-IV Req. 8.5, 20.4
C7	**Monotone disclosure**	Disclosure may widen, never narrow. No `unpublish` exists. A schedule may be shortened, never extended.	R11 ·P-IV Req. 12.1, 12.4
C8	**Separability**	Content lives in files separate from the skeleton, referenced by hash. Removing content leaves the skeleton and its signature chain valid.	R12 ·P-IV Req. 13.2
C9	**Independence**	Works with no model, no network, no service. AI assistance is optional and additive.	R14 ·P-IV Req. 20.5
C10	**Portability**	Any participant obtains the complete record and continues it elsewhere without permission.	R7 ·P-IV Req. 16.4

	Constraint	Consequence for the code	Requirement
C11	**Plain durable formats**	The authoritative record is human-readable text. No database is the system of record; caches are reconstructible.	R13 ·P-IV Req. 17.1
C12	**Bind, do not reinvent**	Relations → CiTO, contributor roles → CRediT, provenance → PROV.	R2 ·P-IV Req. 7.1

48.1.3 M0 — Skeleton [check]

- ☒ Repository layout: `.grrp/` and `trajectories/<id>/{states,transitions,disclosure,releases}/`
- ☒ `profile.yaml` — protocol version, tier, hash, canonicalisation, party, bound vocabularies
- ☒ `.grrp/.gitignore` — `events/` and `keys/*.key`, so the event plane is never committed *(P-IV Req. 3.1)*
- ☒ Canonical serialisation — JSON, sorted keys, no insignificant whitespace, UTF-8
- ☒ Content hashing — `state:sha256:<hex>` over the exact bytes written *(P-IV Req. 5.2)*
- ☒ Transition identifier over the **covered payload and parent identifiers**, excluding `registration` and `disclosure` *(P-IV Req. 8.3 — the named most-likely serious bug)*
- ☒ `grrp init` — profile, keypair, layout
- ☒ **Test:** two runs over the same payload produce the same identifier
- ☒ **Test:** altering a covered field, or a parent, changes the identifier
- ☒ **Test:** adding `registration` or `disclosure` does **not** change the identifier

---

48.1.4 M1 — Personal tier [check] ·*ship here*

The tier that has to be worth using by one person, alone, on the first day. It delivers **utility and no evidential weight**, and the two must never be confused. *(R15 ·P-II Req. 11.4 ·P-IV Req. 20.2)*

48.1.5 Acts

- ☒ `grrp new "<question>"` — open a trajectory; the question anchors the first claim *(C4)*
- ☒ `grrp claim` — state a position
- ☒ `grrp challenge <state>` — object to an identified state; **does not alter it** *(P-IV §6.2)*
- ☒ `grrp transform <state> [--answering <tx>]` — produce the successor
- ☒ `grrp decide <state> [--abandon]` — record a decision **with its reason** *(the demanding act)*
- ☒ `grrp release <state>` — publish, enumerating the objections standing *(P-IV Req. 12.6)*

48.1.6 Record and views

- ☒ Append-only writer; refuses to rewrite a recorded transition *(C3)*
- ☒ Five-dimension factored type: `act × target × relation × trigger × disposition` *(P-IV Req. 6.1)*
- ☒ `disposition` fixed at exactly three values, `unresolved` among them *(P-IV Req. 6.3)*
- ☒ `grrp state` — live positions, derived; **no branch marked principal** *(P-IV Req. 10.3)*
- ☒ `grrp log` — parents before children; **graph order, not clock order** *(P-IV Req. 10.1)*
- ☒ `grrp open` — the register of unresolved states: **the entry path** *(P-IV Req. 6.5)*
- ☒ `grrp export <release>` — citable document with lineage, contributors, standing objections *(R16 ·P-IV Req. 12.7)*
- ☒ `grrp check` — identifier recomputation, acyclicity, vocabulary, granularity, scalar exclusion
- ☒ `grrp profile` — what another implementation needs to read the record
- ☒ Every transition marked **unattested**, on every display and every export *(P-IV Req. 20.3)*
- ☒ Commit to git automatically when inside a work tree — **only the paths grrp wrote**

48.1.7 Tests

- ☒ The philosophy case: claim → objection → transformation answering it → an objection that is never resolved → divergence → release enumerating it *(P-IV Case 22.3)*
- ☒ The mathematics case: claim → `decide --abandon` with the reason; the direction is retired and the reason kept *(P-IV Case 22.1)*
- ☒ A challenge does not supersede the state it challenges
- ☒ Divergence preserves both directions and designates neither
- ☒ Every command's `--help` contains `Purpose (for you):` *(C1)*

48.1.8 M1 usability pass [check]

Not features — the difference between a tool that gets used on a Tuesday and one that does not. The byproduct principle is a claim about *cost to the participant*, so friction on the acts is a conformance concern and not a matter of polish *(C1 ·P-II Claim 11.1)*.

- ☒ **Omitting `-m` opens `$GRRP_EDITOR` / `$EDITOR`**, with a prompt for the act being performed. Writing a paragraph inside shell quotes is friction, and it falls hardest on the **decision** act — the one whose purpose for the performer is weakest and on which reuse depends entirely
- ☒ The prompt sits below a cut line and is never recorded; an empty message records nothing
- ☒ A 30-line editor launcher rather than a dependency — `typer` 0.27 no longer bundles `click`, and every command still accepts `-m` and `--file`, so an environment with no editor loses nothing
- ☒ **`challenge`, `transform`, `decide`, `release` default to the live position** — no copying a hash out of one command's output into the next. Still references a specific identified prior state *(C4)*
- ☒ A divergence **refuses and lists both positions with their text**, rather than picking — nothing in the design gives a basis for picking *(P-IV Req. 10.3)*
- ☒ **`grrp show`** — one screen per trajectory: question, live positions, what is unanswered, what has been released. Derived; per-trajectory; nothing compared across trajectories or people; no number summarising how it is going *(C6)*
- ☒ Refusals reach the user as guidance on stderr, naming the constraint and what to do instead
- ☒ `new` points at the next act

48.1.9 Gate — use it, before writing another line [unchecked]

The point of M1 is to find out whether the tool is worth using at all. M2 onward invites architecture the early tiers do not need.

- ☐ Use `grrp` on real work for two weeks
- ☐ Record what was annoying — **those notes are the input to M2 and beyond, and they belong in a trajectory**
- ☐ Check the two signals the papers name as diagnostic:
  - ☐ Is the **`decision` act rare while transformations are common**? That would mean the act on which reuse depends is not being performed, and making it cheap was insufficient *(P-IV §24.4, finding 2)*
  - ☐ Did anything want to be a score, a ranking or a dashboard? Record what, and refuse it *(C6)*

48.1.10 M2 — Integrity [check]

- ☒ Complete the act vocabulary — `grrp connect <state> --to <ref>` and `grrp verify <state>` *(the eight acts, P-IV Def. 6.2)*

  - ☒ External references carry a persistent identifier and **its scheme**, plus **the date the reference was made** — a reference to something since changed is uninterpretable without it *(P-IV Req. 5.5)*
  - ☒ A connection to another **state** needs no new field: the transition that produced it becomes a parent, so the link is in the graph and travels with the record
  - ☒ A **failed** verification is recorded `unresolved`, so it stands on the open register until something answers it — which is also where a stranger could take it up
  - ☒ Neither connection nor verification supersedes the state it concerns
- ☒ `grrp check` verifies the **whole chain**, not each record in isolation
  - ☒ An altered early transition invalidates every descendant (parents are inside the payload)
  - ☒ Content missing **without a recorded redaction** is a failure, not an absence
- ☒ Administrative operations: same envelope, **mandatory `kind`**, `act`/`target`/`relation`/ `disposition` **absent**, an `operation` field in their place; never presented as transitions *(P-IV Req. 4.6)*
- ☒ `grrp redact <state> --ground <g>`
  - ☒ Removes content; the skeleton stays valid and verifiable *(C8)*
  - ☒ Recorded as an operation with performer, time and **ground covered by the identifier**, so a ground that could be altered afterwards would be no ground at all *(P-IV Req. 13.4)*
  - ☒ **The graph is unchanged** — parent links, state references and the induced ordering survive *(P-IV Req. 13.5)*
  - ☒ The redaction record is not removable; redacted content is **never represented as never having existed** — `show`, `log` and `export` all say so, with the ground
  - ☒ Confirmation before removal, and a plain statement that **earlier git commits still contain the text** and that a copy already obtained by another party is beyond reach of both

48.1.11 Decided in the course of M2 — flagged, not settled quietly

- **Content stays inside the versioned tree.** The specification prefers content held outside it (§21.5, weakness 3), because git history is immutable and a redaction cannot reach a prior commit. Moving it out would mean a `git clone` no longer carries the record, and portability would then depend on `grrp bundle`, which does not exist until M4. So content is versioned, `redact` removes it from the working tree, and the tool **says plainly what it has and has not achieved**. *Revisit at M4, when bundle can carry content.* **Touches C8, C10.**
- **Redaction grounds are a local vocabulary** (`erasure_request`, `consent_withdrawn`, `personal_data`, `hazard`, `legal_order`). No deployed vocabulary covers *why content was removed*, and this is deliberately separate from the four closed grounds of **restriction**, which concern disclosure rather than removal. A charter may replace it. **Touches C12.**
- **The per-record secret is still not decided** — see Open decisions. It has to be settled before any short redactable content is hashed, because it changes identifier construction.
  - ☐ Decide it.

48.1.12 M3 — Group tier [unchecked]

Where credibility begins. **Minimum viable adopting unit: two parties who register each other's transitions** *(P-II Claim 13.4)*.

48.1.13 Identity and signatures [check]

- ☒ `grrp key add <name> <pubkey>` — known parties in `.grrp/keys/`; `grrp key mine` prints what to hand to a colleague; adding a second party's key **moves the record to the group tier**
- ☒ Detached ed25519 signatures over `{id, registrar, time}` — **never over `disclosure` or any field a later lawful operation may change** *(P-IV Req. 8.3)*

- ☒ **Pseudonymous participation** — nothing anywhere requires a legal name, telephone number, affiliation or government identifier *(P-IV Req. 14.3)*
- ☐ Passphrase on the private key *(still deferred; a signature is what it protects)*
- ☐ Optional **bindings** to external identifiers: recorded as operations, visible wherever the party is shown, attributed, revocable *(P-IV Req. 14.4–14.5)*
- ☐ Assurance **by class and by act kind, never as an entrance gate** — gating a stranger's challenge to a publicly disclosed claim reproduces the bootstrap failure *(P-IV Req. 14.6)*
- ☐ Key rotation by an operation **signed with the old key**; loss via a charter procedure that is **marked as weaker than a signature** *(P-IV Req. 14.7)*
- ☐ Compromise = revocation with a date; prior registrations stay, marked

48.1.14 Attestation [check]

- ☒ At the group tier **an act is a proposal**, not a log entry — a party cannot register their own act, so what they perform waits for someone else. Proposals live outside `transitions/`, so registering never edits a file under it *(C2, C3)*
- ☒ `grrp pending` — what waits on you, and what of yours waits on someone else
- ☒ `grrp register <tx>` — **refuses when performer and registrar are identical**, naming the constraint and what to do instead *(C2 ·acceptance test 7)*
- ☒ Registration is **outside the identifier**, so registering a proposal does not change the thing its children point at
- ☒ `grrp check` verifies the signature, and catches a record marked attested whose registrar is its own performer
- ☒ `grrp withdraw <tx>` — a further **challenge** that retracts, naming the registration among its parents. Nothing is deleted; a reader sees both *(P-IV Req. 8.7)*. **A withdrawal is itself an act, so at the group tier it too must be registered by another party** — the rule does not bend for the party undoing something
- ☒ **No aggregate over attestations** — not counts, depths, ratios or derived scores *(C6)*
- ☐ A standing arrangement (a supervisor routinely registering a student's transitions) **recorded, not forbidden** *(P-IV Req. 8.2)*

Decided: `GRRP_KEY` selects which local key acts, for a machine two parties share and for the tests, which need a second party to exercise registration at all. One key is the ordinary case.

48.1.15 Attribution and absorption [check]

- ☒ `--contributor name=Role` on every act — CRediT identifiers stored, **never display labels**, because a record holding the word "Methodology" is uninterpretable once a second vocabulary uses it differently *(C12 ·P-IV Req. 7.3)*
- ☒ `--from <state>` on every act — the link records the state, **the party who produced it** (looked up from the record, so nobody types a key), and the transition that took the content *(P-IV Req. 9.3)*
- ☒ `grrp attribute <proposal>` — adds contributors or absorption **to a proposal**, before anyone has registered it. A recorded transition is never edited, and attempting it **refuses with C3 and points at `grrp contest`** *(C3)*
- ☒ Absorption links **presented alongside the transition wherever it is displayed** (`export`)
- ☒ **No veto.** No `approve`, `deny`, `block`, `veto`, `permit` or `consent` anywhere in the command surface, and a test that keeps it that way. A party who does not want their state absorbed has **one instrument: its disclosure class** *(P-IV Req. 9.4)*
- ☒ `grrp contest <tx>` — a challenge that **disputes** (`cito:disputes`), naming the transition among its parents. Nothing deleted or altered; **no party is empowered to resolve it** *(P-IV Req. 9.5)*
- ☒ **No measure of the influence of an absorbed state** *(C6)*
- ☒ `grrp transform --with <state>` — a **synthesis**: a state its performer composed from what several branches reached. It does **not** close them, and nothing is combined by rule *(P-IV Def. 10.4, Req. 10.5)*

Found and fixed in the course of it: the release record stored an `attested` flag captured when the release was still a proposal, so an exported document went on saying "unattested"

after the release had been registered. Now derived at export time from the log — the stored-derived-value mistake, in miniature *(P-IV Req. 4.4, 5.3)*.

48.1.16 Disclosure [check]

- ☒ `grrp disclose <tx> --class <c> --ground <g> [--release-at <date>]`
- ☒ `grrp charter adopt --classes a,b,c` — classes exist, are **ordered by inclusion** (narrowest first), are enforced, and are **opaque to the protocol**. **No model charter and no default set**: a specification supplying one would be a specification of governance *(P-IV §18.5)*. Without a charter there is nothing to disclose at, and the tool says so
- ☒ `grrp charter adopt` again bumps the version; amendments are **prospective only** *(Req. 18.4)*
- ☒ **Four grounds, closed set.** A value outside it is refused, naming the four *(P-III Req. 2.5)*
- ☒ **Reject a restriction that declares no ground**, and display the ground wherever it is shown *(Req. 11.3)*
- ☒ **Surface the residue.** Declaring a ground prints what it leaves disclosable **and the named failure it becomes if misapplied**. `grrp grounds` prints the whole typology *(P-III Req. 2.6 — the only part of the design that gains without giving something up)*
- ☒ **Composition = intersection of residues**, and the tool says declaring more grounds is not free, since each is an assertion a reader may find false *(P-III Req. 7.2)*
- ☒ **Monotone enforcement** *(C7)*
  - ☒ Narrowing is refused, naming C7 and why a withdrawal cannot be effected
  - ☒ No `unpublish`, `unrelease`, `hide`, `conceal` or `restrict` command exists
  - ☒ A schedule **fires without a further act by any party** — derived from the log and the clock, so there is nothing to fire and nothing that can be forgotten *(Req. 12.4)*
  - ☒ A schedule may be **shortened**; **extending or cancelling is refused and the attempt recorded** as an operation, because a charter may in some circumstances allow it and it should be visible that it was made
  - ☒ `--release-at` **only with** `vulnerability` — the only ground with a terminus. Rivalry and appropriability end unobservably from here, and **hazard does not end** *(P-III Claim 7.4)*
- ☒ **Per record**, never per repository or trajectory: records in one trajectory carry different classes *(Req. 11.5)*
- ☒ Charter identifier **and version** recorded on every disclosure *(Req. 18.3)*
- ☒ `grrp show` surfaces what is restricted, on what ground, and when it widens

48.1.17 Decided in the course of M3c — flagged, not settled quietly

- **An undisclosed record is not a restriction without a ground.** Req. 12.2 fixes a restrictive default and Req. 11.3 demands a ground for anything below the widest class; read together they would demand a ground for every record ever made. The reading taken: a record with no disclosure operation is **not yet published**, which is a different thing from **withheld**. The ground requirement bites when a restriction is imposed. **Touches C7.**
- **Redaction grounds and grounds of restriction are separate vocabularies**, as flagged at M2 — one concerns removal, the other disclosure. `grrp grounds` prints only the four.
- **Operations carry** `subject` **and** `payload` rather than a field per operation type. Both are covered by the identifier, so a declared ground that could be altered afterwards would be no ground at all. Redaction was migrated to the same envelope.
- **Disclosure operations chain**, each taking the previous as a parent. Ordering by recorded time does not work: two changes made in the same second have no path between them, and the tie would be broken by identifier, which is arbitrary. *(Found by a failing test, not by argument.)*

☐ **Test 5:** changing a class, or a schedule firing, invalidates no signature

☐ **Test 7:** `grrp register` refuses when performer and registrar keys are identical

---

48.1.18 M4 — Open tier [check]

- ☒ `grrp bundle [<traj>] -o traj.zip` — transitions, skeletons, signatures, attributions, absorption links, parent structure, profile, charter and public keys — **obtainable without anyone's permission** *(C10)*
- ☒ `grrp continue traj.zip` — appended transitions reference the obtained ones as parents, so the result is **one graph and not two** *(Req. 16.4 ·acceptance test 8)*
- ☒ Restricted content travels **only where it can be honoured**. The default is to withhold, and the manifest **names what was withheld** — a reader is entitled to know a record travelled without part of its content
- ☒ `grrp profile --json` — the machine-readable declaration: protocol version, tier, hash, canonicalisation, **covered and excluded fields**, signature scheme and signing input, bound vocabularies with versions, custody and succession *(Req. 16.3)*
- ☒ A receiving implementation **records the declaration under which records arrived**
- ☒ Received records: **copied byte for byte**, never parsed and re-serialised. The prohibition on alteration extends to normalisation, which would invalidate signatures *(Req. 16.5)*
- ☒ Failure cases *(Req. 16.5)*
  - ☒ **Version mismatch** — retained unprocessed, and said so. A record created under one version asserts what that version's fields meant
  - ☒ **Unverifiable signature** — retained and marked, never discarded
  - ☒ **Partial records** — missing parents named; **nothing synthesised to fill the gaps**
  - ☒ **Divergent continuation** — a divergence. Both retained, neither principal, no reconciliation
- ☒ `grrp deposit <release> -o <dir>` — the citable document, its release record, the declaration and the continuable record. **Released material only**: depositing sealed or restricted content with a third party would place it outside the regime governing it *(Req. 17.5)*
- ☒ `grrp deposit <release> --identifier doi:⋯` — records the identifier an archive issued
- ☒ `grrp custody add` / `custody succession` — **durability is not claimed without a published succession arrangement**, and a record held by one party is named as not surviving that party *(Req. 17.4, 17.6)*
- ☒ Sealed registration *(§15)*
  - ☒ `grrp seal` — content-derived identifier, party and time recorded; **content disclosed to nobody**, held in a gitignored local store
  - ☒ `grrp openseal` — verifies the content yields the identifier registered earlier
  - ☒ **Never described as establishing priority**; the tool says plainly that an unanchored time is the registrant's own assertion, and that a sealed state **generates nothing** *(Req. 15.7)*
- ☐ Resolvable identifiers at state granularity — **still open**, and expensive. Content-derived identifiers are stable and are not resolvable by a party holding no copy *(§24.2)*
- ☐ Redaction notices forwarded to implementations records were propagated to *(Req. 13.6)*

48.1.19 Decided in the course of M4 — flagged, not settled quietly

- **Content still lives inside the versioned tree**, as flagged at M2. Now that `bundle` exists it could move out, and the trade is real: out-of-tree content makes redaction reach further, and makes `git clone` alone stop being the record. **Not taken unilaterally.**
- **A gap the record explains is not tampering.** `check` fails on content missing with nothing to account for it, and notes it where a redaction was recorded, the state is sealed, or the manifest says the sender withheld it. An earlier attempt downgraded all four to a note and lost a real guarantee; a failing M2 test caught it.
- **`deposit_recorded` was added to the operations vocabulary.** The specification's list is illustrative rather than closed, and Req. 17.5 requires the deposit identifier to be recorded in the trajectory. **Touches C12.**

48.1.20 M5 — Conformance suite [unchecked]

- ☐ Automated tests for **C1–C12**, each naming the constraint it enforces

- ☐ The three conformance tests as executable checks inside `grrp check` *(P-IV Req. 20.4–20.6)*
  - ☐ **Scalar test** — fails on any total order or numeric measure over participants or trajectories. Within-trajectory counts shown without comparison pass
  - ☐ **Independence test** — the record can be created, registered, read, verified, exported and continued **with a text editor and a version-control system**
  - ☐ **Byproduct test** — every required act has a purpose *for the party performing it*, stated in the documentation
- ☐ `grrp check --self-declare` emits the conformance declaration *(P-IV Req. 20.7)*
- ☐ Container run with **no network and no model**: create, register, verify, export, bundle, continue
- ☐ Field documentation published **outside the implementation**: vocabularies with versions, identifier construction, signature construction *(P-IV Req. 17.2)*
- ☐ Attack cases from P-IV §23 exercised: collusive fabrication, retroactive alteration, backdating, flooding, registrar gatekeeping, misapplied grounds, disclosure by inference, reflexive confirmation

---

48.1.21 Level 3 — applications, outside conformance

The protocol is implementable with none of it, and requires none of it *(C9 ·R14)*. Anything here is optional, additive, and clearly marked as outside conformance.

> The applicative graph model — node kinds, edge kinds, components, actions — is specified in spec-graph-model.md (v1 kernel; extension machinery deferred), with the design-pass records in design-pass-graph-model/. Its build order: recording acts from the page → attestation → the four-component panel → the meeting flow → disclosure/redaction UI → import/fork surfaces.

- ☒ **`grrp ui`** — a local page for starting records, recording acts, and seeing the trajectory drawn. Stdlib only, loopback only, no account, nothing leaves the machine, a per-run token on every form. It shows the question, the live positions, the open register, what is proposed, what is restricted **with its residue beside it**, and the lineage — and it declares itself Level 3 on every page
  - ☒ Tested for what the design forbids, because a screen is where the temptation is strongest and where a reader would most readily believe a number: no quantity over participants or trajectories, no branch marked principal, **the word merge appears nowhere**, no control that narrows disclosure, no approve or veto
  - ☒ A test asserts **no module of the record imports it**, so the claim that the protocol is implementable without it is checked rather than asserted
  - ☒ **Starts records**: a directory, a git repository inside it if wanted, a keypair, and the opening question — so the first thing anyone meets is not a terminal
  - ☒ **Draws the trajectory** as a DAG in inline SVG, no libraries: one column per step from the question, edges labelled by the act that made them, **divergent branches drawn identically**
  - ☒ Records every act, registers a colleague's proposal, and releases
  - ☒ Record-writing logic extracted to `actions.py`, shared with the command line. A test asserts a record written from the page and one written from the terminal are **the same record** — otherwise the page is a second implementation rather than an application over the first
- ☐ Capture assistant proposing candidate transitions from the local event plane
  - ☐ A model may **occasion** a transition and may **not author or register one**; a model-originated proposal is **marked** *(P-IV Req. 4.3)*
  - ☐ Registration stays an **affirmative act** — a default that registers unattended proposals is forbidden, because the record's credibility rests on registration meaning something
- ☐ Visualisation of a trajectory graph — **no branch marked principal, no ordering exported**

- ☐ Retrieval over one's own record
- ☐ Import of git history / OSF projects / DOI-identified works as **artefact references and external references**, never as transitions *(C4)*

48.1.22 Excluded, and not by taste

	Why
progress reports, "project health", trajectory risk analysis	scalars over trajectories *(C6, R10)*
contribution scores, reputation, contributor ranking	scalars over participants *(C6)*
absorption counts, attestation depth	scalars, and **farmable by reciprocal registration** *(P-II Claim 8.4 ·P-IV Req. 8.5)*
similar-trajectory search, cross-field matching **as an adoption argument**	not decomposable by tier, returns nothing to any adopting party, and the matching problem is unsolved *(P-II Claim 13.5 ·P-I Claim 18.3)*
automatic classification of a user's work by a model without confirmation	*(C1, C9)*
any merge, auto-reconciliation, or canonical-branch selection	*(C5)*
a new identifier service	content hashes locally, repository DOIs on deposit
a web application, hosted service, or accounts	not in v0.1

48.1.23 Open decisions — needed from the maintainer [unchecked]

- ☒ **Licence — settled: MIT.** Discharges both dependent requirements: **the specification is forkable** *(P-IV Req. 19.4)*, so custodianship is a service rather than a position; and **a record is licensed to permit continuation elsewhere** *(P-I Req. 16.2, property 4)*, which is the property that distinguishes portability from export.
  - ☐ The four PDFs still carry an embedded **CC BY-NC 4.0** notice and remain under it until their author revises them. Regenerate the licence block if MIT is intended there too.
- ☐ **Per-record secret before hashing redactable content** *(M2 above)* — decided in advance or not at all, because it changes identifier construction.
- ☐ **Custodial separation.** Serendip Commons Society would maintain the specification and operate an implementation. Req. 19.4 requires the two functions separated, **or the conflict recorded with the arrangements limiting it.** Which, and where is it recorded?

48.1.24 Evaluation — what would show this was wrong

Not a retrospective. These are stated in advance so they can be looked for.

- ☐ **Personal-tier adoption without progression to the group tier**, over a substantial population and period → private utility without the attested records on which every evidential claim rests. The tool would have become **a note-taking convention** *(P-IV §24.4 ·P-II Claim 16.1 — the prediction the account is most exposed on)*
- ☐ `decision` **acts rare while transformations are common** → the act on which reuse depends is not being performed
- ☐ **Group-tier declarations alongside pairs who register only each other** → attestation operating as a formality
- ☐ **A widely used external score computed over conformant records** → the scalar exclusion displacing the dynamic rather than preventing it

And the difficulties the papers record as **unaddressed** — no mechanism with an identified cost-bearer for whom bearing it is rational. Nothing in this plan solves them: **assessment capacity** *(the one most likely to determine whether a conforming arrangement survives at scale)*, **maintainer labour**, **the regressive incidence of overhead**, and **recognition of attributed contribution** *(P-II §17.2)*.

48.1.25 Sequence

check M0, M1.
unchecked **Use it for two weeks on real work.** Write down what was annoying.
unchecked Those notes are the input to M2 and beyond — and they belong in a trajectory.
unchecked M2 → M3 → M4 → M5, in order. Do not start M3 before the group tier has a second party willing to register.

49 spec graph model

Original source: `applicative_infrastructure/gr_academia_application/plans/spec-graph-model.md`.
Original source SHA-256: `676b45a3d77c2de84d5fe725b430c4ba993d508efef481143664a5d119b13d85`.

49.1 The graph model: node kinds, edge kinds, components, actions

Specification, v1 — draft for discussion. Applicative-layer specification over GRRP v0.1. Builds on design-nodes-time-and-occasions.md; where they overlap, this document governs.

How it was produced: three independent design passes (research practice, component architecture, adversarial conformance), then three verification passes (constraint audit — 17 findings, completeness — 28 gaps, simplicity — 22 cuts). Every finding is either incorporated below or answered in §10. The synthesis leans deliberately toward the simplicity verdict: **v1 commits to a small kernel, and defers the extension machinery until a second real community exists.**

49.1.1 1. The model, affirmed

The requested reading — *each vertex is an event; relations are typed; both nodes and edges carry types, components, and actions* — is not a departure from the protocol. It **is** the protocol:

requested	in GRRP
an event	a **transition** — something happened to an understanding
an event's type	the five-dimension factored type: act × target × relation × trigger × disposition
a typed relation	a `parents` entry (structural) or a **connection transition** carrying a CiTO relation (semantic)
a relation with components	already true: a semantic relation *is* a transition, so it has content, artefacts, provenance — and a workspace

Two invariants govern everything below:

I1 — Kinds are lenses, not types. No kind adds a field to a transition, mints a record type, or changes what `grrp` writes. Delete every kind and the record is untouched. This is what makes the whole applicative layer safe to build, rebuild, and throw away.

I2 — `grrp` is the sole record-writer. Every record-writing action is a thin form over exactly one `grrp` invocation. The UI never constructs a transition skeleton, never computes an identifier, and surfaces `grrp`'s refusals verbatim. One implementation owns lawfulness. (Already the rule in `web/packages/server/src/records.ts`.)

49.1.2 2. Subjects — what can be selected

A **subject** is a thing that can be selected, carries components, and offers actions.

49.1.3 v1 subjects

subject	identity	exists when
transition (any of the 8 acts, connections included)	its id	recorded
material — held artefact	`state:sha256:⋯` over its bytes	**cited by at least one transition**
material — external work	`doi: arxiv: isbn: url:`	cited by at least one transition

A workspace file that nothing cites is not a subject and does not appear in the graph (C1, C4).

49.1.4 Deliberately not subjects

- **Structural edges** (`parents` entries, artefact citations). They are facts inside a signed payload, not claims — no identity, no components, no actions. *To contest a parent link, challenge the **child** transition: the link lives in its signed payload, and C4 hands you the specific state.* This paragraph exists so that edge identity is never added "just for commenting" — the request will come, and this is the answer.
- **States.** A state is reached through the transition that produced it. Pickers pick states; the panel opens the producing transition. One subject per event.
- **Persons, projects.** Refused outright — §8.

49.1.5 3. Node kinds

Three families, hardcoded in v1 (no plugin machinery — §9).

49.1.6 3.1 Transition kinds — the eight acts, as they read to a person

label shown	act underneath	disposition default
Question	`question`	unresolved — and it stays so; that is the design
Position	`claim`	accepted
Position, changed	`transformation`	accepted
Objection	`challenge`	unresolved / contested
Decision	`decision`	accepted
Connection	`connection`	accepted
Check	`verification`	accepted (or unresolved when it failed)
Release	`release`	accepted

Label discipline (C12): labels map 1:1 onto acts; the protocol term is always inspectable one gesture away (shown in the record panel); labels are never persisted into anything that travels. No ninth label may exist, because no ninth act exists.

49.1.7 3.2 Material kinds

- **Held artefact** — bytes in the project store or a workspace, identified by hash. The digest is always displayed: it is what a transition cites and what a reader elsewhere checks.
- **External work** — `doi:` / `arxiv:` / `isbn:` / `url:`. Renders **fully offline** (identifier + citing transitions); live metadata fetch is an optional enhancement cached under C11, never a dependency (C9). The same identifier cited from anywhere in the project is **one node** — this is how a paper read by the whole group appears once with many edges.

49.1.8 3.3 Occasion kinds — derived, never created

An **occasion** (meeting, experiment run, observation session, reading, failure…) is not a record type and not a creatable node. It is a *reading* of the graph:

> an artefact node whose citing transitions carry an occasion trigger (`discussion`, `experiment`, `observation`, `simulation`, `literature`, `failure`, or a charter-local trigger).

The trigger is the label: an artefact cited with `discussion` presents as a meeting-like occasion. Three rules, each of which closes a hole the review found:

1. **No create-occasion affordance exists.** An occasion with no transitions behind it is a calendar entry, not a node (C1). The button will be asked for; it does not get built.
2. **No roster, ever.** The occasion panel lists its *transitions*. It never unions their performers into a "participants" view — that would rebuild the attendance list from signed parts, and it is the single most likely quiet violation in this design.

3. **Occasion membership is the citation itself.** No time-window clustering, no inference: the shared artefact's citing edges *are* the gathering.

49.1.9 4. Edge kinds

49.1.10 4.1 Structural — facts

edge	read from	drawn
follows	`parents`, same trajectory	plain line
crosses	`parents`, another trajectory	distinct line — the structure the graph view exists to show
cites	`artefacts`	dashed line to the material node
absorbs	`absorption`	shown in the panel; drawn on demand
registered-by	`registration`	a badge on the node — **never aggregated per registrar** (C6)

No identity, no components, no actions (§2).

49.1.11 4.2 Connection — the reified semantic edge

One presentation covers **all** relations: the sixteen CiTO bindings and the three charter-locals (`generalises`, `specialises`, `transfers` — flagged as unbound, never presented as CiTO). Not nineteen kinds; one kind that renders its `relation` field.

- **Drawn as an edge** in the graph (its parent link to what it connects); **opened as a node** in the panel. One subject, two renderings.
- **Multi-parent connections are first-class.** A transition citing two divergent states as parents — saying in its content what it makes of the divergence — is the lawful neighbour of the refused combining operation (C5). It draws as a fan; it is still one subject.
- **This is where "edges have components" is true** — and only here. A connection has content, a workspace (the dossier of a disagreement lives *on the edge*), provenance, disclosure. Each component earned its place on this subject under the same twelve constraints as anywhere else; nothing is inherited "for free".

49.1.12 5. Components — exactly four

One per storage class. The class fixes where data lives, who writes it, and whether it travels — so "does it travel?" is answerable by grep.

component	class	lives at	written by	in a bundle?	in git?
Record panel	record-facet	signed YAML + state files	`grrp` only	**yes — it is the record**	yes
Disclosure panel	sidecar-facet	disclosure sidecar + operations	`grrp disclose` / `redact`	yes	yes
Workspace	workspace-facet	`nodes/t/<id>/` `·nodes/a/<hash>/`	any project party, via the app	**never**	yes
Calendar entry	local-plane	`.gra/calendar/`	the host app	**never**	**no — gitignored**

49.1.13 5.1 Record panel

The whole signed payload, read-only: act (with its presentation label *and* the protocol term), target, relation (with its CiTO binding, or flagged `local:`), trigger, disposition, performer, contributions (CRediT), absorption, **the state content rendered as markdown**, artefact citations with digests, attestation status, and the identifier in full.

- **Two timestamps.** Registration may lawfully be later than performance (offline field work; C2 applies at registration, not at recording). Chronology orders by `performed`; the panel shows both times whenever they differ materially. This is the honesty surface for offline recording.
- **Counts live here and only here.** The C6 carve-out (counts within one trajectory, uncompared) renders exclusively in the *selected* subject's panel — "this question has 4 objections, 2 unanswered" — never as decorations across the canvas. Badges on many nodes at once are comparison by juxtaposition.

49.1.14 5.2 Disclosure panel

Class, ground (with its object and residue), `release_at` (shorten-only — and a refused extension shows here **as a recorded fact, not an error**), plus the operations history touching this subject: disclosure changes, redaction notices (with ground), contested attributions. **Operations render as panel facts, never as graph nodes.**

49.1.15 5.3 Workspace

The one **universal** component: every transition subject and every material subject carries one — which, by reification, means every semantic edge carries one (the requirement that edges have storage, satisfied structurally). Folders allowed; the path guard already refuses escape.

The workspace is project-shared scratch, not private. It travels with a git clone (though never in a bundle), and every project party can read it. Anything private — personal notes, drafts not for colleagues, pins — belongs in the **local plane**, which never leaves the machine. The review found the drafts quietly contradicting each other here; this paragraph is the ruling.

Deleting workspace content costs nothing and records nothing — test-enforced: *every applicative action leaves* `transitions/` *byte-identical* (the existing upload test, generalised).

49.1.16 5.4 Calendar entry

When / where / link. **The schema contains no people fields** — not attendees, not organiser, not RSVP. Attached to occasion subjects where one exists; **future occasions are free-standing entries** in `.gra/calendar/`, attached to nothing (the meeting node cannot exist before its minutes are cited — the review caught that a subject-bound schedule would pressure someone into building a create-meeting-node path).

Legitimate calendar content: scheduled occasions, `release_at` commitments, embargo expiries, deadlines *of the calendar's owner*. Never: anyone's activity, anyone's presence, a deadline attached to a question or an objection ("resolve by Friday" — the vocabulary keeps `unresolved` precisely so closure is never owed on a date).

49.1.17 6. Actions — exactly two classes

The review considered and rejected two more (a separate "bridge" class, and a declarative precondition vocabulary). Both rejections are load-bearing:

- **Citing material is a parameter, not an action.** A free-standing "cite this file" button would produce a transition that exists so that a record exists (C1). Instead, every recording form carries an **artefact picker** — material is cited from *within* a real act with real content. That picker is the entire bridge between the layers, and crossing it is always deliberate.

- **No precondition layer beside `grrp`.** A declarative lawfulness vocabulary drifts from the implementation, and both candidates the drafts proposed encoded violations: an "open question" test would quietly mint the fourth disposition the protocol refuses, and a registrar-differs gate at recording time would block lawful offline work (C2 constrains *registration*, which may come later). The UI checks exactly one thing — a parent state is selected where the act needs one (C4) — and everything else is `grrp`'s refusal, shown verbatim.

49.1.18 6.1 Record-writing actions (through `grrp`; exactly one invocation each)

Acts — each a form: content (required, markdown) ·parent/subject picker (C4; defaults to the live position when unambiguous; `grrp` refuses ambiguity and the refusal is shown) ·artefact picker (optional; workspace files by digest, external ids by scheme) ·vocabulary pickers constrained to the bound sets, charter-locals flagged ·contributions (optional; CRediT role per named party — unilateral, and contestable by that party through `attribution_contested`, which is the protocol's own consent mechanism).

action	act	notes
Ask	`question`	opens a trajectory; the origin state
Take a position	`claim`	
Change a position	`transformation`	parent = the position changed
Object	`challenge`	disposition `unresolved` is the honest default
Decide	`decision`	including abandoning a path (`trigger: failure`)
Check	`verification`	outcome in content; a failed check stays `unresolved`
Connect	`connection`	relation required, from the bound set; cross-trajectory target makes that transition a parent
Release	`release`	disclosure act about specific states and artefacts — never a project-status marker

Operations — same class, same discipline (one `grrp` invocation, refusal verbatim):

action	operation	notes
Register a colleague's act	registration	completes an existing unattested transition. Refused when the keys are identical (C2). **Attestation is witnessing, not approval** — it asserts that an identified party registered an act at a time, and nothing about the content. Endorsement-as-record is an `agrees`/`supports` connection under the endorser's own key.
Widen disclosure	`disclosure_changed`	ground with object + residue; `release_at` shorten-only
Redact content	`redaction`	ground from the redaction vocabulary; bytes go, skeleton and signatures stay (C8)
Continue a bundle	import	unknown *act* → `grrp` rejects (closed vocabulary); unknown `local:` values → retained and flagged; same id with different bytes → refused loudly; dangling parents → rendered as "not held here" stubs

action	operation	notes
Declare a fork	`fork_declared`	C10 made first-class, not an edge case
Contest an attribution	`attribution_contested`	the dispute path for contributions
Record a binding / deposit	`binding_recorded` / `deposit_recorded`	DOI and archive identifiers, shown in the record panel

Global actions (no subject yet exists): create a project, open a question, import a bundle, generate/register a key. These live on the project shell, not on kinds — most are already built.

49.1.19 6.2 Applicative actions (record nothing — test-enforced)

Workspace file operations ·calendar add/edit ·**the join launcher** — a hyperlink stored in the calendar entry that opens `{link}` and *writes nothing anywhere*; the moment joining leaves a trace it is presence logging ·private local-plane pins and bookmarks (invisible to every other party, uncounted) ·search (filters; any transient match ordering is never displayed as a number, never persisted, never applied to performers) ·bundle export (reads the record, writes a file; C10 is owed, so friction here is a bug).

49.1.20 6.3 Where refusals surface

1. **Never offered** — the constitutive refusals of §8 have no UI surface at all.
2. **Disabled with the reason shown** — the one UI precondition (no parent selected).
3. **Refused by `grrp`** — stderr verbatim; nothing written.
4. **Refused and recorded** — where the protocol itself records refusals (a refused schedule extension), shown as a fact of the record, not as an error.

49.1.21 7. The meeting, end to end

The motivating example, run through the whole model:

Before. A free-standing calendar entry in `.gra/calendar/` — when, where, link. Agenda drafted wherever its author likes (a workspace, the local plane). *Add to calendar* and *Join* are applicative; join opens the link and writes nothing. There is no attendee field to fill in, because the schema has none. Nothing has been recorded (C1).

After, if it changed something. The minutes land in a workspace. Each outcome is recorded as its own act — a decision, an objection, a changed position — with `trigger: discussion`, citing the minutes' digest through the artefact picker, contributions typed per act (CRediT: who conceived, who analysed, who supervised — a role in an act, never a presence at an event).

The meeting node is the minutes artefact: same hash, one node, its citing edges are the gathering. Components: record panel (the citing transitions, the digest), workspace (source notes, follow-ups), calendar entry (the past schedule, locally). The panel lists transitions — never a merged list of people.

After, if nothing came of it. It remains a calendar entry. That is not a failure to record; that is C1 working.

49.1.22 8. Constitutive refusals — one page, closed

Each will be asked for. Each answer is one sentence a user can accept.

refused	constraint	the sentence
Person / profile nodes; per-performer views, filters, timelines	C4, C6	The moment a person is a node, everything they did aggregates to them and the graph becomes a dossier; a performer is a key on a transition, not a place things pile up.
Project-level nodes, project status	C4	Nothing in the record attaches to a project as a whole; the record's version of stopping is silence.
Attendance, RSVP rosters, presence dots, "last active"	event-plane ruling	A log of who was present is a monitoring record by construction — presence is never written down in any layer that travels, and not in the ones that don't.
Shared bookings pairing a name with a time and place	C6	Book slots, not people: shared state shows taken/free; your own bookings stay in your own local plane.
Activity feeds across projects, heatmaps, streaks, nudges	C1, C6	Silence is a permitted state of work; an operation that exists so that a record exists is the definition of the failure.
Progress bars, importance, priority, weights, scores, centrality, size-by-degree, canvas count badges	C6	Any computed prominence is a ranking with extra steps; a node with many edges is a node with many edges.
Kanban columns	closed dispositions, C12	A column is a disposition vocabulary in disguise: "done" is the fourth value the protocol deliberately refused.
Reactions, emoji, votes	C1, C2, C6	A reaction is an endorsement with no content and no attestation that exists to be counted; the record's [approval] is an `agrees` connection where you say why, under your key.
View counts, read receipts	C6, monitoring	Counting reads requires logging readers — a record of attention on both sides of the number.
Relevance as a standing index	C6	Search filters; a stored ranking over trajectories is a measure adopted to direct attention.
Combining divergent states — and the word never appears	C5	Both remain true records of what was understood; a transition may take both as parents and say what it makes of the divergence, but nothing collapses them.
Edit-in-place, delete, unpublish	C3, C7	The signature covers the bytes; a corrected understanding is a new transition, so the record shows both that you were wrong and that you noticed. Others may have continued from what you shared — the ground under their work cannot be pulled back.
Mark-answered / close-question	closed dispositions	The lawful neighbour: record a decision or check that *answers* it, standing beside the objection forever; or it stays unresolved, which is the point.

refused	constraint	the sentence
Approval as a gate	C2, C10	Nobody's permission is required to continue the record — including yours; endorsement is a record, never a lock.
Model as performer or registrar	C2	`trigger: ai_suggestion` marks that a model occasioned a transition; a person performs it, and attestation between a person and their own tool is theatre.
Auto-recording runs/commits; template-solicited records	C1	The workspace holds everything; the record holds what somebody deliberately said changed their understanding.
Occasion rosters	C6, monitoring	The occasion panel lists transitions, never a merged list of the people behind them.

49.1.23 9. Extension — deferred, and why deferring is safe

The architecture pass designed a full manifest system: community kinds distributed with charters, `degrades-to` fallbacks, a loader denylist, a projection mini-language. It is good design and it is **not in v1** — it is a plugin architecture for an ecosystem of zero communities, and every piece of it polices an extension surface that does not need to open yet.

What a charter can already extend **today**, through `grrp` alone: `target` values, `trigger` values, local relations, and the redaction-grounds set (a local vocabulary by design). A community occasion — "instrument calibration" — is a charter-declared trigger plus this spec's occasion pattern, with no new machinery.

Deferral is safe **because of I1**: kinds are lenses that never touch the record. Any future manifest system can re-read everything v1 writes. When a second real community exists, the manifest sketch (three worked examples included) lives in the design pass records.

49.1.24 10. Rulings on the sharp questions the review surfaced

- **Redaction aftermath.** The node stays; the record panel shows *(redacted, on the ground of X)* where content was; kind matching never depends on bytes, only on signed fields, so redaction changes no node's kind. The app must purge its own derived caches (search text, previews) on redaction. Workspace copies of redacted material are the holder's obligation, surfaced as a notice — the git-history tension that paper IV itself names is real and stays open here too.
- **Import conflicts.** Same identifier, different bytes: refused loudly — that is tampering surfacing, not a a situation to smooth over.
- **Restricted disclosure rendering.** Each ground's stated residue determines which panel fields render for an out-of-audience viewer. The detailed per-ground table is deferred to the disclosure-UI milestone — marked open, not silently skipped.
- **Workspace path collisions.** Workspaces key by family-prefixed id (`nodes/t/⋯`, `nodes/a/⋯`), so a transition and an artefact sharing a digest tail cannot collide.
- **The charter as a subject.** A plain page rendering `charter.yaml` — which values it defines, which version — added to the build order; cheap, and the `local:` flags link to it.
- **Contributions consent.** Attribution is unilateral and contestable (`attribution_contested`). The spec states this rather than inventing a countersign flow the protocol does not have.

49.1.25 11. Build order

Unchanged in spirit from the design note; sharpened by this spec:

1. **Recording acts from the page** — the §6.1 act forms. The system is a viewer until this exists.
2. **Attestation** — register-a-colleague's-act (§6.1 operations). C2 is the credibility mechanism and is currently unreachable; two accounts already exist to test it.
3. **The panel → this spec's four components** (record, disclosure, workspace, calendar).
4. **The meeting flow** (§7): free-standing calendar entries + the artefact picker polish.
5. **Disclosure & redaction UI** (with the per-ground rendering table, resolving §10's open item).
6. **Import / fork surfaces.**

The standing gate remains: **use it on real work for two weeks** before building further layers on top. Nothing in this specification has been lived with yet.

49.1.26 12. Open decisions

1. **Workspace = project-shared scratch** (travels with a clone, readable by all parties; private material goes to the local plane). This is a privacy ruling — confirm it.
2. **The manifest/plugin system stays out of v1.** Confirm the deferral.
3. **Contributions are unilateral and contestable** — the protocol's own mechanism, no countersign flow. Confirm.
4. Tab naming: this spec uses "graph" for the whole-project view currently labelled *Trajectories*. Rename or keep?

50 LICENSING NOTES

Original source: `applicative_infrastructure/gr_academia_application/provenance/LICENSING_NOTES.md`.
Original source SHA-256: `f3a48306d7939ed63ce550e103b6fb84dc9adde565ff85b4da5e40fb36ce946c`.

50.1 Licensing transition record

Document class: Informative provenance record. **Date:** 2026-09-22. **Current repository licence:** MIT for project-authored material, within the scope of LICENSE.md.

50.1.1 Import baseline

The import from source commit `b98730b46eca5fdf441937aef0180f5b3d4f94dd` initially preserved the source's AGPL-3.0-or-later software and CC BY 4.0 documentation declarations. The four PDFs contained CC BY-NC 4.0 notices. A stale MIT reference in the original GRRP README was aligned with the then-current AGPL statement during relocation. That historical inconsistency remains recoverable in the source bundle.

The original licensing statement referred to a missing `LICENSE` file. The relocation added the official GNU AGPL v3 text (34,523 bytes; SHA-256 `0d96a4ff68ad6d4b6f1f30f713b18d5184912ba8dd389f86aa7710db079abcb0`). That exact text is now retained at docs/history/AGPL-3.0.txt. The earlier scope statement and import licensing notes are preserved byte-for-byte. References inside those snapshots describe their original context.

50.1.2 Current decision

After the migration, the project owner explicitly instructed that all four repositories use MIT and include contributor lists. The active repository licence, scope statement, README licence summaries, Python metadata and npm package declarations now implement that instruction. The new CONTRIBUTORS.md records the author and organizational credits found in the source notices and metadata. It does not invent additional contributors or a copyright assignment.

MIT applies as an additional grant for project-authored documentation and papers as well as code. It does not retract earlier permissions or silently rewrite historical terms. External works and user research records remain outside the project's grant. See the current scope statement for redistribution of PDFs with preserved embedded notices.

The dated machine-readable transition record lists the preserved notice hashes and unchanged PDF and bundle hashes. It is separate from the original import and relocation manifests, which continue to describe their own historical states. The original Git bundle and original external source checkout are unchanged.

The MIT text was checked against the Open Source Initiative version. The earlier AGPL text came from the official GNU source.

51 README

Original source: `applicative_infrastructure/gr_academia_application/provenance/README.md`.

Original source SHA-256: `78135aa644a03da87c7b760069c84133235b77ff38a7ac78564356ef3ac4daec`.

51.1 Academia import provenance

Status: Informative preservation record, 2026-09-22.

The import contains 121 committed source files from `b98730b46eca5fdf441937aef0180f5b3d4f94dd` in `git@github.com:huangwanhong-maker/Generative-Relational-Academia-Application.git`. The original working tree was clean when inspected and was not modified by this import.

The import baseline was captured **before relocation edits**. The corrected import manifest distinguishes raw Git blob bytes, Git archive export bytes, source working-tree bytes, the initial imported bytes, and the final relocated bytes. Every form has its own SHA-256 hash and byte length. The import used `git archive` output; it did not copy raw Git blob bytes directly.

A subsequent independent audit identified an incorrect label in the initial manifest: `committed_sha256` described archive export bytes, and the accompanying text called them committed bytes. Git's archive export converted LF to CRLF in 56 of the 121 files in this Windows configuration. The correction recomputed all raw blob hashes with `git cat-file blob`, verified that a fresh archive matched all 121 initial imported hashes, and recorded the distinction explicitly. The initial manifest is preserved verbatim as import_manifest.initial.json, an explicitly superseded record whose original labels remain incorrect. Its hash and the correction details appear in the corrected manifest.

The baseline `imported_sha256` values have not changed. After relocation, **111 files remain byte-identical to that initial archive-export import**, and 10 have documented edits. This count does not claim byte identity with the raw Git blobs. The relocation change inventory uses the initial imported bytes as its before-edit basis and records final hashes separately.

Original path	Imported path
`web/`	`web_application/`
`grrp/`	`domain_packages/grrp/`
`README.md`	`docs/history/original_README.md`
Other tracked paths	Same relative path

`original-history.bundle` contains all source Git references and their reachable history, created with `git bundle create --all` and successfully checked with `git bundle verify`. It is a portable history archive, separate from the parent programme's working-tree history. It does not pretend that the imported files were always at their new paths.

```
git bundle verify provenance/original-history.bundle
## Restore into a NEW directory when the original layout or history is needed:
git clone provenance/original-history.bundle <new-restore-directory>
```

The source archive excludes untracked and ignored state. No `.git` directory, virtual environment, `node_modules`, build output, account database, record runtime, private key file, or `.env` file was copied as source. An all-history tracked-path audit found no runtime database or private-key paths. This path audit is not a claim that a comprehensive secret scan was performed.

Runtime migration is a separate operation managed by the programme: `.runtime/academia` holds retained application state, while `.runtime/environments/academia` holds the recreated Python environment. Neither belongs in this source bundle.

The validation report distinguishes relocation changes from inherited implementation limitations. The root README and runtime helper describe current launch paths; imported plans and papers remain historical material and may use the earlier layout or describe unfinished work.

52 relocation validation

Original source: `applicative_infrastructure/gr_academia_application/provenance/relocation_validation.md`.

Original source SHA-256: `7da0c3e4ca8db57ac4d63e62133a7a9b15eadd56a8eb0b504c78d13aa81bb508`.

52.1 Relocation validation

Status: Informative implementation report, 2026-09-22.

The academia application was imported from source commit `b98730b46eca5fdf441937aef0180f5b3d4f94dd` without modifying that repository. Its GRRP v0.1 semantics, canonicalization, identifiers, protocol test vectors, and TypeScript package names remain unchanged. Python `grrp` and TypeScript `@gra/protocol` remain academia-specific packages.

52.1.1 Relocation changes

- Moved `web` to `web_application` and `grrp` to `domain_packages/grrp`.
- Added a server runtime resolver that derives source and runtime paths independently of the process working directory. The server and account CLI use the same retained database location.
- Set the independent server port to 8001 and the client development proxy to the same port.
- Selected the isolated Python executable with `GRA_PYTHON`, passed as one argument even when the executable path contains spaces. The default environment is `.runtime/environments/academia`.
- Kept retained records and the account database under `.runtime/academia`, outside source and environments. Corrected inherited wording that implied the account database was entirely disposable or that private keys could never exist anywhere on the host.
- Updated demo tool locations; demo seeding requires an explicit separate runtime and server URL. Corrected an inherited malformed string literal in `tools/demo.ts`. Demo seeding was not run against migrated data.
- Preserved the original root README, licensing statement, research documents, and complete Git history. Added current installation documentation, the missing official AGPL licence text, and explicit licensing preservation notes.

52.1.2 Executed checks

Check	Result
Source archive import	121 files; initial imported hashes preserved; corrected manifest distinguishes raw blobs, archive export, source worktree, and final relocated bytes
Provenance correction	56 archive exports differ from raw blobs only by LF-to-CRLF conversion; all 121 initial imported hashes independently reproduced
Relocation comparison	111 files unchanged against the initial archive-export import; 10 files contain documented edits
Original Git history	7,255,564-byte bundle; `git bundle verify` succeeds and reports complete history
Original repository after import	Same HEAD and clean working tree
Python package	Installed editable from the relocated domain package into the isolated environment
Python suite	**208 passed, 1 skipped**; the skipped test is a POSIX editor fallback on Windows
TypeScript protocol vectors	**43 passed**
Relocated Python vector generator	Reproduces the original TypeScript fixture byte for byte
Fastify application and path tests	**48 passed**, including 3 new runtime-boundary tests
Production build	Protocol, server, and React client builds pass

Check	Result
Optional demo tool	TypeScript syntax transform passes; no seeding performed
Deep Windows runtime path	Isolated project and question creation both return 201; graph returns 200; `grrp check` succeeds

The Python tests used a fresh explicit `--basetemp` because the machine's pre-existing shared pytest temporary directory was inaccessible. Windows sandbox ancestor-directory access also blocked esbuild configuration discovery; running the scoped build/test commands outside that sandbox restriction succeeded. Neither issue required changing machine-wide long-path or execution-policy settings.

The server suite creates temporary accounts and projects, invokes the relocated Python implementation, tests Git repositories and record operations, and checks graph behavior. These checks do not certify conformance to the generalized protocol or establish production readiness.

The long-path check used a separate `.runtime/academia-relocation-smoke` tree under the programme, with an in-memory account database. It exercised the new runtime depth without adding records to retained user data. That temporary tree was removed after verification.

52.1.3 Inherited dependencies and limitations

`npm ci` reproduced the existing lockfile without a dependency upgrade. The npm advisory report on 2026-09-22 reported six affected packages: three high (`@fastify/static`, `drizzle-orm`, `fast-uri`) and three moderate (`fastify`, `vitest`, `@vitest/mocker`). Several suggested fixes require version changes outside the existing declared ranges. A separate dependency-maintenance review is needed before public deployment; advisory presence alone is not a finding that every reported path is exploitable in this application.

Installed Python and Node versions are recorded separately in `installed_dependencies.json`; this is a validation environment record, not a new dependency lock or compatibility guarantee.

The migration preserves application behavior, including existing custody choices and historical documentation. It does not introduce the generalized application's transaction receipts, relation module semantics, concurrency behavior, or standards-alignment claims. Future convergence requires an explicit domain compatibility design.

Actual retained-data backup, transfer, and live-service verification are handled separately by the programme migration. The source import did not include account databases, runtime records, private keys, or generated dependency trees.

53 README

Original source: `applicative_infrastructure/gr_academia_application/web_application/README.md`.
Original source SHA-256: `0527be3cce58696c4e28074f2daead5eaa83a29761c228ebcb3335df29c6d7c8`.

53.1 GRA — the web platform

A host for records, which is **not** their authority.

Three packages, and the boundary between them is the design:

`packages/protocol`	GRRP v0.1 in TypeScript	canonicalisation, identifiers, signing — the same code in the browser and on the server
`packages/server`	Fastify + SQLite	accounts, sessions, an index. Owns no protocol decisions
`packages/client`	React + Vite	the pages. Disposable by design

The front page is public. Reading what people have shared, and searching across it, needs no account — an account is access to this host, not permission to look, and a front door that demanded a login before it showed you anything would have already decided it was the authority. Signing in adds one thing: your own projects, and the ability to open one.

Project is the top-level object, the way a repository is on a forge. It is created with a name and, if you want, a description — kept as a plain `README.md` in the project directory, so it travels with the record and outlives this server.

A project starts **empty**, and a question is opened separately inside it. The two are different things: a project is a container, a question anchors a *trajectory*, and a trajectory is what transitions attach to (C4). Demanding a question at creation conflates them, and implies a project is one enquiry.

Nothing can be recorded in a project with no question open — every act changes an identified state, and the question is the first state there is. The interface says so rather than preventing the situation.

The reference implementation, `grrp`, stays Python and stays the thing the protocol is defined against. This server invokes it as a subprocess to create records, for the same reason a git forge shells out to `git`.

53.1.1 Running it after relocation

See the application guide for installation, the independent port 8001, and absolute runtime settings. Source packages stay under this directory; retained accounts and records live under `applicative_infrastructure/.runtime/academia`. The source location determines defaults regardless of the process working directory.

The Python implementation is installed from `../domain_packages/grrp` into `../../.runtime/environments/academia`. `GRA_PYTHON` selects its interpreter; `GRA_RECORDS`, `GRA_DB`, and `GRA_CLIENT` can select explicit absolute paths. Back up the account database together with the complete records tree.

53.1.2 What the database is not

No database is the system of record (C11). The record is plain files: transitions in YAML, state content in files named by the hash of their bytes. The SQLite file holds two things — *accounts*, which are local to this host and part of no record, and *an index*, which is derived and rebuilt by `POST /api/reindex`.

This is tested rather than asserted. Delete `index.sqlite`, restart, and every record comes back identical from the files. Accounts do not, because they are the one thing not derived from anything — back them up, or make them again.

53.1.3 What this platform refuses to do

Each of these will be asked for, and each request is the design working:

- **No count, score, ranking or index over participants or trajectories** (C6). There is no `stars` column and there will not be one. A count *within* one trajectory, shown beside its own question and never next to another's, is permitted — that is the line.
- **Search filters; it does not rank.** No relevance ordering, no "best match". The API says so in its own payload so a second client cannot present results as ranked without contradicting it.
- **Disclosure widens and never narrows** (C7). There is a route that lists a record and none that unlists it.
- **No combining of two divergent states, and not the word for it** (C5).
- **No directory of people.** Not of accounts here, and certainly not of records elsewhere. A service that knew where everyone's records were would be party to every entry.

53.1.4 Keys

An **account** is a name and a password. It reaches an identity; it signs nothing. An **identity** is a keypair, and the keypair is what signs.

The account database stores public keys only. The record runtime can also contain private GRRP signing keys used by subprocess operations. Browser-generated keys and record-local signing keys have different custody paths; a database schema alone does not establish that the host cannot sign for a party. Back up and restrict access to the complete runtime accordingly.

The bootstrap path is the weak point and is not glossed: `account add` without `--party` generates a keypair in this process and prints the private half once. Prefer `--party` with a key the person generated themselves. Browser-side key generation is the next piece of work.

53.1.5 Two implementations

`packages/protocol` and `grrp` must agree on every identifier for every input. `../domain_packages/grrp/tools/make_vectors.py` generates the vectors; the TypeScript suite must reproduce all of them. A disagreement is a specification bug.

The first run of that suite found one: Python and TypeScript stripped different sets of trailing whitespace, so the same document got two different state identifiers. See `TRAILING_WHITESPACE` in `canonical.py` and `TRAILING` in `canonical.ts`.

54 CONTRIBUTING

Original source: `applicative_infrastructure/gr_generalized_application/CONTRIBUTING.md`.
Original source SHA-256: `b5537fa667fdefc6d15430987f2e27b0ab9495a6d7af16b91e9d917bba7d0670`.

54.1 Contributing

Use this repository for generalized application behavior, presentation and integration. Shared record protocol and Git-store changes belong in the infrastructure repository. Describe the user-visible problem, explain affected record semantics and provide proportionate validation. Keep account data, signing keys and project records outside the source repository.

The project-authored material is offered under the MIT licence, with scope and exceptions. By intentionally submitting original work for incorporation, you offer it under MIT while retaining your copyright. Identify third-party material and its licence separately, and state your authority when contributing on another rights holder's behalf.

Add your preferred contributor name or organization and a brief contribution description to CONTRIBUTORS.md when your work is incorporated. Preserve the separate Cytoscape attribution and all other third-party notices. AI tools may be acknowledged as tools, not as copyright holders.

56.1 Licensing scope

Effective date: 2026-09-22. **Licence:** MIT, under the project owner's explicit instruction for the repository family.

The MIT licence covers project-authored application code, documentation, tests and other project-controlled material in this repository. Its copyright notice refers to all contributors listed in CONTRIBUTORS.md, for their respective contributions. The licence text follows the Open Source Initiative MIT text.

The vendored Cytoscape.js distribution retains the Cytoscape Consortium's own MIT notice and provenance record. Do not replace this third-party attribution with the project's contributor list. Other dependencies retain their own licences and notices.

User-created records, evidence, attachments, account information and private project Git histories are not licensed under MIT simply because the application stores or presents them. Their applicable rights and access conditions remain separate from the software licence.

Contributions and attribution are described in CONTRIBUTING.md. Contributors retain rights in their respective contributions; no collective ownership of every file is implied.

57.1 Generalized GR application

Class: Application and development guide
Status: Experimental application; gsp-record-protocol/0.2 and gsp.general/0.2
Source repository: Generalized-Generativity-Relational-Social-Science-Application

The generalized application is a local web workspace for recording situations, their relations, the grounds of accounts about them, and their subsequent revision. A visual graph lets users create and connect records, inspect their modules and return to a coherent historical view.

It is one application within the Generativity Standards Program. The programme's operational recording roles and working specifications inform its model; neither saving a record nor passing its validation establishes factual truth or formal Standard conformance.

57.1.1 Current capabilities

- Register and sign in; create multiple private projects, each with its own record Git repository.
- Create records with overlapping Entity, State, Event, Process, Relation and Property roles, attributed context, knowledge basis, uncertainty and alternatives.
- Create first-class Relations with named participants and qualified direction/reference scope; connect to an existing record or create a record and its relation in one save.
- Explore, select, filter and arrange the graph or browse a record list. Layout choices affect the display without creating record revisions.
- Explore event-defined spacetime: record precedence claims, select consistent temporal cuts, and inspect scoped ontology topology and subject trajectories independently of Git recording order.
- Attach notes and retained files through record modules, replace material, or detach its current association with an attributed reason.
- Revise records with a reason and change category; inspect historical labels, relations, modules and file bytes at one selected revision.
- Export JSON metadata, a material-bearing snapshot ZIP, or a Git bundle of reachable project history.
- Preview and explicitly migrate a legacy workspace while preserving earlier revisions.

The web application guide gives the detailed interaction model, resource limits and account behavior. A Relation can itself have properties, notes, files and history. The graph's position and arrows add no causal, epistemic or legal meaning beyond the records they present.

57.1.2 Demo gallery

Explore **River Commons**, a fictional inquiry into shared care of a garden. Its 31 records cover all six operational roles, five Events, notes, six retained files and seven Git revisions. The scenario includes retrospective recording, branching event precedence, changing State accounts, contested interpretations, an unrealized alternative and a correction whose earlier account remains accessible.

[Image description: River Commons record graph and the selected stewardship Relation]

[Image description: Event-defined spacetime with precedence independent of Git recording order]

57.1.3 Visualized spacetime

Choose an event boundary to see the ontology topology applicable there. The two views below use the same retained revision: the first includes the encounter and agreement; the second also includes the workday and review.

After the agreement: 10 projected records. Trial access and a provisional stewardship arrangement apply.

[Image description: Agreement frontier, scoped ontology graph and trial-access State]

After the review: 13 projected records. Trial accounts end; revised access, renewed stewardship and the workload concern apply.

[Image description: Review frontier, changed ontology graph and revised-access State]

The trajectory view connects descriptions under their recorded subjects. For the garden, follow **Access not yet arranged → A garden open for a trial → Access under a revised rota**, with their inclusive start and exclusive end boundaries:

[Image description: Subject trajectories with event bounds and applicability]

The independent water observation remains unordered. These are selected partial-order cuts, not equally spaced instants or assertions that incomparable events occurred simultaneously. Moving between cuts changes the projection without creating a Git revision.

The full gallery contains ten actual interface screenshots, including two temporal cuts at the same revision, subject trajectories, temporal editing, file attachment, historical contradiction and mobile use. The graph overview shows the visible **care** filter (11 of 31 records) and locally arranged node positions.

The demo guide provides the narrative walkthrough and commands to create a separate synthetic account and project, then reproduce the images. Demo credentials stay in the ignored infrastructure runtime. The example illustrates implemented behavior; its invented accounts and files do not establish facts about a real community.

57.1.4 Source repository and dependencies

```
gr_generalized_application/             This application Git repository
├── README.md  LICENSE  CONTRIBUTORS.md
└── web_application/
    ├── run.py                          Local Waitress entry point
    ├── generative_app/                 Flask application, templates and interface
    ├── tests/                          API and opt-in browser journeys
    ├── requirements.lock              Application dependency versions
    ├── DESIGN.md
    └── TESTING.md
```

This repository is a submodule of applicative_infrastructure. It consumes the sibling record-protocol package and Git-store package. Common tools and packages belong to the infrastructure repository; this application does not depend on academia.

The supported setup expects the infrastructure checkout with its submodules initialized. With GitHub SSH access configured:

```
git clone --recurse-submodules git@github.com:huangwanhong-maker/Generativity-Relational-Epistemic-Applicative-Infrastructure.git
↪  applicative_infrastructure
cd applicative_infrastructure
```

To obtain only this application's source, use `git clone git@github.com:huangwanhong-maker/Generalized-Generativity-Relational-Social-Science-Application.git gr_generalized_application`. That clone does not include the common packages or setup tools. Programme specifications and design decisions resolve in the complete programme checkout. The Git workflow guide covers Windows SSH setup and repository remotes.

Application source commits and user project commits are separate histories. A parent infrastructure commit pins the application revision; runtime project repositories retain the users' record revisions.

57.1.5 Install and run

Requirements: Python 3.11 or later and Git on PATH. No Node build, hosted fonts or external service is needed for the interface. Its vendored Cytoscape.js component includes its own notice and source manifest.

From the **parent infrastructure directory**:

```
python common/tools/setup_application.py generalized --dev
python common/tools/run_application.py generalized
```

Open **http://127.0.0.1:8000**. On Linux/WSL, use the system's Python 3 command. The setup tool creates the generalized environment, installs the common packages and application dependencies, and optionally installs test tools. No default account is created; registration is available in the interface.

The launcher binds to loopback, accepts a different port and stops with Ctrl+C:

```
python common/tools/run_application.py generalized --port 8002
```

The application has independent account/session storage and the gsp_session cookie. Existing credentials from the local migration remain in that runtime; a fresh source clone has no migrated account data.

57.1.6 Records, configuration and recovery

```
applicative_infrastructure/.runtime/generalized/
├── accounts.sqlite3                Users, sessions, ownership and rate limits
└── repositories/
    └── <project-uuid>.git/          Bare Git repository for one user project
```

The GSP_DATA_DIR environment variable selects another absolute runtime path. GSP_COOKIE_SECURE and GSP_TRUSTED_HOSTS configure HTTPS-only cookies and accepted request hosts; details are in the configuration guide.

A transaction publishes record changes, retained assets and its receipt atomically. If another edit advances the project, the application rejects a stale save and preserves the user's draft for reconciliation. Retrying an unchanged transaction can recover its original receipt.

Revision and withdrawal retain earlier text in Git history. Detaching a file removes the current association, while earlier descriptors and bytes can remain retrievable. A project bundle includes reachable history but excludes accounts and application ownership; it is an inspection/export artifact, not a complete running-service backup. Importing arbitrary edited Git history is not implemented.

For a complete backup, stop the writer and copy the entire runtime, including the account database, journals and project repositories. Restore a matched runtime and application version together. Source submodule updates do not transfer or convert these records. The infrastructure recovery guide describes the retained relocation backups.

57.1.7 Verification

After development setup, from this application directory on PowerShell:

```
& ../.runtime/environments/generalized/Scripts/python.exe -m pytest -c web_application/pytest.ini web_application/tests
↪  ../common/packages/gsp_record_protocol/tests ../common/packages/gsp_git_store/tests --basetemp
↪  ../.runtime/test-output/generalized -q
```

Use bin/python on POSIX. The temporary-output directory is disposable and must not contain valuable records. Set GSP_BROWSER to msedge for the browser journeys if Edge is installed. See TESTING.md for browser alternatives and shared verification for scope.

The migration's combined generalized/common run passed **128 tests**, including three browser journeys. Its verification report records the tested revision and preservation boundary.

57.1.8 Current limits and development

The application currently provides owner-private projects. Sharing, invitations, email verification, password recovery, selective erasure, remote synchronization, independent custody witnessing and a formal contestation workflow remain outside the implemented experience. Public hosting requires deployment-specific administration and operating controls. The web guide documents size limits, exports and failure recovery.

Academia remains a separate native GRRP application; a shared domain adapter is future work. Preserve the distinction between retained material and assessed evidence, the account owner's status choice and independent review, and application attribution and authenticated external identity.

Commit application edits here, then update its pinned commit in infrastructure and the infrastructure pin in the programme. Changes to common packages belong in infrastructure.

Link conceptual changes to programme requirements and ADRs rather than redefining GR theory in application code alone.

Publish this application’s commits before publishing an infrastructure commit that references them, then publish the programme’s updated infrastructure reference. Inside a submodule, select a development branch before committing because initialization normally checks out the pinned commit with a detached HEAD.

57.1.9 License and contributors

Project-authored material is available under the MIT License, with copyright held by contributors recorded in CONTRIBUTORS.md. See LICENSE.md for scope and retained third-party notices. The license does not assign rights over records or uploaded files created by application users.

Original source SHA-256: `f905ec649c101e31f830caffbe16ef2c010f1193cd54af056530830dd77bc1a4`.

58.1 River Commons gallery

Class: Informative application demonstration
Status: Synthetic example of the experimental generalized application

The River Commons project follows a fictional inquiry into shared care of a garden. Its 31 records include all six operational roles, five Events, scoped State descriptions, qualified Relations, notes, six retained files, an unrealized alternative and a corrected chronology. Every account and source file is invented.

These images are generated from the running application and its retained project, using ordinary controls. They are screenshots, not UI mockups. See the demo guide for the story, local account setup and reproduction commands. The generated capture manifest records source and project revisions, viewport dimensions and image hashes without credentials.

58.1.1 See the visualized spacetime

Read the following views together: **event precedence defines possible boundaries; a selected boundary reveals an ontology topology; subject trajectories connect scoped descriptions across those boundaries.** Here, “space” means the topology of applicable ontology records. Selecting a boundary changes the view of one retained account, without creating a Git revision.

58.1.2 Event order defines the available boundaries

[Image description: Event precedence graph with an event-defined boundary and the retrospective encounter account]

2. A partial order of represented events. The later review was recorded first; the encounter and other earlier events were added retrospectively. Recorded precedence branches from the encounter through the agreement and workday, then reaches the review. The agreement and workday have no established mutual order. The independent water observation has no established order relative to the other events. Incomparable events are not asserted simultaneous, and horizontal positions are layout rather than a clock scale.

58.1.3 The ontology topology changes with the selected boundary

The two screenshots below use the **same current Git revision**. Their boundary labels identify different selections of passed events. Recorded predecessors are included automatically.

Chosen boundary	Events included	Records in the topology	Accounts to compare
After the provisional access agreement	Encounter and agreement: 2 of 5	10	Trial access and provisional stewardship apply
After the shared review	Encounter, agreement, workday and review: 4 of 5	13	Revised access, rotating care and renewed stewardship apply

[Image description: Ontology topology at the access-agreement boundary, with the trial-access State selected]

3. After the access agreement. The selected State, **A garden open for a trial**, and the Relation **A provisional stewardship arrangement** apply at this boundary. The workday is outside the chosen cut: no retained claim orders it before the agreement. Records with unknown or unscoped presence remain separately inspectable.

[Image description: Ontology topology at the shared-review boundary, with the revised-access State selected]

4. After the review. Both branches now lie before the selected boundary. The trial State and provisional arrangement have ended within this account. **Access under a revised rota**, **Care shared through a rota** and **A renewed agreement to care** are applicable. The independent observation is still outside this cut and remains unordered. These changes follow declared temporal extents; the visualization does not infer that an event caused them.

58.1.4 Subject trajectories connect the scoped descriptions

[Image description: Record trajectories with event boundaries and presence classifications]

5. Follow changing and competing descriptions. Under **River Commons garden**, the State accounts describe **Access not yet arranged**, then **A garden open for a trial**, then **Access under a revised rota**. Their inclusive start and exclusive end boundaries connect them to the agreement and review. The provisional and renewed stewardship Relations have their own extents under the same subject.

Under **Stewardship team**, **An informal team taking shape** ends at the review and **Care shared through a rota** becomes applicable. The workload concern remains visible beside those descriptions. Subject grouping does not independently establish identity, continuity or agreement. Unknown water applicability remains indeterminate; it is not placed into a definite period merely to complete the picture.

To explore these views, open **Spacetime**, choose **Before all**, then mark **A provisional access agreement** as passed. Read the topology and trajectories, then mark **A shared review** as passed and compare. Keep **Current project** selected throughout; no project revision is saved by these controls.

58.1.5 Records and their relationships

[Image description: Record graph with the provisional stewardship Relation selected and its participant roles visible]

1. A record graph with inspectable Relations. The selected arrangement has its own account and named participant roles. The visible search query **care** shows 11 of the project's 31 records for readability; it does not remove the other records. The capture script arranges these nodes into a local display grid, equivalent to manual dragging, without changing records or connections. Graph layout does not establish causation or chronology.

58.1.6 Describe temporal scope

[Image description: Temporal-extent editor showing inclusive and exclusive event boundaries, subject grouping and grounds]

6. Record the grounds for temporal scope. The actual editor distinguishes event, unknown and unbounded boundaries, and retains the stated basis and optional subject grouping. This pictured editor is opened for the trial-access State and canceled during capture.

58.1.7 Retained materials and usable controls

[Image description: Files module showing fictional review materials attached to their account]

7. Material accompanies the account. Fictional review evidence is retained through the Files module, with download links and custody details. Preserving bytes establishes what was retained, rather than independently verifying their content.

[Image description: Styled native upload chooser with a synthetic encounter-notes file selected]

8. Attach material through the real upload dialog. The native file chooser uses the application's button styling. The selected synthetic file is a screenshot-only draft; capture discards it instead of creating a duplicate attachment.

58.1.8 Preserve contradictions and their revision

[Image description: Read-only historical snapshot with contradictory event order and record history]

9. A historical contradiction remains inspectable. This pinned revision contains the mistaken claim that the review preceded the encounter. The cycle prevents a consistent temporal cut. The current account withdraws that claim while retaining this historical record; it also corrects the reported attendance from 18 entries to 16 distinct attendees. Those are revisions of the account, not changes to past events.

58.1.9 A narrow viewport

[Image retained in source archive.]

10. The same project on mobile. Ordinary workspace controls and the event-order view remain available at a 430-pixel viewport. This bounded screenshot shows a portion of the scrollable workspace.

58.1.10 Capture and preview maintenance

The capture script reads the synthetic project's saved revision, operates the UI, captures these ten images and checks that the project head remains unchanged. Its generated manifest describes the particular capture; this gallery is not a substitute for application test results.

Five deliberate preview copies are generated inside each of the programme and infrastructure repositories for their READMEs:

Canonical screenshot	Parent preview filename
`01-record-graph.png`	`generalized-record-graph.png`
`02-event-order.png`	`generalized-spacetime.png`
`03-earlier-topology.png`	`generalized-spacetime-earlier.png`
`04-later-topology.png`	`generalized-spacetime-later.png`
`05-subject-trajectories.png`	`generalized-spacetime-trajectories.png`

The copy mapping and source hashes are recorded in the manifest. Keeping previews inside each repository avoids broken image paths across Git submodule boundaries. The complete gallery and reproducible demo sources remain here in the generalized application repository.

59 README

Original source: `applicative_infrastructure/gr_generalized_application/web_application/.pytest_cache/README.md`.

Original source SHA-256: `73fd6fccdd802c419a6b2d983d6c3173b7da97558ac4b589edec2dfe443db9ad`.

59.1 pytest cache directory

This directory contains data from the pytest's cache plugin, which provides the `--lf` and `--ff` options, as well as the `cache` fixture.

Do not commit this to version control.

See the docs for more information.

60.1 Project workspace — implementation design

Document class: Informative application design
Maturity: EXPERIMENTAL; initial implementation
Date: 2026-09-22
Draft reference baseline: GR-100/110/200/210 Working Draft 0.3
Decision: ADR-0007

Historical scope: The text below records the initial `gsp-workspace/0.1` design and its original gaps. The current graph/module/transaction architecture is in graph_workspace_design.md and ADR-0008. That extension replaces the implementation restrictions on single-role records, structured relations, attachments, revision categories, migration and project graph views; the broader epistemic, governance, custody and legal limitations remain. See the current operation guide.

60.1.1 Purpose and supported use

The application lets a person register, sign in, create private projects, and record qualified accounts within a project. A person can revise a record with a reason, inspect its retained versions, export the project's current snapshot as JSON, or download its complete reachable history as a Git bundle. Its immediate purpose is to make trajectory recording usable enough to examine the programme's proposed distinctions and practical burden.

The application does not claim conformance to any GR draft. It implements selected recording functions with declared information limits. Choosing a role or filling a field does not establish occurrence, target identity, evidential warrant, ethical acceptability, or legal effect. A project's owner-assigned record status is separate from the represented effect's modality and from any independent review.

60.1.2 Components and storage authority

Component	Responsibility	Authority boundary
Browser interface	Registration, login, project navigation, recording, revision, history, and export	User input is validated again by the server; a visible interface control is not an authorization rule
Flask application	Authentication, access checks, validation, server audit attribution, and bounded Git operations	The trusted server mediates every project operation
SQLite	Accounts, credential verification material, sessions, and project ownership/index lookup	Authentication and access data stay outside project content history
Per-project bare Git repository	Project manifest and JSON records, retained through commits	The committed project snapshot is authoritative for project content; the database is not a second record-content store

Projects are private to their owning account through this application. The first version provides no project invitation, shared editing, public link, or Git push/fetch service. An authorized owner can download a Git bundle and clone it locally. Host filesystem access remains an administrative trust boundary. The application is bounded to 1,000 records per project and limits request and field sizes; these are prototype resource limits, not GR requirements.

The storage design avoids a shared writable checkout. A mutation reads the current project tree, creates new content/tree/commit objects, and conditionally advances one project reference using the previously read commit. Git documents the conditional old-object check in `upd`

ate-ref. A competing successful update causes a conflict; the client can reload and reconsider its edit. This prevents one accepted write from silently replacing an intervening accepted write through the application. It does not authenticate represented observations or make all infrastructure operations atomic.

An object written before an unsuccessful reference update can remain unreachable in Git storage. It is not an accepted project revision. A crash between repository initialization and database registration can also require operator reconciliation. Recovery must inspect the authoritative committed project manifest and access records; an orphan repository is not automatically published or assigned to another account. Database and Git backups need a consistent recovery procedure before operational dependence.

60.1.3 Recording semantics

Field names below describe the application's narrow data model, not a standardized interchange vocabulary. Project and record JSON declare `schema_version: gsp-workspace/0.1`. The server controls record identifiers, audit account identifiers, and recording timestamps.

Information	Application representation	Interpretation and limit
Stable record reference	`id`	Identifies this application record; does not establish target identity
Account content	`title`, `content`	Recorder's description; a compound account can still require finer claim separation
Primary recording role	`record_type`: Entity, State, Event, Process, Relation, Property	One primary role per record; overlapping target descriptions can use linked records; role-specific criteria are not fully enforced
Epistemic mode	`epistemic_mode`: observed, reported, inferred, interpreted, retrospective	A primary account mode, not a truth rating; combined modes require qualification in prose
Asserted modality	`modality`: realized, intended, possible, unrealized, unknown	Describes the asserted effect or occurrence, separately from how it is known
Recorder's status	`status`: unreviewed, contested, revised, withdrawn	Owner-assigned description; not an independent assessment or institutional case state
Attributed source	`attributed_to`	Reported observer, speaker, source, collective, or explicit uncertainty; distinct from the signed-in recorder
Method and grounds	`method`, `evidence`	Supplied method description and grounds/references; no automatic evidence verification, external retrieval, or preserved evidence attachment
Qualification	`uncertainty`, `alternatives`	Space for limits and competing accounts; empty content does not establish certainty or absence of alternatives
Generative context	`conditions`, `consequences`	Enabling/constraining context and asserted effects; no mechanism, beneficial effect, or completed repair is inferred automatically
Represented time	`occurred_at`	Recorder-supplied occurrence/target-time description, distinct from server recording time; uncertainty can be stated in the description

Information	Application representation	Interpretation and limit
Cross-references	`related_records`	Links within the project; a link does not establish identity, causation, support, or a typed Relation
Audit information	Server-assigned creation/update time and recording-account identifiers	Captures application activity under the server's clock and access model; does not verify real-world identity or independent time
Revision rationale	Reason supplied with the revision and retained in its history	Explains the edit; the first version does not structurally classify target, evidence, and descriptive-regime changes

A Relation can be recorded as a separately referenceable record with its own account and history. The cross-reference list is a navigation facility. It does not replace a Relation record when that relation's own properties or history matter, nor does it yet provide structured relation participants and identity criteria.

The selected mode, modality, and status can coexist. For example, a recorder can describe a realized event through retrospective reconstruction while marking its account contested and explaining the dispute. If both inference and reconstruction matter, the primary mode alone is insufficient; the content and method explain their separate contributions. This known limitation is a candidate input to a richer information-model specification.

60.1.4 History, conflict, and export behavior

The authoritative current project is a Git commit containing its manifest and records. An accepted record revision preserves the record identifier and creates a new commit with its reason and accountable recording actor. Earlier snapshots remain accessible while their commits are retained. Ordering in this history is recording order; the account can describe an earlier occurrence or an uncertain time.

Updates carry `expected_head`, the project revision the client edited, and `revision_reason`. A stale update is rejected instead of being automatically merged. This is project-wide conflict detection: even an intervening change to another record can require a reload. The conservative boundary keeps the first implementation's behavior explicit. The application does not expose branch creation, concurrent interpretation branches, semantic merging, or a claim that the latest account has the best evidence.

History and historical record reads pass through the same project ownership checks as current reads. A revision identifier is a locator, not a permission token. A version inspected in the application needs to belong to that project's retained history. The history endpoint returns the latest 100 revisions affecting the selected record. It is not a project-wide timeline or a complete browser listing of longer histories; the Git bundle permits examination of the complete reachable history with Git tools.

The JSON export is a current snapshot identified by its source project revision. It contains project records and their available qualifications. It does not contain credentials, authentication sessions, prior snapshots, externally referenced evidence, or confirmation that downstream recipients obtained later corrections. It is a local experimental format, not GR-130 conformity or a complete repository backup.

The separate Git bundle contains the main reference and its complete reachable commit history. It therefore contains earlier and withdrawn account content, revision reasons, and recorded actor names/identifiers, even when the current snapshot no longer displays the earlier formulation. It does not contain the account/session database, authentication credentials, access configuration, or unreachable objects from unsuccessful writes. The owner can clone the bundle for independent inspection, but the bundle alone does not restore a complete running service.

60.1.5 Traceability to draft needs

Each row identifies a design relationship, not a fulfilled requirement. Exact obligations and conditional triggers remain in the cited 0.3 sources: GR-100, GR-110, GR-200, and GR-210.

Draft references	Implemented contribution	Material gap or assessment boundary
R110-001; E200-001	Project name/description, identifier, owner, version, and private access boundary	No complete collection declaration, purpose/claim-selection assessment, descriptive-regime register, or allocation of independent institutional responsibilities
V100-005/010/011; R110-006/009	Stable records, primary operational role, first-class Relation records, cross-references	Target identity and role admissibility criteria remain descriptive; linked records are not a tested multi-role semantics or a metamodel mapping
V100-016; R110-012; E200-005	Separate primary epistemic mode, modality, and owner-assigned status	Limited mode vocabulary; combined modes, perspective, and assessment disposition are not comprehensively structured
E200-004/029/030	Separate authenticated recorder and attributed source; method field	No verified source identity, complete attribution/transformation chain, instrument version, calibration record, or observation window
V100-006; R110-008; E200-008	Represented time separate from application creation/update time	Observation, acquisition, assessment, intervals, and uncertain ordering lack separate structured fields
E200-006/010/011/014/015	Method, supplied evidence text, uncertainty, and alternatives	No separate versioned material items, claim-relative evidence-role assignments, assessor record, custody chain, or completed examination of alternatives
R110-010/015/017/058/112	Conditions, consequences, and alternative-account descriptions	No automatic generative attribution; no structured link-specific evidence, counterfactuals, recirculation stages, or generativity-return assessment
V100-007; R110-020/021; E200-017/038	Retained revisions, accountable actor/time, required revision reason, accessible earlier versions	No structured classification of revision grounds, parallel interpretation branches, independent retention guarantee, or dependent-claim follow-up
R110-025/085/087/092; E200-023/043	Owner-only access across current content and history; credentials kept out of project history	No per-record disclosure, protected-source arrangement, retention schedule, selective erasure, legal hold, or backup disposition workflow
R110-029/030/093; E200-026	Qualified record presentation and current export identified by source revision	No complete transformation/omission declaration, standardized interchange validation, external correction delivery, or observed user-comprehension assessment
R110-023/082; E200-021; C210-005/009/013/048	The owner can describe a dispute and revise their account	No third-party intake, responsible independent reviewer, service periods, notice, appeal, evidence determination, or operative GR-210 case procedure
R110-032/033/034/099; E200-002/045/049	Tests can examine application behavior and distinguish selected checks from a whole-package claim	No per-requirement conformance dossier; passing application tests does not establish the full GR-200 dependency or any unqualified draft-conformity claim

60.1.6 Security, custody, and participation boundaries

The server authenticates each account and checks ownership on project, record, history, and both export operations. Authentication credentials and session state are not project records. Password verification uses Werkzeug's scrypt hashing. Browser session cookies carry opaque random tokens; SQLite retains their SHA-256 digests with a twelve-hour absolute expiration. Session identifiers and anti-forgery tokens rotate at authentication changes. Anonymous sessions also receive anti-forgery protection for login and registration. Cookies use HttpOnly and SameSite=Lax; Secure is configurable for HTTPS deployment. Authentication throttling uses server-observed direct IP addresses and an email digest, without trusting arbitrary forwarded headers.

Write requests require the application's anti-forgery protection as well as authorization. Content is presented as text rather than executed as user-supplied HTML. Git receives bounded arguments and server-controlled repository paths. The initial configuration binds to loopback, limits trusted hostnames to localhost and the IPv4/IPv6 loopback addresses, and sets a content security policy. These controls address ordinary application attack surfaces; deployment controls still matter. Flask's security guidance addresses complementary browser, cookie, request, and resource protections. Configuration and operating instructions accompany the implementation. The initial release does not offer email verification, account recovery, or a claim of production readiness.

An authenticated account is not a verified person or qualified reviewer. Attribution to a different person does not imply their consent or endorsement. A host administrator can read stored content and rewrite or delete repository history. This version offers no encryption-at-rest, signed record attestations, trusted timestamps, or independently witnessed history. A commit hash identifies retained content within Git's model; it does not establish the truth of that content.

Withdrawal is an account status, not erasure. Earlier record content can persist in Git objects, repository copies, and backups. Exports place another copy under the recipient's control. The application cannot establish the removal of those copies. A project owner therefore needs a purpose and permission basis appropriate to what they choose to record; the application does not determine that legal or institutional basis.

The first version is suitable for bounded local experimentation with material appropriate to these limits. Organizational use involving other people's consequential records requires agreed custody, access, retention, recovery, participation, and review arrangements. Such arrangements are not created by deployment or by a technical conformance label.

60.1.7 Follow-on design questions

The following are OPEN or DEFERRED rather than hidden capabilities:

- **OPEN — Shared access:** membership, roles, invitations, revoked access to history, exports, and disclosure of protected sources.
- **OPEN — Representation:** separate claims/material/evidence-role objects; combined epistemic modes; target and observation times; typed missingness; role criteria; parallel accounts and revision grounds.
- **OPEN — Retention and recovery:** authorized selective erasure, repository copies, backup restoration, orphan initialization, and consistency across database and Git.
- **DEFERRED — Review practice:** actual challenge intake, reviewer independence, service clocks, replies, reasoned disposition, notification, and repair follow-up.
- **DEFERRED — Interchange:** migration, import validation, attachment custody, independent implementations, and promotion of stable elements into a separately reviewed Specification.

The next empirical step is to record a bounded case, revise it after new evidence, inspect what another intended reader can reconstruct, and measure the burden and missing distinctions. Results can inform the draft programme through its development procedure. They do not automatically convert this implementation into an adopted model.

61 README

Original source: `applicative_infrastructure/gr_generalized_application/web_application/README.md`.
Original source SHA-256: `f3202d4676a9c54344f519d3b51a71ac9cda06f4bcd0b68b536d5af1df8249ce`.

61.1 Generativity workspace

Document class: Software implementation guide
Status: EXPERIMENTAL; application schema `gsp-workspace/0.2`, protocol `gsp-record-protocol/0.2`; 2026-09-22.

A working web application for private projects, connected records, retained files and revisable accounts. Explore an interactive graph, select a record to inspect its modules, and create attributed relations through participant controls. Each project has its own Git repository. This is an experimental implementation informed by the programme's Working Drafts, not an adopted Standard or a conformance claim.

61.1.1 Run locally

Requirements: Python 3.11 or later and Git on `PATH`. Python 3.12 and Git for Windows were used for development. The interface needs no Node build, external fonts or hosted services. Cytoscape.js is vendored locally with its MIT license and source/hash manifest under `generative_app/static/vendor/`.

From the programme root, use the shared setup and launch tools:

```
python applicative_infrastructure/common/tools/setup_application.py generalized --dev
python applicative_infrastructure/common/tools/run_application.py generalized
```

Open **http://127.0.0.1:8000**. The setup tool recreates the application's own environment and installs both shared packages. It handles Windows extended paths for nested dependencies; the same commands also work with `python3` on Linux or WSL. No demonstration account or default password is installed. Existing migrated accounts and sessions remain available.

The launcher uses Waitress, binds to loopback by default and resolves source/data locations independently of the shell's working directory. Use `--port 8002` if the default port is occupied. Stop it with Ctrl+C. Development previews record their process ID and logs under `build/application-servers/` at the programme root.

61.1.2 What you can do

- Register, sign in and sign out; sessions expire after 12 hours.
- Create multiple private projects, each accessible only to its creator through the application.
- Add records with overlapping recording roles, content, primary knowledge basis, occurrence/modality and owner-assigned status.
- Record attributed sources, methods, evidence references, uncertainty, alternatives, enabling/constraining conditions and consequences.
- Explore the graph or record list; select nodes, filter, pan, zoom, arrange and fit the view. Layout is a local display preference and creates no record revision.
- Open Spacetime to inspect asserted event order, select an event-defined temporal cut and view the corresponding scoped ontology subgraph and trajectories.
- Create a Relation record with named participant roles, record/target reference scope, direction and completeness qualifications. Add further participants or relate a Relation to another record. Create a new record and its connection in one save.
- Add retained notes and files through a record's modules. Replace a file or detach its current reference with an attributed reason.
- Revise a record with a reason and change category; inspect its previous versions and the project's latest 100 revision entries. Historical views pin labels, relationships, modules and file bytes to the same revision.
- Export selected-revision metadata as JSON, download a snapshot ZIP with material referenced by supported file modules, or a Git bundle containing complete reachable project history.

- Preview and explicitly migrate an earlier workspace. Reading a project never migrates it; earlier revisions remain unchanged.

Retained files are material, not automatically assessed evidence. The application does not fetch evidence URLs. A selected status such as `contested` describes the owner's account; it does not establish an independent review finding. The form records one primary knowledge basis; use method/context fields to preserve qualifications and mixed bases. The graph's placement and arrows establish no additional causal, evidential, ethical or legal meaning.

If another edit advances the project while your form is open, saving returns a conflict and preserves the draft. Review the latest version and reconcile before saving again. This applies across records in the same project. A retry of an unchanged transaction uses its original identifier; the server returns the original receipt if it already succeeded. Editing the request creates a new transaction identity.

61.1.3 Demonstration and screenshots

The **River Commons** demo contains 31 synthetic records across all six roles, five Events, six source files and seven preserved project revisions. Follow an inquiry from retrospective event recording through two topology cuts, subject trajectories, competing accounts and a correction of the retained history.

[Image description: The synthetic River Commons graph and Relation inspector]

[Image description: River Commons event order in the Spacetime view]

61.1.4 See the ontology change across event boundaries

After the access agreement: the encounter and agreement are included, with 10 scoped records in the topology. The inspector shows **A garden open for a trial**.

[Image description: Spacetime topology at the agreement boundary with trial access]

After the review: its declared predecessors are included, with 13 scoped records. The inspector shows **Access under a revised rota**. Both views use the same Git revision.

[Image description: Spacetime topology at the review boundary with revised access]

Subject trajectories retain successive descriptions and their event bounds, including accounts that ended or remain indeterminate:

[Image description: Subject trajectories for the garden and stewardship team]

To reproduce this in the demo, open **Spacetime**, choose **Before all**, then mark **A provisional access agreement** as passed. Inspect the topology and trajectories; next mark **A shared review** as passed and compare. This changes the chosen partial-order cut without saving a revision. The independent water observation remains unordered, and incomparable events are not asserted simultaneous.

See the ten-image gallery and demo setup and walkthrough. The scripts create a separate test account through the ordinary API and capture the actual UI. Credentials remain in ignored `.runtime/demo/river-commons.json`. The pictured graph uses the visible **care** filter and a local display arrangement; neither changes retained records.

61.1.5 Spacetime and trajectories

Here, space means the topology of the represented ontology at an event-defined boundary. Geographic coordinates can be part of a contextual State or Property account; graph layout positions do not record geographic position.

1. Create Event records, including events learned about retrospectively. Their save order does not determine their represented order.
2. In **Spacetime**, add an event-order account identifying which Event precedes another and the grounds for that claim. It is retained as a first-class Relation with its own qualifications and history.
3. Select a record's **Time & trajectory** panel to state the temporal applicability of its account. Boundaries can reference Events, remain explicitly unknown, or be explicitly unbounded within the stated scope. An optional subject groups related State, Property or other accounts into a trajectory; explain the continuity judgment in the basis.

4. Choose included Events in Spacetime. Selecting a later Event includes its asserted predecessors. The topology displays records established active at that cut, alongside separate coverage and uncertainty information. Changing the cut creates no Git revision.
5. Use the existing project revision selector to choose which retained account supplies those claims. Historical projections and their record inspectors use that same revision.

The selected Events form a downward-closed set in a partial order. A shared display column does not establish simultaneity, and no relation between two Events means their relative order remains unspecified. Event ranks do not measure elapsed time. The first extension uses Events as operational boundary markers; extended occurrences, onset/completion distinctions and overlapping intervals need further work.

Extent starts are inclusive and ends exclusive. An unknown boundary does not establish presence. Records lacking a scope remain **unscoped**, and an extent with incomparable, identical or reversed Event boundaries remains **indeterminate**. When a scoped Relation has participants not established active at the cut, the view discloses the omitted incidences. Contradictory order cycles remain inspectable and prevent a consistent cut until the account is revised. Unsupported event-order versions also prevent a cut; unsupported extent versions leave the affected account indeterminate. Withdrawal is an attributed revision, not deletion of the earlier claim.

This is a projection of explicit temporal accounts. It does not simulate event effects or treat the latest description as evidence of every earlier target state. Preserve distinct historical State accounts and their bounds when the target changes. Competing and non-realized accounts retain their qualifications; a temporal projection is not factual adjudication.

The read-only API is `GET /api/projects/<id>/spacetime?revision=<40-hex-head>` for the all-event cut, or `POST` to the same URL with `{"after":["event-uuid"]}` to select a cut. POST requires the ordinary session and CSRF token but creates no transaction. `after: []` selects the empty cut. Requests are limited to 1,000 distinct Event identifiers and 64 KiB. Both methods return the selected `head`, `current_head`, event order, cut, scopes, topology and diagnostics.

61.1.6 Where records live

By default, private application data is stored outside the source files in ignored `applicative_infrastructure/.runtime/generalized/`:

```
.runtime/generalized/
  accounts.sqlite3             # users, password hashes, sessions, ownership, rate limits
  repositories/
    <project-uuid>.git/          # bare Git repository, one per project
```

Each repository contains `project.json`, `records/<record-uuid>.json`, `.gsp/protocol.json`, `.gsp/transactions/<transaction-uuid>.json`, and `assets/<sha256>` on its `main` branch. A transaction publishes its records, material and receipt atomically. Git commits attribute saves to the account's display name and a pseudonymous account identifier, not its login email. Account passwords and session tokens are never placed in project repositories. Record text can itself contain personal information supplied by the author.

Changing a record or marking it withdrawn preserves its earlier text in history. Detaching a file removes the current record association; retained bytes and earlier descriptors remain available through history. A history bundle includes that earlier content and retained material. Git hashes and application attribution do not establish factual truth, independently authenticated identity or an immutable archive against the server operator.

To inspect a downloaded bundle, replace the example filename with your download:

```
git clone .\generativity-PROJECT-ID.bundle .\project-history
git -C .\project-history log
```

That checkout is an inspection copy. Importing edits back into the application is not implemented. JSON excludes all attachment bytes. Snapshot ZIPs exclude older revisions, receipts and unreferenced retained assets; their manifests disclose unsupported module dependencies. A Git bundle preserves project history but does not include accounts or application ownership. None of these exports alone is a complete running-service backup.

For a complete local backup, stop the server and copy the entire data directory, including the SQLite database and any journal files, plus repositories. Restore the whole directory with

the same application version into a controlled location. Crash recovery across initial Git-repository creation and the SQLite ownership transaction remains a manual administration task; an interrupted creation can leave an inaccessible orphan repository. Individual record writes publish atomically through Git reference comparison.

61.1.7 Configuration

Environment variable	Default	Purpose
`GSP_DATA_DIR`	`applicative_infrastructure/.runtime/generalized`	Absolute path recommended for a different private data location
`GSP_COOKIE_SECURE`	unset	Set to `1` when serving exclusively over HTTPS
`GSP_TRUSTED_HOSTS`	`localhost,127.0.0.1,[::1]`	Comma-separated request hostnames

Only use a data directory controlled by the application administrator. Protect filesystem access; private project access here is application authorization, not encryption at rest. The server deliberately does not trust forwarded client-IP headers. There is no production proxy configuration included.

The current version has no invitations, sharing, email verification, password recovery, account deletion, selective erasure, independently witnessed custody, remote Git synchronization or formal contestation workflow. The academia application is a subsequent adapter/upgrade project; it has not been modified here.

The HTTP/Git binding allows 1,000 records per project, 100 operations per transaction, 32 incidences per Relation, eight binary parts, 10 MiB per file, 20 MiB combined uploaded bytes and 128 MiB retained asset bytes in the main tree. Transaction JSON is limited to 1 MiB; resource JSON to 2 MiB and aggregate snapshot JSON to 32 MiB. Core account/compatibility requests retain a 128 KiB bound. Logical retained-asset limits exclude Git metadata and unreachable prepared objects and are not a physical disk quota. Public hosting needs deployment-specific TLS, registration controls, recovery, operational quotas, monitoring and an exercised retention/backup policy.

61.1.8 Verification and design

Install test tools with the setup command's `--dev` option. The shared verification guide gives the combined package/API/browser command; TESTING.md retains the original graph-release evidence and current reproduction instructions.

Tests use isolated temporary databases and real Git repositories. The browser test is opt-in; its instructions and observed results are recorded in TESTING.md.

The current design and ADR-0008 connect manuscript interpretation, user interaction and architecture. The academia review records useful patterns and incompatibilities without copying its implementation. DESIGN.md retains the earlier design and initial traceability baseline.

The reusable protocol package, GR-SPEC-120, GR-SPEC-121 and GR-SPEC-130 define the experimental model and binding. The event-spacetime design records manuscript grounding and the operational limits. Official implementation references include Git update-ref, Flask security guidance and Cytoscape.js.

62 TESTING

Original source: `applicative_infrastructure/gr_generalized_application/web_application/TESTING.md`.
Original source SHA-256: `4d3a64a97f2d4eaea26c3de5f07d9f99f73a3e476f6fe53f398b8809a319a7ae`.

62.1 Application verification

Document class: Informative implementation verification record
Status: EXPERIMENTAL; implementation checks, 2026-09-22; preview verification, 2026-09-27.

62.1.1 Observed results

The following checks passed against the local implementation. They establish the tested behavior in this environment, not a comprehensive security audit, accessibility conformance, standards conformance, or observed institutional practice.

62.1.2 River Commons demonstration and gallery (2026-09-27)

The synthetic demo was created through the authenticated local API in a separate account. Its verified inventory contains 31 records, all six roles, five Events, five order accounts (one withdrawn), six retained files and seven project revisions. All six downloaded materials matched their authored source bytes. The initial revision contains the later review before the earlier encounter is recorded; a historical cycle remains readable, while the current account supports consistent cuts. The agreement and review cuts project 10 and 13 records respectively without changing the accepted Git head.

The capture script produced ten actual Edge screenshots at desktop and mobile sizes. Visual review covered the graph, both topology cuts, trajectories, temporal editor, files, native upload control and historical contradiction. Capture discarded the unsaved editor/upload drafts and verified that the project head stayed unchanged. No page errors, captured CSP errors or horizontal mobile overflow were reported. The refreshed topology captures retain the selected event frontier and compare trial access with revised access; capture assertions check the 10-record and 13-record projections. Image hashes and the ten parent preview copies matched; 139 local links across the six related READMEs resolved. The gallery manifest records the capture inputs and image hashes without credentials.

An additional isolated server check began with the server unavailable, then recovered the saved unconfirmed registration. It produced exactly one account and one project. Repeating the seeder preserved that account, project, accepted head and complete seven-revision history. The check did not use the live demo runtime. These are focused demo and reproduction checks; the implementation suite results below were not rerun as part of adding the gallery.

62.1.3 Event-defined spacetime extension

The completed checks total **185 passing tests across separate runs**: 178 non-browser tests and seven Edge browser tests. The reusable protocol package is version 0.3.0; protocol, record-schema and profile identifiers remain at 0.2. The implementation review records the scope and limits.

The non-browser run includes 100 protocol cases, existing real-Git storage and API regressions, and six new temporal API cases. It checks retrospective ordering, ancestor-closed cuts, incomparable events, retained cycles and withdrawal, inclusive/exclusive boundaries, unknown and unscoped presence, subject grouping, partial Relation topology, unsupported interpreter behavior, historical projections and authorized read-only cuts. A 1,000-record case checks iterative traversal within the profile's limit.

Three temporal browser journeys cover event-order and extent forms, cut controls, desktop/mobile topology, historical read-only views, conflicting claims, exact cut retry, preserving concurrent unseen relation qualifications, and retaining a selected zero-byte file when discard is declined. The existing registration, graph and retained-file journeys also pass. One existing graph test exceeded its five-second assertion during concurrent browser/Git activity; the

fixture now allows 20 seconds, and that journey passed in an isolated rerun. Tests keep their behavioral assertions.

A seventh browser test covers a connected pair beside an isolated topology node. Final visual review found force-layout overlap; edgeless views now use a grid, with collision fallback for connected views. The new test and affected temporal journey passed together on 2026-09-27, checking node separation, retained edges and desktop/mobile layout.

All three JavaScript files pass syntax checks, and the editable package installation passes `pip check`. Screenshots include `build/webapp-review/spacetime-desktop.png`, `spacetime-mobile.png`, and the native file-picker views. These are isolated authored scenarios; assistive-technology and participant-comprehension studies remain open.

On 2026-09-27 the refreshed preview at port 8000 advertised `gsp.spacetime/1` and served the temporal script. Both existing project heads matched their earlier private capture; preview startup did not migrate or seed user projects.

62.1.4 Graph protocol release, schema 0.2 (historical baseline)

The combined non-browser run passed **125 tests**, with three opt-in browser journeys skipped in that command. The checks exercise the shared package together with the real storage/API implementation:

Check	Result	Scope
Independent protocol package	53 passed	Role overlap; same-batch references; unary, cyclic, repeated, parallel and higher-order incidence; opaque modules; profile guards; explicit migration; canonical digests; exact identifiers; byte descriptors and budgets; packaged schema and CLI
Real-Git storage	46 passed	Original storage regressions plus atomic graph/files/receipt publication, failure, racing writers, durable receipts, historical replacement/detachment, long paths, batch reads, quotas, supported binding manifests and bundle restoration
Flask API	26 passed	Original account/authorization regressions plus atomic graphs, pinned labels/material, durable replay/restart, altered transaction IDs, deterministic retry races, verified uploads and limits, exact multipart/JSON parsing, migration-only legacy mutation and precise ZIP scope
Browser journeys	3 passed	Registration and two-tab conflict regression; actual canvas selection and blank-canvas draft creation; multi-participant, higher-order and self relations; explicit completeness and change category; notes/files; pinned historical replacement bytes; lost-response replay after a later edit; list/keyboard alternatives and mobile layout
JavaScript and dependencies	Passed	Both application scripts passed `node --check`; `pip check` found no broken requirements

Check	Result	Scope
Publication/navigation integrity	Passed within stated scope	Local Markdown links resolve; 45 new bounded Working Draft clause IDs are unique; historical validation dossier checks remain valid

The browser trio passed independently with `GSP_BROWSER=msedge`. After final focus, canvas and historical-replay corrections, the two affected journeys passed again individually. Browser review artifacts use authored test accounts and isolated data, not the user's project. The live preview was refreshed after an offline copy of its existing data directory; its existing legacy project remained readable and unmigrated. This backup operation is not a general restoration certification.

Important defects identified during this cycle included legacy compatibility routes bypassing explicit migration, an identical-request race between receipt lookup and snapshot loading, undeclared opaque-module export limitations, permissive trailing-newline identifier patterns, and unsupported binding manifests being overwritten. Regression checks now cover those cases. Browser integration also required a local external stylesheet rule for the vendored graph renderer under the existing CSP and a renderer resize after connection controls change the canvas position. A recovered receipt for an earlier successful save now remains explicitly historical when newer edits exist; the browser does not label that older accepted snapshot current.

62.1.5 Initial schema 0.1 baseline (historical)

The earlier observed results below are retained as the initial implementation baseline; current graph scope is described above.

Check	Result	Scope
Real-Git storage integration	22 passed	Historical content, authorship/reasons, stale and concurrent writers, unreachable revisions, project isolation, path/ref input, isolated Git environment, failed writes, bundle restoration, and long Windows paths
Flask API integration	11 passed	Registration/login/logout, session rotation/revocation/expiry, password hashing, CSRF/origin/host checks, ownership on all project routes, revision reasons/conflicts, restart persistence, exports, validation, related-record boundaries, rate limits and Unicode handling
Browser journey	1 passed	Registration, project creation, record creation/revision, historical viewing, two-tab conflict/reconciliation, draft preservation, safe HTML-text display, search, both downloads, mobile layout, logout and login
JavaScript syntax	Passed	`node --check applicative_infrastructure/gr_generalized_application/web_application/generative_app/static/app.js`
Installed Python dependencies	Passed	`python -m pip check` reported no broken requirements

Check	Result	Scope
Visual review	Four screenshots inspected	Registration, record/history, desktop project, and 390-pixel mobile project; no observed overlap or horizontal overflow in these views

The tests ran on Windows with Python 3.12.10, Git 2.50.0.windows.1, Flask 3.1.3, Waitress 3.0.2, pytest 9.1.1 and Playwright 1.63.0 using the installed Microsoft Edge in headless mode. The runtime dependency versions are retained in requirements.lock.

Browser screenshots are generated under `build/webapp-review/` at the repository root. Their project and account content is authored test data, isolated from the application's private runtime directory. The visible HTML-looking string is an intentional injection probe verified to remain text, not an image element or executed script.

62.1.6 Infrastructure relocation verification (2026-09-22)

The relocated application and both common packages passed the combined suite: **128 passed**, including all three Edge browser journeys, with isolated test data and the new Python environment. The Git-store implementation remains byte-identical to the source before extraction. Storage tests now live with the reusable Git package; application tests import it through its public package. See the migration evidence for runtime preservation and academia checks.

62.1.7 Reproduce

From the repository root in PowerShell:

```
python applicative_infrastructure/common/tools/setup_application.py generalized --dev
.\applicative_infrastructure\.runtime\environments\generalized\Scripts\python.exe -m pytest -c
↪  applicative_infrastructure/gr_generalized_application/web_application/pytest.ini
↪  applicative_infrastructure/gr_generalized_application/web_application/tests --basetemp build/webapp-tests
.\applicative_infrastructure\.runtime\environments\generalized\Scripts\python.exe -m pytest
↪  applicative_infrastructure/common/packages/gsp_record_protocol/tests --basetemp build/protocol-tests
```

The browser test is skipped unless `GSP_BROWSER` is set. To include the browser journey using an installed Microsoft Edge:

```
$env:GSP_BROWSER='msedge'
.\applicative_infrastructure\.runtime\environments\generalized\Scripts\python.exe -m pytest -c
↪  applicative_infrastructure/gr_generalized_application/web_application/pytest.ini
↪  applicative_infrastructure/gr_generalized_application/web_application/tests --basetemp build/webapp-tests-with-browser
```

Use `chrome` for installed Google Chrome, or install Playwright Chromium with `python -m playwright install chromium` and set `GSP_BROWSER=chromium`. Browser checks start and stop an isolated Waitress server on a dynamically allocated loopback port; they do not require the ordinary application to be running. The chosen `--basetemp` directory is disposable test output; do not point it at application data or other valuable files.

The release integration command for all non-browser tests is:

```
.\applicative_infrastructure\.runtime\environments\generalized\Scripts\python.exe -m pytest -c
↪  applicative_infrastructure/gr_generalized_application/web_application/pytest.ini
↪  applicative_infrastructure/gr_generalized_application/web_application/tests
↪  applicative_infrastructure/common/packages/gsp_record_protocol/tests
↪  applicative_infrastructure/common/packages/gsp_git_store/tests --basetemp build/graph-release-tests -q
```

The graph browser journey generates `build/webapp-review/graph-multi-participant.png` and `graph-mobile.png`. The earlier manual smoke review generated `graph-desktop.png` and `graph-relation.png`. Pointer, form and list interactions are exercised; assistive-technology evaluation and measured user comprehension remain open.

62.1.8 Defects found and corrected

- A non-ASCII CSRF header reached a comparison requiring ASCII text. The API now rejects it with 403 rather than a server error.
- JSON containing an unpaired Unicode surrogate could reach password hashing or persistent storage. The API now rejects malformed Unicode with 400, while the regression test preserves valid Japanese, accented text and emoji.
- Browser integration exposed Git for Windows rejecting a long absolute `--git-dir` with `'$GIT_DIR' too big`, even with long-path configuration enabled. Repository operations now run from the selected bare repository using `--git-dir=.`. A storage regression exercises the long path without shortening the test location.
- Interface review corrected skip-navigation hash handling and invalidated pending route responses on logout, so those responses cannot re-render a signed-out workspace.

The Git storage tests deliberately leave unreachable objects when publication fails; the old main reference and current snapshot remain unchanged. Such objects are not accepted revisions and do not appear in the exported reachable history. This behavior is distinct from crash recovery across project creation and account ownership, which remains an operational limitation described in the design.

63 README

Original source: `applicative_infrastructure/gr_generalized_application/web_application/demo/README.md`.
Original source SHA-256: `3483e59c1efb28a1b20937f833e617817d09b62d3161f139d0ef215cb68eecf6`.

63.1 River Commons demonstration

Class: Informative application example and reproduction guide
Status: Synthetic demonstration for the experimental generalized application
Scenario: `river-commons/1`

River Commons is a fictional inquiry into shared care of a garden: how an encounter opens a possibility, how a provisional arrangement changes, and how accounts of those changes are questioned and revised. Every person, institution, place, observation and source file is invented. The example makes no claim about a real community or legal arrangement.

Start with the visualized spacetime walkthrough: see the event partial order, compare ontology topologies at two boundaries, then follow the garden and stewardship trajectories. The gallery also shows the record graph, temporal editor, retained files and historical contradictions. Its screenshots come from the running application, using ordinary controls.

63.1.1 What the project contains

The project contains 31 records, all six operational recording roles, notes, six retained source files and a deliberately nonchronological recording history.

Primary role	Records	Examples
Entity	4	The garden, residents' circle and stewardship team
State	5	Trial access, revised access and changing stewardship arrangements
Event	5	Encounter, access agreement, workday, review and an observation with no usable temporal anchor
Process	1	Learning to care for a shared place
Relation	12	Seven qualified relationship accounts and five event-order accounts
Property	4	Contextual location, unknown water suitability, proposed capacity and disputed workload

Four event-order claims are active in the final account. A fifth is withdrawn after it creates a contradictory chronology. The withdrawn record and its earlier assessment remain available in history.

Six materials in materials/ are attached through the normal file API: encounter notes, an access memorandum, water observations, a review summary, an attendance ledger and a chronology reconciliation. They contain synthetic evidence for the story, not independent verification of it.

63.1.2 Follow the story

The seeder preserves five narrative stages, followed by one attachment transaction:

1. **Begin with the later review.** The first record describes the end-of-trial review. Earlier occurrences have not yet been recorded.
2. **Add retrospective context.** Record the encounter, agreement and workday, their participants, and explicit event precedence. The independent water observation remains unordered.

3. **Describe scoped accounts.** Add successive and competing State accounts, contextual Properties, first-class Relations, an unrealized alternative and temporal extents.
4. **Preserve a contradiction.** An imported index is mistakenly interpreted as placing the review before the encounter. The historical temporal projection reports a cycle and does not invent a consistent cut.
5. **Revise the account.** Withdraw the mistaken order claim and correct reported review attendance from 18 entries to 16 distinct attendees. Both earlier assertions remain inspectable.
6. **Retain the materials.** Save the six fictional files alongside their associated records in one project revision.

Recording order and represented event order therefore differ visibly. The correction changes the recorded account; it does not change what happened in the fictional review.

63.1.3 Explore the visualized spacetime

Here, **space is the topology of applicable ontology records**, and an event boundary selects which temporal extents apply. A contextual location Property, **A place beside the footpath**, provides a geographical description within the story. It does not define the coordinates of this visualization.

Keep **Current project** selected so every view below uses the same retained revision. In **Spacetime**:

1. **Read the event partial order.** Follow the arrows from **The riverside encounter**, through two branches (**A provisional access agreement** and **The first shared workday**), to **A shared review**. No claim orders the two middle events relative to one another. **An independent water observation** is incomparable with all four. Neither graph columns nor the absence of arrows assert simultaneity.
2. **Select the trial boundary.** Choose **Before all**, then mark **A provisional access agreement** as passed. Its predecessor, the encounter, is included automatically: 2 of 5 events have passed. The ontology topology contains 10 records, including **A garden open for a trial** and **A provisional stewardship arrangement**. The workday remains outside this selected cut because it is not an established predecessor of the agreement.
3. **Select the review boundary.** Mark **A shared review** as passed. Both branches and the encounter are included: 4 of 5 events have passed. The topology contains 13 records. Trial access and the provisional arrangement have ended; **Access under a revised rota**, **Care shared through a rota** and **A renewed agreement to care** are applicable. The independent observation remains outside the cut and unordered.
4. **Follow the subject trajectories.** In **Record trajectories**, inspect the garden's State descriptions: **Access not yet arranged**, **A garden open for a trial**, then **Access under a revised rota**. Their inclusive starts and exclusive ends connect them to the agreement and review boundaries. Compare the stewardship team's informal and rotating-care descriptions, together with the contested workload concern.

The gallery's two boundary screenshots make this comparison visible, with the actual boundary labels and selected State accounts. Choosing cuts and viewing trajectories do not save project revisions. These projections apply recorded extents; they do not infer event effects or causation.

Unknown water applicability remains indeterminate, and the proposed six beds remain unscoped. A subject grouping connects descriptions without independently establishing identity, continuity or agreement among them. A consistent cut is a selected event boundary, not evidence that every applicable description shared a physical clock instant.

63.1.4 Inspect the accounts and their preservation

In **Graph**, select **A provisional stewardship arrangement** and open **Relation** to inspect its three participant roles. Open **Notes** or **Files** for associated context and material. The higher-order relation **Access is more than an open gate** refers to accounts being qualified, making its epistemic role explicit.

Select **A garden open for a trial**, open **Time & trajectory**, and choose **Revise temporal extent** to inspect its inclusive agreement boundary, exclusive review boundary, subject and stated basis. Cancel to keep the demonstration unchanged.

Finally, use the **Project revision** selector to open the stage whose reason begins **Retain a contested chronology claim**. Its event-order cycle prevents a consistent topology projection. Returning to the current project shows the withdrawn claim alongside the remaining active order. Record **History** and **Read full account** expose the preservation and attribution details.

63.1.5 Create the demonstration

Use the complete application/infrastructure checkout and the development environment described in the application guide. From `applicative_infrastructure/`, install the environment if needed:

```
python common/tools/setup_application.py generalized --dev
```

If the generalized application is not already running, start it in another terminal:

```
python common/tools/run_application.py generalized
```

Then create or resume the demo through its local HTTP API:

```
& .runtime/environments/generalized/Scripts/python.exe gr_generalized_application/web_application/demo/seed.py
```

The default origin is `http://127.0.0.1:8000`. Use `--base-url http://127.0.0.1:8002` when the application runs on another local port. The client accepts local HTTP origins only. On Linux/WSL, use `.runtime/environments/generalized/bin/python` instead of the Windows interpreter path.

The script creates a separate **Demo curator** account with an `example.test` email address and a generated password, then creates its private project through the ordinary API. It prints the project link and the path to local sign-in details. It does not select another user's project.

Credentials, project identifiers, transaction-recovery data and accepted revision identifiers are kept in the ignored file:

```
applicative_infrastructure/.runtime/demo/river-commons.json
```

Read that file locally when signing in to explore the project. It contains a plaintext generated demo password; do not add it to source control or include it in screenshots. The actual account database and project Git repository remain in the application's configured runtime.

Rerunning the seeder resumes recorded stages and retries a pending transaction with its original identifier. It does not reset the project. If registration was interrupted before confirmation, it first tries the saved credentials and retries registration only when no account or project has been confirmed. If other edits have advanced the demo, the script stops rather than overwriting them. A different server or scenario is also rejected while this manifest belongs to the existing demonstration. Preserve the manifest together with the relevant runtime if you need to resume that instance later.

63.1.6 Reproduce the gallery

After seeding, run from `applicative_infrastructure/`:

```
& .runtime/environments/generalized/Scripts/python.exe gr_generalized_application/web_application/demo/capture.py --browser msedge
```

The development dependencies include Playwright. The default browser is installed Microsoft Edge; `--browser chrome` uses installed Chrome, and `--browser chromium` uses a separately installed Playwright Chromium browser.

The capture script signs in using the private manifest, reads the actual project and operates ordinary UI controls. It opens the temporal editor and selects a synthetic upload file, then discards both drafts. It checks that the project head is unchanged, rejects captured browser errors and checks the narrow viewport for horizontal overflow.

The script writes ten PNG images and a public `manifest.json` into the gallery directory. The manifest records the synthetic scenario, capture time, application source commit, project head, viewport dimensions and image hashes; it excludes credentials. Five preview images

are synchronized into each of the programme and infrastructure repositories' `docs/gallery/` directories: the record graph, event order, earlier topology, later topology and subject trajectories. The gallery maintenance table gives the exact canonical-to-preview filename mapping. These deliberate copies let parent READMEs render locally and on GitHub across submodule boundaries. Regenerate previews through this script instead of editing the copies independently.

The graph overview uses the visible search query **care**, showing 11 of the 31 records. That filter makes the pictured relationships readable; the other records remain in the project. The capture script arranges those visible nodes into a local display grid, equivalent to dragging them into position; it does not change records or invent connections. Desktop captures use a 1680 × 1120 viewport and the mobile capture uses 430 × 1050. Scrolling, selected cuts and graph layout affect presentation without creating project revisions.

63.1.7 Source and limits

- scenario.py describes deterministic record identifiers, staged operations and attachment inputs.
- seed.py submits those stages through authenticated, CSRF-protected application endpoints and verifies the scenario's principal temporal distinctions.
- capture.py produces the actual UI images and synchronizes parent previews.

This example illustrates implemented recording and projection behavior. It does not simulate unrecorded event effects, infer causation from precedence, establish a common physical clock, or demonstrate factual truth or formal Standard conformance. Its unresolved access concerns, unknown observation scope and unrealized alternative are part of the example rather than missing setup steps.

64 ADR 0001 project architecture

Original source: `decisions/ADR-0001-project-architecture.md`.
Original source SHA-256: `6ba33b7be65700312a75ad66df2bb998bda194899534ae16b6465a407e5e29f1`.

64.1 ADR-0001 — Separate Governance, Standards, Manuals, and Technical Reports

Status: Accepted

64.1.1 Context

The project combines procedural governance, normative standardization, practical guidance, and theoretical research.

64.1.2 Decision

Maintain four primary publication layers:

1. governance documents;
2. normative standards;
3. non-normative manuals/guides;
4. technical reports.

64.1.3 Rationale

This reduces category confusion and allows philosophical or mathematical work to mature without prematurely becoming normative.

64.1.4 Consequences

Every substantive contribution should be placed in the appropriate publication class.

65 ADR 0002 standards first specifications on demand

Original source: `decisions/ADR-0002-standards-first-specifications-on-demand.md`.
Original source SHA-256: `56874fe4b95f53cbadb8a21b71044cff33150cdb74e86bddb176d11b76282751`.

65.1 ADR-0002 — Standards-First, Specifications-on-Demand Development

Status: Accepted

65.1.1 Context

The programme distinguishes Standards from Specifications.

A Standard expresses programme-level normative requirements and conformance expectations. A Specification defines technical or infrastructural details needed to implement, exchange, validate, or automate those requirements.

Developing specifications before the normative need is understood risks creating unnecessary infrastructure. Finalizing standards without testing technical realizability risks producing requirements that cannot be implemented coherently.

65.1.2 Decision

The programme will generally begin from the **Standard track**.

The Standard should first establish:

- purpose;
- scope;
- terminology;
- normative principles;
- minimum requirements;
- conformance boundaries;
- institutional and ethical constraints.

During standards development, contributors shall identify requirements that cannot be implemented or tested without additional technical infrastructure.

Those requirements may create one or more **Specification work items**.

Preferred development pattern:

Standard Working Draft → Infrastructure Need → Specification → Pilot / Implementation → Standard Revision → Adopted Standard

Specifications are therefore developed when required by the Standard, rather than as the default starting point.

65.1.3 Clarification

“Standards-first” does not mean that the Standard must be finalized before specifications are written.

The Standard and its dependent specifications may co-evolve during working-draft and pilot stages.

The Standard should define **what shall be achieved**.

A Specification should normally define **how a technical representation or infrastructure realizes part of that requirement**.

65.1.4 Example

A draft Generativity Recording Standard may require:

> A conforming record shall preserve the identity, temporal placement, provenance, and epistemic status of a recorded Event.

If implementation shows that interoperable exchange requires a common identifier format and a machine-readable epistemic-status model, the programme may then initiate:

- an Identifier Specification;
- an Epistemic Record Specification;
- an Interchange Specification.

The Standard should not contain unnecessary serialization details merely because they are needed by one implementation.

65.1.5 Consequences

- Standards remain conceptually and institutionally primary.
- Specifications remain demand-driven and technically scoped.
- Technical experimentation can feed back into the Standard before adoption.
- The programme avoids building infrastructure that has no normative use case.
- Published Standards may normatively reference stable Specifications where required.

65.1.6 Affected documents

- `AGENTS.md`
- `docs/framework/publication_taxonomy.md`
- `docs/planning/preliminary_plan.md`
- `PROGRAMME_BRIEF.md`

66 ADR 0003 epistemic praxis development plan

Original source: `decisions/ADR-0003-epistemic-praxis-development-plan.md`.
Original source SHA-256: `beabbdbea78da1f3913070c5760f82015d6726bd0251bbc29a9d9f70946b0bed`.

66.1 ADR-0003 — Epistemic and Practical Development Architecture

Document class: Architecture Decision Record
Status: Proposed
Date: 2026-09-22

66.1.1 Context

The programme initiator confirmed that symbolic crisis and the conditions of warranted recognition and practical action are the organizing motivation. Existing programme documents support these concerns but foreground archival loss and AI provenance. The previous plan postpones some epistemic, presentation, protection and institutional work until after recording and information-model development.

The initiator requested comprehensive planning for standards, protocols and specifications. This authorizes preparing a reviewable plan; it does not itself adopt technical Standards, establish legal authority, or settle every proposed allocation below.

The initiator further specified comparison with established approaches such as ISO and IEEE and substantive coverage of governance, jurisprudence, public policy, ethics and related domains. Those domains require their own inquiry and review, not merely technical metadata or an adoption-stage checklist.

Accepted ADR-0002 already establishes Standards-first, Specifications-on-demand development. The specification-first statement in the historical preliminary plan is inconsistent with that accepted decision.

66.1.2 Proposed direction

1. Use epistemic and practical infrastructure as the programme-level purpose. Treat archival preservation and AI provenance as important components of it.
2. Develop a bounded initial cycle spanning recording, evidence, contestation, revision, presentation, protection and practical response. Preserve the distinction between changes in the situation, knowledge, and descriptive regime.
3. Develop protocols within Specifications as behavior involving participants, states, exchanges, transitions and failures; protocols can also be specified in an adopted Standard. Do not create a fourth publication authority class or equate institutional procedures with network protocols.
4. Preserve existing publication codes. Clarify Standards-track requirements versus Specification implementation responsibilities for GR-120/130/200. Open additional work items only when a distinct need is demonstrated.
5. Use source traceability, staged governance, pilots and explicit conformance subjects to determine readiness. Retain the earlier plan as historical evidence and use the comprehensive plan for current proposed sequencing.
6. Compare ISO/IEC and IEEE development mechanisms and document proportionate local choices. Maintain a cross-domain programme connecting motivations, substantive questions, publication roles, reviewers and evaluation; distinguish public-policy and legal proposals from technical conformance.

This is the selected direction for the present planning draft. The architecture proposal remains subject to recorded review; the confirmed mission framing and accepted ADR-0002 are distinguished from newly proposed scope and gates.

66.1.3 Alternatives considered

Alternative	Reason not selected for this planning draft
Begin with an exhaustive six-class schema	Settles implementation before epistemic and institutional needs; risks treating record forms as ontology
Complete the recording model before adding epistemic and procedural work	Does not test the confirmed mission in the first usable cycle
Create a separate publication family for every protocol	Confuses a technical subject with publication authority and adds maintenance overhead
Attempt the complete standards portfolio in the first release	Exceeds demonstrated capacity and delays evaluation of a useful bounded cycle
Replace the earlier plan with a clean narrative	Removes evidence of the programme's changing emphasis and contradictory sequencing
Copy an established standards body's procedures wholesale	Imports organizational and resource assumptions without establishing their fit or authority
Treat legal, ethical and policy questions only as metadata	Omits substantive conflicts, justification, institutional options and practical consequences

66.1.4 Rationale

GRE Chapter 1 links symbolic production, referential reliability, classification and practical trust. Chapters 3–5 distinguish generative effects, reality, manifestation, evidence, interpretation and intervention. Metamodel Part II distinguishes formation, description and institutional uptake as well as possible transformations, occurrences and records. These sources motivate the proposal without directly conferring normative authority.

The foundation traceability map records passages, operational proposals and unresolved differences. The comprehensive plan supplies the portfolio, dependencies, evidence and work queue.

66.1.5 Consequences

- Initial pilots evaluate an epistemic and practical cycle, not only record serialization.
- Presentation, access, contestation and conformance become early design concerns.
- Technical choices remain conditional on demonstrated requirements.
- Proposals for legal profiles, metrics and stronger formal semantics remain explicitly unresolved or deferred.
- The plan does not certify historical truth, the goodness of generativity, or institutional legitimacy.

66.1.6 Affected documents

- `PROGRAMME_BRIEF.md` and `README.md`
- `docs/framework/publication_taxonomy.md`
- `docs/planning/comprehensive_development_plan.md` and supporting planning documents
- `docs/planning/preliminary_plan.md` and `docs/planning/open_questions.md`
- `foundation_manuscripts/MANIFEST.md`
- `specifications/README.md`
- `CHANGELOG.md` and `PROJECT_INDEX.txt`

66.1.7 Supersedes

No accepted ADR. ADR-0001 and ADR-0002 remain in force. The comprehensive plan replaces the earlier preliminary plan only as the current planning proposal; the historical text is retained.

66.1.8 Superseded by

None.

67 ADR 0004 initial working draft package

Original source: `decisions/ADR-0004-initial-working-draft-package.md`.
Original source SHA-256: `ca7520d7610091b6ecd00fe39eeb0a22645b92ada900ef6e8653a878fded058e`.

67.1 ADR-0004 — Initial working drafts and bounded operational requirements

Document class: Architecture Decision Record
Status: Proposed; implemented provisionally for drafting and review
Date: 2026-09-22
Related decisions: Accepted ADR-0002; Proposed ADR-0003

67.1.1 Issue and authorization

The programme initiator requested that development begin according to the comprehensive plan and authorized TeX sources and WSL compilation. The repository's governance-first rule requires coherent procedures before formal technical project initiation. Preparing substantive drafts and synthetic cases is authorized; authoring does not appoint a committee, adopt governance, approve GR/NWIP-001, settle manuscript disagreements, or publish an adopted Standard.

The earlier Markdown files are valuable scope outlines but are insufficient to assess obligations, responsibility, evidence, and failure behavior. An implementation-first schema would also prematurely settle the representation of claims, evidence, and the six record roles.

67.1.2 Alternatives

1. Draft governance alone and defer all technical clauses. This respects sequence but gives little concrete material with which to test drafting rules or discover conceptual problems.
2. Produce the entire technical family and schema now. This spreads review capacity thinly, conceals unassigned institutional responsibilities, and risks premature ontological and protocol decisions.
3. Produce a governance package plus a bounded preparatory vocabulary/recording/evidence/contestation cycle, assess synthetic cases, and derive later infrastructure needs from those requirements.

67.1.3 Provisional direction

Use alternative 3 for this authoring cycle. Prepare five governance Working Drafts and GR-100, GR-110, GR-200 and GR-210, with stable clause identifiers and assessment guidance. Preserve publication numbers and historical outlines. Use descriptive titles for governance documents; build filenames are not additional adopted publication codes.

The canonical substantive text for these editions is TeX. Shared presentation lives in `publications/preamble.tex`; a manifest drives repeatable WSL/LuaLaTeX compilation. Markdown supplies navigation, examples, review records, templates and decisions. PDFs are generated review artifacts, excluded from source control by default but available locally. Source and PDF hashes identify the built package. Compilation and text inspection are distinguished from substantive conformance, accessibility assurance and formal release.

67.1.4 Operational choices and their bounds

Choice	Rationale and alternatives	Source or issue	Affected clauses
Keep target, manifestation, representation, claim, evidence role and assessment distinguishable without selecting schema classes.	A single fact/truth field hides attribution and competing warrants; a mandatory class hierarchy is premature.	FM-004 §§4.2/4.6; FM-005 §5.4; Q-06	GR-100 definitions; E200-003–016
Use six operational roles with scoped identity and admissibility.	Roles can overlap; they are neither metaphysical atoms nor an asserted one-to-one interpretation of weak formal states/mechanisms. Property/Attribute remains unresolved.	FM-007 §§7–12; Q-05/09	GR-100 role definitions and V100 requirements; R110-006–009
Separate occurrence/modality from epistemic mode.	A realized event can be retrospectively inferred. Planned/possible and reported/inferred answer different questions.	FM-005 evidence distinctions; conceptual cross-review	GR-100 Event/Process; E200-005; R110-012
Require scoped, attributed generative accounts with grounds, alternatives, maintenance and loss.	A universal generativity score would exceed the current sources and evidence. Output count alone is insufficient.	FM-005 §5.14; FM-003 §§3.10/3.12; Q-10/16	R110-010–018; E200-024
Preserve changes in situation, evidence/assessment, and descriptive regime as distinguishable revision reasons.	Silent overwrite erases earlier knowledge and consequences. More than one reason can apply.	FM-005 §5.20; FM-007 §§16/19; Q-07	E200-017–020; R110-019–022; C210-017/020/025
Treat challenge handling as an accountable institutional procedure with a separate case record.	Supplying challenge fields does not establish meaningful receipt, review, action or remedy. This is a new operational proposal, not a claim that manuscripts prescribe this exact procedure.	FM-003 §3.12; FM-005 §§5.18–5.20; Q-14/17	E200-021; R110-023; C210-001–032
Permit bounded unknowns, restrictions and lawful disposal while recording their limits.	An immutable public history can expose protected information; removal without any permitted disposition can conceal consequential changes. Neither extreme is mandatory.	Programme privacy/jurisprudential discipline; Q-11	E200-023/026; R110-024–030; C210-027–029
Make GR-200 package obligations an explicit dependency of material-claim packages in GR-110/210.	Claim-level field checks alone miss package scope, assessment and transformed-view obligations.	Cross-document review; Q-12	R110-005; C210-030
Treat package-only/case-only reviews as partial documentary assessments in this edition.	A document cannot prove that a procedural action occurred. No reduced conformance profile is yet established; unobserved behavior is not assessed, not automatically inapplicable.	Q-12/14	R110-032–034; C210-030–032

Page-level source locators and limitations appear in the TeX source rationale and founda-

tion traceability map. FM-002/FM-003 chronology remains unresolved; this decision does not reconcile those manuscripts or resolve the formal issues in Q-09.

67.1.5 Governance choices

The Charter proposes an explicit founding instrument grounded in the signatories' actual authority, with accepted appointments, review evidence and declared limits. The committee is not treated as already constituted. D1 proposes 60-day public review, 30-day substantive re-review, a two-thirds returned-ballot quorum, at least three substantive votes and two-thirds approval of substantive votes. These are local proposals with alternatives and rationale, not imported ISO/IEEE rules. Separate Specification and policy release routes preserve their classes. Numerical defaults, representativeness, rights terms and independent-review capacity remain open before adoption.

67.1.6 Consequences and assessment

- Governance M1 remains incomplete until real authority, appointments, rights, review and adoption evidence exist. Technical documents remain preparatory Working Drafts.
- The first fixture is fictional; it is usable without collecting personal data. It tests distinctions and failure expectations, not live institutional effectiveness.
- No network protocol, canonical schema, universal confidence scale, universal generativity metric or legal entitlement is selected.
- GR-120/130/140/150/160/300/310/400 remain coordinated future work. Their contextual constraints appear in this draft cycle, but these four documents do not replace those projects.
- Implementation trials can now identify concrete Specification needs. A technical binding follows a demonstrated requirement and its own work-item decision.
- TeX/PDF accessibility is not established by a successful build. The initial source format and inspection limitations are recorded in the review report.

67.1.7 Affected artifacts and acceptance

Affected artifacts are the nine documents in the publication manifest, publication tooling, navigation, templates, the synthetic case, review evidence, issue register and changelog. Existing historical outlines and earlier ADR reasoning remain retained.

Acceptance of this ADR requires a recorded architecture decision by the programme's responsible authority. The user has authorized authoring; this record remains Proposed so that the operational choices remain available for explicit review rather than being represented as already approved normative interpretations.

68 ADR 0005 expanded drafts and source models

Original source: `decisions/ADR-0005-expanded-drafts-and-source-models.md`.
Original source SHA-256: `78639e78e531d7d2ffc6d31dfcbe49029399ad3dbb01bd2bdaef61bdbb4fcc52`.

68.1 ADR-0005 — Expanded drafts and external publication models

Status: PROPOSED; implemented as reversible preparatory authoring
Date: 2026-09-22
Class: Architecture and editorial decision record
Related: ADR-0004; Q-21–30

68.1.1 Issue

The first nine Working Drafts contained 318 requirement identifiers across 84 compiled pages. They established a bounded programme, but compressed definitions, operational procedures, application conditions and assessment evidence. The user requested more substantive documents and a more formal style, with ISO, IEEE and UN-system publications as possible models. Increasing page count without developing those functions would not address that request.

68.1.2 Alternatives

1. Retain 0.1 and change typography alone. This leaves important procedure and assessment detail underdeveloped.
2. Copy one organization's complete template and institutional model. This risks implying an authority the programme does not possess and importing requirements suited to another mandate.
3. Expand the existing nine drafts, preserve historical sources and stable requirement identifiers, and use a documented combination of verified editorial and institutional models.
4. Begin every planned GR publication immediately. This spreads source and review capacity across unresolved dependencies and contradicts the governance-first priority.

68.1.3 Selected direction

Use alternative 3 for Working Draft package 0.2. Preserve the 0.1 sources, preamble, manifest and build/check scripts under `publications/archive/0.1/`, with hashes. Existing IDs remain stable. Dependency references change explicitly to the coordinated 0.2 editions. New obligations receive new IDs. This decision neither adopts governance nor promotes a draft to a Standard.

Use the ISO annotated model and accessible IEEE rules for formal structure and drafting discipline; use the ITU author guide as a UN-system technical-writing comparator; use the UN NQAF manual for comparison of institutional, process and output quality. The source study records distinct purposes, actual access and limits. UN/CEFACT catalogue verification establishes a relevant technical publication class, but inaccessible clauses are not reconstructed from memory.

68.1.4 Operational changes and alternatives

Proposed direction	Reason and rejected alternative	Affected documents
Add formal front matter, stable clause hierarchy, normative schedules and informative annexes	Gives readers identifiable scope, dependencies and assessment obligations; cosmetic expansion alone is insufficient	All nine drafts; shared preamble; D2
Specify authority, resources, participation, delegation, review, maintenance, transitions and records	An institution cannot be established by writing a role name; fictional appointments or presumed capacity would obscure the development gate	Charter; D1; TC Charter

Proposed direction	Reason and rejected alternative	Affected documents
Specify conduct-case stages and distinguish evidence for findings from justification of remedies	A complaint label alone gives no workable response or protection process; automatic sanctions or unreasoned discretion are unsuitable	Ethics/IP policy
Propose 'more likely than not on the assessed evidence' for an internal substantiated conduct finding	Provides a reviewable local decision criterion; alternatives include a higher threshold, a context-specific schedule, or non-adjudicative findings only. The choice remains PROVISIONAL and needs governance/ethics review	EIP-069/070; Q-29
Expand terminology, six-role conditions, epistemic methods and generative accounts without imposing a schema	Keeps source interpretation, conceptual roles and encoding distinguishable; a new universal fact object or numerical generativity measure would exceed the evidence	GR-100/110/200
Specify case states, assessment and response, review capacity and dependent correction	Makes procedural action assessable; possession of a case record alone is insufficient	GR-210
Treat semantic and assessment schedules as proposed normative material	Makes missing information and incomplete assessment visible; arbitrary implementation field names remain avoidable	D2; GR-110/200/210 and governance annexes
Preserve partial-assessment limits and exact dependency editions	Prevents a package or case-only check from standing in for unobserved institutional behavior	All conformance clauses

The conduct evidence threshold is an internal programme proposal. It does not describe the standard of proof in any court or jurisdiction, establish external liability, or authorize a remedy without an identified institutional basis. Formal governance review can change it with a traced revision.

68.1.5 Scope and conceptual continuity

The programme continues to address symbolic crisis through inspectable recognition, evidence, contestation, revision and practical action. Metamodel, record roles, epistemic assessment, normative evaluation, jurisprudence, governance and implementation remain distinct. Foundation manuscripts supply conceptual authority, not institutional adoption. The Property/Attribute issue, manuscript chronology and limits of fixed-carrier formal results remain unresolved.

New semantic schedules are operational proposals. Their record components are not additional ultimate constituents of reality. They allow justified missingness, protected references, uncertainty, plurality, maintenance and loss. Historical actors are not assigned knowledge or categories that appeared later.

68.1.6 Consequences and review evidence

There are more obligations and therefore potentially greater recording and institutional burden. Q-26/28 require assessment of that burden and decisions about justified profiles. More pages, automated artifact checks and AI-assisted cross-review do not demonstrate stakeholder acceptance or successful implementation.

The expanded review record records actual build results, comparisons and unresolved checks. Historical fixtures P0 and P1 retain their 0.1 basis until separately reassessed; they are not evidence of fulfillment of newly added 0.2 obligations.

Affected files comprise the nine TeX sources, shared presentation, publication manifest/navigation, build/check tools, requirement change register, archive, source study/register,

Programme Brief development status, issue register, changelog and project index. Earlier ADRs and historical review findings remain available.

69 ADR 0006 validation and assessment boundaries

Original source: `decisions/ADR-0006-validation-and-assessment-boundaries.md`.
Original source SHA-256: `19800a59cc16fdeb25b5463d6fa261c178249a07c128ed515ae665b1c105bdf1`.

69.1 ADR-0006 — Validation of 0.2 and assessment boundaries

Status: PROPOSED; implemented in preparatory Working Draft 0.3
Date: 2026-09-22
Class: Architecture and operationalization decision record
Predecessors: ADR-0004 and ADR-0005 remain historical decisions

69.1.1 Issue and alternatives

The expanded 0.2 package needs substantive source and scenario review. Successful PDF production does not establish that requirements preserve distinctions, identify failures or work in an institution. The user authorized continuing with a substantive review matrix and updated P0/P1 assessments leading to a traced revision.

Alternatives considered were: expand the publication family immediately; claim full conformance from authored examples; or fix a baseline, review its provisions and source relationships, assess bounded synthetic components, and revise only supported defects and clarifications. This cycle selects the third alternative. It preserves the Standards-first development sequence and avoids treating a local fixture as an adopted information model.

69.1.2 Selected direction

Preserve the nine 0.2 sources, presentation, manifest, tools, Programme Brief and review records with hashes. Review all baseline requirement identifiers through explicit topical groups, with full source text and locators in a coverage matrix. Keep editorial review, component assessment, numerical execution and institutional readiness distinct.

The term `reviewed` in the matrix means that the identified text received the stated editorial/source examination. It is not a conformance result. A selected P1 component can receive a documentary result while a procedural component remains not assessed. Group coverage does not establish that every obligation or application was exercised. The baseline remains 0.2 even after current documents become 0.3.

69.1.3 Proposed changes

Finding	Direction and rationale	Alternatives and limits	Affected material
GOV-F01: an invalid/unresolved submission can disappear into non-response	Distinguish valid counted ballots, eligible participants with attributable unsuccessful attempts and no counted ballot, and eligible participants without an attributable submission. Retain a separate inventory for unattributable/ineligible submissions	Counting invalid attempts as abstentions changes quorum; calling them silence erases attempted participation. No change to the two-thirds or three-substantive-vote rules	D1-032/074; ballot dossier; P0

Finding	Direction and rationale	Alternatives and limits	Affected material
GR-210 dependency ambiguity	Import GR-100 terms, record-role meanings and result meanings within an explicit scope; preserve all applicable GR-200 package obligations	A separate blanket vocabulary-conformity claim adds obligations not clearly intended by the existing reference. Reduced claim-only GR-200 checking would conceal package obligations	GR-210 Clause 2
CF-01: a general safeguard can be incorrectly marked inapplicable	Assess V100-011's general metamodel/record distinction independently of its conditional mapping component	Presence or absence of a mapping does not determine whether the general safeguard applies	GR-100 Annex A
CF-02: dispute disposition appears among effect modalities	Separate occurrence/modality, epistemic basis and assessment/dispute disposition explicitly	An actual occurrence can be retrospectively inferred and its contribution contested; these are compatible states, not competing options for one field	R110-012
CF-03: recirculation link uncertainty can disappear within a generic return account	When recirculation is asserted, identify initial generation, conversion/transfer, return pathway and effect on later conditions, with stage/link-specific grounds and uncertainty	Do not define all generativity return as recirculation, require a universal quantity or infer entitlement. Missing links remain unresolved rather than invented	New R110-112; related assessment row and source rationale

The recirculation provision is an operational narrowing for a particular claim. Its conceptual basis is FM-005, section 5.17.3, PDF page 145, which distinguishes the uncertainty inherited across these stages. It does not settle the broader definition of generativity return, its valuation or any distributive rule. The conceptual review preserves source limits and unresolved terminology.

69.1.4 Baselines and evidence

P0/v2 and P1/v2 are new artifacts, not rewrites of the original fixtures. Numerical checks in P0 can be executed and reported as such. Fictional review, notification, custody and repair events remain fictional even when the narrative is internally consistent. A retained document can establish what the example says, but not that a real process occurred.

The current coordinated publication edition advances to 0.3. All historical IDs remain; changed text and dependency editions are separately recorded against 0.2. The new R110-112 is outside the 753-ID baseline matrix and has its own source and discriminating assessment route. No founding instrument, appointment, contribution licence, external partnership or standard adoption is created by this revision.

69.1.5 Open matters and consequences

Actual authority, independent capacity, rights, representation, accessibility and burden remain evidence gaps. Calendar-day boundary conventions and possible overlap of reply and ballot windows need an explicit governance choice before use. A conservative sequential synthetic schedule does not silently adopt that choice.

The revision adds one conditional recording obligation and clarifies several assessment boundaries. Its practical cost remains unmeasured. A future GR-150 profile proposal uses observed evidence and states precisely which subject and parent obligations it addresses; it does not convert this cycle's partial assessment into full conformity.

Affected documents are D1, GR-100, GR-110 and GR-210 substantively, the coordinated nine-document edition and dependencies, validation artifacts, archive, comparison/check

tooling, issue register, Programme Brief development status, publication navigation and changelog.

70 ADR 0007 git backed project workspace

Original source: `decisions/ADR-0007-git-backed-project-workspace.md`.
Original source SHA-256: `fa15ab564010e034c8d1a3302d8485ecb2d93273da73b695becbe4dbcb8f559f`.

70.1 ADR-0007 — Git-backed project workspace

Status: PROVISIONAL; selected for experimental implementation
Date: 2026-09-22
Class: Application architecture and scoped operationalization decision record
Related decisions: ADR-0002, ADR-0006

70.1.1 Issue and authorization

The user requested a web application implementing the programme's ideas, with registration, login, project creation, recording within projects, and Git as each project's record backend. The current Working Drafts identify practical needs for distinguishable records, qualified assertions, attributed revision, historical inspection, and bounded access. An application can expose implementation difficulties and recording burden that authored examples alone cannot establish.

The application is an experimental implementation of selected functions. It is not an adopted Standard, a complete GR information model, a formally approved institutional pilot, or a finding of conformity to GR-100, GR-110, GR-200, or GR-210. The user has authorized implementation now. This follows ADR-0002's provision for implementation during draft development; it does not constitute programme adoption or work-item approval. The accompanying design is informative implementation documentation, without a new GR publication number.

70.1.2 Alternatives

Alternative	Benefit	Limitation relevant to this request
Store projects and record history solely in a relational database	One transactional system and straightforward queries	Does not provide the requested per-project Git record backend
Store accounts, sessions, projects, and records together in Git	One storage mechanism	Replicates credential and session material into retained history; weak fit for authentication queries and expiration
Use SQLite for application accounts and access lookup, with a separate Git repository for each project's manifest and records	Separates authentication from retained project content; project history is inspectable using Git	Requires explicit authority and failure boundaries between the database and repositories
Depend on a hosted Git service for every operation	Reuses remote collaboration and repository administration	Adds a service account, network dependency, and permission system before the local recording workflow is established

The third alternative is selected. Flask serves the application and JSON endpoints, SQLite holds account/session information and project ownership lookup, and a separate bare Git repository holds each project's authoritative manifest and record snapshots. A browser interface uses ordinary HTML, CSS, and JavaScript. This bounded stack can run locally without an external hosting account.

70.1.3 Decisions and rationale

Projects initially have one owning account and private application access. The application does not infer that account ownership establishes legal ownership of recorded material. Registration establishes an application identity; it does not verify a person's real-world identity, evidence, competence, or authority.

Each accepted project or record mutation creates a new Git snapshot. A record has a stable application identifier; a commit identifies a retained project version. Revision requires a reason and records the authenticated actor and server time. The client supplies the project revision it edited, and the server advances the main reference only if its previous value still matches. Git's `update-ref` old-value check supplies this conditional update; `commit-tree` constructs a commit from a tree and parent. A conflicting writer receives a conflict rather than silently overwriting the intervening update. These mechanisms do not make SQLite and Git one transaction.

Project content is represented as versioned JSON, not as arbitrary user-selected filesystem paths or executable files. Password material and sessions remain outside project Git history. Git authorship identifies the recording account through server-assigned attribution; a record's separate `attributed_to` field identifies the source or observer as represented by the recorder. Attribution remains a claim unless separately examined.

The six role labels are Entity, State, Event, Process, Relation, and Property. One primary role is selected for a particular application record. This is an interface limitation, not a claim that targets fit exclusive kinds. Multiple linked records can describe the same target from different roles, without the linkage itself proving target identity. Role-specific admissibility and identity criteria remain incomplete. The application retains the programme's current label Property without deciding the unresolved relationship to the manuscript's Attribute.

The interface keeps epistemic mode, asserted modality, and owner-assigned status separate. This preserves a useful part of V100-016 and R110-012. Its finite mode list remains narrower than the drafts: a retrospective inference, for example, needs a primary choice with further qualifications in prose. Neither a completed form nor a status choice constitutes an evidence assessment. Evidence references and alternatives can be supplied without being described as verified or exhaustive.

70.1.4 Source basis and operational limits

The design was checked against PROGRAMME_BRIEF.md, the active 0.3 drafts, and these local foundation passages:

- FM-001, section 1.14.4, PDF page 81, distinguishes authenticity, provenance, and epistemic trust. This motivates separating the record's history from the warrant of its content.
- FM-005, section 5.4.1, PDF page 29, treats evidence relative to a claim and an inquiry. The application's evidence text therefore records supplied grounds or references, without automatically assessing their evidential role.
- FM-005, section 5.20, PDF pages 168 and 170, motivates reasoned, traceable revision with earlier formulations retained. The first application captures revision reasons and earlier snapshots but does not implement the full distinction among evidence updates, target changes, and category changes.
- FM-007, PDF page 2, presents overlapping analytical categories and leaves exhaustiveness and metaphysical priority open. Application role selection does not settle those questions.

These are scoped design translations. No foundation manuscript is promoted to a conformance authority. No new metamodel class, equivalence claim, universal generativity score, or legal determination is introduced. Exact feature-to-draft references and gaps appear in the design document.

70.1.5 Consequences, protection, and maintenance

Git provides retained versions while the repository and its history are preserved. It is not an immutable ledger: a server administrator can alter references, rewrite history, or remove objects. A commit identifier alone does not prove the factual truth, independent time, real-world authorship, or legitimacy of the represented claim. This version does not add independent signatures, external timestamp witnesses, replication guarantees, or content encryption at rest. The record-history view lists the latest 100 revisions; a separate owner-authorized Git bundle export contains the complete history reachable from the current main reference.

The `withdrawn` status changes the current account of a record. It does not delete content from earlier commits. Private application access does not remove access held by server operators or anyone with a repository copy. A current-snapshot JSON export excludes history and credentials. A Git bundle includes prior content, including withdrawn or subsequently edited content, but excludes account credentials, sessions, and application access configuration. Neither export is a complete service backup. Custodians need arrangements covering repositories, the account/access database, secrets, backups, and copies before relying on the service for consequential retention. Selective erasure, legal holds, retention schedules, and controlled disclosure are unresolved application work, not functions implied by using Git.

The initial owner-only model permits personal recording and revision. It does not establish third-party challenge intake, reviewer independence, participant notification, appeal, remedy, or completed practical repair. Broad sharing would require an explicit access model and protection review, including historical content and export permissions.

Future changes to schema meanings, role restrictions, access scope, and retention behavior need recorded migration and design decisions. Feedback from actual use can propose draft revisions; application behavior does not silently redefine the drafts. Automated checks establish only their tested behavior and environment. They do not establish user comprehension, evidential sufficiency, or institutional performance.

70.1.6 Affected artifacts

The new `webapp/` application, its design and operating instructions, application tests, repository navigation, changelog, and open-question register are affected. The normative text and maturity of the nine Working Drafts remain unchanged by this implementation decision.

71 ADR 0008 record graphs transactions and modules

Original source: `decisions/ADR-0008-record-graphs-transactions-and-modules.md`.
Original source SHA-256: `a053a5b6333ec15962ec92396f06f3755ee1703c1e139437de6d24bde72bcd79`.

71.1 ADR-0008 — Record graphs, atomic transactions and modules

Status: PROVISIONAL; selected for experimental implementation
Class: Architecture and scoped operationalization decision
Date: 2026-09-22
Extends: ADR-0007

71.1.1 Issue and sources

The initial workspace provides separately versioned records and untyped cross-references but cannot faithfully express multi-participant relations, relations on relations, coordinated graph changes, modular file custody or snapshot-consistent graph inspection. The user requested careful design and implementation of those functions before a later academia upgrade, and authorized corresponding specification/draft revisions. Current GR manuscripts take precedence over conflicting older academia design choices.

The graph source review cites actual FM-007 passages on overlapping roles, role-indexed incidence and relation continuity, together with GR-100/110/200 requirements. The academia comparison identifies useful modular panels and reified connections, plus implementation gaps and profile differences. Source conflicts remain explicit; old records and signed payloads are not revised retrospectively.

71.1.2 Alternatives and selected direction

Decision	Alternatives considered	Selected direction and rationale
Graph connections	Anonymous binary edges; every cross-reference promoted to a relation; first-class relation records	First-class Relation records with role-indexed incidence preserve identity, several participants, relations on relations and modules. Old cross-references stay neutral.
Role typing	One exclusive record class; unrestricted untyped tags; overlapping declared roles	Preserve primary display role and add an explicit role set, following the current manuscripts without equating record IDs with targets.
Revision protocol	Sequential REST writes; database content transactions mirrored later; one complete Git tree per transaction	Build/validate a whole candidate graph and publish one Git reference conditionally, so references and files are never partially accepted.
Retry evidence	In-memory token cache; SQLite receipt; receipt inside the accepted Git tree	A committed receipt remains recoverable after restart, export and a lost response without introducing a second content authority.
File custody	Mutable named paths; external content store; bounded retained Git blobs	Git blobs keep descriptors, bytes and history portable and atomic at this scale. A future external store needs an explicit completeness/recovery protocol.
Module extension	Hardcoded exclusive screens; executable user plugins; versioned declarative record modules	Fixed built-in interpreters with namespaced data preserve safe extensibility. Unknown optional modules remain intact and read-only; required unknown constraints prevent mutation.

Decision	Alternatives considered	Selected direction and rationale
Historical display	Old selected record mixed with current neighboring data; whole-project pinned view	One source commit resolves graph, labels, modules and downloads. View filtering/layout remains explicitly separate.
Academia alignment	Replace general roles with GRRP acts; rewrite academia immediately; shared substrate with later explicit adapter	Develop the generalized application first; preserve academia's native history and document mappings before changing its independent interface.

The full selected contract, limits, failure cases and sequence are in the implementation design. Experimental Specifications provide the concrete representation and Git binding. Existing 0.3 conceptual clauses remain unchanged where sufficient; preliminary model/interchange/presentation/preservation work items receive the newly identified implementation-neutral requirements.

71.1.3 Consequences and limits

The semantic graph can be cyclic even though the initial storage branch is a linear commit history. A relation predicate, preserved file, structural validation or Git hash does not establish causation, evidential sufficiency, truth, target identity or institutional authority. Module changes and file detachment retain older content under the declared custody policy; they do not claim erasure.

The project-level conditional update deliberately rejects unrelated concurrent changes too. Prepared but unpublished objects can remain unreachable. Initial file/operation/history budgets are implementation limits, not GR requirements. Cross-project protected references, large external assets, shared membership, independent signatures, semantic merging and governed erasure remain further work.

Migration is an explicit new commit, never a read-time mutation or historical rewrite. Existing unstructured relations and untyped references retain their scope. Shared package availability is not evidence that academia already conforms or that independent interchange has passed.

71.1.4 Affected artifacts

The independent protocol package and schemas; GR-SPEC-120/130; bounded working drafts for GR-120/130/140/160; generalized web application, Git adapter and tests; source reviews, application documentation, changelog, issue register and index. The academia repository remains a read-only reference in this phase.

72 ADR 0009 applicative infrastructure consolidation

Original source: `decisions/ADR-0009-applicative-infrastructure-consolidation.md`.
Original source SHA-256: `7a1fda1b90901d1a338717c65fa236ebfe7a16057f35750b55394fd4d58bc866`.

72.1 ADR-0009 — Applicative infrastructure consolidation

Status: Accepted for implementation by the user, 2026-09-22
Class: Repository and application architecture decision
Extends: ADR-0007 and ADR-0008; does not adopt a technical Standard
Subsequent decision: ADR-0010 adds independent nested source repositories and current MIT licensing. This decision remains the historical source/runtime relocation record.

72.1.1 Issue and authorization

The generalized application occupied `webapp/` while its shared record package occupied `packages/`. Academia remained in a separate source repository. The user requested a common implementation area and independently runnable domain applications, reviewed the proposed arrangement, and explicitly authorized migration. Current GR manuscripts continue to guide conceptual changes; relocation does not reinterpret historical academia records or adopt its older restrictions as general GR rules.

72.1.2 Alternatives

1. Retain separate repositories and distribute shared code as separately published dependencies. This preserves independence but leaves the requested local integration and joint inspection incomplete.
2. Combine application code, accounts, domain protocols and storage into one service. This would couple distinct workflows, identities and technologies before their semantic mapping is validated.
3. Consolidate source beneath `applicative_infrastructure/`, extract bounded common packages, retain independent domain applications and runtime, and preserve imported source provenance. This is the selected direction.

72.1.3 Selected arrangement

`applicative_infrastructure/common/packages/` contains the independent `gsp_record_protocol` package and extracted `gsp_git_store` package. Application-independent validation and storage remain distinct responsibilities. A future domain can depend on these packages or implement their versioned contracts without depending on another application's interface.

`gr_generalized_application/web_application/` contains the relocated Flask/Waitress application. `gr_academia_application/web_application/` contains the existing npm client/server/protocol workspace; `gr_academia_application/domain_packages/grrp/` contains its Python domain package. Academia's native protocol remains domain-specific pending an explicitly assessed adapter. Files are relocated and launch paths repaired before any new semantic alignment is attempted.

The programme's `standards/`, `specifications/`, `governance/`, `foundation_manuscripts/`, `decisions/` and publication history remain canonical at their existing locations. Shared implementation documentation links to these sources. Existing conceptual papers imported with academia remain historical domain source material, not newly designated programme foundations.

72.1.4 Source provenance and repository boundary

The programme is currently a directory within the larger `relational_being_infrastructure` Git repository. The academia source has its own independent repository. This migration does not rewrite or merge the outer repository's history. Academia's complete source history is preserved in a verified Git bundle, with source origin, commit, path mappings and file digests recorded in its provenance manifest. Its original checkout remains intact. Dependency directories, runtime, credentials and generated builds are excluded from the source import.

Original notices remain with imported components. The import does not extend academia's component-specific terms to independently authored common packages or change the terms of historical papers. Missing/stale source notices are documented rather than silently rewritten as new grants.

72.1.5 Runtime and failure boundaries

Ignored development runtime is located under `.runtime/generalized/` and `.runtime/academia/`, with separately recreated environments under `.runtime/environments/`. Applications use explicit resolved data locations. They retain separate account databases, session-cookie names, record stores and processes, with default ports 8000 and 8001. No shared account or cross-application access authority is introduced.

Runtime migration includes account data, records, project Git histories, files, and native identity material. Source provenance manifests exclude private runtime contents. Existing record/project identifiers and accepted Git heads remain unchanged. The generalized legacy schema is not automatically migrated. Database integrity, account/project counts and file digests are compared before the new location becomes active.

The old generalized writer is stopped before copying its data. Original data and source backups remain available for rollback. The original academia checkout and runtime remain untouched. Launch verification and regression tests use isolated test data; they do not register test accounts in the migrated user databases.

72.1.6 Verification and consequences

The migration is assessed through shared-package tests, generalized API/browser tests, academia Python/TypeScript tests and builds, independent launch checks, consistent runtime comparisons, verified source-history export, and corrected active documentation links. These establish relocation behavior, not cross-application semantic interoperability, security certification, institutional practice or Standard adoption.

Remaining work includes explicit GRRP/shared-protocol adapters and fixtures, source-notice reconciliation, independently assessed authorization and preservation procedures, and any later deliberate source-history integration. Separate application operation does not itself establish those capabilities.

72.1.7 Affected artifacts

Application source paths, common package metadata/imports/tests, independent launch configuration, application and infrastructure guides, source/runtime migration evidence, specification implementation links, project index, changelog and the open-questions register.

73 ADR 0010 nested git repositories and mit licensing

Original source: `decisions/ADR-0010-nested-git-repositories-and-mit-licensing.md`.
Original source SHA-256: `2117a2c1007e4a4bfe339b75baa601d89eb776166ec8bc9af1cc62266c25ad7c`.

73.1 ADR-0010 — Nested Git repositories and MIT licensing

Status: Accepted by explicit user instruction, 2026-09-22
Class: Repository architecture and current project licensing decision
Extends: ADR-0009; does not adopt a technical Standard

73.1.1 Issue and authorization

The user requested independent repositories for both applications, an infrastructure repository containing them as submodules, and an independent programme repository containing infrastructure as a submodule. The same instruction requests comprehensive READMEs, MIT licensing and attribution to all contributors through contributor files. The user subsequently confirmed that hosted repositories will be created after local commits are complete.

73.1.2 Alternatives

1. Keep one repository with ordinary application directories. This does not supply the requested independent version histories and commit pointers.
2. Create nested repositories without submodule entries. This leaves parent clones without a reproducible way to identify and obtain their child revisions.
3. Create four repositories and explicit nested submodules. This is the selected arrangement. Parent commits identify exact child commits; application record repositories remain private runtime repositories outside these source histories.

73.1.3 Repository boundaries

The programme root is a new independent Git repository. Its former enclosing repository neither tracks the programme files nor receives a commit or index change from this operation. The programme contains one submodule at `applicative_infrastructure/`.

Infrastructure tracks `common/`, its operation tools and repository documentation. It contains submodules at `gr_generalized_application/` and `gr_academia_application/`. Each application tracks its own web application and domain-specific source. All four default branches are named `main`.

Academia imports its preserved original Git history and creates a relocation/licensing commit whose ancestry includes source commit `b98730b46eca5fdf441937aef0180f5b3d4f94dd`. Existing working files are not replaced by checking out the old layout. The original external checkout and the retained history bundle remain unchanged. The other three repositories begin with local initial commits; no earlier source history is fabricated.

Commits proceed from applications to infrastructure to programme. The parent gitlink is updated only after the corresponding child commit exists. Submodule Git directories are absorbed into their parent's metadata using Git's supported operation.

73.1.4 Local URLs and later publication

The initial `.gitmodules` URLs use `./applicative_infrastructure`, `./gr_generalized_application` and `./gr_academia_application`, relative to their respective parent repository locations. They resolve to this local source hierarchy and support a recursive clone from this workspace. No hosted URL or remote publication is invented.

Before publishing, replace these local-layout URLs with actual hosted URLs and synchronize the local submodule configuration. Push applications first, then the infrastructure commit referring to them, then the programme commit. A parent push does not publish every child commit automatically. Detailed procedures appear in the repository guide.

Local file transport is enabled only on individual trusted local clone/initialization commands. Global Git transport policy and global user configuration are not changed.

73.1.5 Preservation and licensing

Each repository owns its own ignore rules; a parent's exclusions are insufficient inside an independent child repository. Private runtime, account databases, signing keys, local backups, dependencies and generated builds remain untracked. Source Git history and application-managed project record histories are separate layers.

Byte-preserving attributes avoid implicit line-ending conversion of retained source and archival files. Shell scripts retain an explicit LF rule. Historical provenance manifests describe their original capture and are not rewritten to claim that later README/licensing edits were part of the earlier relocation.

Each repository receives an MIT `LICENSE`, scope notes and `CONTRIBUTORS.md`. Copyright attribution refers to all contributors listed in that repository's contributor file; the grant does not transfer their ownership to a collective entity. The user's MIT instruction applies to project-controlled material. Third-party dependencies, vendored notices and independently contributed runtime material retain their own applicable terms. Existing historical licensing records and embedded notices are preserved with an explicit current licensing explanation.

Current repository licensing is distinct from formal adoption of the standards-development governance drafts. Those historical drafts remain inspectable and are not retrospectively rewritten as adopted decisions.

73.1.6 Verification

Check the four actual repository roots, clean committed trees, exact `160000` gitlink entries, matching checked-out child revisions, nested `.gitmodules`, academia ancestry, ignored private paths, source history integrity and a fresh recursive clone. Confirm the enclosing repository's index and references are unchanged. These are repository-preservation checks, not an application protocol or institutional conformance claim.

73.1.7 Affected artifacts

Git metadata and gitlinks, boundary-local ignore/attribute files, four repository READMEs, licensing/contributor files and package metadata, repository workflow and verification tooling, changelog, project index and Q-44. The application record protocol and retained user data are unchanged.

74 ADR 0011 event partial orders and spacetime projections

Original source: `decisions/ADR-0011-event-partial-orders-and-spacetime-projections.md`.
Original source SHA-256: `b9e3b0f43ef237c556d9560f553244c2ca8e34924be0c4cbe5f0ab3a20003152`.

74.1 ADR-0011 — Event partial orders and spacetime projections

Status: Accepted for experimental implementation under the user's request, 2026-09-22
Class: Information-model and application architecture decision
Extends: ADR-0008; does not adopt a Standard

74.1.1 Issue and authority

The ordinary graph describes retained records at a Git revision. The user also needs the topology of represented entities, states, relations and other operational roles at an event-defined temporal position. They explicitly distinguish occurrence order from recording order: a later occurrence can be recorded before an earlier one. Their clarification identifies space with the ontological topology at that position; geographical coordinates can be described through State or Property accounts.

The source-grounded design records actual manuscript passages and the proposed narrowing. FM-007 section 9.7, PDF p.42, explicitly identifies partial-order event records as an extension needing its own treatment of endpoints and linearizations. FM-005 section 5.14, pp.114–116, distinguishes continuity-based relational trajectories from causal-generative contributions. Neither source makes recording sequence the chronology of its target.

74.1.2 Alternatives

1. Replay Git commits as world changes. Rejected because recording revision and target occurrence are different histories, including retrospective corrections.
2. Sort `occurred_at` text or timestamps into one timeline. Rejected because the field is descriptive, uncertainty can be substantive, and unsupported ordering or simultaneity would be invented.
3. Simulate state transformations under every possible event linearization. Deferred because the records do not yet declare executable effects, commuting updates, or sufficient initial states.
4. Record explicit precedence and applicability, then project a selected consistent cut. Selected as a bounded addition that preserves the existing ordinary graph and historical storage.

74.1.3 Selected direction

An event-order account is a first-class Relation record containing `gsp.event_order/1` and matching `gsp.relation/1` target incidences. `gsp.temporal_extent/1` scopes any record using event, unknown or explicitly unbounded start/end boundaries and a stated basis. An optional subject reference groups accounts for a trajectory without proving identity or continuity.

Both new module envelopes require `required: true`. Transaction preparation supplies true when omitted for these supported modules; explicit false is rejected. Stored schema validation requires the flag. An older implementation unable to interpret these constraints therefore refuses mutation under the existing required-module rule. Protocol, record schema, profile and Git binding identifiers remain at 0.2; the new modules and `gsp.spacetime/1` projection are additive capabilities, not a silent legacy migration.

Event references are operational boundary markers. This does not redefine extended or consequential GR events as instantaneous. Start is inclusive and end exclusive. Two event bounds need supported strict precedence; unknown or inconsistent extents remain indeterminate. Missing scope remains unscoped, and explicit unboundedness is limited to the stated inquiry scope.

A cut is the predecessor closure of selected events. The projection identifies both the recording revision and included event set. No rank, UUID ordering, layout coordinate, Git

position, or descriptive date asserts otherwise unsupported temporal order. Incomparable events are not declared simultaneous.

Contradictory strict-order accounts remain retained. A cycle yields diagnostics, `consistent : false`, and no cut or topology result. Withdrawn order accounts do not constrain the active order. Contested and non-realized accounts remain visibly qualified. A withdrawn Event referenced by an active order remains inspectable with a warning rather than having its reference silently erased.

An unsupported retained event-order version also prevents a complete cut/topology result, even if its old envelope was optional; otherwise necessary order constraints could disappear silently. An unsupported temporal extent instead makes the affected account indeterminate without blocking an otherwise usable order. The `consistent` flag therefore concerns a usable interpreted ordering, not independent factual warrant.

The derived topology and trajectory boundaries are presentations of retained applicability assertions. The topology is the induced subgraph of active record nodes, retaining only edges with two active endpoints. Active Relation accounts remain inspectable even when some participant incidences are omitted; diagnostics disclose that boundary and any declared participant incompleteness. This preserves an applicable account without inventing a complete relationship. The projection does not execute events, choose a unique true State, supply causal attribution, or infer target persistence from record retention. The ordinary graph remains available for all records, including those without temporal scope.

74.1.4 Binding and preservation

The pure projection consumes one snapshot. The generalized application's authenticated GET/POST spacetime endpoint resolves one authorized revision; POST supplies a bounded event selection and requires anti-forgery protection despite being read-only. Projection creates no commit, receipt, layout record, or migration. Late insertion of an earlier occurrence can revise the present reconstruction while earlier Git snapshots remain available.

No automatic change is made to user records or academia's native protocol. Broader academia alignment remains its separate work item. Source changes follow the existing nested repository boundaries.

74.1.5 Rationale and limits

This choice implements the user's topology-over-event-order requirement while preserving uncertainty and the distinction between a recorded account and its target. It directly develops GR-110 R110-008/049 and the existing information/presentation Working Draft needs through a separate experimental Specification.

Alternative coherent chronologies, event durations and overlaps, calendar/coordinate systems, formal state-effect execution, identity adjudication and measured usability remain open. The FM-004 consequential relational-event formulation and FM-007 occurrence-record formulation remain separately traceable; the application does not settle their full theoretical relationship.

74.1.6 Affected artifacts and assessment

Affected artifacts are GR-120, GR-140, GR-SPEC-121, additive references in GR-SPEC-120/130, shared module schemas and projection code, generalized application controls/API, open questions and changelog. Historical TeX editions remain unchanged.

Assessment cases include reversed recording/occurrence order, incomparable events, ancestor closure, retained cycles, uncertain extents, subject grouping, historical labels, relation-boundary omissions, authorization and absence of writes during projection. This decision states the intended assessment boundary; it does not itself establish that those checks have passed or that the programme has adopted a Standard.

75 GR background

Original source: `docs/background/GR_background.md`.
Original source SHA-256: `28cdc8edc3a1b2d3a2336ed5188adefc0472bd3ce3c38a7e5f486e12e2feaeb4`.

75.1 Generative Relational Background

Status: Informative / evolving

75.1.1 1. Role of this document

This document provides a project-level orientation to Generative Relational (GR) thought for contributors working on the standards programme.

It does not replace the foundation manuscripts. When a precise GR claim, definition, notation, or historical development matters, contributors should consult the relevant source in `foundation_manuscripts/`.

75.1.2 2. General orientation

GR treats many apparently stable objects, categories, values, and institutional forms as historically and relationally generated rather than as self-explanatory starting points.

The programme has repeatedly emphasized:

- relations and relational conditions;
- generativity and changes in future possibility;
- emergence and manifestation;
- differences and constraints;
- self-reinforcing relational realities;
- historical trajectories;
- contingency and recognition;
- generativity return;
- preservation of conditions that permit future generation.

75.1.3 3. Deep metamodel and operational ontology

A recurring architectural distinction is maintained between:

75.1.4 Deep metamodel

- Change
- Structure
- Constraint
- Difference

75.1.5 Operational record ontology

- Entity
- State
- Event
- Process
- Relation
- Property

The six operational record classes should not be treated as a claim that reality fundamentally consists of six kinds of things.

75.1.6 4. Relational and historical sensitivity

GR-oriented recording should remain capable of representing:

- changes in relations;
- changes in available distinctions;
- changes in possibilities;
- changes in interpretive frames;
- multiple perspectives;
- unrealized branches;
- later reinterpretation;
- the conditions under which something became recognizable or actionable.

75.1.7 5. Standards implication

GR theory supplies conceptual motivation, but a standard requires additional constraints:

- clarity;
- interoperability;
- implementability;
- testability where appropriate;
- stable versioning;
- explicit conformance language.

The standards programme therefore translates GR concepts into operational structures selectively and transparently.

75.1.8 6. Source discipline

When this overview conflicts with a foundation manuscript, treat this file as secondary. Record the discrepancy and consult the manuscript and relevant ADRs before changing a normative document.

76 background

Original source: `docs/background/background.md`.
Original source SHA-256: `388c32e0a503c9ad6c76c0dc7f584fb120bba352ab37df9d24b7f632479c02a7`.

76.1 Background

76.1.1 1. Purpose

This document records the conceptual background motivating a standards program for generativity records and their presentation.

It is informative, not normative.

76.1.2 2. Problem setting

Conventional archival, provenance, and publication practices often preserve outputs more reliably than the processes through which those outputs became possible.

A finished paper, policy, institution, artwork, dataset, or decision may survive while the following become difficult to reconstruct:

- enabling conditions;
- contingent encounters;
- changes in interpretation;
- unrealized branches;
- transformations of relations;
- losses of possible continuations;
- later reinterpretations;
- the role of infrastructures, tools, communities, and non-human systems.

The program therefore investigates standards for recording and presenting generativity as trajectory rather than only as output.

76.1.3 3. Existing metamodel background

The current theoretical background uses a deliberately weak highest-level formalism built around:

- a carrier of states;
- mechanisms acting on states;
- an equivalence relation or observational indistinguishability structure;
- a notion of action/composition.

At that level, four central formal dimensions have been emphasized:

- Change
- Structure
- Constraint
- Difference

The protocol and standards program should remain compatible with that abstract layer while avoiding the assumption that the operational recording vocabulary is itself metaphysically fundamental.

76.1.4 4. Candidate operational record ontology

The current candidate operational ontology contains six classes:

1. Entity
2. State
3. Event
4. Process

5. Relation
6. Property

These classes are intended as standardized forms for recording and exchange. They remain provisional until GR-100 defines them.

76.1.5 5. Important conceptual distinction

The program currently distinguishes:

$$\text{formal substrate} \neq \text{record ontology} \neq \text{record instance} \neq \text{presentation}$$

This prevents, for example:

- identifying formal change directly with an Event;
- treating a Process as simply a mechanism;
- treating every Property as an intrinsic essence;
- treating a presentation as identical to the archived record.

76.1.6 6. Generativity and evolving distinctions

A future record model may need to represent not only changes of state but changes in what distinctions are available to an observer or system.

This suggests possible representations of:

- evolving equivalence or discrimination structures;
- emergent vocabulary;
- newly recognizable possibilities;
- transformed ontology or classification regimes.

This remains a research issue.

76.1.7 7. Why a standards program

The aim is not merely to write a single protocol.

A durable public standard requires:

- transparent development procedures;
- stable document classes;
- public review;
- recorded objections and dispositions;
- versioning;
- maintenance;
- conformance criteria;
- implementation guidance;
- technical interoperability.

Accordingly, the project is organized as a standards-development program rather than a single manuscript.

77 epistemic background

Original source: `docs/background/epistemic_background.md`.
Original source SHA-256: `c164468d68e0ef4acad3319e7955a31171f6c8d7f4f609cbb6857435ebdd88a9`.

77.1 Epistemic Background

Status: Informative / evolving

77.1.1 1. Problem

Generativity records are not direct copies of reality.

They are produced through observation, selection, interpretation, categorization, memory, measurement, documentation, and later reconstruction.

The standards programme therefore requires an explicit epistemic layer.

77.1.2 2. Candidate distinctions

The programme should preserve distinctions among:

- Trace
- Observation
- Claim
- Evidence
- Interpretation
- Judgment
- Attribution
- Retrospective interpretation

These categories are provisional and may become classes, relations, profiles, or metadata structures.

77.1.3 3. Epistemic provenance

A record should be capable of expressing:

- who or what produced the observation;
- by which method;
- at what time;
- from which source;
- under which interpretive frame;
- with what uncertainty;
- whether it is direct, inferred, reconstructed, or disputed;
- whether later evidence modified its status.

77.1.4 4. Contestation

Different observers may maintain incompatible interpretations of the same underlying traces.

The standard should support plurality without requiring immediate collapse into a single canonical narrative.

77.1.5 5. Historical revision

Later interpretations should not erase earlier epistemic states.

A record system should be capable of representing:

- what was believed at time t1;
- what evidence was available at t1;
- what changed at t2;
- how the interpretation was revised.

77.1.6 6. Epistemic justice

The programme should remain attentive to asymmetries in whose observations are recorded, whose categories become authoritative, whose records survive, and whose interpretations become institutionally visible.

Detailed normative treatment belongs in later standards and technical reports.

78 era background

Original source: `docs/background/era_background.md`.
Original source SHA-256: `2daf178e6cd8a9be81170be4879f7dda6b6e7c4ace84ef3beeef2594ef2d9c69`.

78.1 Era Background

Status: Informative / preliminary

78.1.1 1. Purpose

This document records the historical and technological context motivating the Generativity Standards Program.

It should evolve as the programme develops.

78.1.2 2. Proliferation of generated outputs

Contemporary research, administration, communication, education, and creative work increasingly produce large volumes of outputs through combinations of:

- human work;
- AI systems;
- automated agents;
- digital platforms;
- distributed collaboration;
- machine-mediated search, synthesis, and transformation.

The existence of an output increasingly reveals less about the trajectory that generated it.

78.1.3 3. Heterogeneous agency

Many domains previously organized around predominantly human participants now include heterogeneous actors and quasi-actors:

- humans;
- institutions;
- AI models;
- software agents;
- automated pipelines;
- data infrastructures;
- algorithmic decision systems.

This complicates conventional accounts of authorship, action, responsibility, provenance, learning, and contribution.

78.1.4 4. Compression of generative history

Digital workflows often optimize for the current state:

- latest document;
- final answer;
- accepted version;
- current database row;
- published artifact.

Intermediate possibilities, rejected branches, contextual judgments, accidental encounters, and changing interpretations may disappear.

The programme treats this historical compression as a standards problem as well as an archival problem.

78.1.5 5. AI-era provenance

Simple declarations such as “AI was used” often provide little information about:

- what was supplied to a model;
- what role a model played;
- how outputs were selected;
- which judgments remained human;
- how ideas changed through interaction;
- which later steps depended upon earlier AI-mediated encounters.

A richer generativity record may therefore become increasingly useful.

78.1.6 6. Knowledge abundance and recognizability

As the quantity of generated material grows, future significance may depend less on preserving outputs alone and more on preserving enough relational and historical context for later actors to:

- recognize why something mattered;
- distinguish independent emergence from repetition;
- reconstruct a generative pathway;
- reinterpret earlier judgments;
- continue unrealized possibilities.

78.1.7 7. Institutional relevance

Potential application areas include:

- scholarly research;
- cultural archives;
- AI-assisted knowledge production;
- education;
- organizational decision making;
- policy development;
- collaborative design;
- scientific discovery;
- historical reconstruction.

78.1.8 8. Caution

This document provides motivating context. It should not be used to justify strong empirical claims without appropriate evidence. External factual claims intended for formal publication should be separately researched and cited.

79 jurisprudential background

Original source: `docs/background/jurisprudential_background.md`.
Original source SHA-256: `71797a5fefe307d7d32a1d94cb50be677cdad2684f2d45634cd491334fab96be`.

79.1 Jurisprudential Background

Status: Informative / preliminary

79.1.1 1. Purpose

This document identifies legal and jurisprudential questions that arise when generativity records move from research or archival tools into institutional practice.

79.1.2 2. Core distinction

A technical standard can define data structures, procedures, and conformance conditions.
It does not by itself determine:

- legal validity;
- legal responsibility;
- evidentiary admissibility;
- rights and duties;
- remedies;
- jurisdiction.

Those questions require jurisprudential and legal analysis.

79.1.3 3. Areas for development

Potential areas include:

- evidentiary status of generativity records;
- provenance and attribution;
- correction and reply rights;
- preservation duties;
- privacy and confidentiality;
- institutional accountability;
- due process in automated or AI-mediated decision histories;
- legal treatment of contested or incomplete records;
- archival duties toward future publics;
- legal recognition of heterogeneous participation.

79.1.4 4. Jurisprudential questions

The programme should ask, among other things:

- When may a record be relied upon?
- What does procedural fairness require when a record is disputed?
- Who may correct, annotate, restrict, or challenge a record?
- When does preservation conflict with privacy or erasure interests?
- How should legal institutions distinguish observed facts from interpretations or attributions?
- How should legal responsibility be handled when human and computational participation are deeply entangled?

79.1.5 5. Relation to standards

These questions may lead to:

- technical requirements;
- implementation guidance;
- legal profiles;
- policy proposals;
- model institutional procedures.

They should not be resolved by ontology design alone.

80 git repository layers

Original source: `docs/development/git_repository_layers.md`.
Original source SHA-256: `3d4bf617e907506c5402d855a4e6f366ae7b1139096371986c42339abc3cc851`.

80.1 Repository layers and contributor workflow

Class: Development and operation guide
Status: Repository arrangement authorized 2026-09-22; hosted SSH remotes configured for publication

ADR-0010 records the decision. Source histories have four boundaries:

```
generativity_standards_program/               Git repository, main
└── applicative_infrastructure/               submodule, own repository
    ├── common/                              ordinary infrastructure source
    ├── gr_generalized_application/           submodule, own repository
    └── gr_academia_application/              submodule, own repository
```

The programme contains canonical manuscripts, governance, standards-track drafts, specifications, policy proposals and programme decisions. Infrastructure owns shared Python packages and orchestration. Domain repositories own their applications and domain packages. The four repositories retain distinct contributor and MIT licensing files.

Private project repositories used by the applications are a separate recording layer. They remain under ignored `.runtime/` alongside accounts and native identity material. Creating source submodules neither publishes those records nor changes their accepted commits, access controls or licences.

80.1.1 Hosted repository addresses

Each source repository has its own `origin`. Both `.gitmodules` files use the matching SSH addresses, so recursive cloning can retrieve all referenced source commits.

Repository	SSH address
Programme	`git@github.com:huangwanhong-maker/Generativity-Epistemic-Infrastructure.git`
Infrastructure	`git@github.com:huangwanhong-maker/Generativity-Relational-Epistemic-Applicative-Infrastructure.git`
Generalized application	`git@github.com:huangwanhong-maker/Generalized-Generativity-Relational-Social-Science-Application.git`
Academia application	`git@github.com:huangwanhong-maker/Generative-Relational-Academia-Application.git`

80.1.2 Obtain the complete workspace

With GitHub SSH access configured for all four repositories:

```
git clone --recurse-submodules git@github.com:huangwanhong-maker/Generativity-Epistemic-Infrastructure.git
↪  generativity_standards_program
cd generativity_standards_program
```

For an existing checkout, including one originally created from the local repository layout:

```
git submodule sync --recursive
git submodule update --init --recursive
git submodule status --recursive
```

Synchronizing updates local submodule URL settings from the committed `.gitmodules` files within this checkout. Unrelated clones retain their own settings; inspect their origins separately when repurposing an older clone. The hosted URLs do not need a file-transport allowance.

Submodules normally check out the revisions pinned by the parent. This often gives a detached HEAD; before developing inside one, select or create a branch deliberately. Do not use `update --remote` as a substitute for restoring the committed parent snapshot.

80.1.3 Windows SSH identity

The maintainer's Windows identity is `~/.ssh/serendip_id_ed25519`. Its contents remain outside the repositories. Other contributors use their own GitHub-authorized identities. The following PowerShell example selects Windows OpenSSH and the named key without changing global Git or SSH configuration:

```
$sshExecutable = 'C:/Windows/System32/OpenSSH/ssh.exe'
$identityPath = ($env:USERPROFILE -replace '\\', '/') + '/.ssh/serendip_id_ed25519'
$sshCommand = '"' + $sshExecutable + '" -i "' + $identityPath + '" -o IdentitiesOnly=yes -o StrictHostKeyChecking=yes'

git config --local core.sshCommand $sshCommand
git -C applicative_infrastructure config --local core.sshCommand $sshCommand
git -C applicative_infrastructure/gr_generalized_application config --local core.sshCommand $sshCommand
git -C applicative_infrastructure/gr_academia_application config --local core.sshCommand $sshCommand
```

These commands run from the programme root after its submodules are initialized. The settings are local machine configuration and do not accompany source clones. They select the identity, not the key's contents. Strict host checking expects a previously verified GitHub host key in the local known-hosts file; verify a new or changed host key before accepting it. A passphrase-protected identity can still prompt because `BatchMode` is not persisted.

For the first recursive clone with this identity, define the same variables and pass the command for that operation:

```
git -c core.sshCommand="$sshCommand" clone --recurse-submodules
↪  git@github.com:huangwanhong-maker/Generativity-Epistemic-Infrastructure.git generativity_standards_program
```

After entering the clone, use the repository-local settings above if this identity should remain selected for future fetches and pushes. On another operating system or with another SSH installation, substitute that system's executable and identity path.

80.1.4 Commit from children to parents

For an application change, work inside that application's repository, review and commit its changed files, then review and commit the new gitlink in infrastructure. Finally review and commit infrastructure's new gitlink in the programme. From the programme root:

```
git -C applicative_infrastructure/gr_generalized_application switch main
git -C applicative_infrastructure/gr_generalized_application status --short
## Stage the intended application files and commit there.
git -C applicative_infrastructure diff --submodule=log
git -C applicative_infrastructure add gr_generalized_application
git -C applicative_infrastructure commit -m "Update generalized application revision"
git diff --submodule=log
git add applicative_infrastructure
git commit -m "Update infrastructure revision"
```

Academia follows the same order. Common-package changes begin in infrastructure. Programme-only changes begin in the programme root. Review a changed child pointer as a substantive source dependency change, including its actual commits and tests.

These commands do not commit application files automatically: a parent records the child commit identifier, not uncommitted changes inside that child. Use `git status` in each affected repository and `git submodule status --recursive` from the root.

80.1.5 Maintain remotes and publish

The configured origins and submodule URLs can be inspected from the programme root:

```
git remote -v
git -C applicative_infrastructure remote -v
git -C applicative_infrastructure/gr_generalized_application remote -v
git -C applicative_infrastructure/gr_academia_application remote -v
git config --file .gitmodules --get-regexp '^submodule\..*\.url$'
git -C applicative_infrastructure config --file .gitmodules --get-regexp '^submodule\..*\.url$'
```

If an existing clone still has local origins, update them to the hosted addresses. Use `remote add origin` instead of `remote set-url origin` only when that repository has no origin:

```
git -C applicative_infrastructure/gr_generalized_application remote set-url origin
↪  git@github.com:huangwanhong-maker/Generalized-Generativity-Relational-Social-Science-Application.git
git -C applicative_infrastructure/gr_academia_application remote set-url origin
↪  git@github.com:huangwanhong-maker/Generative-Relational-Academia-Application.git
git -C applicative_infrastructure remote set-url origin
↪  git@github.com:huangwanhong-maker/Generativity-Relational-Epistemic-Applicative-Infrastructure.git
git remote set-url origin git@github.com:huangwanhong-maker/Generativity-Epistemic-Infrastructure.git

git -C applicative_infrastructure submodule set-url gr_generalized_application
↪  git@github.com:huangwanhong-maker/Generalized-Generativity-Relational-Social-Science-Application.git
git -C applicative_infrastructure submodule set-url gr_academia_application
↪  git@github.com:huangwanhong-maker/Generative-Relational-Academia-Application.git
git submodule set-url applicative_infrastructure
↪  git@github.com:huangwanhong-maker/Generativity-Relational-Epistemic-Applicative-Infrastructure.git
git submodule sync --recursive
```

Commit any infrastructure `.gitmodules` change before committing the root's `.gitmodules` and infrastructure pointer. Before publishing, fetch existing remote branches and inspect their relationship to local work. Preserve existing ancestry; if a normal push would reject divergent history, reconcile that history deliberately. The publication commands below use ordinary pushes.

Publish in dependency order so every referenced commit is available:

```
git -C applicative_infrastructure/gr_generalized_application push -u origin main
git -C applicative_infrastructure/gr_academia_application push -u origin main
git -C applicative_infrastructure push -u origin main
git push -u origin main
```

Use each command only after that repository's intended changes are committed and reviewed. Verify that the remote `main` commit matches the intended local `HEAD` in every repository after publication. A parent push cannot publish an unpublished application commit on its own.

A Git archive of the root alone does not contain submodule source; distribute the four repositories or an explicitly assembled recursive source snapshot when complete offline source is needed. Trusted offline clones can still use command-scoped file transport, but hosted `.gitmodules` URLs need explicit local overrides if network access is unavailable.

80.1.6 Preservation and verification

Academia's original source history is real ancestry of its new branch, with its original complete bundle retained as independent import evidence. New licensing and layout changes are later commits. Historical migration manifests retain their recorded baseline; compare later work through Git history rather than overwriting earlier evidence.

Each repository ignores its own generated and private files. Keep the full runtime separately backed up; source Git commits do not back up accounts, native record histories or signing keys. Do not use recursive `git clean` as a housekeeping command over a working application installation.

From the programme root after committing:

```
python tools/check_repository_layers.py
git submodule status --recursive
```

The checker examines repository identities, committed child pointers, clean trees, attribution artifacts and bounded private-path exclusions. It does not read user records or scan every source blob for secrets. The initial verification record records repository creation and local clone checks; the hosted publication record records remote-history integration and publication.

These procedures follow Git's official submodule command reference and .gitmodules format. In particular, relative child URLs resolve against the parent's default remote repository; they are not arbitrary paths relative to wherever a terminal happens to be opened.

81 multilayer architecture

Original source: `docs/framework/multilayer_architecture.md`.
Original source SHA-256: `7a538b8e8114cd25a3a894afca2ea879d4ad0d49ee9427c76baccb27dc1e3821`.

81.1 Multilayer Architecture of the Generativity Standards Program

Status: PROVISIONAL
Purpose: Expand the programme beyond a narrow ontology-and-data-model approach.

81.1.1 1. Rationale

A generativity record cannot be adequately designed by specifying recordable beings or structures alone.

The programme must also address:

- how a phenomenon becomes knowable;
- how observations, claims, interpretations, and judgments are distinguished;
- how evidence is generated, transmitted, contested, and revised;
- how normative significance is assigned;
- how law and jurisprudence recognize, classify, protect, or constrain generative relations;
- how institutions use generativity records in governance;
- how political and economic structures shape what can be generated, preserved, recognized, or returned.

Accordingly, ontology is only one layer of the programme.

81.1.2 2. Proposed layers

81.1.3 L0 — Generative metamodel

Concerned with highly abstract formal dimensions such as:

- change;
- structure;
- constraint;
- difference.

81.1.4 L1 — Record ontology

Candidate operational classes include:

- Entity;
- State;
- Event;
- Process;
- Relation;
- Property.

These remain open to extension.

81.1.5 L2 — Epistemic layer

Concerned with how a record comes to be known, asserted, interpreted, and revised.

Candidate concepts include:

- Observation;
- Trace;
- Claim;
- Evidence;
- Interpretation;

- Judgment;
- Attribution;
- Perspective;
- Confidence;
- Uncertainty;
- Contestation;
- Revision;
- Retrospective reconstruction.

The epistemic layer should prevent a record from collapsing occurrence, observation, and interpretation into one field.

81.1.6 L3 — Normative and ethical layer

Concerned with:

- value;
- harm;
- benefit;
- justice;
- fairness;
- recognition;
- responsibility;
- generativity return;
- preservation obligations;
- competing claims over records and their uses.

This layer should distinguish descriptive records from normative evaluations.

81.1.7 L4 — Jurisprudential and legal layer

Concerned with how generativity-related records interact with legal concepts and procedures.

Potential topics include:

- legal status of records;
- admissibility and evidentiary weight;
- authorship and contribution;
- attribution and provenance;
- rights of access, correction, objection, and reply;
- privacy and data protection;
- confidentiality and privilege;
- retention and destruction;
- procedural fairness;
- institutional accountability;
- legal recognition of heterogeneous human/AI participation;
- preservation of contested histories.

The programme should avoid assuming that a technical standard itself creates legal rights or duties.

81.1.8 L5 — Institutional and governance layer

Concerned with how organizations use records in:

- research governance;
- public administration;
- international cooperation;
- education;
- cultural heritage;
- scientific collaboration;
- AI governance;
- institutional memory;
- accountability and review.

81.1.9 L6 — Political-economy layer

Concerned with:

- ownership and control of generative infrastructure;
- extraction of value from generative relations;
- asymmetries in capacity to record and preserve;
- concentration of archival power;
- access to knowledge infrastructure;
- generativity return;
- resource allocation;
- institutional incentives.

81.1.10 L7 — Technical implementation layer

Concerned with:

- information models;
- identifiers;
- graph structures;
- serialization;
- APIs;
- validation;
- interoperability;
- cryptographic integrity;
- versioning.

81.1.11 3. Cross-layer principle

The layers should interact without being collapsed.

For example:

- an Event record is ontological/operational;
- a statement that the Event occurred is epistemic;
- a judgment that the Event was unjust is normative;
- a finding that it violated a legal duty is jurisprudential;
- a requirement that an institution preserve the record is governance/legal;
- a JSON representation of the record is technical.

These should remain distinguishable even when represented together.

81.1.12 4. Standards implication

The programme should develop coordinated standards rather than one ontology-only specification.

A future conformance claim may need to state which layers it implements.

81.1.13 5. Political and institutional proposals

The programme may also publish policy proposals for international organizations and other public-interest institutions.

Those proposals should be grounded in the standards work but remain a separate publication class.

A standards document defines interoperable requirements.

A policy proposal may recommend institutional adoption, pilot programmes, governance arrangements, capacity-building, or legal/policy experimentation.

The two should reference each other without being conflated.

82 publication taxonomy

Original source: `docs/framework/publication_taxonomy.md`.
Original source SHA-256: `99f67d5411ff85cc38f14299ea547bed7f8397f488282c2bcf358f91e5f2b8eb`.

82.1 Publication Taxonomy

82.1.1 Specifications, Standards, and International Political / Policy Proposals

Status: PROVISIONAL
Document class: Informative programme framework
Purpose: Define the principal publication classes of the Generativity Standards Program.

82.1.2 1. Why the distinction matters

The programme produces documents with different kinds of authority.

A technically precise document is not automatically a standard.

A formally adopted standard is not automatically law or public policy.

A proposal addressed to an international organization is not a technical conformance document.

Accordingly, the programme distinguishes at least three primary publication families:

1. **Specifications**
2. **Standards**
3. **International Political / Policy Proposals**

The three families may reference one another, but their authority, review process, and intended use remain distinct.

82.1.3 2. Specification

82.1.4 2.1 Definition

A **Specification** defines a technical, informational, procedural, semantic, or interoperability model with enough precision to be implemented, tested, or compared.

A specification may be:

- experimental;
- provisional;
- candidate;
- stable;
- implementation-oriented.

A specification may contain normative technical language such as `shall`, `should`, and `may`, but it does not become a programme Standard merely by doing so.

82.1.5 2.2 Typical purposes

Specifications may define:

- data models;
- ontologies;
- record structures;
- schemas;
- interchange formats;
- API behavior;
- identifier rules;
- conformance tests;
- mathematical or computational semantics.

82.1.6 2.3 Authority

A specification has **technical authority within its declared scope**, but not the institutional status of an adopted Standard unless formally promoted through the standards-development process.

82.1.7 2.4 Examples

Possible examples include:

- Generativity Information Model Specification
- Generativity Interchange Specification
- Epistemic Record Specification
- Validation Specification

82.1.8 2.5 Maturity path

A specification may remain a specification indefinitely, or may later become part of a Standard.

A possible promotion path for a specification is shown below. It is not the programme's default starting sequence; section 5A and accepted ADR-0002 establish Standards-first development.

Research Draft → Specification → Pilot Specification → Candidate Standard → Standard

Promotion is not automatic.

82.1.9 2.6 Protocols and procedures

A **protocol** specifies behavior among participants: roles, inputs, interactions, states, transitions, outcomes, failure handling and applicable obligations. A protocol can be described in a Specification and referenced by a Standard. Protocol is a technical subject, not an additional publication authority class.

Institutional procedures describe responsibilities, grounds for action, review, contestation and disposition. Machine protocols describe interactions that implementations can execute and test. A network exchange does not itself establish the institutional authority or evidential warrant of the act it carries.

Schema validity alone does not demonstrate protocol conformance. Protocol assessment can examine allowed transitions, authorization, duplicate or conflicting requests, unsupported features, disclosure boundaries and failure behavior, according to the declared scope.

The candidate allocation to existing publication families is in the protocol and specification plan. New protocol bindings are proposed only when draft requirements identify a reusable technical need.

82.1.10 3. Standard

82.1.11 3.1 Definition

A **Standard** is a formally adopted normative publication developed according to the programme's standards-development procedures.

A Standard specifies requirements, recommendations, permissions, terminology, procedures, or conformance conditions intended to support consistent practice across multiple independent users or institutions.

82.1.12 3.2 Minimum conditions

A document should normally become a Standard only after:

- approved work-item initiation;
- defined scope;
- technical review;
- relevant horizontal review;
- public review;
- comment disposition;
- demonstrated implementation or pilot evidence where applicable;
- formal approval;
- assigned edition and maintenance responsibility.

82.1.13 3.3 Authority

A programme Standard establishes **programme-level normative authority** for conformance.

It does not by itself create:

- statutory law;
- treaty obligations;
- international legal obligations;
- governmental duties;
- jurisdictional authority.

External institutions may voluntarily adopt, reference, incorporate, or legally recognize a Standard through their own procedures.

82.1.14 3.4 Examples

Possible examples include:

- Generativity Recording Standard
- Generativity Preservation and Access Standard
- Generativity Conformance Standard
- Institutional Generativity Record Standard

82.1.15 4. International Political / Policy Proposal

82.1.16 4.1 Definition

An **International Political / Policy Proposal** is a non-standard publication that presents policy, governance, institutional, legal, or cooperative options for consideration by international organizations or other transnational public-interest actors.

For formal publication, the programme should normally use the label **International Policy Proposal (IPP)** or **International Institutional Proposal (IIP)**. The broader phrase “international political proposal” may describe the family, but should not imply partisan advocacy.

82.1.17 4.2 Typical purposes

Such proposals may address:

- institutional adoption of generativity-record practices;
- international pilot programmes;
- research-integrity infrastructure;
- AI provenance and accountability;
- cultural and scientific preservation;
- institutional memory;
- capacity-building;

- cross-border interoperability;
- model governance procedures;
- international cooperation mechanisms.

82.1.18 4.3 Authority

An international policy proposal is **recommendatory and deliberative**.

It does not define technical conformance merely by recommending a practice.

It does not acquire legal or political authority unless adopted through the procedures of the relevant organization or jurisdiction.

82.1.19 4.4 Required distinctions

Each proposal should clearly distinguish:

- factual background;
- analytical interpretation;
- normative objectives;
- policy options;
- legal or mandate constraints;
- implementation implications;
- technical dependencies;
- unresolved questions.

Where more than one reasonable institutional option exists, proposals should describe the alternatives without presenting one as technically inevitable.

82.1.20 4.5 Relationship to political neutrality

The programme may formulate institutional options, model procedures, implementation pathways, and comparative consequences.

Policy proposals should avoid converting a technical standard into a claim that one political choice is mandatory.

82.1.21 5. Relationship among the three families

The relationship can be represented as:

$$\text{Specification} \longrightarrow \text{possible technical basis} \longrightarrow \text{Standard}$$

and separately:

$$\text{Specification or Standard} \longrightarrow \text{possible input} \longrightarrow \text{International Policy Proposal}.$$

Neither arrow implies automatic promotion or adoption.
A policy proposal may recommend use of a Standard.
A Standard may reference a Specification.
A Specification may implement concepts motivated by policy needs.
The three remain separate publication classes.

82.1.22 5A. Default development direction

The programme generally begins from a Standard work item.

The Standard defines the normative objective and requirements. When those requirements reveal a need for reusable technical infrastructure, the programme initiates one or more Specifications.

Typical dependency:

Standard requirement → technical need → Specification

During development, feedback may flow in both directions:

Standard Working Draft ↔ Specification + Pilot

Thus, Specifications are subordinate in purpose but may be essential to demonstrating that the Standard is implementable.

82.1.23 6. Authority matrix

Publication class	Technical precision	Conformance authority	Formal adoption by programme	Policy recommendation	Creates law
Specification	High	Within declared spec scope	Not necessarily	Usually no	No
Standard	High	Yes	Yes	Not primarily	No
International Policy Proposal	Variable	No	Published, not standards-adopted	Yes	No

---

82.1.24 7. Proposed identifiers

The programme may use class-sensitive identifiers:

- `GR-SPEC-xxx` — Specification
- `GR-STD-xxx` — Standard
- `GR-TR-xxx` — Technical Report
- `GR-G-xxx` — Guide
- `GR-M-xxx` — Manual
- `GR-IPP-xxx` — International Policy Proposal
- `GR-IIP-xxx` — International Institutional Proposal

Existing `GR-100`, `GR-110`, etc. numbers may be retained as project-family numbers while publication-class prefixes identify the document's current status.

Example:

- `GR-SPEC-120:2027` — Generativity Information Model Specification
- `GR-STD-110:2028` — Generativity Recording Standard
- `GR-IPP-001:2028` — International Research Provenance Infrastructure Proposal

---

82.1.25 8. Promotion and cross-reference rules

82.1.26 Specification to Standard

Promotion requires an explicit standards-development decision.

A Specification should not silently become a Standard through editorial renaming.

82.1.27 Standard to policy use

A policy proposal may recommend adoption or piloting of a Standard, but should specify:

- intended institution;
- mandate;
- expected benefits;
- costs and burdens;
- legal implications;
- safeguards;
- alternatives.

82.1.28 Policy proposal to Standard

Political or institutional preference alone should not determine technical conformance requirements.

If a policy proposal identifies a new technical need, that need should enter the standards process as a separate work item.

82.1.29 9. Repository placement

Recommended repository structure:

- `specifications/`
- `standards/`
- `policy_proposals/`
- `manuals/`
- `technical_reports/`
- `foundation_manuscripts/`

During the current transition, existing standards-track drafts may remain in `standards/`, but each document should declare its publication class and maturity status explicitly.

83 NWIP 001 generativity recording and presentation

Original source: `docs/planning/NWIP-001-generativity-recording-and-presentation.md`.
Original source SHA-256: `e527d808520b93d302635f2c0bf43652e422ac9d7f83ba6cedb625723d34fe6a`.

83.1 GR/NWIP-001 — Generativity Recording and Presentation Infrastructure

Document class: New Work Item Proposal
Status: PROVISIONAL — draft for review; not submitted or approved
Version: 0.1
Date: 2026-09-22

83.1.1 Identifier and proposer

The identifier and title were proposed in the earlier preliminary plan and are retained. Proposer, project lead and participating institutions remain to be assigned. This draft does not represent an external institution's commitment.

83.1.2 Problem statement

People and institutions act through records and representations whose grounding, interpretation and history are often difficult to inspect. Symbolic crisis makes the connections among referents, claims, evidence, classifications and practical trust a central programme concern. Final artifacts also underdescribe the relations, judgments, alternatives and changes in future possibilities through which they emerged.

The initial work item investigates what shared recording and procedural requirements make these connections inspectable and revisable without equating provenance, institutional acceptance, technical validation or consensus with truth.

83.1.3 Scope

A coordinated, bounded development package for representing a situation, attributing claims, identifying evidence and limitations, tracing relevant generative conditions, presenting competing interpretations, receiving a challenge, recording a reasoned response or revision, and preserving usable history under declared access and retention conditions.

The first case is proposed to be the programme's own documented decision history, paired with a synthetic institutional decision case. Both can expose methodological and implementation problems before real external participants or sensitive institutional data are involved.

83.1.4 Out of scope for the first package

- A universal metaphysics, truth certification, or numerical score for trust or generativity.
- Exhaustive capture of lived experience or every unrealized possibility.
- Automated adjudication of disputed substantive claims.
- General legal admissibility, jurisdiction-independent rights, or binding policy adoption.
- A mandated platform, distributed ledger, global identity provider or federated network.
- Completion or adoption of every publication in the portfolio.

83.1.5 Need for standardization

Independent records and implementations need a shared account of what an assertion means, whose assertion it is, how evidence bears on it, which histories and disagreements are preserved, and what an exchange or presentation omits. Common procedural expectations can make review and correction usable across institutions while permitting scoped local decisions and legal profiles.

83.1.6 Intended users and stakeholders

Initial users include researchers, record custodians, reviewers, implementers, institutional decision makers and people represented or affected by records. Relevant participation includes people with limited recording resources, users needing accessible presentations, epistemic and archival expertise, and protection and procedural expertise. Representation and recruitment arrangements are governance work, not established facts.

83.1.7 Existing standards and related work

The standards-development comparison informs how the work is governed; the cross-domain programme identifies substantive epistemic, ethical, legal, institutional, policy and political-economy questions. Source mechanisms and local adaptations remain distinct. The first package is a bounded test within that wider programme.

See the verified candidate landscape. Candidate reuse does not imply compatibility, selection or conformance. The work item will document gaps, dependency editions and the cost of extensions before selecting a technical binding.

GR conceptual sources and unresolved mappings are in the foundation traceability map.

83.1.8 Proposed deliverables

Deliverable	Publication responsibility	Evidence expected
Bounded vocabulary and operational definitions	GR-100 with GR-TR101	Source mapping, examples, counterexamples and OPEN questions
Recording and epistemic requirements	GR-110/200/210	Attribution, evidence, disagreement, generative history and revision cases
Presentation, protection and procedural constraints	GR-140/160/400, with GR-300/310 boundaries	Restricted and contested presentations; practical review and response
Conformance scope and methods	GR-150	Distinct claims for records, implementations, views and procedures
Minimum implementable representation and behavior	GR-SPEC-120/200/130 only where requirements justify them	Portable examples, protocol traces, errors and loss-aware exchange
Guidance and pilot findings	GR-M101, examples and pilot reports	Recording burden, interpretability, contestability and failures

Approval can split this coordinated proposal into linked work items while retaining traceability to GR/NWIP-001. It does not automatically approve all parent publications or assign them a new lifecycle stage.

83.1.9 Required expertise and organization

Roles include a coordinating editor, source/terminology reviewer, epistemic reviewer, implementer, archival/protection reviewer, procedural reviewer and affected-user participants. Names and availability are OPEN. The existing GR/TC 1 mandate and working-group structure are candidates for assignment after governance launch; no additional committee is presumed.

83.1.10 Risks and controls to evaluate

Evaluate misleading truth signals; category reification; forced agreement; erased uncertainty; exposure of sensitive content; burdens on underrepresented participants; malicious or repetitive challenges; and unmaintainable technical complexity. Protection measures are use-case-specific and evaluated alongside usability. Retaining a revision trail does not imply indefinite retention of deleted sensitive content.

83.1.11 Expected implementation and pilot evidence

Use the initial cycle and proposed gates in the comprehensive plan and governance and pilot plan. Evidence includes a full challenge/revision cycle, preserved disagreement, a change in available evidence or categories, a traced enabling or constraining relation, restricted or absent evidence, and explicit failure handling.

Interoperability maturity requires independently implemented exchange of the declared features. Two datasets processed by one implementation do not demonstrate independent interoperability. A conforming structure does not establish substantive truth or legal validity.

83.1.12 Dependencies and schedule

Formal initiation depends on coherent programme governance and a recorded decision. Source work and synthetic preparation can proceed earlier. Delivery follows milestones M0–M5 rather than committed dates; capacity, funding and external participation remain OPEN.

83.1.13 Decision

- ☐ Accept
- ☐ Revise
- ☐ Defer
- ☐ Reject

No decision recorded. The initial review considers scope, responsible people, evidence needs and whether the proposal is best administered as one coordinated package or several linked work items.

83.1.14 Rationale

Pending work-item decision. The planning rationale is recorded in ADR-0003, which remains Proposed.

84 comprehensive development plan

Original source: `docs/planning/comprehensive_development_plan.md`.
Original source SHA-256: `49ba67c606cd2161523abbeb63291f8dc5d7ce69d66d8299342cdc788fd14e27`.

84.1 Comprehensive Development Plan

Document class: Informative programme planning
Status: PROVISIONAL — proposed work, not project approval or adopted requirements
Version: 0.1
Planning date: 2026-09-22
Basis: Confirmed programme orientation; Programme Brief; ADR-0002
Decision record: ADR-0003

Implementation update, 2026-09-22: The initial working-draft package implements the first authoring cycle: five governance drafts and GR-100/110/200/210, templates, synthetic cases and recorded review. M1 governance adoption, formal NWIP approval, independent domain review and participant pilots remain incomplete. No milestone is advanced solely because documents compile.

84.1.1 1. Purpose and intended outcome

This plan organizes development of epistemic and practical infrastructure for warranted recognition of reality, evaluation and revision of factual claims, and preservation of relational and generative trajectories. Its motivating problem is the symbolic crisis: instability in the connections among representations, their referents, institutional classifications, and practical trust. This is the programme's source-grounded diagnosis, not a claim that all representations or institutions have become unreliable.

The intended outcome is a family of shared practices and interoperable implementations through which people and institutions can investigate what happened, explain the grounds of a judgment, contest an interpretation, reconstruct changes over time, and understand how action changed conditions for further generation. Future re-recognizability, reinterpretability, and regenerability remain orienting capacities rather than guarantees of complete reconstruction.

The programme follows three distinguishable histories:

1. changes in the situation, relations, capacities, constraints, and possibilities under inquiry;
2. changes in evidence, claims, interpretations, judgments, and institutional responses;
3. changes in categories, methods, models, and recording or recognition regimes.

Their interactions matter. A classification can affect access and subsequent behavior; its efficacy does not establish its truth or legitimacy. A missing record does not establish nonexistence. An authenticated assertion can still be mistaken. Generativity can include maintenance, depletion, domination, or foreclosure as well as beneficial creation.

84.1.2 2. Scope, authority, and planning boundaries

This is a development plan, with candidate allocations and exit criteria for review. It does not adopt Standards, authorize external pilots, decide legal obligations, establish a certification body, or resolve open GR theory.

Publication or artifact	Role in this plan	Authority boundary
Governance directive or policy	Establish the programme's development, review, decision, and maintenance process	Authority depends on recorded programme adoption
Standards-track draft	Define purpose, scope, requirements, and conformance expectations	A draft becomes a Standard only through the established adoption process

Publication or artifact	Role in this plan	Authority boundary
Specification	Define implementable models, representations, algorithms, or interactions needed by draft requirements	Technical requirements apply within its declared scope and maturity; no automatic Standard status
Protocol	Specify participants, interactions, states, transitions, outcomes, and failures	A technical subject described in a Specification or adopted Standard, not a separate authority class
Manual and examples	Explain practical use and demonstrate intended behavior	Informative; examples do not add conformance requirements
Technical Report	Develop theory, unresolved semantics, comparisons, and research findings	Informative or experimental; no hidden normative dependencies
Policy or institutional proposal	Offer mandate-specific adoption, capacity-building, and governance options	Recommendatory; separate institutional decisions remain necessary

No storage platform, universal trust score, universal generativity metric, cryptographic system, or centralized truth authority is selected. External standards are candidate resources pending gap analysis and tests. Existing publication numbers and paths remain stable. Planning package labels below are not new publication codes.

84.1.3 3. Starting position and historical continuity

The repository contains a programme scaffold: governance outlines, preliminary standards scopes, three specification placeholders, an experimental mathematical report, and foundation manuscripts. No adopted technical Standard, validated schema, independent implementation, or completed pilot is evidenced by the present repository.

The earlier preliminary plan is retained as a historical draft. Its specification-first sentence in section 12 conflicts with accepted ADR-0002 and its own section 13. Current sequencing follows ADR-0002: normative need first, technical specification when needed, with pilot feedback before adoption.

The present plan broadens the earlier emphasis on archival loss and AI provenance to the confirmed epistemic and practical purpose. It brings evidence, contestation, institutional uptake, access, and conformance into initial development rather than postponing them until a record model is complete.

84.1.4 4. Development architecture

84.1.5 4.1 Motivation and objectives

The full programme exceeds the first implementation package. Comprehensive development combines a theory of the problem, a justified institutional process, domain-specific inquiry, operational requirements, technical behavior and evidence of practical effects.

Motivating problem	Programme objective	Evidence of progress, without promising social outcomes
Unstable connections between representations and their referents	Make grounds, methods, uncertainty and alternative interpretations inspectable	Reviewers can reconstruct why a claim was made and identify limits or counterevidence
Authority and acceptance can conceal weak warrant	Separate evidential assessment, institutional decisions and normative or legal judgments	Cases preserve those distinct judgments and responsible decision makers
Histories disappear behind final outputs and current classifications	Preserve relational, generative and epistemic trajectories under explicit limits	Later readers recover consequential changes, historical categories, alternatives and known gaps
Recognition and record control shape participation and resources	Support accessible challenge, correction and accountable practical response	Affected participants can exercise the procedure; barriers and unequal burdens are reported

Motivating problem	Programme objective	Evidence of progress, without promising social outcomes
Standards themselves can concentrate interpretive and infrastructural power	Establish transparent development, meaningful participation, appeals and maintenance	Decisions, conflicts, objections, resource constraints and routes to revision are inspectable
Present action can deplete future generative conditions	Examine capacities, enabling relations, foreclosed options and distribution across time	Pilots trace supported consequences and preserve uncertainty about effects not yet observable

Restored social trust, epistemic justice and sustainable generativity are long-term aims requiring separate evaluation. Passing tests or publishing a Standard does not demonstrate that those aims have been achieved.

84.1.6 4.2 Conceptual and technical separation

The conceptual layers remain metamodel, operational record vocabulary, epistemic representation, normative assessment, jurisprudential interface, institutional governance, political economy, and technical implementation. A record can connect these layers while retaining their distinct sources of warrant and authority.

The six candidate record classes remain Entity, State, Event, Process, Relation, and Property. Their adequacy and identity criteria are research and design questions. Observation, Claim, Evidence, and Interpretation are candidate epistemic roles; their realization as classes, relations, or wrappers remains OPEN. Part II's use of Attribute is not silently equated with Property.

The working development loop is:

```
flowchart TD
    A[Governance and source orientation] --> B[Normative problem and use cases]
    B --> C[Coordinated Standards Working Drafts]
    C --> D[Identified technical infrastructure need]
    D --> E[Specifications and protocol definitions]
    E --> F[Pilots and implementation evidence]
    F --> C
    F --> G[Committee and public review]
    G --> H[Recorded adoption decision]
    H --> I[Maintenance and renewed review]
    I --> B
```

Source analysis, synthetic examples, and editorial drafting can begin during governance preparation. Formal project initiation follows coherent governance and a recorded work-item decision. Standards and Specifications can co-evolve; adoption is not a prerequisite for prototyping.

84.1.7 5. Coordinated publication portfolio

84.1.8 5.1 Substantive domain programme

Each domain has its own questions, sources and reviewer competence. A technically valid record cannot settle these domains by serialization. The cross-domain programme develops the following allocations, their external sources and a worked institutional case.

Domain	Initial research and design deliverable	Route into the publication family
GR foundations and ontology	Source concordance; bounded operational definitions; identity, emergence and formal limitations	GR-TR101/102 inform GR-100/120 through recorded decisions
Epistemology and research methods	Warrant, evidential roles, alternative explanations, uncertainty, historical revision and inferential limits	GR-200/210; scoped representation in GR-SPEC-200

Domain	Initial research and design deliverable	Route into the publication family
Archival and information science	Appraisal, provenance, preservation, absence, custody, description and long-term interpretability	GR-110/140/160 with manuals and preservation profiles
Ethics and normative assessment	Value plurality, recognition, harm, responsibility, distribution of burdens and generativity return; reasoned tradeoffs	Informative analysis and GR-110/160/210/400 requirements where operationally justified
Jurisprudence and legal procedure	Legal concepts, claimed authority, evidentiary standing, identity, responsibility, rights and remedy under declared contexts	GR-300/310; contextual profiles and separately labelled model rules or policy proposals
Programme governance	Participation, representational balance, independence, consensus, appeals, contribution rights and maintenance	Charter, Directives and supporting policies; comparative process study
Institutional and public governance	Mandates, decision authority, contestability, oversight, repair and evidence-to-action procedures	GR-400; institutional profiles and governance manuals
Public and international policy	Problem analysis, organization-specific mandates, adoption alternatives, costs, capacity, pilots and evaluation	Policy/institutional proposals; technical needs enter the work-item process separately
Political economy	Ownership and control, unequal recording capacity, infrastructural dependency, contributions and allocation of benefits	Cross-domain impact studies; requirements review and institution-specific options
Technical infrastructure and human use	Semantic interoperability, protocol behavior, security, accessible presentation, validation and maintenance	GR-120/130/140/150; justified Specifications and implementations

Policy analysis and ethical or jurisprudential research can begin in parallel with governance and source work. Binding legal conclusions, organizational mandates and political choices remain separately warranted. International policy work compares at least a voluntary pilot, shared stewardship where feasible, and use of existing infrastructures or deferral; it identifies the intended organization or class and its actual decision authority before recommending adoption.

84.1.9 5.2 Existing project allocation

All allocations below are PROVISIONAL. The current scopes are starting points for work-item review. “Initial” means a bounded contribution to the first demonstrator, not completion of the entire publication.

Existing project	Normative problem and planned scope	Specification or supporting output triggered by need	Initial evidence and dependency
GR-100 — Foundations and Vocabulary	Distinguish reality, manifestation, representation, claim, evidence, judgment, identity, time, trajectory, and generativity; scope operational definitions	GR-TR101 source analysis; vocabulary mapping used by SPEC-120/200	Initial: definitions with examples, counterexamples, identity criteria and unresolved cases; foundation traceability

Existing project	Normative problem and planned scope	Specification or supporting output triggered by need	Initial evidence and dependency
GR-110 — Generativity Recording Requirements	Establish the minimum record needed for stated reconstruction and review purposes; record enabling conditions, uncertainty, alternatives and losses	Capture guidance in GR-M101; SPEC-120 record structures	Initial: reconstruct a decision and its grounds without treating a current summary as its full history
GR-120 — Generativity Information Model	Define implementation-neutral semantics, identity, temporal relationships, versions, and extension boundaries	GR-SPEC-120 implementable model and identifiers	Initial subset only after GR-100/110/200 needs; test contested identity and loss-aware conversion
GR-130 — Generativity Interchange Specification	Existing title retained; standards-track role is interoperability requirements and declared preservation of meaning	GR-SPEC-130 encodings, exchange behavior, protocol bindings and migration rules	Initial portable package; later independent implementations; depends on agreed semantic subset
GR-140 — Generativity Presentation Requirements	Make occurrence claims, evidence, inference, uncertainty, disagreement, revisions, omission, and mediation understandable	View profiles and presentation fixtures; machine binding only if reuse requires it	Initial: readers can distinguish current judgment from historical views and a restricted view from a complete archive
GR-150 — Conformance and Validation	Define conformance subjects, versions, profiles, test methods, exclusions, and claims	Validation rules and fixtures linked to the relevant Specifications	Initial test design alongside requirements; conformance never certifies substantive truth
GR-160 — Preservation, Privacy, Access, and Retention	Preserve interpretability while governing restricted access, correction, sealing, retention, deletion and custodial change	Access and lifecycle behavior in Specifications; preservation profiles and manual guidance	Initial restrictions and unavailable evidence; later migration and continuity trials
GR-200 — Epistemic Recording Framework	Distinguish assertions and their authors, targets, methods, evidence roles, perspectives, scope, uncertainty and revisions	GR-SPEC-200 epistemic structures linked to SPEC-120	Initial: multiple claims about one situation remain attributable and separately revisable
GR-210 — Evidence, Interpretation, and Contestation	Make grounds, counterevidence, alternatives, replies, reviews and dispositions inspectable	Review/revision procedures; SPEC-200 interaction semantics where needed	Initial: a challenge can alter a judgment or receive a reasoned disposition without erasing the challenge
GR-300 — Jurisprudential Interface	Represent asserted legal context, jurisdiction, source, authority and procedural status without creating legal validity	Informative analysis first; scoped legal metadata profiles after expert review	Initial boundary statement; fuller work after a named institutional use case and relevant expertise
GR-310 — Rights, Duties, and Procedural Profiles	Relate access, notice, objection, correction, restriction and review to a declared institutional basis	Mandate- or jurisdiction-specific profiles, reviewed separately	Initial generic procedural needs inform GR-160/210; legal entitlements remain context-specific

GR-400 — Governance and Institutional Use	Connect evidence and judgments to accountable decisions, review, practical response, and recorded downstream effects	Organizational profiles, manuals and pilot reports	Initial synthetic decision procedure; later voluntary institutional pilot with a declared mandate

GR-200 covers representation of epistemic status; GR-210 covers practices of assessment and contestation. GR-120 describes the semantic contract; GR-SPEC-120 realizes it technically. GR-130 and GR-SPEC-130 similarly separate interoperability obligations from concrete exchange behavior. Review identifies duplication before scopes are stabilized.

Normative and political-economy concerns cross the portfolio: whose contributions receive recognition, whose evidence survives, who bears recording costs, who controls access, and whose future possibilities are affected. Initially these are addressed through GR-110/160/210/400 and informative research. A separate normative-assessment publication is DEFERRED until a distinct, testable need and review competence are demonstrated. Generativity return remains an explicitly scoped research and requirements question, not an assumed quantity.

Supporting work includes GR-M101, GR-TR101, GR-TR102, examples, validation artifacts, and later mandate-specific policy proposals. Category-theoretic semantics remain experimental and are not on the critical path for the first demonstrator.

84.1.10 6. First development package

Retain the existing proposed identifier and title: **GR/NWIP-001 — Generativity Recording and Presentation Infrastructure**. The draft proposal defines a coordinated package, not an omnibus adopted Standard. Its first objective is to demonstrate a complete cycle of warranted recording, interpretation, challenge, revision, presentation, and practical response.

Use the programme's own documented decisions as the accessible first case. Pair it with a synthetic institutional case so success is not inferred from a single cooperative author. The package draws bounded requirements from GR-100/110/140/150/160/200/210/400 and creates only the SPEC-120/130/200 components those requirements need.

The candidate minimum demonstration includes:

1. A represented situation, a claim, its responsible source, the record creation time, and the time or interval asserted about the situation.
2. A trace linked as evidence for a specified claim, with the method, relevant limitations and at least one materially plausible competing explanation where applicable.
3. A consequential relation or contribution, its proposed continuity criterion, and a grounded account of how it enabled, constrained, preserved, or closed a later possibility.
4. A distinct challenge and response, with a revised or maintained judgment, its reasons, and a recoverable account of what was known earlier where retention and access permit.
5. A distinction between a change in the situation, a change in knowledge, and a change in classification or method.
6. A presentation that exposes relevant uncertainty, attribution, revision, and evidence availability without leaking restricted content; a protected fixture exercises correction and an authorized retention, deletion or access-withdrawal decision, including its effects on derived views.
7. A portable representation and a validation report that declare supported features and preserve disagreement through exchange.
8. A recorded institutional or participant response, plus a follow-up question about consequences; the record does not fabricate evidence for effects not yet observed.

These are proposed demonstration criteria, not mandatory facts about every future record. Unknown, unavailable, restricted, not assessed, and not applicable need distinguishable treatment when relevant. Feasible alternatives and causal-generative claims need their own grounds; the presence of a branch or dependency field does not establish them.

84.1.11 7. Candidate requirement themes and traceability

The labels below are planning references only. Stable normative clause identifiers will be assigned in the corresponding Working Drafts.

Planning theme	Candidate obligation to investigate	Lead projects	Demonstrating case
Attribution and epistemic scope	Identify whose claim is represented, its target, grounds, method and limits	GR-110/200/210	Accurate provenance attached to a disputed or false assertion
Temporal and identity discipline	Distinguish subject continuity, record versions, asserted time and recording/review time	GR-100/120/200	Backdated report; disputed identity; late evidence
Generative trajectory	Ground connections between earlier relations and later conditions; preserve relevant alternatives and loss	GR-110/210	Same final output, different enabling history or foreclosed options
Contestation and revision	Record challenge, response, disposition and revision reasons without forced agreement	GR-210/400	Unresolved disagreement survives publication and export
Protection and availability	Express access, retention and absence without assuming universal disclosure or indefinite retention	GR-160/310	Restricted evidence, withdrawn access and justified deletion
Presentation and practical uptake	Distinguish summaries and reconstructions from the record; expose the basis of action	GR-140/400	Viewer distinguishes an allegation, a judgment and a decision
Interoperability and conformance	Preserve declared semantics and disclose unsupported features or transformations	GR-120/130/150	Import/export does not silently merge claims or convert unknown into false

For each candidate clause, the planning record links: motivating problem → source or operational proposal → alternatives → decision → responsible publication → specification dependency → example or test → pilot finding → revision. The foundation map begins the conceptual traceability; it does not confer normative authority.

84.1.12 8. Milestones and dependencies

There are no committed delivery dates or staffing assumptions. A milestone advances when its evidence is available; preparation can overlap without bypassing governance or review. These planning milestones do not replace the programme's 00–90 document stages.

Milestone	Main work and output	Proposed completion evidence	Next work enabled
M0 — Orientation and scope	Source index, conceptual tensions, use cases, objectives, portfolio, comparative standards-development study, cross-domain agenda and candidate NWIP	Sources linked; source practices distinguished from proposed adaptations; current claims distinguished from proposed requirements; sponsor reviews scope	Governance drafting, domain research and bounded conceptual examples
M1 — Governance launch	Charter, Directives 1/2, committee mandate, review/decision/appeals, ethics/IP, maintenance and records arrangements	Founding authority, adopted procedures, responsible roles and a simulated contested decision are documented	Formal work-item decisions and committee drafting

Milestone	Main work and output	Proposed completion evidence	Next work enabled
M2 — Requirements baseline	Coordinated vocabulary and minimum clauses for the first package; conformance subjects; evidence and protection scenarios	Every proposed initial requirement has a purpose, owner, example/ test method and known limitation; source conflicts logged	Demand-driven specification work and synthetic implementation
M3 — Pilot-ready Specifications	Small semantic model, epistemic binding, portable exchange and necessary interaction behavior	One implementation exercises the complete cycle; negative fixtures and restriction behavior checked; no silent conversion losses	Controlled pilots and independent implementation
M4 — Pilot and interoperability evidence	Programme self-pilot and synthetic decision case for the initial package; AI-assisted research and incomplete archive for broader claims as material and capacity permit	Results report usefulness, burden, exclusions, failures and revisions; a separately built consumer/producer pair exchanges declared features when interchange maturity is claimed	Committee stabilization and public-review readiness for the evidenced scope
M5 — Review and adoption readiness	Committee review, horizontal review, public review, comment dispositions, revised artifacts and maintenance assignment	Review history and objections are inspectable; significant changes receive appropriate re-review; formal decision and edition are recorded	Publication of only the approved scope
M6 — Maintenance and extension	Corrections, compatibility monitoring, periodic review, new domains and optional protocol profiles	Maintainer and review triggers active; migration and withdrawal histories preserved; new needs enter work-item process	Revised editions and evidence-backed expansion

Epistemic, ethical, jurisprudential, institutional, political-economy, accessibility and technical review begin with scope and requirement formation, with privacy and test design explicit by M2. Before pilots and publication, a review dossier records the applicable domain questions, reviewers and competence, affected perspectives, evidence, conflicts, findings, dispositions and residual limitations. A domain cannot be marked complete merely because a field exists in a schema. An unassessed domain remains visible and limits claims or progression where material.

No external institution is presumed to participate. Real data use depends on the pilot's actual permissions, governance, and protection arrangements.

The governance and pilot plan supplies detailed proposed gates and cases. Its local gate labels are supporting detail; M0–M6 are the programme-level sequence.

84.1.13 9. Conformance design

Conformance is scoped to a subject: record or package, producing implementation, exchange implementation, presentation, archive service, or organizational procedure. A claim identifies the publication and edition, profile, features, limitations, assessment method, and assessor. Passing a syntax validator is one form of evidence, not an assessment of all these subjects.

Assessment distinguishes structural validation, preservation of declared semantic distinctions, protocol behavior, presentation comprehension, procedural performance, and substantive evidential judgment. The last remains contestable and context-dependent; programme conformance does not certify truth, moral goodness, legal admissibility, or complete historical coverage.

The existing proposed Core, Standard, and Deep/archival profile names are retained as unresolved candidates. Profile design first separates capability from recording depth: a small record can still need attribution, uncertainty, restriction and correction. Terminology such as "Standard profile" needs review to avoid confusion with publication status.

First-release criteria concern the bounded cycle in section 6. Wider federation, registries, cryptographic attestations, credential ecosystems, automated confidence aggregation, generativity measurement, and domain-specific legal profiles are DEFERRED until a requirement and credible evaluation justify their cost.

84.1.14 10. Protocols, specifications, and external reuse

The protocol and specification plan defines candidate interactions and their implementation triggers. An institutional procedure can be tested through a manual workflow before a network protocol is justified. A portable package is sufficient for early exchange if it demonstrates the required semantics.

The external standards landscape records verified candidate sources and their limits. Before selecting a dependency, a work item records the exact edition, reuse or extension boundary, semantic mismatch, licensing review where needed, maintenance responsibility, and an interoperability experiment. A cited standard is not evidence of compatibility.

Security and integrity requirements derive from the use case: misleading attribution, alteration, unauthorized access, hidden loss during exchange, conflicting revisions, and abusive review requests are concrete test cases. Evidence integrity and source authentication remain distinct from the validity of a claim.

84.1.15 11. Responsibilities and working rhythm

84.1.16 11.1 Learning from established standards development

The ISO/IEC, IEEE and WTO comparative study is a design input. It separates official source practice from the programme's proposed adoption, adaptation or deferral. The programme does not claim ISO or IEEE affiliation or procedural conformity.

Governance drafting evaluates transparent scope and work-item initiation; meaningful stakeholder participation and balance; documented consensus with reasons for unresolved objections; review and decision records; independent appeals; clear drafting and conformance boundaries; contribution/IP arrangements; and maintenance. Exact voting rules, timelines, membership structures and patent policies remain explicit local choices.

Two organizational approaches receive comparison: participation by individual experts and affected people, and organizational representation with safeguards for less-resourced participants. A hybrid is a candidate rather than an assumed solution. For a small programme, combining administrative roles is possible only with disclosed conflicts and an actual route for independent consideration of contested decisions.

The first governance drafting dossier records each borrowed mechanism, its purpose, its source, why it is proportionate here, its cost, the alternative, and how its effectiveness will be tested. A list of well-known standards bodies is not evidence that the programme's governance is credible.

84.1.17 11.2 Responsibilities and work cycles

Roles are proposed and unassigned unless separately recorded. A programme sponsor coordinates scope; the founding authority establishes governance; a designated editor owns each active deliverable; conceptual and epistemic reviewers assess interpretation; implementers test realizability; affected participants assess contestability and burden; access/ethics reviewers assess protection; the maintenance role owns published artifacts. The programme documents combined roles and conflicts where a small team cannot separate every function.

Each work cycle selects a small set of requirements and cases, drafts the relevant text, tests the proposed behavior, records disagreements and decisions, and updates dependencies. Parallel work is useful for source analysis, governance and use-case preparation; mutually dependent normative clauses are reviewed together. External participation, organizational structures and sustained staffing remain planning questions rather than existing commitments.

84.1.18 12. Immediate work queue

Order	Concrete next deliverable	Responsible role, currently unassigned	Completion evidence
1	Review this plan, draft NWIP-001, foundation map, comparative study and cross-domain agenda; select the bounded first case	Sponsor and programme editor	Recorded objectives, scope, exclusions, adaptations, unresolved questions and chosen case
2	Draft Charter and Directives 1/2 with the missing governance procedures and source-to-local-choice rationale	Founding authority and governance editor	Coherent launch package and explicit decisions on participation, consensus, appeals, IP and maintenance
3	Build a synthetic example distinguishing situation, claims, evidence, interpretation, decision and revision	Epistemic editor and pilot lead	Two competing accounts, changed evidence, protected material and a traced generative consequence
4	Prepare the coordinated GR-100/110/200/210 requirements subset with GR-140/150/160/400 constraints	Assigned document editors	Requirement-to-case and source-to-definition maps; no premature schema dependence
5	After governance launch, decide NWIP scope and Specification work items	Established decision body	Recorded decisions, owners and technical needs; pending proposals remain pending
6	Implement the smallest representation and interactions needed for the chosen cycle	Implementer and reviewer	Demonstration plus failures and burden report; revision proposals returned to draft requirements

This table preserves the initial work sequence. Items 2–4 now have first authoring outputs in the working-draft package: governance texts, P1 and the four preparatory technical drafts. Their institutional decisions and empirical assessment evidence are still incomplete. Item 5 awaits governance launch; item 6 has not begun. The review record identifies what was checked and what remains unassessed.

84.1.19 13. Risks, decisions, and expansion criteria

Risk or unresolved choice	Planned response and evidence
Ontology or formalism dictates what counts as real	Preserve source distinctions and explicit operational scope; test overlooked and disputed cases
Records turn acceptance or consensus into truth	Separate claim, assessment, institutional action and grounds; use counterexamples
Scope expands beyond team capacity	Limit the first cycle, reuse existing publication families, defer independent work without a justified need
Rich recording becomes surveillance or excessive labor	Measure burden and participation; minimize data; test selective disclosure and proportionate retention
History preservation conflicts with correction or deletion	Decide content, metadata and audit retention separately; retain only permitted traces; never promise immutable sensitive history
More structure creates false precision	Support unknowns and scoped judgments; avoid uncalibrated numeric confidence or universal generativity scores
One implementation defines the semantics	Use independently authored examples and implementations before claiming interchange maturity

Risk or unresolved choice	Planned response and evidence
Legal or institutional diversity is flattened	Develop bounded profiles under declared authority; keep policy recommendations separate
Established standards-body procedures are copied without capacity or legitimacy	Compare mechanisms, document tailoring, test them with real role availability and an appeal rehearsal
Ethical or public-policy choices are disguised as technical inevitabilities	Record alternative values and institutional options, affected perspectives and the authority making the choice

Decision priorities and unresolved theory are maintained in open questions. Expansion requires a demonstrated gap, identified users, a responsible editor, review competence and pilot evidence appropriate to the new scope. A need for research can produce a Technical Report without forcing a new Standard.

85 cross domain programme

Original source: `docs/planning/cross_domain_programme.md`.
Original source SHA-256: `669c071ef6364871666cea84d52123ebdf0b1653a5b77ff32b543fa3ef226e0c`.

85.1 Cross-Domain Research, Standards, and Institutional Programme

Document class: Informative programme planning
Status: PROVISIONAL development proposal; no adoption or institutional endorsement
Version: 0.1
Date and source check: 2026-09-22, Asia/Tokyo (2026-09-21 UTC)
Programme context: Comprehensive development plan

85.1.1 1. Purpose and development approach

The programme's scope includes the conditions under which people recognize reality, assess evidence, make judgments, act together, and preserve or reopen possibilities. A comprehensive development programme therefore needs substantive work in epistemology, jurisprudence, ethics, governance, political economy, public policy, archival practice, and technical design. These domains contribute objectives and constraints, not merely metadata fields for an already selected ontology.

The proposed organizing question is: **what practices and institutions make a factual or practical judgment inspectable, contestable, revisable, and appropriately actionable, under unequal conditions of knowledge and power?** Technical recording is one part of the response. Better records alone do not establish warranted beliefs, legitimate authority, justice, or beneficial outcomes.

This plan extends the multilayer architecture. It uses existing GR families; domain headings are work areas, not new publication numbers or ontology classes. Standards-track work identifies the normative problem first. Specifications follow demonstrated infrastructure needs. Technical Reports develop unresolved concepts and comparisons; manuals support practice; international policy proposals compare institutional choices. No draft is an adopted Standard.

All programme actions below are **GR operational proposals** unless explicitly described as source-derived. Foundation manuscripts remain the conceptual sources for GR terms. External instruments offer questions and constraints for review; they do not establish equivalence with GR or automatically become programme requirements.

85.1.2 2. Bounded external orientation and authority

Structural role: distinguish the nature of relevant source material before using it. These sources supplement the technical reuse landscape; they are not a normative dependency list.

Primary source, edition, and status	Source-derived orientation	Proposed use and limit
UNESCO Recommendation on the Ethics of Artificial Intelligence, adopted 23 November 2021; Recommendation	Addresses dignity, diversity, fairness, social/economic justice, environmental effects, human oversight, and ethical impact assessment.	Review AI-mediated recognition and institutional use across more than privacy. Its AI scope does not establish a complete ethical framework for every GR use.
UNESCO Recommendation on Open Science, adopted 23 November 2021; Recommendation	Addresses equitable participation, access, diverse knowledge systems, shared infrastructures, and scientific practice.	Examine recognition, knowledge access, stewardship, and capacity differences. Openness requires contextual treatment of legitimate restrictions.

Primary source, edition, and status	Source-derived orientation	Proposed use and limit
OECD, Mobilising Evidence for Good Governance, 2020; analytical report	Separates evidence quality from the governance of its use; identifies contestability, representation, transparency, and accountability alongside ethical, economic, and political considerations.	Develop institutional evidence-use questions. The report is analysis, not an adopted GR requirement or universally applicable legal rule.
OECD, Building Capacity for Evidence-Informed Policy-Making, 8 September 2020; analytical report	Examines individual skills, organizational capacities, and conditions enabling evidence use.	Plan training, staffing, participation, and evaluation alongside technical infrastructure. Institutional feasibility needs local evidence.
OHCHR official ICCPR text, adopted 16 December 1966, entered into force 23 March 1976; treaty	Relevant provisions include remedy (article 2), courts/tribunals (14), privacy (17), expression/ information (19), public affairs (25), and equality before the law (26).	Orient rights and procedure questions. Application depends on the provision, parties, jurisdiction, context, and applicable legal interpretation; no applicability finding is made here.
UNCITRAL Model Law on Electronic Commerce, adopted 12 June 1996, additional article 5 bis in 1998; model legislation	Official overview identifies nondiscrimination against electronic form, technological neutrality, functional equivalence, attribution, and receipt of data messages.	Examine electronic-record legal interfaces where relevant. A model law supplies legislative options; a GR serialization does not enact it or establish evidentiary admissibility.

Recommendations, analytical reports, treaty provisions, model legislation, technical standards, and local institutional policies carry different authority. Record that distinction whenever a source informs a requirement or policy option. A source's use of "standard" does not confer the programme's adopted-Standard status.

Access limits: UNESCO texts and OECD overviews/executive summaries were accessible. OHCHR's principal instrument page/PDF failed to open; its official covenant microsite supplied the text. UNCITRAL's page/PDF returned access errors, so this review uses its official-domain indexed overview, not a full clause analysis. No jurisdictional enactments, reservations, case law, or inaccessible normative requirements were reviewed. Detailed legal profiles require those additional sources and qualified review.

85.1.3 3. Substantive development domains

Structural role: give each domain its own questions, outputs, dependencies, reviewers, and evidence of practical usefulness. Proposed roles are unassigned.

85.1.4 3.1 Epistemology and inquiry methodology

Objective and questions: develop practices of warranted recognition, not only labels for confidence. What differentiates observation, testimony, trace, inference, interpretation, and institutional acceptance? How do methods establish their scope and limitations? How are counterevidence, absent evidence, conflicting accounts, and changing categories handled? When is judgment sufficiently supported for a specified action, while remaining revisable?

Outputs and dependencies: GR-100/200/210 standards-track requirements; source analysis in GR-TR101; a methods/assessment manual contribution; GR-SPEC-200 only for reusable representation and interaction needs. Depend on foundation interpretation, domain methods, presentation design, and institutional decision contexts. Keep empirical, interpretive, and normative warrant distinguishable rather than imposing one confidence scale.

Review and validation: epistemologists, qualitative and quantitative researchers, domain practitioners, and affected knowledge holders examine an inquiry with competing explanations. Test whether an independent reviewer can reconstruct the grounds, limits, and reasons for changed judgment, including whether important testimony was excluded by the recording categories.

85.1.5 3.2 Ontology, concepts, and formal semantics

Objective and questions: establish enough conceptual precision for interoperability while exposing the limits of operational categories. What makes a recorded subject persist? How do event, relation, and record identity differ? What changes when an institution changes its classification? Which theoretical distinctions are lost in a proposed formalization?

Outputs and dependencies: GR-100/120 drafts, GR-TR101 interpretation, GR-TR102 experimental semantics, and bounded GR-SPEC-120 models. Definitions remain grounded in manuscripts; unresolved formulations are preserved. Formalism is evaluated against epistemic, archival, and institutional cases rather than deciding their ontology in advance.

Review and validation: GR scholars, philosophers, formal-methods researchers, and implementers compare ordinary, disputed, and counterexample cases. Evidence includes explicit assumptions, mapping limits, and failures of equivalence. Category-theoretic work remains exploratory until it demonstrates an operational need; no mathematical representation is treated as proof of empirical or institutional legitimacy.

85.1.6 3.3 Archival practice and information science

Objective and questions: preserve interpretable evidence and trajectories through changing custody, formats, and descriptions. What is selected, excluded, appraised, or lost? Whose history survives? How are restricted evidence, custodial changes, retrospective description, and documented destruction handled without suggesting completeness?

Outputs and dependencies: GR-110/140/160 requirements, GR-M101 archival guidance, and GR-SPEC-120/130 packaging and migration details when needed. Compare existing archival approaches through the technical landscape. Depend on legal retention context, ethical access decisions, temporal semantics, and resource limits.

Review and validation: archivists, records managers, information scientists, community archives, and access specialists test an incomplete collection and a migration. Evaluate interpretability, recoverable relationships, disclosed losses, selective access, and maintenance burden. Preservation quality is not measured simply by the volume retained or made public.

85.1.7 3.4 Jurisprudence, legal recognition, and procedure

Objective and questions: investigate how legal systems recognize records, persons, contributions, authority, and procedural acts. Separate authenticity, reliability, admissibility, evidentiary weight, and a competent body's finding. Examine notice, reply, correction, restriction, confidentiality, privilege, retention, and review without assuming identical rules across institutions or jurisdictions.

Outputs and dependencies: informative comparative legal analysis first; scoped GR-300/310 profiles after review; interfaces to GR-160/210/400. Each proposal identifies the legal concept, forum, relevant actors, legal source and edition, asserted application, procedural consequences, and unresolved conflicts. A data field saying "right," "consent," or "binding" is a recorded assertion, not a legal conclusion.

Review and validation: relevant jurisdictional counsel, evidence/procedure scholars, institutional legal officers, and affected-party representatives examine a synthetic dispute before real deployment. Test whether readers distinguish a party's legal claim, an institutional policy, a pending proceeding, and an operative decision. Use the profile worksheet in section 4; no generic conformance result substitutes for legal analysis.

85.1.8 3.5 Ethics, value pluralism, and justice

Objective and questions: examine who benefits, who bears costs, who is heard, and which relationships or future possibilities are damaged. Include distributive justice, recognition, epistemic exclusion, autonomy, care, non-domination, ecological effects, and intergenerational consequences. How are conflicting values represented and reasons for prioritization made answerable to affected people?

Outputs and dependencies: an ethical-assessment Technical Report and deliberation guidance; candidate process requirements within GR-110/140/160/210/400 where testable. Cross-reference UNESCO's AI ethics and open-science recommendations within their scope.

Keep descriptive consequences, value commitments, and proposed remedies distinct. No universal ethical ranking or generativity score is proposed.

Review and validation: ethicists, disability/access specialists, labor and community representatives, and people bearing the proposed practice's costs examine alternative designs. Test inclusion of dissent, unjustified credibility discounts, unequal recording burdens, coercive visibility, and meaningful refusal. Evaluate whether review changes decisions and remedies harms, rather than treating completion of a checklist as evidence of ethical adequacy.

85.1.9 3.6 Institutional and public governance

Objective and questions: specify accountable uses of evidence in decision-making. Who sets categories, appoints assessors, controls access, can contest a finding, and provides remedy? How are conflicts of interest, unequal participation, institutional capture, urgent decisions, and failures to act exposed? Distinguish governance of this standards programme from governance of an institution using its outputs.

Outputs and dependencies: programme governance procedures; GR-400 organizational requirements; GR-210/310 review interfaces; decision-record and oversight manuals. OECD evidence-governance analysis motivates examining the conditions of evidence use alongside evidence quality. Depend on legitimate mandates, resourced review roles, ethics, and practical access.

Review and validation: public-administration specialists, institutional practitioners, civil-society participants, and independent oversight reviewers conduct a contested decision exercise. Assess who can trigger review, whether reasons address the challenge, whether remedial action occurs, and whether downstream effects are examined. More documentation alone is not evidence of accountability.

85.1.10 3.7 Political economy, contribution, and generativity return

Objective and questions: investigate ownership, infrastructural control, incentives, labor, access, and distribution of benefits. Who funds recording and preservation? Who can extract value, control classifications, or exclude contributors? How do documentation requirements alter bargaining power? Which maintenance, care, community, or environmental contributions remain invisible?

Outputs and dependencies: source-grounded research on contribution and generativity return; comparative institutional/economic Technical Reports; GR-110/160/400 candidate requirements for disclosure and contestable attribution; separate policy options for funding and stewardship. Generativity return remains a theoretical and operational research question, not an assumed monetary amount, entitlement, or contractual distribution rule.

Review and validation: political economists, labor researchers, infrastructure operators, community stewards, and contributors compare centralized custody, distributed stewardship, and existing repositories. Record cost allocation, exit/migration capacity, uncompensated work, access barriers, and concentration of control. A policy decision about benefit-sharing remains distinguishable from an empirical claim about contribution.

85.1.11 3.8 Public policy and international institutional options

Objective and questions: determine whether a public intervention is justified, for whom, under which mandate, and with what alternatives. Separate evidence about a problem and expected effects from political choices about priorities, funding, authority, participation, and acceptable risk.

Outputs and dependencies: mandate-specific proposals in the international-organizations track, using its policy template; options appraisal, theory of change, capacity-building plan, and evaluation design. Standards supply referenced technical requirements only after adoption; pilot Specifications are explicitly identified as experimental. Section 5 supplies initial options.

Review and validation: policy analysts, relevant institutional mandate/legal specialists, development and capacity-building practitioners, affected communities, and evaluators compare benefits, costs, alternatives, failure conditions, and exit paths. No organization is presumed to sponsor or participate; real pilots follow its own authorization and governance.

85.1.12 3.9 Technical implementation, security, usability, and accessibility

Objective and questions: implement the agreed practices without losing semantic distinctions or excluding participants. Can people inspect, challenge, correct, restrict, and move their records? What happens under forgery, coercive access, link failure, malicious submissions, conflicting updates, or inaccessible interfaces? Which tasks remain feasible offline or with limited resources?

Outputs and dependencies: GR-120/130/140/150/160 drafts, GR-SPEC-120/130/200, protocol behavior, conformance evidence, and user guidance. Use the protocol plan and verified external candidates. Security mechanisms follow threat analysis; accessibility assessment includes assistive technology, language, comprehension, bandwidth, and supported human alternatives.

Review and validation: independent implementers, security/privacy specialists, interaction designers, accessibility practitioners, and users test positive and failure cases. Combine semantic exchange tests with task-based comprehension and contestation exercises. Technical validation, source authentication, evidential assessment, ethical judgment, and legal status receive separate results.

85.1.13 4. Legal and institutional profile worksheet

Structural role: make proposed legal interfaces reviewable without universalizing a local conclusion.

Element	Information to establish for a concrete profile
Concept and action	For example electronic writing, evidentiary weight, notice, confidentiality, access, correction, preservation, or remedy; precise operation affected
Context and competence	Named jurisdiction, institution/forum, actors, territorial and temporal scope, and decision-maker's asserted authority
Basis and status	Exact instrument/provision/version; treaty, enacted rule, case, institutional policy, model rule, or proposal; application and interpretation verified separately
Evidence and procedure	Material relied on, evidentiary assessment method, ability to respond, relevant deadlines, notice route, review/appeal and remedies
Tensions and exclusions	Conflicting duties, confidentiality versus disclosure, preservation versus disposal, cross-border issues, unresolved authority, and unavailable evidence
Technical implication	Limited record/protocol behavior implementing the reviewed profile; distinctions and assumptions retained in exchange and presentation

The initial output is a worksheet completed for a synthetic institution, with legal applicability left OPEN. A live profile needs named expertise and current primary legal sources. Treaty guarantees are not mechanically converted into software permissions, and UNCITRAL's commercial-law model is not presumed applicable to noncommercial archives or public decision processes.

85.1.14 5. International policy options and institutional fit

Structural role: compare institutional arrangements rather than presenting technical adoption as an inevitable political choice. The audiences below are possible recipients, not partners or endorsers.

Possible audience and relevant remit	Candidate proposal	Mandate boundary to verify
UNESCO-related science, education, culture, and information communities	Voluntary research/knowledge-preservation pilots, inclusive participation, and capacity-building, informed by the two recommendations above	Specific programme authority, funding, participant protection, and relation to existing open-science infrastructure
OECD public-governance and policy-evaluation communities	Comparative study of evidence-to-decision practices and organizational capacities	Participation arrangements and policy-learning remit; no assumption of legal authority over national decisions
Institutions considering electronic-record legislative reform, informed by UNCITRAL work	A bounded comparison of technical record functions with locally relevant legal requirements	Commercial scope, actual enactment, competent lawmakers and courts; no claim that GR itself supplies a model law
Human-rights and oversight bodies within their respective mandates	Review of participation, unequal recognition, disclosure, and remedies in proposed pilots	Competence, independence, procedural basis, and protection of affected people; no assumed infrastructure-operating mandate

Every policy proposal compares at least these plausible options where relevant: improve practices using **existing infrastructure**; run a **voluntary bounded pilot** with reversible commitments; develop **shared stewardship** with explicit representation, funding, custody, and exit arrangements; or **defer adoption** while improving evidence, capacity, or safeguards. A broader rollout depends on demonstrated benefits, burdens, and institutional authority.

Appraisal records the baseline, intended beneficiaries, theory of change, costs and opportunity costs, distributional effects, implementation capacity, procurement/control arrangements, safeguards, independent evaluation, and conditions for stopping or revising the intervention. Empirical findings inform these choices; they do not resolve value conflicts or determine the politically legitimate option by themselves.

85.1.15 6. Worked case: contested research-funding decision

Structural role: demonstrate cross-domain distinctions in one synthetic example, without alleging facts or legal duties about a real institution.

A fictional public research fund rejects a community-led project after an AI-assisted summary describes its water-monitoring evidence as unreliable. A reviewer had treated missing instrument-calibration metadata as evidence that no calibration occurred. Community participants provide a restricted maintenance log and oral testimony. They also challenge the funding criteria's treatment of local knowledge. A reconsideration panel later changes its assessment; a small contributor's work still lacks recognition.

Layer	Distinct account and proposed recording/review question
Situation and trajectory	Equipment use, measurements, collaboration, rejection, and later reconsideration are subjects of inquiry. What records support each account, and what capacities were interrupted by the delay?
Evidence and interpretation	The initial reviewer inferred unreliability from missing metadata; the log and testimony offer counterevidence. Record method, provenance, limitations, and rival explanations; neither a missing field nor a valid signature decides the factual question.
Categories and methodology	The fund's scoring rules privilege certain evidence formats. Examine their purpose, validity, and exclusions separately from whether the project satisfied them. A changed rule needs its own history.

Layer	Distinct account and proposed recording/review question
Normative assessment	Participants argue that dismissal of local testimony was unjust and burdens were unequally allocated. Preserve their reasons and counterarguments; the record does not translate this judgment into a universal ethics score.
Legal/procedural position	A participant asserts a right to reconsideration. Record the asserted basis, relevant forum and unresolved applicability; a legal reviewer identifies actual rules before representing an entitlement or violation as determined.
Institutional decision	The panel records authority, recusals, evidence considered, reasons, notice, and disposition. A revised funding decision is distinct from accepting every factual or normative argument.
Political economy and return	Document uncompensated evidence-production labor, repository control, contribution disputes, and funding effects. Recognition, compensation, and future access are separate policy choices requiring reasons.
Preservation and implementation	Maintain authorized access to earlier assessments and the restricted log, disclose public-view limits, and exchange the revised account without erasing dissent or leaking contributors' details.

Pilot evaluation asks whether a participant can understand and challenge the initial reasoning; an independent reviewer can recover the change; protected contributors remain protected; and the institution can demonstrate its response. Follow-up examines actual effects on research participation and capacity. It does not infer restored trust, justice, or generativity from a corrected database entry.

85.1.16 7. Cross-domain review and sequencing

Structural role: make interdisciplinary review part of development decisions, before institutional use and publication.

At requirements development, each work item identifies its conceptual, epistemic, ethical, legal, institutional, economic, archival, and implementation dependencies. Editors document alternatives and disagreements jointly; a technical convenience does not silently settle a dispute about rights, values, authority, or knowledge.

Before a real-data pilot, proposed readiness evidence includes a scoped purpose and institutional basis; affected-participant involvement; proportionate data/custody arrangements; ethics and rights review; accessible challenge and remedy routes; security assessment; resourced oversight; and explicit stop/revision conditions. Missing expertise leads to a narrower synthetic case or deferred live use, not an unsupported assurance claim.

Before public review or publication, each relevant domain supplies a review record with reviewer competence, conflicts of interest, examined cases, unresolved objections, and disposition. Technical exchange, evidential usefulness, procedural legitimacy, accessibility, burdens, distributional consequences, and preservation remain separately assessed. Significant cross-domain changes return to affected reviewers.

Immediate outputs are a domain responsibility/dependency map, the synthetic funding case, initial legal-profile and policy-options worksheets, and a common issue register. Subsequent work develops the smallest coordinated GR-100/110/140/150/160/200/210/400 requirements subset; scoped GR-300/310 legal profiles advance when a concrete context and expertise exist. New independent publications follow demonstrated needs rather than multiplying family numbers now.

OPEN: reviewer recruitment and representation; which institutional context to study first; appropriate evidence for practical benefits and burdens; contribution/return operationalization; differences among knowledge traditions and methods; and when unresolved value or legal conflicts require narrowed scope. Record dispositions in open questions and architecture decisions where appropriate.

86 event spacetime design

Original source: `docs/planning/event_spacetime_design.md`.
Original source SHA-256: `fc4885d0eaacfd3329f45325aff5ae86a2470d30697fdaefc702c720eb148e18`.

86.1 Event order, trajectories, and relational configurations

Document class: Informative design proposal
Status: PROVISIONAL; EXPERIMENTAL version 1 implementation scope
Date: 2026-09-22
Purpose: Explain the source basis, distinctions, and limits of an event-defined spacetime presentation for the generalized application.

This document is an operational design proposal. It is not an adopted Standard, a complete formal semantics of GR, or a claim that the application reconstructs reality without interpretation. The Programme Brief, foundation manifest, and record graph review supply its programme context. The companion implementation Specification defines the exact machine contract.

86.1.1 1. The requested view

The requested space is the topology of the represented ontological configuration at an event-defined temporal cut: which Entity, State, Event, Process, Relation, and Property accounts apply, and which represented connections can be shown together. It is not necessarily geographic space. A physical location or coordinate can be recorded through the existing State or Property roles, with its subject, reference system, context, grounds, and temporal applicability made explicit.

The view has three coordinated parts:

- an event-order graph showing explicit precedence assertions;
- a graph of records whose temporal applicability supports inclusion at the selected cut;
- trajectories showing how related descriptions enter and leave applicability across event boundaries.

The ordinary record graph remains available. Its full inventory is useful even when temporal scope has not been supplied. A temporal view does not retrospectively supply that missing information.

86.1.2 2. Foundation passages and their operational consequences

Page numbers refer to one-based pages of the supplied PDFs. Findings below distinguish what the manuscripts say from the new engineering choices.

Source read	Finding	Consequence proposed here
FM-007, Metamodel II, section 9.2, pp.38–39	Occurrence indices, transition descriptions, and records of occurrences have different roles. Several records can concern one occurrence; repeated occurrences can share a transition description.	Record UUIDs identify retained accounts. Matching timestamps, labels, or effects do not automatically merge events or establish target identity.
FM-007, section 9.5, p.41	A database change can reflect corrected observation of an earlier target event. Inquiry history and target history have distinct carriers and update meanings.	Separate Git revisions from represented event order and temporal applicability.

Source read	Finding	Consequence proposed here
FM-007, section 9.7, p.42	The text explicitly proposes “A partial-order event record” that retains known precedence while leaving unrelated events unordered. It leaves the extension as a modeling obligation beyond the sequential base.	Adopt a bounded explicit precedence graph. Do not claim that the manuscript already supplies the proposed interchange module.
FM-007, section 9.7, p.42	Coarse timestamps can give apparent simultaneity; overlapping events can resist a faithful total order. Deriving an endpoint from a partial order requires justified treatment of its linearizations and any commutation assumptions.	Do not equate an order layer with physical simultaneity. Version 1 projects applicability assertions without executing event effects.
FM-007, section 12.6, p.59	Sequence position, elapsed duration, calendar position, and historical periodization answer different questions.	An event frontier is not a measured duration, calendar timestamp, or universal historical period.
FM-007, section 15.3, p.72	Joining transitions with mismatched endpoints can conceal an unrecorded intermediate step. Coherence of an event chain does not establish actual occurrence.	Do not invent intermediate states, replay unsupported transformations, or equate projection consistency with factual warrant.
FM-007, sections 15.4–15.5, p.73	A continuing entity can have different states. Attributes and incidence require context to preserve change.	A subject can group several temporally scoped descriptions; grouping does not make their contents timeless.
FM-005, GRE Chapter 5, section 5.14.1, pp.114–115	Relational trajectories require a continuity criterion, observational horizon, temporal resolution, boundary, and scale. Latency and gaps remain possible.	Explain the basis of subject grouping. Preserve unknown intervals and distinguish disappearance from the screen from historical dissolution.
FM-005, section 5.14.2, pp.115–116	Generative trajectories concern historically connected contributions; precedence alone is insufficient, and alternatives can remain unrealized.	The view is a temporal reconstruction aid. It does not label every displayed path a causal or generative explanation.
FM-005, section 5.20.4, pp.172–173	Historical revision changes present knowledge of the past while preserving earlier claims and their evidential conditions.	Select both a recording revision and a temporal cut. Later insertion can change a current reconstruction without changing earlier Git snapshots.

86.1.3 2.1 An event-scope difference that remains explicit

FM-004, GRE Chapter 4, section 4.15.2, pp.116–117, describes a relational event as a temporally delimited reconfiguration consequential for later relations. It permits extended duration and retrospective recognition. FM-007, sections 9.5–9.6, pp.40–41, also retains renewals and failed attempts that can leave a selected state unchanged.

These formulations address different analytical questions. The application does not silently replace either. Its Event role identifies an operational occurrence account. Version 1 uses selected Event references as boundary markers for a declared reconstruction. That narrower use does not assert that every GR event is instantaneous, consequential at every scale, or fully understood by its recorded transition.

86.1.4 3. Three independent coordinates of a view

Every projection identifies the following:

1. **Recording revision:** the Git snapshot containing the accounts and their versions.

2. **Event cut:** a selected downward-closed set under that snapshot's usable precedence assertions.
3. **Presentation selection:** filters, layout, grouping, and omitted or unresolved records.

For example, a user first records a dissolution event and later discovers the formation event that preceded it. The later Git revision can contain both events and an explicit formation-before-dissolution account. The represented chronology follows that assertion. The earlier Git revision still records what had been retained before the discovery.

Git commit timestamps do not determine target time. The descriptive `occurred_at` field remains useful context, but version 1 does not parse it into mandatory event precedence. Drawing one node above another likewise adds no precedence assertion.

The account's modality and epistemic basis remain visible. A hypothetical occurrence can be recorded; it does not become actual because its graph has no cycles. Mixing incompatible scenarios can require a narrower account selection in a future profile.

86.1.5 4. Explicit event-order accounts

An order assertion is a first-class Relation record. Its `gsp.event_order` version `1` module carries `before` and `after` Event-record references. Its ordinary `gsp.relation` module carries the matching two target incidences. The required module declares that temporal interpretation is needed to handle the account correctly; it does not turn the assertion into an established fact.

The ordinary record retains attribution, epistemic mode, modality, assessment/dispute status, evidence, uncertainty, revision reasons, and relevant qualifications. The temporal projection therefore remains connected to the statement responsible for an edge.

The selected interpretation is strict precedence between operational boundary markers. Its transitive closure can support additional precedence conclusions. The implementation distinguishes submitted edges from derived reachability and does not create extra source assertions merely because a path exists.

An untyped navigation link, an arbitrary Relation predicate, and a directed incidence are insufficient to assert precedence. Event order also does not establish causal influence or a generative contribution.

86.1.6 4.1 Contradictions and disputed assertions

Structural checks establish whether the typed references and module shapes are interpretable. They do not establish that every temporal assertion is compatible with every other one.

Contradictory precedence accounts remain recordable. A directed cycle prevents the selected edge set from defining a strict partial order. The projection reports `consistent: false`, identifies the affected assertions, and provides no admissible-cut projection until the conflict is resolved or the selected account changes. It does not silently drop an edge or impose an arbitrary order.

Withdrawn order accounts are omitted from the active ordering, while their records and histories remain available. Contested order accounts remain included with visible qualification. Inclusion means that the projection is conditional on those assertions; it is not an endorsement. User-selectable alternative chronology sets and richer adjudication are future work.

Unsupported retained event-order versions also prevent a complete cut/topology projection, even if an older producer marked that module optional. Their constraints cannot safely be omitted from a claimed complete ordering. The result identifies `unsupported_event_order` and `consistent: false`; this flag concerns a usable interpreted order, not truth. Unsupported temporal extents instead make the affected account's presence indeterminate, with a diagnostic, while leaving an otherwise usable event order available. Opaque modules remain retained.

86.1.7 5. Cuts, frontiers, and the limits of "same time"

For a selected acyclic event relation, write `a < b` when there is a directed precedence path from `a` to `b`. A cut `C` includes all predecessors of each included event:

```
b is in C and a < b  =>  a is in C
```

This is a downward-closed set, also called an order ideal. The frontier is its set of maximal included events. Including a later event includes its known predecessors; removing an included predecessor requires removing its included successors. These are consistency rules for navigating an account, not rules governing reality.

If neither `a < b` nor `b < a` is supported, the events are incomparable in this account. This does not by itself establish simultaneity, physical independence, overlap, or absence of a causal connection. An unrecorded order can still exist.

Topological layers can arrange the event graph compactly. Their layer numbers are display coordinates. Equal layer numbers do not assert equal occurrence times; different layer numbers do not establish precedence between every pair.

A frontier describes a configuration relative to the available order and applicability claims. It need not correspond to one uniquely identified physical instant. There can be several admissible cuts through unordered activity. Version 1 keeps the event graph and selected cut explicit instead of presenting one arbitrary total replay as the recovered history.

86.1.8 6. Temporal applicability and trajectories

The required `gsp.temporal_extent` version `1` module can accompany any record role. It contains `start`, `end`, `basis`, and an optional `subject_record_id`.

Each boundary has one of these forms:

Boundary form	Interpretation
`{kind: event, event_id: ...}`	Applicability is bounded by the referenced operational Event marker.
`{kind: unknown}`	The boundary has not been sufficiently established.
`{kind: unbounded}`	No limiting boundary is asserted on this side within the declared account's scope.

An unbounded boundary is a positive scope statement. It is not the default meaning of missing data and does not establish that a target has existed or will exist throughout all time. The `basis` explains the grounds and scope of the applicability account, including relevant continuity assumptions or uncertainty.

Version 1 uses start-inclusive, end-exclusive applicability: an included start marker opens the interval, and an included end marker closes it. If both boundaries name events, their strict start-before-end order needs support in the selected event relation. Without that support, the extent remains indeterminate and receives a diagnostic. The extent itself does not invent the missing precedence edge. Equal or reversed markers do not receive an invented positive duration.

86.1.9 6.1 Classification at a selected cut

The projection distinguishes:

- `active`: the declared boundaries support applicability at this cut;
- `not_started`: the supported opening boundary has not been crossed;
- `ended`: the supported closing boundary has been crossed;
- `indeterminate`: supplied temporal information is insufficient or inconsistent for a definite applicability result;
- `unscoped`: no temporal extent was supplied;
- `withdrawn`: the account is withdrawn and remains available for inspection outside active topology.

Unknown and absent boundaries remain visible. They are excluded from the active topology by default, with counts and an inspection path. A display can include them as explicitly qualified context; it cannot silently promote them to active. Missing temporal data is not a claim of nonexistence.

An unknown boundary can prevent a positive active result even when the other boundary is known. Where a known bound supports a narrower statement, the interface can identify it without treating the unknown bound as resolved. Exact classification priority and diagnostics belong to the implementable projection contract.

86.1.10 6.2 Subject grouping and continuity

The optional `subject_record_id` associates a temporally scoped description with a subject account for trajectory presentation. For example, several State records can describe different conditions of the same organization under a stated continuity criterion.

The reference is a supplied grouping claim, not an identity proof. Its basis matters, especially across renaming, merger, dissolution, succession, or disputed continuity. The renderer does not merge records automatically because their titles match, their endpoints coincide, or they occur in adjacent layers. Without a grouping claim, a record can retain its own temporal trace.

Competing State accounts can both remain visible. This version does not select a unique true state, impose property exclusivity, calculate a next world state, or decide which account defeats another.

86.1.11 6.3 An Event boundary is not its record's lifetime

The Event marker used by the ordering graph identifies a represented boundary in the inquiry. Its recording account can remain available in every later Git snapshot. Availability of that account does not mean the event is still occurring.

Likewise, attaching a temporal extent to an Event-role record scopes the account's applicability under this profile. It does not silently redefine the represented event's physical duration. The separate event-order diagram continues to show the selected event inventory and cut frontier. This avoids disappearing historical occurrences merely because an ontology configuration uses a narrower applicability filter.

Extended events, onset/completion distinctions, interval overlap, and the relation between an event's occurrence interval and its use as a boundary require a richer profile. They remain explicitly deferred rather than being approximated through creation timestamps or arbitrary zero-length intervals.

86.1.12 7. Constructing the topology

At a consistent cut, the primary topology is induced by the records classified as active. Every active record remains a node, including a Relation whose participants are not all established active. An edge is retained only when both endpoint records are active. A Relation with omitted participant incidences or an explicitly incomplete participant account receives a `partial_relation_at_cut` diagnostic identifying the omitted incidences. The interface preserves its full account for inspection and does not present the displayed subset as a complete relation.

This induced-subgraph policy preserves access to an active relational account instead of removing it because another account lacks temporal scope. It also avoids inventing active participants to complete the picture. Keeping the Relation node is a presentation of its scoped account, not a claim that every part of the relationship has been reconstructed.

Relations retain their own IDs and histories. An independently recorded relation can appear, change through a separately scoped account, or cease to apply without changing its participants' identities. The existing incidence representation continues to support n-ary relations and relations whose participants are relations.

Record scope, relation participant completeness, and hidden display filters remain separate limitations. An active Relation with an explicitly incomplete participant account still needs that qualification even when every retained participant is active.

The graph is a projection of temporal assertions at one recording revision. It is not produced by replaying Git edits as world events, and it is not a simulation of all event effects. In particular, unordered events with potentially incompatible effects do not receive a fabricated outcome through identifier sorting.

86.1.13 8. External reference boundaries

Lamport's 1978 paper, pp.559–560, supplies a precise comparison for partial event order and logical-clock displays. Its concurrency relation does not require equal physical time. Its assumptions concern distributed processes and messages; the application does not infer that those assumptions hold for historical or social records. The proposed cut and applicability rules are this programme's declared operational choices.

The 2017 W3C Time Ontology Recommendation, sections 3.1–3.3, distinguishes instants, intervals, interval relations, temporal reference systems, and temporal granularity. It is a useful comparison for a later interval profile. Version 1 neither implements the full ontology nor claims RDF/OWL interoperability. The version-specific citation matters: the generic OWL-Time publication URL currently resolves to a 2022 Candidate Recommendation Draft.

86.1.14 9. Discriminating review cases

Case	Expected design result
A later event is recorded before an earlier event	Explicit precedence determines represented order; Git retains insertion order independently.
Two events have no supported order	They remain incomparable; shared display position does not assert simultaneity.
Two accounts assert opposite strict orders	Both survive; the selected ordering is diagnosed as inconsistent and no cut topology is asserted.
An order account is contested	Its qualifications remain visible and the projection discloses its conditional inclusion.
A State has two boundary events with no supported precedence	The extent is indeterminate; no order is inferred from the extent alone.
An old agreement has no temporal module	It appears as unscoped context, rather than being assigned the date of its first commit.
A Relation is active while a participant's applicability is unknown	The relation's boundary context is exposed; the active graph does not display a complete unsupported arrangement.
Two scoped State accounts make incompatible claims about one subject	Both remain inspectable; temporal projection does not silently adjudicate them.
A later correction changes the claimed onset	The current reconstruction changes; the earlier Git revision still shows the earlier claim.
An Event record remains in later snapshots	Record retention does not imply continued event occurrence.

86.1.15 10. Remaining questions

- **OPEN:** How should users select competing coherent chronology accounts while preserving the sources, exclusions, and reasons for each selection?
- **DEFERRED:** How should extended events, intervals, overlap, approximate calendar dates, and multiple temporal reference systems interact with event boundaries?
- **OPEN:** Which subject-continuity and relation-continuity criteria are suitable for particular domains, and how should competing criteria be compared?
- **DEFERRED:** When should a profile interpret event effects as transformations, and what evidence or formal conditions justify equal outcomes across different linearizations?
- **OPEN:** Do users understand the distinction between a cut, an order layer, an actual time, an unknown interval, and a recording revision? Browser correctness alone does not establish that comprehension.

The implementation advances a bounded presentation capability under the existing temporal and epistemic requirements. It leaves causal inference, complete historical reconstruction, and the broader theory of generativity available for further work.

87 external standards landscape

Original source: `docs/planning/external_standards_landscape.md`.
Original source SHA-256: `44657068d390d7b236756d3558d4ed7776f84ba31f59dfb220e121ae7b33b969`.

87.1 External Standards and Specifications: Candidate Reuse Landscape

Document class: Informative research and planning document
Status: PROVISIONAL candidate assessment; no dependency selection
Version: 0.1
Checked on: 2026-09-22, Asia/Tokyo (2026-09-21 UTC)

87.1.1 1. Purpose and evidence boundary

This bounded review identifies external resources worth evaluating for the protocol and specification plan. The source descriptions below report published scope; proposed GR uses and limitations are programme planning judgments. They do not establish a mapping, conformance, interoperability, or endorsement claim.

This is the technical reuse component of the research. The standards-development comparison covers ISO/IEC, IEEE and WTO procedural approaches; the cross-domain programme covers normative, legal, institutional and policy sources.

Official publisher pages and freely available technical documents were checked. This is an initial scope/status review, not a clause-by-clause compliance or intellectual-property assessment. No inaccessible or paywalled normative requirements are inferred. Dates identify the editions inspected, not a guarantee that each is the newest available edition.

A reuse decision still needs a motivating GR requirement, a precise version/section, candidate mappings and counterexamples, licensing and maintenance review, implementation evidence, and an explicit decision record. External terms retain their own definitions: matching names do not establish conceptual equivalence.

87.1.2 2. Verified source register

Structural role: record the exact primary sources inspected and candidate programme destinations. The checked-on date above applies to every entry.

Source and inspected edition	Official source and observed scope/status	Candidate GR destination
PROV-O, 30 April 2013	W3C Recommendation: PROV-O. OWL representation of provenance with entities, activities, agents, derivation, attribution, and qualified relations.	GR-110/120/200/210; GR-SPEC-120/200 provenance mappings
Web Annotation Data Model, 23 February 2017	W3C Recommendation: Web Annotation Data Model. Annotation bodies and targets, including targeting parts or states of resources.	GR-140/200/210; GR-SPEC-200 annotation and evidence targeting
Time Ontology in OWL, 19 October 2017	Published 2017 OWL-Time Recommendation. Temporal instants, intervals, ordering, durations, and reference systems.	GR-100/110/120/140; GR-SPEC-120 temporal representation
JSON-LD 1.1, 16 July 2020	W3C Recommendation: JSON-LD 1.1. JSON serialization of Linked Data, with contexts and identifier/term interpretation.	GR-130; GR-SPEC-130 candidate serialization
SHACL, 20 July 2017	W3C Recommendation: Shapes Constraint Language. Validation of RDF data graphs against shapes and production of validation reports.	GR-150; validation artifacts for GR-SPEC-120/130/200 if an RDF representation is selected

Source and inspected edition	Official source and observed scope/status	Candidate GR destination
HTTP Semantics, RFC 9110, June 2022	RFC Editor: RFC 9110. IETF Standards Track, STD 97; methods, representations, request conditions, and responses.	GR-130; eventual GR-SPEC-130 HTTP binding
C2PA Technical Specification, version 2.4	C2PA: Content Credentials technical specification 2.4. Technical architecture for signed content provenance manifests, validation, and trust-model handling.	Optional GR-110/130/140 evidence/provenance import; GR-SPEC-130 adapter if a media pilot requires it
PREMIS Data Dictionary, version 3.0	Library of Congress: PREMIS version 3.0. Official indexed overview identifies preservation Objects, Events, Rights, and Agents; full dictionary updated November 2015.	GR-160 and GR-SPEC-120/130 preservation/migration metadata mapping

Version observations: the unversioned OWL-Time publication URL displayed a later Candidate Recommendation Draft dated 2022, so it is not interchangeable with the 2017 Recommendation cited above. The C2PA site exposed 2.4 alongside earlier versions; this review inspected the 2.4 technical specification without claiming programme adoption. PREMIS overview content was available through the official-domain search index; direct page opening failed, and its full dictionary/errata have not been reviewed here.

87.1.3 3. Candidate uses, boundaries, and mapping experiments

87.1.4 3.1 PROV-O

Proposed use: test whether shared provenance vocabulary can express capture, transformation, contribution, and revision without inventing equivalent mechanisms. Its qualified-relation patterns are relevant where a relationship itself needs descriptive detail. Source

Boundary: `prov:Entity`, `prov:Activity`, and `prov:Agent` are source terms, not declarations that GR Entity/Event/Process have identical admissibility or identity criteria. Provenance attribution does not establish the truth of attributed content or its ethical/legal legitimacy.

Experiment: map one observation record, its recorder, an inference, a revision, and two competing interpretations. Record unsupported GR distinctions and reverse-mapping losses. Keep any extension local and explicit until review.

87.1.5 3.2 Web Annotation Data Model

Proposed use: target a claim version, document passage, or evidence fragment with an attributed interpretation, objection, or reply. Inspect selectors and states for durable references to the relevant material. Source

Boundary: an annotation model does not by itself provide an institution's review authority, required response, adjudication process, or a settled account of evidentiary weight. A reference to a changing resource needs an explicit version/selection policy. Annotation content and the occurrence it discusses remain distinguishable.

Experiment: transport an objection about one passage, then revise or restrict the source. Test correct targeting, accessible historical context, and informative handling of unavailable material. Evaluate network annotation protocols separately only if the pilot needs them.

87.1.6 3.3 OWL-Time

Proposed use: represent ordered or overlapping intervals, instants, durations, and temporal reference systems. Source

Boundary: temporal vocabulary does not select which times a GR record needs. Occurrence time, observation time, recording time, assessment time, and version/publication time remain different roles. A precise timestamp format does not warrant precision in the underlying knowledge.

Experiment: map an approximately dated historical account, an observation interval, a retrospective assessment, and a later correction. Test unknown bounds, inconsistent chronology, and partial order without manufacturing certainty. Record which cases require a GR profile beyond the source vocabulary.

87.1.7 3.4 JSON-LD 1.1

Proposed use: evaluate a graph-oriented interchange option with explicit terms and identifiers that can be serialized as JSON. Contexts define how compact terms are interpreted. Source

Boundary: serialization does not supply GR semantics, access control, evidence assessment, validation rules, or preservation policy. Familiar JSON appearance does not eliminate the need to test linked-data processing and context management.

Experiment: exchange the minimum pilot package between two implementations; preserve terms, identifiers, language information, and defined extensions. Assess context versioning, offline interpretation, dependency availability, and loss on conversion. Compare total implementation burden with a simpler documented interchange before selection.

87.1.8 3.5 SHACL

Proposed use: express selected structural constraints and produce inspectable validation reports if an RDF representation is adopted. The source distinguishes validation failure from reported constraint results. Source

Boundary: passing a shapes check does not establish that an event occurred, evidence is adequate, a procedure was fair, access was authorized, or a presentation is intelligible. Cross-system behavior and institutional practice need additional evaluation.

Experiment: test required attribution, allowed reference patterns, and version links against positive and negative fixtures. Keep input defects, processor failure, unsupported validation features, and substantive disagreements distinct in the GR conformance report. Document any constraints checked outside SHACL.

87.1.9 3.6 HTTP Semantics

Proposed use: if a network binding becomes necessary, reuse method semantics, status codes, validators/preconditions, and the distinction between idempotent and non-idempotent operations. Source, especially sections 9 and 13

Boundary: HTTP does not define the GR review procedure, application authorization policy, record meaning, synchronization strategy, or safe retries for an arbitrary application operation. Successful delivery is distinct from successful application processing and substantive acceptance.

Experiment: after batch exchange works, test interrupted submission, repeated delivery, stale revision, partial import, and denied access using a concrete proposed binding. Document application-level receipts and conflict handling. No API endpoint design is selected by this landscape.

87.1.10 3.7 C2PA

Proposed use: evaluate importing or referencing media provenance manifests when an evidence pilot already encounters Content Credentials. Its scope includes cryptographically verifiable provenance and validation under a specified trust model. Source, sections 1.2 and 14–15

Boundary: successful signature/manifest validation does not settle whether depicted events happened as described, a source was candid, a claim is justified, or a signer has institutional authority to decide it. Absence of credentials is not proof of falsity.

Experiment: preserve the credential, validation time/result, applicable trust context, and limitations separately from an assessor's evidentiary judgment. Test missing, invalid, and unavailable credentials and a valid credential attached to contested content. Defer mandatory signing infrastructure pending a demonstrated threat-model need.

87.1.11 3.8 PREMIS

Proposed use: evaluate preservation metadata for retained objects, preservation actions, agents, and relevant rights statements. This review uses the official version 3.0 overview; detailed unit-level selection awaits the dictionary and errata review. Source

Boundary: PREMIS preservation Events and Objects are not automatically the GR operational classes of the same names. Preservation metadata and recorded rights statements do not themselves establish lawful retention, unrestricted disclosure, or legal authority.

Experiment: after source review, map an ingest, format migration, access restriction, and disposal action. Examine the difference between preserving content, preserving permitted evidence of an action, and limiting access. Record information loss and institutional assumptions.

87.1.12 4. Evaluation sequence and decision record

Structural role: limit dependency work to what the next pilot requires.

1. From GR-110/200/210 and early GR-140/150/160 requirements, identify the smallest provenance, epistemic, temporal, exchange, validation, and restriction needs.
2. Evaluate PROV-O, annotation, and temporal mappings against those needs. Preserve mismatches as issues rather than expanding the GR ontology to mirror an external vocabulary.
3. Compare candidate interchange approaches, including JSON-LD; assess SHACL only in conjunction with an RDF-based option. Keep an offline, bounded package within the comparison.
4. Inspect PREMIS's full dictionary and errata before detailed preservation mappings. Evaluate C2PA only for a relevant media case and HTTP only for a demonstrated network requirement.
5. Record costs, unsupported distinctions, loss, implementation evidence, accessibility, security/privacy, licensing, edition pinning, maintenance, and migration implications before selecting a dependency.

For each candidate, the evaluation record includes: GR requirement reference; external edition and exact sections; mapping direction and limits; alternatives; fixture set; independent results; known defects; selected direction or reason for deferral; and affected documents. A selection becomes an architecture decision where it constrains programme design.

OPEN: sufficient semantic preservation for a mapping claim; treatment of external version changes; availability and licensing of supporting artifacts; implementation burden for small institutions; and boundaries between shared GR semantics and domain-specific profiles.

This landscape is deliberately bounded. Later pilots can identify other metadata, identifier, security, accessibility, archival, or domain standards for separate verified review. Inclusion here is an evaluation priority, not a normative reference list for a future Standard.

88 foundation traceability

Original source: `docs/planning/foundation_traceability.md`.
Original source SHA-256: `b4da3d423abe7684064f645da17f2eff7f8db435ba43eac9ba60dc6b5f58cd39`.

88.1 Foundation Traceability for Development Planning

Document class: Informative planning and source-analysis document
Status: PROVISIONAL; proposed operational translations and prospective evidence
Date: 2026-09-22

88.1.1 1. Purpose and limits

This map supports the comprehensive development plan. It connects the foundation corpus to questions for standards, protocols, specifications, and pilots. Its organizing problem is the reliability of relations among reality, manifestations, claims, institutional recognition, and action under symbolic abundance and representational instability.

The manuscript manifest assigns stable FM identifiers to all seven supplied PDFs, including both Chapter 3 variants. Source passages supply conceptual grounds; the candidate requirements below are programme proposals. None is an adopted clause, a claim of completed validation, or a replacement definition of a GR concept.

Existing publication codes route potential work without establishing project approval or maturity. Protocol names describe candidate procedures whose publication placement remains subject to the plan. A protocol is a subject of a Specification or Standard, not a separate authority class. Requirements begin in standards-track work; reusable technical needs can then produce a Specification and a pilot. GR-300/310 routing identifies questions for contextual legal and procedural review, not a legal effect derived from the foundation manuscripts.

88.1.2 2. Reading the trace

Each FT identifier follows this chain:

`manuscript passage → distinction at stake → candidate requirement or question → discriminating evidence → drafting decision`

The evidence column describes a future test or pilot artifact. It does not assert that evidence has been collected. Useful results include failure: an example the proposed record cannot reconstruct, a distinction it silently merges, unmanageable recording burden, or a safeguard a participant cannot actually exercise.

Page numbers are one-based PDF pages. Chapter and section numbers identify the argument more durably than page numbers alone. Source links point to the exact file entry in the manifest. Candidate requirements are expressed as drafting tasks, not normative clauses.

88.1.3 3. Motivation, recognition, and epistemic warrant

ID	Source and actual distinction	PROVISIONAL operational translation and routing	Prospective test or pilot evidence
FT-01	FM-001, §1.14.2–1.14.5, pp. 79–83: authenticity, provenance, evidential adequacy, and epistemic trust answer different questions.	GR-110/140/150/200/210: preserve separate provenance checks, evidential assessments, and reliance decisions, with their scopes and responsible actors. A provenance validation result does not become a truth verdict.	A genuine document containing an incorrect claim and an accurate document lacking verifiable provenance produce distinguishable results. Reviewers can identify what each check establishes and what remains unresolved.

ID	Source and actual distinction	PROVISIONAL operational translation and routing	Prospective test or pilot evidence
FT-02	FM-004, §§4.2, 4.6–4.9, pp. 11–19, 43–74: reality, manifestation, and mediated access are distinct; the registers are not exclusive object kinds.	GR-100/110/120/200: represent claimed target, manifestation or trace, recording activity, and resulting assertion through explicit links. Avoid one undifferentiated “fact” field.	A practice predates recognition; two observers describe it differently; later recognition changes its operation. The record preserves these temporal and epistemic differences without requiring a final metaphysical classification.
FT-03	FM-005, §§5.2–5.4, pp. 13–36: manifestations constrain a compatibility set under conditions, evidence, and assumptions.	GR-200/210, supported by GR-110/120 and a claim/evidence assessment procedure: link a material claim to evidence, method, assumptions, context, inferential mode, and live alternatives at a proportionate level of detail.	Two reconstructions fit the same trace. A reviewer distinguishes elimination through new evidence from elimination through a modeling assumption and recovers alternatives left unresolved.
FT-04	FM-005, §§5.7–5.8 and 5.17, pp. 53–70, 141–150: observation is partial; boundaries, scale, and uncertainty dimensions matter.	GR-110/140/200: declare observational scope, observer position, relevant omissions, boundary, scale, and uncertainty type. Investigate qualified confidence dimensions rather than assume one mandatory score.	Reviewers compare a narrow direct observation with a broad retrospective inference. Missing observations are not displayed as non-occurrence; changing boundary or scale is visible.
FT-05	FM-005, §§5.15–5.16, pp. 122–141, and FM-007, §16, pp. 75–78: mathematical coherence and institutional uptake do not themselves establish factual warrant.	GR-150/210/400: separate syntax/model validation, evidence sufficiency review, and institutional determinations. Define what a conformance result covers.	A structurally valid but unsupported claim passes only the structural check. Review output exposes its missing evidential basis; no “validated fact” badge conflates the assessments.
FT-06	FM-005, §5.18, pp. 150–160: evidence production, preservation, credibility, and contestation are unequally available.	GR-160/210/400 and a contestation procedure: support attributed testimony, challenges, responses, unresolved disagreement, and access-sensitive evidence handling. GR-310 investigates applicable procedural bases separately.	An affected participant challenges a classification, supplies an alternative account, and receives a traceable disposition without exposing restricted evidence. Measure participation barriers, not only field presence.
FT-07	FM-005, §5.19, pp. 160–168: machine mediation adds representational and inferential conditions; computational confidence is not independent authority.	GR-110/140/200/210: record material machine contributions, supplied sources, transformations, human uptake, and limitations needed to examine a claim. AI-specific fields form a profile, not the definition of the programme.	A generated summary contains an unsupported link between events. A reviewer traces it to the machine step, distinguishes source evidence from generated inference, and follows correction into dependent records.

88.1.4 4. Trajectories, revision, and praxis

ID	Source and actual distinction	PROVISIONAL operational translation and routing	Prospective test or pilot evidence
FT-08	FM-005, §5.20, pp. 168–176: new evidence, intervention, historical reinterpretation, and category revision are different sources of revision.	GR-110/120/130/160/200/210 and revision/migration procedures: keep target change, evidential update, and descriptive-regime change distinguishable, allowing combined reasons. Link prior formulation, revision grounds, resulting formulation, and affected dependents.	Three cases use the same visible field update: the world changed; a prior report was corrected; a category changed. The record and exported view preserve which happened and when.
FT-09	FM-005, §§5.14 and 5.20.4, pp. 113–122, 172–173: later knowledge of the past differs from the past and from historical effects of earlier representations.	GR-110/140/160/200/400: preserve evidence available at the time, later interpretation, and consequences of the earlier claim, under declared retention and access conditions. Specify reconstruction scope rather than promise complete recovery.	A disputed claim influenced a decision before correction. A historical view recovers earlier grounds and the decision; a current view displays correction and remaining uncertainty.
FT-10	FM-003, §§3.9, 3.12, pp. 94–104, 129–141; FM-002, §3.12, pp. 128–139: selection and intervention alter future conditions, and praxis is iterative.	GR-110/210/400 and a praxis protocol: preserve diagnosis, alternatives, intended effects, decision grounds, intervention, monitoring, feedback, and revision or repair where relevant. The source does not impose one universal workflow.	A bounded institutional pilot changes action after unexpected downstream effects. The record explains the change, whose evidence mattered, which alternatives remained available, and the cost of recording.
FT-11	FM-003, §§3.10, 3.13, pp. 115, 141–152; corresponding FM-002, pp. 113, 139–151: generativity is not intrinsically beneficial.	GR-110/140/210/400 and evaluation guidance: distinguish attributed generative effects from judgments under specified values, affected groups, boundaries, and horizons. Avoid a compulsory universal generativity score.	An intervention expands one group’s capacity and restricts another’s. Both effects and competing evaluations remain available; a positive output count does not erase loss or dependence.
FT-12	FM-003, §3.2.3, p. 15, compared with FM-002, §3.2, pp. 11–22: access to outputs differs from access to generative capacity and conditions; the dedicated subsection occurs only in FM-003.	GR-110/400 and institutional/policy work: distinguish output distribution from participation in inquiry, tools, institutions, and decision capacities. Retain the source variant explicitly.	A pilot supplies outputs widely while restricting ability to question, revise, or generate them. Evaluation exposes this difference and does not claim that interoperability alone remedies it.

ID	Source and actual distinction	PROVISIONAL operational translation and routing	Prospective test or pilot evidence
FT-13	FM-004, §§4.10–4.11, pp. 74–89; FM-005, §5.6, pp. 44–53; FM-007, §16.2, pp. 75–76: representation can enter action through classification and institutional uptake.	GR-200/400: link a claim or classification to its uptake and later effects. GR-300/310 identify any asserted authority, jurisdiction, applicable source, and procedural status; technical conformance does not supply these.	A classification changes eligibility in a synthetic institutional case. The record distinguishes evidence, classification, institutional decision, and asserted legal basis, including a dispute over authority or procedure.

88.1.5 5. Record roles and technical loss

ID	Source and actual distinction	PROVISIONAL operational translation and routing	Prospective test or pilot evidence
FT-14	FM-007, p. 2 and §§7–12: six analytical categories have overlapping uses and no established exhaustiveness or metaphysical priority.	GR-100/120: document purpose, identity, admissibility, temporal behavior, relations, metadata, examples, and counterexamples for operational roles. Decide how overlap is represented before choosing exclusive schema types.	A relation has its own history and attributes; an occurrence participates in a process. The model represents these views without claiming the roles partition reality.
FT-15	FM-007, §§7, 19.2, pp. 26–32, 87–88: reidentification uses a declared criterion; branching lineage can differ from equivalence-based identity.	GR-110/120/200 and an identity procedure: separate identifiers, continuity claims, identity criteria, and succession/lineage links. Permit disputed identity judgments with evidence.	A merger, a split, and an unchanged name after organizational replacement distinguish continuity from identifier reuse. Reviewers reconstruct the selected criterion and alternatives.
FT-16	FM-007, §§8, 19.3, pp. 32–37, 88: relation formation and potential effects under continuations need different evidence.	GR-110/120/210: keep participants, roles, formation claims, conditions, and prospective effect claims independently attributable.	Two relations have the same current outcome but different histories or responses to a later request. The record preserves the historical and prospective questions separately.
FT-17	FM-007, §§9, 12, 19.4, 19.7, pp. 37–43, 56–61, 88–89: equal effects can hide repeated occurrences, failed attempts, ordering, and intermediate conditions.	GR-110/120/130: distinguish occurrence identity from transition, process from composite effect, and attempted from completed action. Preserve supported partial order and temporal uncertainty.	Repeated idempotent authorizations share an endpoint but retain distinct occurrence counts. A failed intermediate step survives export/import; uncertain ordering remains uncertain.

ID	Source and actual distinction	PROVISIONAL operational translation and routing	Prospective test or pilot evidence
FT-18	FM-007, §§10, 19.5, pp. 43–52, 88–89: Attribute has value, interpretation, scale, and definedness conditions.	GR-100/120: resolve Attribute/Property through an ADR before harmonization. Investigate explicit states for unavailable evidence, inapplicability, disputed classification, and unperformed measurement.	A round trip keeps zero, false, unknown, inapplicable, disputed, and not measured distinguishable where relevant. Numeric recoding does not justify arithmetic unsupported by the measurement scale.
FT-19	FM-007, §§11, 19.6, pp. 52–56, 89: state sufficiency is relative to observations, operations, and a comparison horizon.	GR-120/150 and formal-semantics research: state the questions a reduced record supports and the distinctions it omits. Predictive adequacy and historical recoverability need different tests.	Two cases with identical current records behave differently under a declared continuation. The pilot identifies missing memory or an invalid assumption instead of treating current-record equality as identity.
FT-20	FM-007, §17.1–17.2, pp. 78–80: transition between declared regimes needs alignment; a coarse record cannot recover omitted information merely by switching notation.	GR-120/130/160 and migration specifications: identify source/target regime versions, transformation rules, retained evidence, and known information loss. Leave unsupported fine-grained results unknown.	A new classification splits an old category. Migration marks unrecoverable membership rather than inventing it; retained evidence supports recovery only where sufficient.
FT-21	FM-006, §§3, 7, pp. 5–6, 10–11; FM-007, §§3.4, 17, pp. 12, 78–83: fixed-carrier collapse, preserved equivalence, declared regimes, and normative judgments have different scopes.	Technical reports first: document assumptions and limits of proposed formal semantics. No automatic mapping from mechanism to Process, formal change to Event, or collapse to harm.	Counterexamples contrast loss of distinction, harmless aggregation, a new descriptive distinction, and actual emergence claims. Each result identifies the applicable construction and the question outside it.

88.1.6 6. Decisions and research questions kept open

These questions affect later requirements and belong in the programme's open-question register. This document supplies source context and proposed decision evidence, without assigning conformance authority.

Question	Alternatives needing assessment	Evidence or decision needed
OPEN — Property / Attribute	Scoped operational equivalence; separate concepts; future terminology revision.	Definition comparison and counterexamples from FM-007 §10, impact analysis, and an ADR before changing established terminology.
OPEN — Six-role representation	Overlapping roles; types with declared combinations; profile-specific restrictions.	Cases showing necessary overlap and where restriction improves interoperability without an ontological claim.
OPEN — Claim and evidence structure	Separately identified claims; attributed assertions within records; a hybrid.	Disagreement, correction, provenance, access, and round-trip cases before a schema choice. Manuscript distinctions alone do not prescribe serialization.

Question	Alternatives needing assessment	Evidence or decision needed
OPEN — Revision semantics	Linked histories for target, evidence, and regime; one revision structure with explicit multiple reasons.	FT-08/09/20, including an unrecoverable migration and representation that changes its target through uptake.
OPEN — Formal and normative preservation	Distinct technical and evaluative vocabularies; narrowly justified bridges for specified applications.	Account of FM-006/FM-007 differences; no inference from preservation of equivalence to protection of every valued difference.
OPEN — Emergence and possibility	Records of reported new possibilities; models of declared regime changes; research on unanticipated novelty.	Domain evidence and explicit assumptions. Neither the fixed carrier nor declared regime family establishes universal mathematics of emergence.
OPEN — Chapter 3 precedence	Preserve both variants pending authorial designation; select one for a named drafting task with the choice recorded.	Editorial provenance and substantive collation. Filename and build timestamp alone do not establish authoritative supersession.
OPEN — Burden and scope	Minimal claim/trajectory core with profiles; more demanding domain-specific obligations.	Participant time, privacy exposure, omitted distinctions, query recoverability, and correction usability measured together. More data alone is not success.

88.1.7 7. Evidence package for the next drafting cycle

The plan's first demonstrator can use programme decisions plus a synthetic institutional case, supplemented by counterexamples from FM-007 §19. A later bounded institutional or research pilot provides different evidence. Synthetic cases test a design property; they are not evidence of successful institutional adoption.

For each selected FT row, the drafting record can contain:

1. Manuscript identifier, exact section/page, and the distinction retained.
2. Candidate requirement, intended publication, scope, and conformance target.
3. A normal example, a failure case, and a counterexample to an overbroad interpretation.
4. Evidence collected, including recording burden and unresolved access restrictions.
5. Test result and limits, including differences between independent implementations or reviewers.
6. Disposition: retain, revise, split into a profile, move to a technical report, or defer; with rationale and affected documents.

External mappings require separate verification of the exact external edition and claimed relationship. This map establishes no compatibility, legal effect, factual guarantee, or automatic equivalence between a foundation formulation and a programme requirement.

89 governance and pilots

89.1 Governance launch and pilot evidence plan

Document class: Informative programme planning document
Status: PROVISIONAL
Version: 0.1
Authority: Proposed work and evaluation criteria; no governance adoption, project approval, or conformance requirements are established by this document.

89.1.1 1. Role and planning basis

Authoring update, 2026-09-22: Substantive governance drafts, expanded templates, P0 arithmetic/design rehearsal and P1 disputed-record fixture are available. The original outline links in the checklist below now point onward to those drafts. Actual appointments, review, participation, adoption and live pilot evidence remain pending; authored cases do not satisfy the operational completion criteria.

This plan connects the programme's governance infrastructure to the evidence needed to develop standards, protocols, and specifications. It accompanies the programme brief, the comprehensive development plan, and the publication taxonomy.

The planning objective is an inspectable practice of recognizing, recording, contesting, revising, and presenting generative trajectories. Archival preservation and AI-assisted work are important cases within that objective. Recording final outputs alone is insufficient to exercise it.

The standards-development comparison supplies verified ISO/IEC, IEEE and WTO source practices and proposed adaptations for governance drafting. The cross-domain programme supplies substantive epistemic, ethical, jurisprudential, institutional, policy and political-economy work and review. Neither is reduced to a technical validation checklist.

Existing publication numbers remain project-family identifiers. References below to GR-100, GR-110, and other families identify preliminary scopes, not adopted Standards or approved projects. Protocol experiments acquire their publication class and authority from their containing Specification, Standard Working Draft, or other declared publication; the word "protocol" does not itself confer authority.

Named roles below are proposed responsibilities. Their holders, availability, institutional mandates, and resources are **UNASSIGNED**. The existing repository does not establish that the proposed Council, committee, or working groups are constituted. Sequencing is based on evidence and capacity, without committed dates, budgets, or external partners.

89.1.2 2. Governance launch checklist

Role: Identify the difference between repository preparation and an operational development process. The checklist is open; inclusion of an item is not evidence of completion.

Launch item	Existing repository evidence	Proposed completion deliverable and evidence
Programme charter	Working outline	Scope, publication authority, membership, appointments, accountability, amendment route, and founding authority; explicit adoption record and published current text.
Directives Part 1	Procedural skeleton	Executable procedures for proposals, review, decisions, publication, maintenance, appeals, and withdrawal; worked rehearsal showing who acts and what records result.

Launch item	Existing repository evidence	Proposed completion deliverable and evidence
Directives Part 2	Drafting skeleton	Publication classes and maturity labels, requirement identifiers, normative/informative boundaries, references, profiles, conformance claims, and coordinated document/artifact versioning; example reviewed against the rules.
Technical committee charter	Draft GR/TC 1 charter	Bounded mandate, participation routes, appointment/removal, reporting, delegation, and liaison limits; actual role assignments before committee powers are exercised. Working groups activated only where capacity exists.
Work-item initiation	NWIP template	Add publication class, proposed conformance subjects, dependency links, source basis, stakeholder impact, capacity, maintenance ownership, and pilot evidence; trial proposal with recorded accept/revise/defer/reject rationale.
Public review and comment	Comment template; process not yet written	Draft distribution, notice and response periods, accessible submission routes, confidential submissions where justified, comment identifiers, disposition, reply, and re-review triggers; sample comment-to-change trail. Review periods remain a governance decision.
Consensus, decisions, and appeals	Topics listed in Directives Part 1	Define participation eligibility, quorum if voting is used, handling of sustained objections and abstentions, decision criteria, recusal, escalation, appeal grounds, independent consideration, and remedies; rehearse an unresolved objection and an appeal. Numerical rules remain OPEN.
Ethics and conflicts of interest	Topics in outlines; no operational policy	Declarations, updates, recusal, handling of domination or retaliation, complaints, and protected participation; conflict register with disclosure limits and an exercised recusal case.
Intellectual property and licensing	Topic listed in Directives Part 1	Contribution terms; separate choices for publications, code, schemas, examples, and third-party material; handling of known patent or other rights claims; recorded review of redistribution and implementation implications. Licensing choices remain OPEN.

Launch item	Existing repository evidence	Proposed completion deliverable and evidence
Maintenance and versioning	Lifecycle and maintenance topics in outlines	Edition/version authority, correction versus amendment versus revision, compatibility/deprecation notices, issue intake, review triggers, supersession, and withdrawal; simulated correction and incompatible revision with assigned maintenance responsibility.
Records and transparency	ADRs, changelog, and public-comment structure already available	Decision, issue, ballot where applicable, objection, disposition, and release registers; public/restricted handling, retention, correction, and deletion procedures; demonstration that a public reader can follow a decision without unnecessary personal disclosure.
External liaison and exceptional procedure	Topics listed in Directives Part 1	Limits on representation, authorization to make commitments, expedited decisions and subsequent review, continuity if a role becomes vacant; no external representation presumed by this plan.

These deliverables can be clauses or annexes within a small number of coherent governance documents. Separate policies are useful where distinct review or maintenance is needed; document proliferation is not a launch objective.

89.1.3 3. Founding sequence and accountable roles

Role: Avoid treating draft governance as already operative or using a technical project to manufacture its own approval authority.

89.1.4 3.1 Proposed founding sequence

1. **Declare the founding basis.** Record who is proposing the programme, in what capacity, and through which explicit founding decision governance can be adopted. Select a provisional stewardship arrangement or a constituted governing body after examining available participation. Neither arrangement is established by this plan.
2. **Prepare the coherent governance package.** Resolve dependencies across the charter, directives, committee mandate, review/decision/appeal procedures, contribution policies, maintenance, and transparency. Preliminary drafting, source studies, and synthetic rehearsals can proceed during this step without formal standards-project status.
3. **Review the package and rehearse its procedures.** Invite relevant perspectives, document participation gaps, and exercise a proposal, contested comment, conflict recusal, appeal, correction, and withdrawal. Record failures and revisions. Avoid presenting an internal rehearsal as independent public review.
4. **Record explicit founding adoption.** The identified founding participants record the authority, text versions, decision basis, dissent, and remaining limitations. A transitional arrangement includes its scope, limits, review trigger, and replacement route. The adoption record remains separate from an architecture ADR.
5. **Constitute and assign.** Appoint actual accountable holders; publish participation and contact routes; establish a functioning comment, complaint, and appeal route with appropriate confidentiality. Multiple responsibilities can be combined in a small team, with conflicts recorded and independent review arranged for contested decisions.
6. **Approve bounded work items through the operative procedure.** Only after governance coherence is evidenced, consider formal approval of GR-100/GR-110 and coordi-

nated dependent work. A family-wide NWIP can provide context, while each deliverable retains a bounded scope, owner, dependencies, and progression decision.

An unresolved founding-authority question, unusable appeal route, or unfilled approval responsibility keeps formal project/adoption decisions pending. This does not prevent preliminary research and openly labelled experiments. The founding decision is a future governance action, not an outcome claimed by this planning revision.

89.1.5 3.2 Proposed responsibility allocation

Responsibility	Accountable role to assign	Supporting or reviewing roles	Current assignment
Founding basis and governance adoption	Identified founding decision authority	Governance editor; participating stakeholders	UNASSIGNED
Governance coherence and procedural oversight	Authorized programme governance lead/body	Secretariat; procedural reviewer	UNASSIGNED
Work-item scope and standards-track progression	Authorized project approval authority	Project lead; affected-family editors	UNASSIGNED
Draft integrity and source traceability	Document editor	Foundation/source reviewer; technical reviewers	UNASSIGNED
Pilot purpose, execution, and evidence	Pilot lead	Participants; implementation and usability reviewers	UNASSIGNED
Participant/data stewardship and access decisions	Pilot data steward	Privacy/ethics reviewer; authorized institutional contact when applicable	UNASSIGNED
Bounded legal or jurisdiction-specific review	Qualified reviewer selected for the identified context	Data steward; institutional representative	UNASSIGNED
Comment disposition and consensus assessment	Authorized review chair or decision authority	Editors; commenters; procedural reviewer	UNASSIGNED
Appeals and conflicts that compromise a decision	Independent appeal reviewer/body established by governance	Secretariat with restricted access as appropriate	UNASSIGNED
Publication, compatibility, and maintenance	Release/maintenance owner	Editors; validation and preservation reviewers	UNASSIGNED

Independence is a property to document, not a title. Where the same person performs several roles, the decision record identifies the overlap. If impartial consideration cannot be arranged for a consequential contested decision, that decision remains pending under the proposed process.

89.1.6 4. Evidence gates

Role: Define proposed exit evidence for planning. These are not substitutes for the future adopted directives or automatic promotion rules.

Gate	Evidence considered for progression	Accountable decision role, once assigned	Consequence of an unresolved material gap
GOV — governance ready	Adopted coherent package; founding record; assigned authorities; usable review/appeal/contact routes; completed procedural rehearsals and dispositions	Founding decision authority, then constituted oversight role	Continue preliminary work; defer formal standards-project approval.
SCOPE — work item ready	Defined normative problem, users, conformance subject and exclusions, sources, dependencies, alternatives, affected stakeholders, pilot plan, and feasible ownership	Project approval authority	Revise or defer the proposal.
PILOT — experiment ready	Versioned candidate clauses and protocol/specification dependencies; scenario questions; minimal data plan; participants and access authorization when relevant; stop/recovery procedure	Pilot lead, with data-steward clearance for the proposed data	Use synthetic material or defer dependent data collection.
REVIEW — draft ready for public review	Integrated pilot evidence; source/requirement/test traceability; negative cases; known limitations; privacy, accessibility, and institutional impacts; disposition of material internal defects	Authorized review/progression authority	Narrow scope or revise; do not conceal failed cases.
ADOPT — publication ready	Public review and dispositions; justified treatment of sustained objections; completed technical and horizontal review; precise conformance claims; operative normative dependencies; formal approval under adopted procedure; maintenance ownership	Adoption authority defined by governance	Retain draft or Specification status, or defer adoption.
MAINTAIN — release remains supportable	Issue and incident handling; correction/revision history; compatibility evidence; maintenance capacity; reasons for confirmation, revision, supersession, or withdrawal	Maintenance owner and authorized decision authority	Publish limitations and use the adopted maintenance/withdrawal procedure.

There is no universal pass percentage or fixed pilot count in this plan. Reviewers examine whether the evidence supports the specific claim and whether failures change that claim. Future numerical thresholds need a stated purpose, baseline, and rationale. Passing a pilot is evidence for review, not procedural approval.

89.1.7 5. Pilot sequence and first integrated release

Role: Exercise the programme's epistemic and practical purpose before multiplying formats or institutional commitments.

The first integrated experimental release combines vocabulary and recording with epistemic representation, generativity-related trajectory, correction/contestation, presentation, and protection. It draws on the preliminary scopes of GR-100/110/140/150/160/200/210; GR-120 and technical Specifications supply infrastructure only where candidate requirements need it. GR-300/310/400 inform bounded institutional and procedural questions without asserting legal authority.

Pilot	Proposed material and question	Distinctive evidence and limits
P0 — programme decision history	The programme's own publicly shareable proposal, alternatives, objection, source interpretation, decision, and later revision. Can another reader reconstruct what was known and decided at each point?	Links between issues, drafts, reasons, and changed scope; conflicting accounts preserved with attribution; restrictions applied to contributor information. Useful as a self-pilot, but its authors' familiarity limits independent usability evidence. A rehearsal before GOV does not imply a formal standards decision.
P1 — contested institutional decision	Synthetic allocation or eligibility decision involving conflicting accounts, incomplete evidence, disputed identity, and a revised classification. Can a participant challenge the representation and understand the resulting revision?	Separates occurrence claims, evidence, institutional acceptance, normative evaluation, and claimed legal status; demonstrates reply, correction, review, and differentiated access. Synthetic ground truth is confined to the scenario and does not establish a general truth-detection method.
P2 — AI-assisted research trajectory	A bounded research task with human and AI contributions, source checking, rejected suggestions, a change of judgment, and an enabling encounter or constraint.	Records consequential contributions and decisions, uncertainty about system behavior, and branches relevant to the research. No demand for inaccessible internal model reasoning or exhaustive interaction capture. AI output and detailed provenance do not establish factual correctness.
P3 — incomplete archive	Licensed/public or synthetic fragments with conflicting dates, missing material, retrospective interpretation, and uncertain attribution.	An account that remains useful while explicitly distinguishing surviving evidence, inference, unknown chronology, restricted access, loss, and retrospective reconstruction. It does not fill gaps with invented events or probabilities.
P4 — consenting external institution	A bounded workflow selected later with a willing partner, participants, appropriate access authority, and contextual review.	Tests ordinary work burden, contestability, power asymmetries, access, correction, and maintenance outside the authors' own setting. No partner, consent, mandate, or deployment commitment is currently assumed.

P0 and synthetic P1 preparation can begin as exploratory work. P2 and P3 depend on suitable material and access; neither needs to wait for a broad platform implementation. P4 follows satisfactory protected trials and an explicit partner arrangement. Pilot ordering can change with capacity, while preserving governance prerequisites and the integrated coverage

below.

The first release package consists of candidate clauses, a declared minimal profile, versioned fixtures, a worked recording-to-presentation example, correction/contestation and access exercises, a pilot report, and a known-limitations register. A field recording claims, an output log, or a graph screenshot alone is not evidence for the integrated package.

89.1.8 6. Scenario and failure-case coverage

Role: Make proposed requirements reviewable through concrete cases without pre-deciding whether epistemic elements become ontology classes or profiles.

Case	Exercise	Evidence sought and failure to detect
Fact and claimed fact	In P1, two participants give incompatible accounts of whether a meeting occurred; an institution accepts one for a specified purpose.	Record and display the assertions, sources, methods, uncertainty, and scoped institutional judgment separately. Failure: an accepted or signed assertion is displayed as unqualified truth.
Disputed identity	Two archive fragments in P3 appear to concern the same person or event; another account disputes the linkage.	Coexisting attributed identity hypotheses, link rationale, and reversible correction of an erroneous merge. Failure: canonicalization erases the dispute or silently propagates the mistaken identity.
Uncertain or conflicting evidence	P1/P3 combines direct testimony, inference, an unavailable source, and incompatible confidence assessments.	Explicit evidentiary relationships and appropriately scoped uncertainty without a fabricated common probability scale. Failure: missing evidence becomes evidence of non-occurrence or low numerical confidence becomes an objective fact.
Generative change and unrealized alternatives	In P0/P2 an encounter introduces a previously unused distinction, opens a research option, and closes another under a constraint.	Account of the changed options, conditions, contributors, and limits of the retrospective interpretation. Failure: options are presented as equally feasible, exhaustive, or directly observed when they were reconstructed.
Category revision	P1 revises an eligibility category after a challenge; P3 reinterprets an earlier classification.	Identify the category version and affected judgments, distinguish earlier recognition from later interpretation, and expose migration effects. Failure: old decisions appear to have used the revised category.
Restricted, missing, or destroyed data	P3 contains a restricted source, a never-collected record, and a known destruction event.	Distinguish the states only to the extent their disclosure is safe and supported; preserve uncertainty when the state is unknown. Failure: restriction is presented as nonexistence, or a marker exposes sensitive membership or existence.

Case	Exercise	Evidence sought and failure to detect
Correction, deletion, and withdrawal	P1 includes a mistaken attribution and a request for correction or deletion under the chosen scenario procedure.	Route the request, record authority and disposition, correct derived views, and test allowed retention/deletion consequences. No default immutable copy of sensitive original content; minimal audit information or tombstones only where justified and safe. Failure: history preservation silently defeats an applicable deletion decision.
Presentation and public access	Render P1/P3 for an authorized reviewer and a public reader.	Disclose selection, redaction, reconstruction, uncertainty, and revision where appropriate; test whether a reader can distinguish an account from its evidentiary basis. Failure: search, export, graph labels, or cached views disclose restricted information or conceal consequential mediation.
Procedure interruption and retry	Interrupt a correction or access change, retry a message, and deliver an older update after a newer decision in a protocol experiment.	Defined authorization, ordering/conflict handling, acknowledgments, failure reporting, and recovery for the declared protocol. Failure: retries duplicate consequential actions or an old message restores withdrawn access.

These exercises document both successful behavior and cases the chosen profile cannot represent. Unresolved differences remain visible rather than being normalized into one authoritative history.

89.1.9 7. Pilot evaluation and conformance boundaries

Role: Identify what evidence means before collecting it.

Each pilot report records its question, publication/artifact versions, participants and reviewer relationships, evidence provenance, data permissions, actions taken, failures, recording burden, and resulting draft changes. A traceability table links proposed requirement or protocol step to scenario, evidence, reviewer finding, disposition, and affected version. Unassessed requirements remain explicitly unassessed.

Evaluation covers:

- **Representation:** Can a reviewer locate the actor, claim, evidence, method, perspective, uncertainty, temporal scope, alternative, and revision relevant to the scenario without conflating them?
- **Generativity:** Can the account explain the recorded changes in conditions, relations, distinctions, or possible continuations, while identifying the evidence and limits of that explanation?
- **Practical use:** Can participants submit, contest, correct, restrict, and revisit records through the declared procedure? What expertise, time, cognitive burden, and inaccessible steps were observed?
- **Presentation:** Can readers distinguish source material from reconstruction, earlier from later judgment, and absence from restricted knowledge? Reader misunderstandings count as findings even when serialization validates.
- **Protection:** Do the exercised access, export, correction, deletion, retention, and failure paths have the stated effects, including derived views and known copies under the pilot's control?
- **Maintenance:** Can a later editor explain and apply a version change without losing the declared meaning or recreating content that was intentionally removed?

Interchange claims need additional evidence when GR-130 or a related Specification is ready. The proposed test uses independently developed implementations of the declared sender/receiver roles, with independence documented. Two datasets processed by the same implementation are insufficient. Exchange exercises cover preserved meaning, permitted loss, identifiers, epistemic scope, restriction metadata, revisions, invalid input, and version mismatch. Round trips are useful only where the format claims reversible exchange; no requirement for byte identity is presumed. Independent software implementations are not a prerequisite for a vocabulary or organizational procedure that makes no software-interoperability claim.

Conformance targets remain distinct: a record, dataset/package, recorder, presentation tool, protocol participant, organizational procedure, and preservation service have different observable obligations. A claim identifies its target, edition/profile, applicable requirements, exclusions, evidence, and assessment method. Automated schema checks establish only the constraints they actually check; human procedural or semantic review is reported separately.

A bounded conformance result does not establish the truth of an assertion, completeness of history, moral legitimacy, trustworthiness of an institution, beneficial generativity, or legal validity. Nor does an internal pilot establish certification or independent assurance. Evidence for those claims would require separately justified methods and authority.

89.1.10 8. Participant protection and contextual review

Role: Plan bounded review before real data use; this section does not give legal advice or interpret a jurisdiction's law.

Pilot preparation identifies the institutional context, intended purpose, affected participants and third parties, required data, access authority, permissions or consent where applicable, custody, retention, and available routes to challenge a record. Consent is not assumed to resolve every institutional or third-party issue. Synthetic and minimized materials provide an initial route when authority or protection is unresolved.

Before P4 or other sensitive real-data use, the proposed contextual review covers applicable correction/deletion/access duties, confidentiality, contribution and reuse permissions, records-management duties, participant vulnerability, and any cross-institution or cross-border handling actually planned. A qualified reviewer evaluates the identified jurisdiction and activity. Findings identify their scope, assumptions, unresolved conflicts, and limits; they are not generalized to other institutions.

The pilot plan also identifies who can pause collection or publication, restrict affected material, notify responsible participants, investigate a problem, and authorize resumption. Public pilot reports use appropriate minimization. Technical auditability does not require a public or permanent sensitive event history; even hashes, identifiers, and deletion markers receive review for disclosure risk.

89.1.11 9. Decisions to resolve before execution

Role: Provide inputs to the programme's open-questions register and subsequent governance decisions.

- Who participates in the founding decision, and what authority and limits are declared?
- Which responsibilities can be staffed now, and how are independent appeals and material conflicts handled with that capacity?
- What review periods, participation expectations, consensus criteria, and exceptional procedures are proportionate and credible?
- Which publication, software, schema, and contribution licensing terms support the programme's intended openness?
- What is the bounded first integrated profile, and which candidate assertions or generativity-related descriptions remain experimental?
- Which pilot materials are available with appropriate permissions, and which can safely be public?
- What evidence is sufficient for each proposed conformance claim, and what recording burden is acceptable to the affected participants?
- Which correction, deletion, retention, and access tensions require contextual legal review or a separate policy proposal rather than a universal technical rule?

The next concrete governance deliverable is a reviewable launch package with tracked alternatives and unresolved choices. The next concrete experimental deliverable is the P0/P1 integrated scenario package. Neither is represented here as completed, adopted, or externally endorsed.

90 graph semantics review

Original source: `docs/planning/graph_semantics_review.md`.
Original source SHA-256: `a7bd6f555a3b03d58c2f3a124801cdc13f2338ceb7e2b1f4e02a665f6dc5cd1e`.

90.1 Record graph semantics: source review and design proposal

Document class: Informative design review
Status: PROVISIONAL proposal; implementation decisions require a separate ADR
Date: 2026-09-22
Purpose: Identify a bounded graph model for the general application and a future shared implementation substrate for the academia application.

This review is grounded in the Programme Brief, the current experimental application design, the 0.3 Working Drafts, and passages read directly from FM-007. It is not a Specification, an adopted Standard, or a conformance assessment. The recommendations below are proposed operational choices. They do not redefine GR theory.

90.1.1 1. The central distinction

A project has at least three distinguishable structures:

1. **The semantic record graph:** records and the connections represented or asserted through them, at one declared project revision.
2. **The recording history:** Git commits that retain successive project snapshots and accountable changes.
3. **The displayed graph:** a selected rendering of a snapshot, with layout, filtering, and optional simplification.

A semantic cycle is compatible with a linear recording history. Two records can describe an earlier and a later occurrence in the opposite order from their creation. A new commit can change several graph nodes, a relation, and its associated files atomically. Graph layout or closeness does not assert identity, causal influence, temporal priority, or evidential support.

The Git commit identifies the project snapshot being examined. It is not the identifier of the real situation, the time that situation occurred, or proof of its represented content. The application currently publishes a single main reference. That operational choice need not prohibit recording alternative accounts or semantic branches within a snapshot.

90.1.2 2. Source findings

Page numbers below are PDF page numbers in FM-007.

Source passage read	Finding relevant to this design	Proposed consequence
Research Paper Note, p. 2; section 10.5, p. 46	The six categories form an overlapping analytical repertoire; exclusivity, exhaustiveness, and metaphysical priority are not established.	Record roles can overlap. An application can choose a primary display role without claiming that other roles are impossible.
Sections 7.1–7.3, pp. 26–28	A focal subject can be tracked under different declared criteria. A convenient database key settles only the identity question built into that database.	Separate record identity from target identification; preserve disputed identity and competing accounts.
Sections 8.1–8.2, pp. 32–33	Incidence describes participants or conditions with role positions. Binary incidence is a special case; formation and potential effect need further structures.	Represent a relation through a role-indexed participant list, not only source and destination columns.

Source passage read	Finding relevant to this design	Proposed consequence
Sections 8.3 and 8.8, pp. 33–34 and 36	Equal participants or types do not establish the same historical relation. Arity and terms can change under a continuity criterion.	Give each relation record its own identity and revision history. Do not deduplicate relations by endpoint pair and label.
Sections 8.5–8.9, pp. 34–36	Present incidence, formation history, possible efficacy, and causal interpretation answer different questions.	A saved connection is an attributed account. Add context and grounds rather than infer efficacy from the graph.
Section 8.11, p. 37	Relation accounts coordinate entities, formation events, attributes, states, and process histories.	Permit records about relations and relations whose participants are other relations.
Sections 9.9–9.10, p. 43	One happening can receive several descriptions; event/process segmentation depends on purpose and evidence.	Avoid automatic creation of six supposedly separate real things from one account.
Sections 10.1–10.5, pp. 43–46	Attribute domains, context, scale, definedness, and overlap carry meaning; unknown is not automatically false.	Distinguish interface/module properties from substantive Property assertions; preserve missingness and scope.
Section 16.4, p. 76	A registry entry, its asserted content, and warrant remain distinguishable.	Authenticated edits and valid Git content do not establish factual truth or institutional authority.

FM-007 uses **Attribute** where this programme provisionally retains **Property**. This review does not equate them. Nor does it identify the record graph with the deeper metamodel of constraint, change, structure, and difference.

90.1.3 3. Proposed minimum model

90.1.4 3.1 Records and subjects

A record is an identified retained representation. It contains a description of its target, applied recording roles, attributed content, qualifications, and technical recording metadata. Its stable identifier survives ordinary revisions. Different records can concern the same or a possibly identical target without being merged automatically.

The model can retain a primary role for color, icon, and default module selection while also recording additional applicable roles. Relation behavior depends on the presence of the Relation role, not on its being the sole role. The user can describe an agreement as both Relation and Entity. Its negotiation, signing, and time-specific terms can be separately linked descriptions where that distinction is useful.

A target designation can remain an unresolved description. The design does not need a universal target registry in the first graph release. It does need to state whether a participant reference concerns the **referenced record** or **the target described by that record**. Otherwise a link about a document's quotation can be confused with a claim about the document's subject. A profile can provide a clearly labeled default, but the distinction needs inspectable representation.

90.1.5 3.2 Relation records and incidence

A relation record uses the ordinary record envelope plus a relation component containing:

- a relation type or predicate, its local definition or vocabulary locator, and a human-readable title;
- participants, each with a stable participant-entry identifier, participant role, record reference or explicit unresolved designation, and reference interpretation;
- the stated context and represented temporal scope;
- the criterion for treating this as the identified arrangement, including whether continuity remains unresolved;

- the ordinary record's attribution, epistemic basis, modality, assessment/dispute status, grounds, and uncertainty.

Participant-entry identifiers distinguish two roles occupied by the same referenced record. For example, one organization could be both issuer and recipient under a stated arrangement. A duplicate exact participant entry is a validation error; repeated record references with different roles need not be. Self-reference or relations on relations are not universally invalid. Their admissibility depends on the declared relation meaning rather than a graph-wide acyclicity rule.

Direction is defined by participant roles or a declared relation type. An arrow is a rendering of that direction. It is not a universal meaning of Relation. The initial model can support directed binary relations, symmetric binary relations, and n-ary arrangements through the same participant structure. At least one participant incidence is a reasonable experimental profile boundary; there is no source basis for requiring two distinct target records in every admissible relation. A two-entry relation can refer to one record in distinct roles. Excluding an empty participant list is an implementation boundary rather than a universal theory of mathematical relations.

For an unknown party, an explicit unresolved participant preserves the limitation more accurately than a fabricated Entity. A narrower first implementation can accept a known subset of resolvable local participant references while recording that incidence is incomplete and explaining the limitation. It must not present that subset as a complete account. If the first implementation restricts the available forms, the restriction needs to be documented as a profile limit rather than generalized into GR. An unresolved identity criterion can be recorded for exploratory work, but it cannot receive a fulfilled result for a criterion-dependent obligation under V100-025.

An initial same-project reference boundary is appropriate for the application's private projects. Cross-project participant references require a later access and resolution design. An unresolved outside participant description is different from a resolvable cross-project record link.

90.1.6 3.3 Navigation links and other meanings

The existing `related_records` list is an untyped navigation aid. Migration can preserve it unchanged and render it with a visibly neutral style. It supplies no basis for creating a claim of collaboration, identity, causation, or evidential support. A user can explicitly create a Relation record with its own meaning and grounds.

An evidence file is not automatically accepted support. A structured evidence-role assignment needs a specified claim, material/version, attributing assessor, role, rationale, time, and limitations. If the current application has only account-level evidence text, the interface can expose that limit and preserve file references without inventing independent claim-level assessments.

Similarly, revision ancestry is technical history. A semantic relation such as "derived from," "revises an interpretation of," or "possibly the same target" requires separately stated meaning. Two records created in consecutive commits are not thereby connected semantically.

90.1.7 4. Projection and interaction

The most faithful general graph is an **incidence view**: every retained record is selectable; a Relation record has its own node; labeled spokes connect it to participant records. This naturally supports n-ary relations, relation properties, and relations on relations.

A simplified binary view can collapse an eligible two-participant Relation node into one labeled connection. That connection retains the relation record identifier and opens the same inspector. Collapsing is inappropriate where it would hide a relation that is itself a participant of another relation, hide additional participants, or merge separately identified parallel relations. The interface can allow the user to expand a simplified connection.

Creating a connection visually opens a small relation editor prefilled with the chosen participants. Saving creates a first-class Relation record. A form/list alternative supports keyboard, touch, and precise selection. Dragging nodes changes layout; drawing a connection changes represented content only after the user supplies its meaning and confirms the save.

Every graph request and inspector response needs one source snapshot. Opening a historical graph resolves participant names, roles, relation content, module data, and files from that same snapshot. The interface identifies filters and hidden records, so absence from the screen does not imply absence from the project or non-occurrence in the world. Selecting a historical version makes editing unavailable until the user returns to the current project or explicitly starts a supported revision operation.

Saved coordinates, viewport, collapsed state, and display preferences are presentation data. They are not target-time, epistemic status, or ontological properties. Shared versioned layouts can be stored separately from record content; transient panning need not generate a substantive history entry.

90.1.8 5. Modules and file custody

Modules are versioned record components: for example attachments, notes, a temporal account, relation participants, or a domain-specific academic annotation. A module descriptor identifies its type and version. An application registry determines rendering and validation. The common protocol can preserve extension data without claiming to understand its domain meaning. Unknown module types remain visible as unsupported data and are not discarded during an unrelated edit.

Choosing a recording role can suggest modules. It does not make those modules metaphysical constituents of the target. Attaching a PDF to a Relation record is storage associated with that representation; it does not turn the PDF into a participant or prove the relation. A richer material record can later describe source, acquisition, custody, transformations, and evidence use.

For the initial bounded local implementation, keeping immutable file bytes within the project Git object store offers a straightforward historical model. A file descriptor can retain a content digest, byte count, original display name, declared media type, creation/acquisition context where supplied, and the responsible uploader. Browser downloads use authenticated application routes; untrusted filenames are never repository paths or executable page content.

The descriptor and bytes need atomic publication with the associated record change. A historical download resolves the attachment as it existed in the requested reachable project commit. Removing a current attachment link does not claim erasure from retained commits or exported bundles. A filename match does not establish that two files are identical; identical bytes do not establish independent sources or identical acquisition histories.

Large-file storage, selective erasure, retention schedules, malware scanning, protected source identities, and external repository references require additional design. The first version can declare conservative file limits and safe download behavior without claiming those deferred features.

90.1.9 6. Commit protocol implications

The existing compare-and-swap publication of a new Git head is a useful primitive. The graph release needs an atomic **project transaction** above it:

1. Identify the expected project revision and submitted operation/revision reason.
2. Build the proposed next records, module descriptors, and file entries without publishing them.
3. Validate references and constraints against the complete proposed snapshot, including records created in that same transaction.
4. Retain transaction metadata identifying the protocol version, accountable actor, changed objects, reason, and applicable change categories.
5. Create one complete commit and publish it only if the expected parent still matches.

The transaction permits creating a new node and its connecting Relation together. Mutual references are validated against the final snapshot rather than an arbitrary write order. A rejected transaction exposes neither a partial node nor a partial relation. Preparing unreachable Git objects is different from accepting a project revision.

The transaction's recording timestamp and reason are distinct from target, observation, and assessment times. Change categories can distinguish a changed situation, new evidence

or interpretation, descriptive-regime change, and technical/presentation maintenance. More than one can apply. A stale expected revision is reported as a conflict; a new graph preview is obtained before a reconsidered save. Automatically merging relation endpoints can change substantive meaning and needs a later explicit conflict policy.

Existing records and commits retain their original schema and meaning. Reading old snapshots can provide a documented view adaptation; migration of current content is a new traceable commit. No migration converts neutral navigation links into asserted social or causal relations, supplies invented role criteria, or rewrites historical records in place.

90.1.10 7. Discriminating acceptance cases

These are proposed software tests and review cases, not evidence of whole-draft conformance.

Case	Expected behavior	Error exposed
Two agreements between the same two parties	Two independently selectable Relation records and histories survive export/reload.	Deduplication by endpoint/type silently erases historical tokens.
One agreement with three parties and distinct roles	One relation retains all participants; the inspector and graph reveal all roles.	Binary-edge conversion invents three independent agreements.
A relation constrains another relation	The second relation is an allowed participant; graph and export preserve it.	Relations are decorative edges with no independent reference.
An agreement described as both Entity and Relation	Both applied roles persist; relation features remain available.	Exclusive type selection makes role overlap an inconsistency.
A record cites a document about an organization	The relation identifies whether its participant is the document record or the described organization.	Record and referent are silently conflated.
A self-referential arrangement uses different roles	Participant entries remain distinct and named; a blanket cycle ban does not reject them.	Graph topology is mistaken for semantic admissibility.
An unknown participant in an asserted arrangement	An explicit unresolved designation appears without a fabricated identified person.	Structural completion is mistaken for factual knowledge.
A realized event is retrospectively inferred and disputed	Modality, epistemic basis, and dispute remain separately visible.	A single status field conflates three questions.
Two semantic records link both ways	Graph round-trips without a DAG constraint.	Git ancestry constraints leak into represented relations.
A new node and Relation are created together, then a concurrent writer wins	The losing save publishes neither partial object; the accepted snapshot remains valid.	Multi-object writes leave a dangling relation or overwrite a newer revision.
A participant is renamed after an older graph snapshot	The older graph retains the earlier label and relation version.	Historical content is rendered using present-day data.
A file is replaced, then removed from the current module	Earlier authorized snapshots download the earlier bytes; current removal is described as unlinking.	Historical attachments drift, or unlinking is misrepresented as erasure.
A current record with an unfamiliar module is edited in a familiar field	Unsupported module data survives unchanged and is identified to the user.	One application silently destroys another application's domain data.
Legacy `related_records` contains two records	Migration preserves a neutral cross-reference until a user supplies a typed relation.	Migration manufactures substantive claims.
The graph hides withdrawn records or an entire role	The filter and hidden-count boundary remain visible.	A reduced display appears to be the complete retained history.
A label says "supports" with an uploaded PDF but no assessment	The application does not declare evidential sufficiency, truth, or an examined claim.	Connection creation becomes an unearned assessment.

90.1.11 8. Traceability to Working Drafts

These are design relationships, not fulfilled-requirement claims. The implementation still needs a declared profile, field validation, examples, and explicit remaining gaps.

Draft locations	Design relationship
GR-100, V100-002/005; section 3 definitions of Record, Target, Record reference	Record identifiers, described targets, and reference interpretations remain distinct.
GR-100, V100-006/007; GR-110, R110-008/020/021; GR-200, E200-008/017/038	Recording history, represented time, revision grounds, and alternative accounts remain distinguishable.
GR-100, V100-009/010/025 and section 5 Relation	Role overlap, independently referenceable relations, contextual participants, temporal meaning, and declared criteria.
GR-110, R110-006/007/009/048/049	Stable record/version references; identity and continuity claims do not follow from keys, equal labels, or link patterns.
GR-110, R110-011/012/051/058; GR-200, E200-005/014	A diagram edge does not establish generative attribution; each asserted connection retains relevant grounds and qualifications.
GR-200, E200-003/010/011/012/016/019	Material, claim-relative evidence, dependence, assessment, and revision follow-up need more than a generic link or attachment.
GR-100, V100-011/012	Graph structure is an operational representation, separate from the metamodel and from legal, normative, or institutional authority.
GR-110, R110-025/026/029/030/093	Protection of content and metadata, explicit missingness, selected view boundaries, source revision, and refresh status.

90.1.12 9. Gaps in the proposed family

The existing GR-100/110/200 clauses already establish the relevant distinctions. Graph implementation does not by itself require changing their 0.3 normative text. More concrete work belongs in the following currently preliminary project outlines and the implementation Specifications they motivate.

Project	Current source state	Concrete requirements-development need exposed by this application	Technical detail for a supporting Specification
GR-120	Short implementation-neutral project outline	Define record, target, claim, version and participant-reference relationships; preservation of overlapping roles; first-class relations and partial incidence; identity, time, missingness and extension boundaries.	Exact JSON envelope; role and participant arrays; reference interpretation; namespaced module descriptors; validators and schema-version transitions.

Project	Current source state	Concrete requirements-development need exposed by this application	Technical detail for a supporting Specification
GR-130	Short interchange outline listing candidate representations	Declare exchange unit and source revision; preserve reference scope and extension data; expose unresolved dependencies; specify import failure, partial receipt and unsupported-version behavior; maintain original meaning through migration.	Concrete wire format; protocol manifest; transaction operation schema; canonical encoding; Git tree paths, commit metadata, conditional publication, and binary representation.
GR-140	Short outline listing possible views	Identify a presentation's source version, transformation, selection and refresh status; retain relation identity in simplified graphs; reveal n-ary/parallel/recursive structures without invented implications; keep mode, modality and dispute readable; provide an alternative to spatial gestures.	Incidence/collapsed-view algorithms, projection identifiers, user-interface contracts, saved layout format, and snapshot navigation endpoints.
GR-160	Short outline of preservation and access subjects	Define retention and availability states for records, files, metadata, derived views and audit trails; distinguish unlinking, withdrawal, restriction and erasure; authorize historical access; define reconstruction and custody limits.	File descriptors and digest rules; authenticated historical download resolution; size/type handling; retention/export manifests and future external-object protocols.

The standards-track drafts can state implementation-neutral expectations and assessment evidence while an experimental shared Specification implements the bounded profile. Neither needs to assert a comprehensive conformance result before pilot evidence exists. A minimal graph pilot does not solve the full GR-160 legal or institutional programme; unimplemented domains remain declared limitations.

90.1.13 10. Decisions still needed

- **PROVISIONAL:** Exact protocol identifier, field names, module registry, and transition from the existing `gsp-workspace/0.1` representation.
- **PROVISIONAL:** Whether the first interface exposes all relation forms immediately or declares a narrower initial profile with preserved extensibility.
- **OPEN:** Structured claim and material identifiers sufficient for claim-relative evidence and independent assessments.
- **OPEN:** Relation identity/admissibility criteria and typed vocabularies suitable for particular domains without imposing their meaning on every project.
- **OPEN:** Protected or cross-project references, shared access, governed retention, and genuinely independent implementation tests.
- **DEFERRED:** Semantically justified branch/merge workflows; Git's ability to represent a commit DAG alone does not settle those workflows.

The general and academia applications can share the record/transaction/file protocol and test fixtures while retaining different module registries, user journeys, and entry points.

That shared substrate is a proposed engineering boundary; it is not a claim that the existing academia model already implements these semantics.

91 graph workspace design

Original source: `docs/planning/graph_workspace_design.md`.
Original source SHA-256: `039f70856862fe48e9ffd44a523a2fd011421ac24ae424ab87941d25fb215545`.

91.1 Graph workspace and shared recording protocol

Class: Informative implementation design and delivery plan
Status: PROVISIONAL design selected for experimental implementation; 2026-09-22
Application: Generalized workspace first; academia adaptation is a subsequent project
Protocol identifier: `gsp-record-protocol/0.2`
Profile: `gsp.general/0.2`

91.1.1 1. Purpose, source precedence, and scope

The user requested a carefully designed graph workspace, visual creation of records and connections, modular record panels and file storage, with a protocol that can support a later independent academia application. The user explicitly prefers the current GR manuscripts where the older academia project conflicts, and authorizes revisions to our specifications and drafts when a concrete deficiency is identified.

The source review grounds graph semantics in actual foundation passages and current GR-100/110/200 requirements. The academia comparison identifies useful interaction patterns and differences between its design and implementation. The current programme remains the conceptual source; academia is a reference implementation of an older, narrower scholarly model. Its eight epistemic acts, append-only signed transition format, disclosure restrictions and prohibitions on some node kinds do not become universal GR rules.

The present implementation covers a general record graph, a reusable protocol package, atomic Git transactions, record modules, bounded retained attachments, consistent historical views and a migration path from the first workspace. It does not modify the academia repository, rewrite its signed records, or claim cross-application conformance. A later adapter needs independently exercised mapping and preservation fixtures.

91.1.2 2. Three distinct structures

Structure	Meaning	Constraints and authority
Record graph	Attributed representations and relationships, including relations whose participants are other relations	Cycles, parallel relations, repeated participants and several roles are possible; no Git DAG constraint is imposed
Revision history	Accepted changes to a project's stored representations and material	The initial Git binding publishes one parented project commit per accepted transaction on `main`; parentage is recording provenance, not causality or occurrence chronology
Display projection	A selected rendering of a particular project revision	Layout, zoom and selection do not change the records; filters and unsupported material remain visible limitations

A record identifier identifies a representation retained by this system. It does not establish the identity of the represented target. An attachment digest identifies bytes, not their independence, truth or evidential sufficiency. A transaction is a storage operation, not automatically a recorded Event or a substantive GRRP transition.

91.1.3 3. Record envelope and overlapping roles

The general profile retains the current descriptive fields so existing accounts remain legible: title, content, primary knowledge basis, modality, owner-assigned status, attributed source,

method, evidence text, uncertainty, alternatives, conditions, consequences and described time. Server-assigned IDs, creator/updater and recording timestamps retain their distinct meanings.

`record_type` remains the primary presentation role. `record_roles` contains one or more of Entity, State, Event, Process, Relation and Property and includes that primary role. Selecting multiple roles does not create additional targets or occurrences. The model does not introduce an ontology class for every user-interface module.

`related_records` remains a set of neutral navigation references. Its preservation is especially important during migration: an earlier untyped link cannot become a causal, evidential or social relation merely because the new interface draws edges.

Records declare `schema_version: gsp-workspace/0.2` and carry a namespaced `modules` mapping. Core descriptions and modules belong to one record revision; a module is not an independently trusted authority. The existing single primary epistemic mode remains limited, with mixed grounds stated in method and qualification text. A richer epistemic representation remains a separate work item.

91.1.4 4. Relations as records

A structured Relation is an ordinary record whose roles include Relation and whose `gsp.relation` module has version `1`. It can carry the same notes, files, attribution and history as other records. The module has:

- `predicate`: an attributed local relationship label; optional `predicate_definition` states its intended meaning;
- `participants`: one to 32 incidence entries, each with its own UUID `id`, `record_id`, descriptive `role`, `reference_scope` and `orientation`;
- `participants_complete`: an assertion about the listed scope, with `participant_limitations` required when false;
- `context`, `identity_criterion` and `temporal_scope`: descriptive text; empty text means not recorded, not false, timeless or resolved.

`reference_scope` is `represented_target` or `record`: relating two organizations differs from relating two records about them. `orientation` is `in`, `out` or `undirected` and controls the declared incidence orientation; it does not by itself mean cause, influence, superiority or evidential strength. Role and predicate interpretation remain inspectable.

Repeated references to one record are allowed as different incidences; incidence UUIDs distinguish them. Unary, self-referential, cyclic, parallel and higher-order relations are permitted. Zero listed incidences are excluded as an explicit first-profile limit. Unknown participants are expressed through incomplete-incidence qualifications; the software does not create fictional participant records to complete a diagram. The first binding permits participant references within one project only. Cross-project protected references need a further design.

No uniqueness constraint on predicate plus endpoints is imposed: two agreements between the same parties can be different historical relations. An existing unstructured Relation record remains valid as an unstructured account and is identified accordingly.

91.1.5 5. Modules and authority boundaries

The first registry implements three persisted record modules:

Module	Meaning	Editing behavior
`gsp.relation`, version `1`	Structured relation account	Available when Relation is among the record roles; complete module replacement validates participant references against the resulting snapshot
`gsp.notes`, version `1`	Retained supplementary notes, `data.text`	Explicit save with a revision reason; not a private scratchpad or independent assessment

Module	Meaning	Editing behavior
`gsp.files`, version `1`	Retained material descriptors, `data.items`	Changes only through file operations so descriptors and bytes cannot diverge

Module envelopes contain `version`, `required` and object `data`. An unfamiliar optional module remains intact during unrelated edits and is displayed as unsupported, read-only data. An unfamiliar required module prevents project mutation because its necessary constraints cannot be evaluated. Known modules at unsupported versions are also not silently normalized. No stored module installs code, runs scripts or selects arbitrary server paths.

An enabled empty files/notes module is distinguishable from an absent module. Module removal is an explicit transaction; removal of a files module with linked material is refused until the links are explicitly detached. Relation-module removal does not erase prior descriptions or the relation record's identity.

Graph layout is local view state, keyed by application, account and project. No credentials or record text are stored there. Record attachments differ from academia's mutable scratch workspace: saving an attachment deliberately retains its bytes in project history. Scratch folders, scheduling and domain-specific module registries can be added later with their own persistence and disclosure boundaries.

91.1.6 6. Shared package and application separation

An independent Python package under `applicative_infrastructure/common/packages/gsp_record_protocol/` provides constants, validation, schema resources, graph projection, transaction preparation and a command-line snapshot validator. It does not import Flask, SQLite or Git. JSON schemas and deterministic fixtures make the contract inspectable without a particular web client. ADR-0009 relocates the original root package and extracts the Git store into the adjacent `gsp_git_store` package without changing their record semantics.

The generalized application supplies authentication, authorization, server attribution, the Git adapter and its own interface. The academia application can later consume the same storage and exchange concepts through a profile adapter while preserving its original native envelope and signatures. UUIDs in the general workspace are not silently substituted for GRRP content identifiers. Shared infrastructure does not imply equal semantic types, equal mutation policy, or shared accounts.

Separate applications retain separate entry points, data roots and session namespaces. Different ports alone do not isolate browser cookies, so an eventual combined launcher needs explicit cookie naming and origin rules as well as port selection.

91.1.7 7. Transaction envelope

The experimental binding uses `POST /api/projects/{id}/transactions`. The logical request contains:

```
{
  "protocol_version": "gsp-record-protocol/0.2",
  "transaction_id": "client-generated UUID",
  "expected_head": "full project commit identifier",
  "reason": "Why these representations or materials are being changed",
  "change_categories": ["description"],
  "operations": []
}
```

Categories are `description`, `represented_change`, `evidence_or_interpretation`, `classification`, `maintenance` and `migration`. They describe the recorder's account of the change, not a verified event classification. Multiple categories can apply. `migration` is reserved to the migration operation.

Supported operations:

Operation	Input and effect
`record.create`	A caller-chosen record UUID and editable record fields; server adds recording attribution and time

Operation	Input and effect
`record.update`	`record_id` and partial `changes`; omitted fields/modules survive unchanged
`module.set`	`record_id`, `module_id`, complete module envelope; files content cannot be forged through this route
`module.remove`	`record_id`, `module_id`; explicit guarded removal
`file.attach`	New `file_id`, owning `record_id`, named binary `part`, filename, declared media type, SHA-256 and byte length
`file.replace`	Existing file descriptor ID with new material and metadata, preserving the descriptor's identity and previous historical versions
`file.detach`	Remove the current descriptor link; no claim of physical erasure
`project.migrate`	Sole operation of a legacy-project migration; explicit mapping and limitations recorded

One request can create several records and a relation among them. Validation examines the final candidate snapshot, so operation order does not manufacture missing participants. Repeated core mutations of one record or repeated mutations of one module/file descriptor are rejected rather than interpreted as last-write-wins. Creating a record and subsequently adding a distinct module or attachment is permitted.

Ordinary commands use JSON. File commands use multipart with one textual `transaction` JSON part and declared binary part names. Duplicate JSON members, duplicate multipart names, extra or missing binary parts, nonfinite numbers, malformed Unicode, unrecognized operation fields and invalid declared hashes are refused.

91.1.8 8. Idempotency and publication

The server authorizes the project before inspecting any receipt. It computes a request digest using RFC 8785 canonical JSON over the logical envelope and verified file identities, excluding multipart boundaries and server-generated attribution/time. A vetted canonicalization library implements the encoding; ordinary Python JSON sorting is not presented as JCS.

The receipt lives in the same tree as accepted changes at `.gsp/transactions/{transaction_id}.json`. It records protocol version, transaction ID, original expected head, authenticated actor, server recording time, reason, change categories, request digest, changed-resource summaries and validation limits. The resulting commit identifier is not embedded in its own tree; the adapter obtains it from the receipt path's introducing commit.

The adapter checks a committed receipt before rejecting an old expected head. Identical actor/request replay returns the original result and `replayed: true`, even after other changes advance the project. Reusing an ID for a different logical request is a conflict. An identical concurrent request rechecks the receipt after a failed publication attempt. A revised request after reconciliation receives a new transaction ID.

After validation, the adapter writes blobs and complete changed subtrees, creates one parented commit, and conditionally updates `refs/heads/main`. The single reference is the publication boundary. Failure before publication leaves no partial accepted graph. Unreachable prepared objects may remain and are not accepted revisions. An uncertain response near publication is recovered through the transaction receipt, not by claiming that no commit occurred.

91.1.9 9. File custody and budgets

Files are stored as Git blobs at `assets/{sha256}`. Filenames are descriptive metadata and never filesystem paths. A descriptor retains `file_id`, filename, media type, SHA-256, byte length, upload actor and upload time. New bytes and the owning record's descriptor publish together. Replacements and detached links remain reconstructable through older commits.

The initial binding limits a file to 10 MiB, combined binary parts to 20 MiB per transaction, binary parts to eight, operations to 100, participant incidences to 32, active records to 1,000, module payloads to bounded JSON and retained asset bytes reachable from the current project tree to 128 MiB. Asset entries are retained in the project tree for this first custody policy;

physical unreachable objects and Git metadata are not covered by that logical byte budget. Operational filesystem quotas and governed garbage collection remain hosting work.

Uploads are spooled and hashed with bounded reads. Downloads and bundles use bounded streaming or temporary files. Arbitrary content is offered as an attachment with `nosniff`, not rendered as active HTML. A digest is not an authorization token: the requested record, descriptor and chosen project revision determine access.

Preservation of a file does not make it assessed evidence. Identical bytes may have different acquisition histories; distinct descriptor IDs preserve those accounts while storage can reuse a blob. No antivirus, media interpretation, legal hold, selective erasure or remote object-store guarantee is implied.

91.1.10 10. Snapshot-consistent reads and exports

`GET /api/projects/{id}?revision={commit}` resolves one authorized reachable project revision and reads all records from that tree. A graph response and its inspector use the same revision. Participant labels, related-record labels, relation structure, notes and downloads do not silently resolve through today's head when viewing history. Historical screens are read-only; returning to the current project is explicit.

The graph projection exposes every retained record as a selectable node. Structured relations appear as relation nodes with incidence spokes; neutral references have a distinct dashed style. Predicate/role labels and reference scope remain inspectable. A selected relation has the same module panel as another record. A future collapsed binary view is optional and cannot discard relation identity, parallel edges or higher arity.

Filtering discloses that it is a selected view and reports hidden nodes/incidences. Layout and distance are not scores, time or causality. A list/form alternative provides creation, selection and connection without requiring precise spatial gestures. The server supplies warnings for unsupported/unstructured modules rather than silently presenting a complete semantic graph.

Current snapshot JSON identifies its source revision and excludes file bytes. A current snapshot ZIP includes only selected current records and their referenced material plus an export manifest. It omits the accumulating receipt ledger and detached assets; otherwise a supposedly current-only export would leak historical reasons and content. A full Git bundle deliberately carries all reachable history, receipts and retained assets. Neither export contains account credentials or restores ownership by itself.

Batch Git object reads replace one-process-per-record loading. Any derived cache is keyed by exact commit and is disposable; it cannot become a competing source of record truth.

91.1.11 11. Explicit legacy migration

Reads never migrate a project. Old commits are interpreted through a declared read adaptation: the primary role becomes the sole displayed role, missing modules are absent, and old navigation references remain neutral. IDs, original bytes and historical Git commits are retained.

An owner can preview and request migration of the current project through a dedicated transaction. The new commit upgrades project/record schema declarations, adds role arrays and module containers, and records the source revision and mapping limitations. It does not infer relation predicates, participant roles, new epistemic grounds or nonexistent attachment bytes. Existing unstructured Relation accounts remain unstructured.

New projects start with the new protocol. Compatibility record endpoints can translate their existing bounded commands into transactions while preserving extension modules; they do not bypass validation or promise the full retry contract of a caller-supplied transaction ID.

91.1.12 12. Academia migration boundary

The later academia upgrade begins with fixtures preserving original GRRP bytes, identifiers, signed-covered fields, registrations, disclosure sidecars and referenced material. The current manuscripts govern new conceptual choices, but old records are not rewritten to pretend they always used the new model. A correspondence explicitly distinguishes exact preservation, partial mapping and unresolved differences.

The reference review identifies concrete repair work: bind web sessions to acting identities; preserve absent references; validate imports for path, collision, size and partial failure; clarify mutable workspace versus retained material; separate administrative operations from substantive graph projections. These are queued migration concerns, not changes made to the academia application by this delivery.

91.1.13 13. Sequence and acceptance evidence

1. Complete source/design comparison and record architectural decisions.
2. Write experimental GR-SPEC-120/130 details and executable schema/fixture contracts. Develop bounded implementation-neutral requirements in the currently preliminary GR-120/130/140/160 projects where needed; leave adequate 0.3 clauses intact.
3. Implement and test the independent validator/projector, then atomic Git binding and HTTP adaptation.
4. Implement graph creation/connection, conditional modules, historical navigation and migration UI.
5. Exercise failure cases and browser journeys, inspect desktop/mobile views, document limits and restart the local application only after tests pass.

Required evidence includes: atomic node-plus-relation-plus-file creation; rollback on a bad final operation; same-batch cyclic/higher-order participants; parallel and unary relations; role overlap; invalid/cross-project references; identical/different replay across restart and advancing heads; racing writers; missing, extra, corrupt and oversized file parts; historic file replacement/detachment; legacy migration without invented semantics; opaque module preservation; current export selection; full bundle reconstruction; pinned historical graph/inspector; visual and nonspatial connection creation; draft preservation after conflict; and no semantic commit for node dragging.

No numerical test count substitutes for inspecting these distinctions. Independent academia interoperability, public deployment, institutional contestation and full GR conformance remain outside this release’s evidence.

92 open questions

Original source: `docs/planning/open_questions.md`.
Original source SHA-256: `27b35ad4879927e41794b876e5ece2042a69d8d9457dd296a4bcb1f8e89aba81`.

92.1 Open Questions

Document class: Informative issue register
Status: OPEN / evolving

92.1.1 Event time and spacetime projection, 2026-09-22

ADR-0011, the source-grounded design and GR-SPEC-121 define the bounded experimental extension. They do not establish historical truth, an exhaustive GR temporal theory or standards adoption.

ID	Status	Question and present treatment	Needed by
Q-45	EXPERIMENTAL	How should alternative coherent chronology accounts be selected without discarding evidence? Version 1 retains conflicting strict-order assertions, diagnoses cycles and provides no cut topology for an unusable ordering. Withdrawn order accounts are excluded; contested and non-realized accounts remain visibly qualified. User-selected competing account sets remain open.	Comparative temporal reconstruction
Q-46	DEFERRED	How should extended events, onset/completion distinctions, overlapping intervals, uncertain calendar dates and multiple temporal reference systems relate to operational event boundaries? Version 1 uses explicit Event markers and start-inclusive/end-exclusive applicability; it infers no ordering from dates, Git or layout and invents no duration.	Richer temporal profile

ID	Status	Question and present treatment	Needed by
Q-47	OPEN	Which identity/ continuity criteria and effect semantics justify a trajectory or reconstructed state? Version 1 groups scoped accounts by supplied subject references with a basis; it does not infer identity, execute effects, resolve competing states or assume all linearizations produce one outcome.	Domain trajectory models and formal semantics
Q-48	OPEN	Do users distinguish event cuts, order layers, physical time, unknown scope and recording revision, including partial Relation views? The induced active subgraph preserves applicable Relation accounts and diagnoses omitted incidences. Automated correctness checks do not establish comprehension or accessibility.	Participatory interface assessment

92.1.2 Graph protocol and modular application, 2026-09-22

ADR-0008, the design, source review and academia comparison record the selected experimental choices. They do not settle the corresponding conceptual or institutional questions.

ID	Status	Question and present treatment	Needed by
Q-38	EXPERIMENTAL	How should relation identity, unknown participants and cross-project references evolve without leaking protected targets or equating record identity with target identity? The first profile uses local UUID references, distinct incidences and explicit participant completeness; zero-incidence and cross-project structured relations remain outside the profile.	Wider graph profile and protected collaboration

ID	Status	Question and present treatment	Needed by
Q-39	OPEN	How should external material stores, physical quotas, selective erasure, sealing and independent preservation custody work with atomic transactions and existing history/bundles? The first binding retains bounded Git assets; detachment is not erasure and logical asset budgets are not disk quotas.	Sensitive records, hosting or larger material
Q-40	OPEN	Do intended users understand Relation nodes, reference scope, hidden incidences, historical selection and changes of epistemic basis? Canvas alternatives and browser tests do not establish accessibility or measured comprehension.	Participatory graph/ interface evaluation
Q-41	DEFERRED	Which academia GRRP records map exactly, partially or not at all to the shared profile while preserving native IDs, signed bytes, registrations, disclosure and material? ADR-0009 completes source/ runtime consolidation and independent entry points; an adapter fixture corpus and identity binding remain required. The original checkout remains unchanged and the imported application retains native GRRP.	Academia upgrade
Q-42	PROVISIONAL	Which optional-module, profile and registry governance preserves extension semantics across independent producers? Unknown optional module envelopes survive unrelated edits, unknown required semantics block mutation, and unsupported binding manifests are not rewritten. This is conservative pilot behavior, not a completed extension-governance system.	Second implementation and import design

ID	Status	Question and present treatment	Needed by
Q-43	OPEN	What deployment, host/cookie isolation, account recovery, dependency maintenance and backup-restoration procedures are required before operating the consolidated applications beyond local development? Separate ports and cookie names support independent local use but do not create a browser security boundary. The inherited academia dependency advisories and historical identity/custody findings require a dedicated upgrade.	Domain deployment and academia maintenance
Q-44	OPEN	Which access policies, CI checks and release procedures will serve the four source repositories? The user supplied all four GitHub URLs, and the submodule URLs now identify those hosted repositories; the current repository guide records their use. Release and repository-governance policies remain open. MIT repository licensing does not license private application records or adopt governance drafts.	Repository governance and releases

The new transaction categories partially address Q-36 without completing structured mixed epistemic grounds or source assessment. Q-34/35/37 remain open; a graph and receipt ledger do not supply shared governance, authorized erasure or actual contestation.

92.1.3 Experimental application, 2026-09-22

ADR-0007 records the private-project Git workspace; its design distinguishes working features from draft conformance. User authorization to implement a pilot does not adopt a technical Standard.

ID	Status	Question and present treatment	Needed by
Q-34	DEFERRED	What membership, invitation, contribution and historical-access rules should shared projects support? The first implementation authorizes only the project creator.	Collaboration release

ID	Status	Question and present treatment	Needed by
Q-35	OPEN	How should retention, erasure, account recovery, repository repair and backup restoration be operated and verified? Revision and withdrawal currently retain historical content, including in bundles.	Sensitive use or hosted deployment
Q-36	EXPERIMENTAL	Which richer claim/evidence objects, mixed epistemic bases, observation/acquisition times and semantic revision distinctions are needed beyond the current primary-role form? Optional prose preserves qualifications but does not enforce the complete draft model.	Pilot feedback and GR-SPEC-120/200 development
Q-37	OPEN	Which accountable actors and workflows can support an actual challenge, reasoned review, notification and practical remedy? Owner-assigned record status is not an independent contestation procedure.	GR-210 application pilot

92.1.4 Substantive validation cycle, 2026-09-22

The 0.2 validation dossier records review coverage, P0/P1 results and corrections implemented in the preparatory 0.3 edition. ADR-0006 explains the operational choices. Fixed drafting defects do not close the broader governance and theoretical questions below.

ID	Status	Question and present treatment	Needed by
Q-31	OPEN	May a final ballot open while the reply-to-disposition window is still open, or must the windows be sequential? P0/v2 uses a conservative sequential design; it does not adopt that choice.	Before a live review/ballot schedule
Q-32	OPEN	How are start events, closing instants and calendar days interpreted across time zones and daylight-saving transitions? Notices need exact times; synthetic elapsed-day examples do not establish a universal civil-calendar convention.	Before a live time-bound procedure

ID	Status	Question and present treatment	Needed by
Q-33	PROVISIONAL	Does conditional R110-112 adequately record recirculation stages and link-specific uncertainty without treating every generativity-return account as recirculation? Its source basis is FM-005 section 5.17.3, p.145; broader definition, valuation and entitlement remain unresolved.	Source/author review and relevant return-account pilot

Q-22/26/28 remain open: all requirements have editorial review coverage, but that supplies no actual founding authority or measured participant burden. P1/v2 leaves retention-decision applicability unresolved and supplies no actual notification, review or repair evidence. Its fulfilled documentary components do not establish whole-practice conformance.

92.1.5 Expanded working-draft review, 2026-09-22

The 0.2 package develops the existing proposals in greater detail. ADR-0005 records why ISO, IEEE, ITU and UN sources have different roles. The earlier questions remain open unless a separate decision closes them.

ID	Status	Question and current treatment	Needed by
Q-27	PROVISIONAL	Is the local formal publication structure suitable for this family? The draft uses ISO-like numbered clauses and labelled annexes, accessible IEEE drafting rules and ITU comparison without importing institutional authority. Full inaccessible external resources need review before more detailed reliance.	Editorial adoption and external release
Q-28	OPEN	Which expanded obligations are proportionate for different practices, and what justified profiles would reduce burden while preserving material uncertainty, protection and accountability? No reduced conformance profile is implied by a short form.	Participatory rehearsal and GR-150 development

ID	Status	Question and current treatment	Needed by
Q-29	PROVISIONAL	Is EIP-069's reasoned 'more likely than not' criterion appropriate for internal conduct findings, with fair-response and independent-review safeguards? Alternatives include a higher threshold, contextual criteria or non-adjudicative findings. Neither the criterion nor a finding establishes external legal liability.	Governance and ethics review before adoption
Q-30	OPEN	Which UN-system institutional model or potential counterpart fits an actual pilot purpose and mandate? ITU, UN/CEFACT and UN statistical guidance perform different functions; no sponsor, partnership or policy adoption is presumed.	Any international policy proposal

Normative schedules in the 0.2 drafts are operational proposals for review. Their presence does not establish that an actual institution can supply the stated evidence or that affected users find the procedure usable. P0/P1 retain their historical 0.1 scope until reassessed.

92.1.6 First working-draft review, 2026-09-22

The initial package supplies proposed operational answers, not resolutions of this register. ADR-0004 records alternatives and affected requirements. The following choices need focused review before progression:

ID	Status	Question and current draft treatment	Needed by
Q-21	PROVISIONAL	Are D1's 60-day public review, 30-day re-review/ballot/appeal periods, two-thirds returned-ballot quorum, three substantive votes and two-thirds substantive approval practicable and sufficiently inclusive? Numerical support alone does not establish stakeholder balance.	Governance adoption

ID	Status	Question and current draft treatment	Needed by
Q-22	OPEN	Who can sign the founding instrument with actual authority over programme resources and publications, accept roles and provide neutral review? The unsigned template does not create those capacities.	Governance adoption
Q-23	PROVISIONAL	Are preparatory GR-100/110/200/210 scopes the right first technical cycle, and do the dependency boundaries prevent hidden package obligations? All remain unapproved projects pending governance.	NWIP decision and next technical draft
Q-24	OPEN	What limited package/case conformance profiles are useful? This draft permits partial documentary assessment but does not treat it as observed practice or procedure fulfillment.	Pilot assessment design / GR-150
Q-25	OPEN	Which alternative reading format and accessibility target can be sustained? LuaLaTeX compilation, extracted text and source availability do not establish PDF accessibility or user comprehension.	Before external formal release
Q-26	OPEN	What are the measured recording/review costs and effects on affected participants? P0 arithmetic and P1 authored scenarios supply no observed staffing, elapsed effort, participation, review fairness or remedy evidence.	Participatory rehearsal / live pilot

Q-05/06/07 now have explicit candidate operational treatments in the TeX drafts, including overlapping roles, distinct modality/epistemic mode and three revision reasons. They remain open to source and pilot review; Property/Attribute, manuscript chronology and formal emergence assumptions are not settled. Q-03 rights choices also remain unresolved: the policy draft supplies a rights-clearance process, not a licence grant.

92.1.7 Decisions needed for the current development plan

These priorities supplement the earlier thematic questions below. Milestones refer to the comprehensive plan. Roles are proposed and unassigned. An operational resolution records alternatives, rationale, source mappings and affected documents; it does not retroactively resolve a philosophical question.

ID	Status	Decision or investigation	Needed by	Proposed accountable role
Q-01	OPEN	Who holds founding authority, and how are governance adoption, delegation, conflicts and independent appeals made credible for a small programme?	M1	Founding authority / governance editor
Q-02	OPEN	Which participation, consensus, review, objection and appeal rules are practicable? Which ISO/IEC or IEEE mechanisms are adopted, adapted or deferred, and why?	M1	Governance editor and stakeholder reviewers
Q-03	OPEN	What licensing and contribution terms apply separately to publications, schemas, examples, software and third-party source material?	M1	Governance and IP reviewers
Q-04	PROVISIONAL	Is GR/NWIP-001 one coordinated package or several linked work items, and which responsible editors have capacity for its first cycle?	M1–M2	Sponsor and established decision body
Q-05	OPEN	How do Part II's Attribute and the repository's Property relate? Are the six roles overlapping, and how are admissibility, identity and persistence scoped?	M2	GR-100/120 editors
Q-06	OPEN	How are claim, observation, trace, evidence, interpretation and judgment represented without conflating target reality, source records and institutional acceptance?	M2	GR-200/210 editors
Q-07	OPEN	What records distinguish world change, evidence change and category/regime change, including revised identity and retrospective recognition?	M2	GR-100/120/200 editors

ID	Status	Decision or investigation	Needed by	Proposed accountable role
Q-08	OPEN	Which version relationships among the foundation manuscripts are author-confirmed, and which apparent formal or terminological differences remain unresolved?	M2 for definitions relying on them	Source editor and author
Q-09	OPEN	How are Part I's fixed-carrier collapse results and stronger interpretive language qualified by Part II? Which emergence claims require additional assumptions?	Before reliance in a requirement	GR-TR101/102 editors
Q-10	PROVISIONAL	What is the smallest useful generative history: which changes in capacity, maintenance, constraints, alternatives and loss need grounds, and when is unknown the appropriate result?	M2–M3	GR-110/210 editors and pilot users
Q-11	OPEN	How are corrections, access withdrawal, retention, deletion and permitted audit traces reconciled without an unconditional immutable-history requirement?	M2 before sensitive pilots	GR-160/310 editors and contextual reviewers
Q-12	OPEN	Which conformance subjects and profiles separate capability from recording depth? Does the candidate name Standard profile confuse publication status?	M2	GR-150 editor
Q-13	PROVISIONAL	Which institutional procedures need machine protocols, and when do portable exchange, notifications or federation justify separate technical work?	M3	GR-130/200/400 editors

ID	Status	Decision or investigation	Needed by	Proposed accountable role
Q-14	OPEN	How will pilot burden, meaningful contestability, presentation comprehension and unequal access be evaluated, and what result warrants redesign?	M2, before measurement	Pilot lead and affected participants
Q-15	DEFERRED	Which jurisdictional profiles, generativity-return assessments, formal semantics or additional publications need development beyond the first cycle?	After relevant pilot evidence	Relevant editors and domain reviewers
Q-16	OPEN	How are ethical disagreement, distributive effects, recognition and responsibility assessed without implying one universal value ordering?	M2 and relevant policy analysis	Ethics reviewer and affected participants
Q-17	OPEN	Which legal concepts and sources of authority are relevant to the selected use case, and which unresolved conflicts require contextual analysis or a policy proposal?	Before contextual pilot claims	Jurisprudential and institutional reviewers
Q-18	OPEN	Which international organization or class of institutions has a suitable mandate, and how do voluntary pilots, shared stewardship, existing infrastructure or deferral compare?	Before any policy recommendation	Policy editor and mandate reviewer
Q-19	OPEN	How are ownership, access, funding, maintenance cost, infrastructural dependency and returns to contributors governed without concentrating recognition power?	M1–M4 as scope develops	Programme governance and political-economy reviewers

ID	Status	Decision or investigation	Needed by	Proposed accountable role
Q-20	OPEN	Which cross-domain review competencies can actually be supplied, and how do participation gaps limit scope or progression?	M1–M2	Sponsor and review coordinator

The foundation map preserves source tensions. The technical landscape, development comparison, and cross-domain programme distinguish external sources from proposed local choices. No external compatibility or institutional affiliation is assumed.

92.1.8 Ontology

- Are Entity, State, Event, Process, Relation, and Property sufficient for the core record ontology?
- Should Observation, Claim, Interpretation, or Agent be first-class ontology classes or profiles built from the six?
- How should identity and persistence be represented without assuming substance ontology?
- How should relation identity be handled through time?

92.1.9 Generativity

- How should a record represent the emergence of a distinction that was previously unavailable?
- How should changes in a possibility field be represented?
- How should unrealized branches be recorded without implying that they were equally feasible?
- How should generativity return be represented?

92.1.10 Formal semantics

- Which category-theoretic structures are most appropriate?
- Should the core information model remain formalism-neutral?
- How can state transition, relational change, and persistence coexist in one mathematical framework?

92.1.11 Standards governance

- What threshold constitutes consensus?
- Which stakeholder classes must be represented in public review?
- What is the minimum viable appeals process for a small NGO?
- What licensing model best supports open implementation and future formal standardization?

92.1.12 Conformance

- What does it mean for a record to conform?
- Should there be Core, Standard, and Deep conformance profiles?
- Which clauses can be automatically validated?

92.1.13 Privacy and ethics

- How should preservation be separated from publicity?
- How are sealed, restricted, anonymized, and destroyed records distinguished?

- How should third-party generative contributions be recorded without creating surveillance risks?

92.1.14 Foundation corpus

- Which GR manuscripts should be designated foundational rather than supplementary?
- Which terms have changed meaning across the GR corpus?
- Which notational conventions should GR-100 preserve?
- Where should a standards-specific operational definition deliberately diverge from a broader GR concept?
- How should manuscript-to-clause traceability be represented?

92.1.15 Epistemics

- Should Observation, Claim, Evidence, Interpretation, Judgment, and Attribution be first-class record classes, or epistemic wrappers/profiles around other records?
- How should evidentiary provenance and uncertainty be represented?
- How should conflicting interpretations coexist without premature canonicalization?

92.1.16 Jurisprudence and law

- Which legal concepts require dedicated profiles rather than generic metadata?
- How should correction, annotation, objection, access, restriction, and preservation rights be represented?
- How should the standards distinguish technical conformance from legal validity?
- What kinds of jurisdiction-specific legal profiles are appropriate?

92.1.17 International organizations and policy

- Which IO functions are plausible first-use environments: research integrity, cultural heritage, AI governance, institutional memory, scientific collaboration, or public administration?
- Which proposals should be global, and which should be mandate-specific?
- What pilot designs can test utility without imposing excessive recording burdens?

92.1.18 Publication classes

- Earlier question: which projects begin as Specifications versus Standards? The default direction is resolved by accepted ADR-0002: begin from the Standards track. The remaining question is which requirements justify particular Specification work items, including the boundaries of GR-120/130/200 and their corresponding Specifications.
- Should project-family numbers remain stable across promotion from Specification to Standard?
- When should a policy proposal be classified as an International Policy Proposal versus an International Institutional Proposal?
- What minimum evidence is required before a Specification may be proposed as a Standard?

93 preliminary plan

Original source: `docs/planning/preliminary_plan.md`.
Original source SHA-256: `17d3acf0abacabfab7866bbbcf0a26e8d9951e7c44c34150c74d5f1c3ce9ea00`.

93.1 Preliminary Plan

> **Historical planning draft.** Retained to preserve the programme's earlier development reasoning. The comprehensive development plan is the current planning proposal. The original text below remains unchanged, including the specification-first sentence in section 12; that sentence conflicts with accepted ADR-0002, which governs the current Standards-first sequence. Earlier maturity targets below are not reports of completed releases.

See also the project-level orientation in `PROGRAMME_BRIEF.md`, which summarizes why, what, and how the standards programme is being developed.
Status: PROVISIONAL
Version: 0.1

93.1.1 1. Objective

Establish a lightweight NGO standards program capable of developing, publishing, maintaining, and revising a family of standards for generativity records and presentation.

93.1.2 2. Development phases

93.1.3 Phase A — Standards governance

Deliverables:

1. Standards Programme Charter
2. Directives Part 1 — Development and Maintenance Procedures
3. Directives Part 2 — Structure and Drafting Rules
4. Technical Committee Charter
5. Public Review and Comment Procedure
6. Consensus and Decision Policy
7. Conflict-of-Interest and Ethics Policy
8. Intellectual Property Policy
9. Maintenance and Versioning Procedure
10. Records and Transparency Policy

93.1.4 Phase B — Foundations

Deliverables:

- GR-100 — Foundations and Vocabulary
- GR-TR101 — Theoretical Foundations
- GR-TR102 — Category-Theoretic Semantics

Primary work:

- define the six candidate record ontology classes;
- define their relations to the deep metamodel;
- identify identity, persistence, time, and perspective semantics;
- specify open theoretical questions.

93.1.5 Phase C — Core recording standard

Deliverables:

- GR-110 — Generativity Recording Requirements
- GR-M101 — Recording Manual
- worked examples.

Primary work:

- minimal and extended record profiles;
- provenance;
- generative dependencies;
- uncertainty;
- branches and alternatives;
- retrospective interpretation;
- contingent encounters;
- access metadata.

93.1.6 Phase D — Information model and interchange

Deliverables:

- GR-120 — Information Model
- GR-130 — Interchange Specification
- schemas and validators.

Primary work:

- identifiers;
- record typing;
- graph semantics;
- temporal semantics;
- machine-readable formats;
- compatibility strategy.

93.1.7 Phase E — Presentation and preservation

Deliverables:

- GR-140 — Presentation Requirements
- GR-160 — Preservation, Privacy, Access, and Retention.

Primary work:

- timeline and graph views;
- disclosure of mediation;
- public and restricted representations;
- retention and deletion;
- future interpretability.

93.1.8 Phase F — Conformance and pilots

Deliverables:

- GR-150 — Conformance and Validation
- implementation test suite;
- pilot reports.

Candidate pilots:

- individual research process;
- AI-assisted scholarship;
- collaborative research project;
- institutional decision process;
- archival reconstruction.

93.1.9 3. Lightweight standards lifecycle

Proposed stages:

Stage	Meaning
00	Preliminary
10	Proposal
20	Working Draft
30	Committee Draft
40	Public Review Draft
50	Final Approval Draft
60	Published Standard
90	Review / Revision / Withdrawal

93.1.10 4. Initial organizational structure

93.1.11 Standards Council

Responsibilities:

- procedural oversight;
- approval of work items;
- adoption and withdrawal of standards;
- appeals and governance.

93.1.12 GR/TC 1 — Generativity Records and Infrastructure

Initial working groups:

- WG 1 — Foundations and Ontology
- WG 2 — Recording Model
- WG 3 — Data and Interoperability
- WG 4 — Presentation and Reconstruction
- WG 5 — Ethics, Privacy, and Preservation
- WG 6 — Conformance and Implementation

93.1.13 5. Minimum viable launch package

The first public-capable version of the program should have:

- governance charter;
- development procedure;
- drafting rules;
- work-item proposal template;
- public comment process;
- issue tracker;
- change log;
- decision log;
- one pilot standard project.

93.1.14 6. First pilot work item

Provisional title:
GR/NWIP-001 — Generativity Recording and Presentation Infrastructure
Expected result:
A coordinated set of technical publications rather than one monolithic standard.

93.1.15 7. Design principles

- standards should remain implementable;
- philosophical foundations should not be hidden;
- philosophical foundations should not overwhelm normative clauses;
- machine readability should be supported without forcing one storage backend;
- relations should be first-class where their own histories matter;
- revision should preserve historical states;
- presentation should disclose mediation;
- records should support uncertainty and absence;
- privacy should be separable from preservation;
- standards development itself should be traceable.

93.1.16 8. Early success criteria

The project reaches a useful v0.5 when:

- governance procedures are coherent;
- GR-100 has stable terminology;
- GR-110 can be implemented by at least one pilot recorder;
- GR-120 supports a machine-readable reference model;
- at least two independent pilot datasets can be exchanged;
- comments and objections can be traced to their resolution.

93.1.17 9. Foundation manuscript integration

The repository shall maintain a `foundation_manuscripts/` corpus.

Before stabilization of GR-100, the project should:

- collect representative foundational GR works;
- index them in `foundation_manuscripts/MANIFEST.md`;
- identify recurrent concepts and notation;
- record historical changes and unresolved tensions;
- map concepts to candidate standards clauses;
- avoid using one later manuscript to silently overwrite earlier conceptual history.

A later tooling phase may add manuscript-to-standard traceability tables.

93.1.18 10. Expanded conceptual programme

The standards programme should now be developed across at least the following coordinated layers:

- metamodel;
- record ontology;
- epistemic representation;
- normative and ethical interpretation;
- jurisprudential/legal interface;
- institutional governance;
- political economy;
- technical implementation.

The project should avoid assuming that the six candidate record ontology classes are sufficient for the entire programme.

93.1.19 11. Policy-proposal track

In parallel with standards development, the project may develop policy proposals for international organizations and other institutions.

The policy track should:

- draw from the standards work;
- remain organizationally distinct from technical standards;
- identify intended institutional mandates;
- distinguish factual analysis from normative proposals;
- present alternatives where appropriate;
- specify pilots, safeguards, and implementation pathways.

93.1.20 12. Publication-class separation

The programme should maintain separate development tracks for:

- Specifications;
- Standards;
- International Policy / Institutional Proposals.

Each document should declare its class and maturity status.

Candidate early technical work should normally begin as a Specification unless there is a clear reason to enter the full Standards track immediately.

93.1.21 13. Standards-first implementation sequence

For each substantive domain:

1. open or refine the relevant Standard work item;
2. define the normative need and conformance boundary;
3. identify infrastructure dependencies;
4. create Specification work items only where reusable technical precision is required;
5. implement pilots;
6. feed implementation results back into the Standard;
7. stabilize dependent Specifications;
8. advance the Standard toward public review and adoption.

This sequence should reduce premature infrastructure design while preserving implementation realism.

94 protocol specification plan

Original source: `docs/planning/protocol_specification_plan.md`.
Original source SHA-256: `dcc8f123518bc66be795495653f35c007c1416aa31545a231cd88e169bf8675d`.

94.1 Protocol and Specification Development Plan

Document class: Informative planning document
Status: PROVISIONAL proposal for programme review
Version: 0.1
Date: 2026-09-22

Implementation update: The original planning text below remains the capability proposal. ADR-0008 subsequently selects a bounded shared record protocol and a Git/HTTP pilot binding. Requirements are developed in GR-120/130/140/160 WD 0.1; GR-SPEC-120 and GR-SPEC-130 contain the experimental details. This records the later infrastructure decision without implying that the original plan had already chosen a transport or that the broader capability register is implemented.

94.1.1 1. Purpose and authority

This plan organizes the technical and procedural capabilities needed to record, examine, exchange, contest, and revise generativity-related accounts. It translates the programme's epistemic and practical purpose into candidate development work. It neither adopts requirements nor certifies factual truth.

The governing development pattern remains the one in ADR-0002: a standards-track Working Draft identifies a requirement and conformance boundary; an identified infrastructure need triggers a Specification; pilots feed back into both. Formal project initiation follows the governance gate in the comprehensive programme plan.

Here, **protocol** means a defined interaction among roles, with inputs, outputs, states, transitions, and handling of failure. A protocol is technical content described in a Specification or an adopted Standard, not a fourth publication authority class. An institutional procedure allocates responsibilities, review, and decisions; a network binding defines messages and technical behavior. The latter cannot supply the former's authority.

The proposed allocation uses the existing publication taxonomy and family numbers. Capability labels below are planning labels, not publication identifiers. No new publication numbers, record ontology classes, transport, storage backend, or cryptographic dependency are assigned.

94.1.2 2. Allocation across existing work items

Structural role: identify which proposed requirements motivate which reusable technical details; resolve overlapping placeholders before substantive drafting.

Existing family	Proposed standards-track responsibility	Candidate specification destination
GR-100	Vocabulary and boundaries used by the capabilities below	Terms referenced by all three existing specification work items
GR-110	Minimum capture, attribution, trajectory, and completeness expectations	GR-SPEC-120 record structure; GR-SPEC-200 attribution and epistemic representation
GR-120	Implementation-neutral model constraints, identity, time, relationships, and versions	GR-SPEC-120 precise representation and mapping rules
GR-130	Information that survives exchange; permitted loss and incompatibility reporting	GR-SPEC-130 packaging, serialization, import/export; network binding only when needed
GR-140	Faithful presentation, visible mediation, epistemic status, and disclosure limits	Existing specifications carry required presentation metadata; rendering guidance belongs in manuals

Existing family	Proposed standards-track responsibility	Candidate specification destination
GR-150	Conformance targets, claim boundaries, and evaluation criteria	Test fixtures and executable checks alongside the applicable specification
GR-160	Preservation, access, restriction, retention, disposal, and interpretability outcomes	GR-SPEC-120 lifecycle representation; GR-SPEC-130 transfer/restriction behavior
GR-200	Distinguishing attributed observations, claims, interpretations, and judgments	GR-SPEC-200 epistemic representation and capture behavior
GR-210	Evidence assessment, competing interpretations, contestation, and revision outcomes	GR-SPEC-200 evidence and review interaction details
GR-300	Explicit interface for jurisdiction, legal assertions, and procedural context	Optional metadata profile after legal review; no universal legal-status field
GR-310	Scoped access, correction, objection, notice, and review procedure profiles	Procedural behavior in an existing specification where reusable precision is needed
GR-400	Accountable operators, decision authority, oversight, and organizational use	Role and policy references in existing specifications; organizational implementation guidance in manuals

GR-120 and GR-130 currently have both standards-track placeholders and specification destinations. The proposed distinction is between required outcomes/model constraints and their implementable realization. If drafting produces no distinct normative responsibility for a placeholder, record whether to retain, narrow, or consolidate it; do not duplicate normative authority. Existing paths and numbers remain stable pending that decision.

Each specification proposal records the motivating draft clause or requirement issue, affected actor, unmet interoperability need, alternatives, maintenance burden, pilot, and acceptance evidence. A local implementation preference alone is insufficient reason to establish a shared specification.

94.1.3 3. Candidate capability register

Structural role: scope a small set of coherent capabilities before selecting formats or service architecture. Each row is a work proposal rather than a present conformance requirement.

Capability and priority	Requirement origin and specification trigger	Inputs and outputs	Candidate conformance actors and essential failure cases
Capture and attribution — first pilot	GR-110/200; different recorders need an exchangeable account of who asserted or recorded what, how, and when. GR-SPEC-120/200.	Input: submitted account, source references, method, attribution, perspective, time/uncertainty, access context. Output: versioned account and receipt with disclosed omissions.	Recorder and receiving repository. Cases: malformed submission, unknown attribution, duplicate delivery, conflicting identifier, insufficient permission. Unknown attribution remains explicit rather than fabricated.
Evidence linking and assessment — first pilot	GR-200/210; independent readers need to distinguish cited material from an assessor's interpretation of its bearing on a claim. GR-SPEC-200 plus GR-SPEC-120 references.	Input: identified account/version, evidence locator, assessor, method, rationale, limitations. Output: separately attributed assessment and links to its basis.	Assessor, recorder, repository. Cases: unavailable or changed source, ambiguous target, incompatible assessments, withheld evidence. Successful linking does not establish evidentiary sufficiency.

Capability and priority	Requirement origin and specification trigger	Inputs and outputs	Candidate conformance actors and essential failure cases
Publication and presentation — first pilot	GR-140/160; different consumers need to disclose selection, reconstruction, uncertainty, and restrictions consistently. GR-SPEC-120 metadata and GR-SPEC-130 export.	Input: authorized record view, selection/transformation description, version and profile. Output: bounded presentation or release with appropriate source/version references and disclosures.	Publisher, presenter, repository. Cases: incomplete reconstruction, stale view, omitted competing interpretation, prohibited disclosure, misleading validation label.
Contestation, review, and revision — first pilot	GR-210/310/400; challenges and dispositions need durable targets and attributable procedural history. GR-SPEC-200; policy-specific procedure profile when justified.	Input: objection, target version, grounds, supporting material, applicable procedure. Output: receipt, review activity, reasoned disposition, linked correction or recorded disagreement.	Challenger, receiving institution, reviewer, revising recorder. Cases: inaccessible target, wrong recipient, missing authority, delayed review, contested disposition, failed notice. Receipt does not mean agreement.
Version and history — first pilot	GR-110/120/160/210; consumers need to identify an earlier account and distinguish editing, correction, withdrawal, and reinterpretation. GR-SPEC-120; GR-SPEC-130 exchange rules.	Input: base version, proposed change, actor and reason, relevant time and access context. Output: identified successor/branch and change relation, or explicit conflict.	Recorder, repository, importer, presenter. Cases: stale base, divergent branches, unavailable predecessor, prohibited history disclosure. Concurrent or incompatible accounts are not silently merged.
Access, restriction, and disposal — first pilot minimum; expanded later	GR-160/310/400; software and institutions need consistent handling of scoped requests and resulting lifecycle changes. GR-SPEC-120/130; procedure semantics from approved profiles.	Input: request, subject/resource scope, applicable policy/authority, reason and review path. Output: bounded decision, authorized view or lifecycle action, receipt and permitted audit trace.	Requester, custodian, policy decision authority, repository. Cases: disputed authority, inconsistent retention instructions, partial propagation, leaked identifiers, irreversible disposal. A request and an executed action are distinct.
Exchange, synchronization, and migration — batch exchange first; synchronization later	GR-120/130/150/160; two implementations need to preserve meaning and disclose unsupported material. GR-SPEC-130 with GR-SPEC-120/200 mappings.	Input: versioned package, declared profile, referenced material/access conditions, destination capabilities. Output: import report, preserved identifiers/links, disclosed loss or rejection, migration provenance.	Exporter, importer, validator, custodian. Cases: unsupported version, partial package, duplicate transfer, identifier collision, denied references, lost extensions. Synchronization adds ordering and conflict behavior only after a pilot demonstrates need.

These capabilities support practical recognition and accountable action by preserving the basis and history of accounts. They do not require agreement among observers, a universal confidence scale, a single institutional adjudicator, or exhaustive capture of experience.

94.1.4 4. Behavior to specify for every approved capability

Structural role: provide a reusable authoring checklist for future Specifications.

1. **Scope and actor:** identify the operation, responsible roles, conformance target, profile, and what an implementation claims to implement.
2. **Inputs and preconditions:** specify identifiers and target versions, authorization context, supported representation, required metadata, and treatment of unknown or unavailable information.
3. **Output and effects:** distinguish a received request, successful validation, committed change, substantive assessment, and delivered notice. Identify observable receipts and permitted audit data.
4. **States and transitions:** identify actor, trigger, guard, action, and result for each transition; distinguish policy decisions from their execution.
5. **Failure and recovery:** distinguish invalid input, policy refusal, unresolved conflict, unsupported capability, unavailable dependency, partial completion, and transient failure. Specify whether retry is safe and how duplicate effects are prevented.
6. **Concurrency and history:** specify base versions, branch behavior, supersession, withdrawn assertions, and out-of-order inputs. Define any merge operation narrowly enough to preserve disagreement and attribution.
7. **Disclosure and correction:** specify audience, visibility of omissions, permitted notice content, stale presentations, and revision propagation. Include cases where exposing even the existence of a record would breach access rules.
8. **Security and abuse:** state actor assumptions, authorization boundaries, forgery/replay risks, malicious inputs, resource limits, and reporting behavior that avoids disclosing restricted content. Select mechanisms after the relevant threat analysis.
9. **Conformance evidence:** provide examples and counterexamples, state-transition traces, testable outcomes, and checks requiring human or institutional review.

An initial procedure model can use `submitted -> acknowledged -> under review -> disposition recorded`, with separate paths for inability to proceed and later reopening. This is an illustrative sequence, not a mandated state vocabulary. Record visibility, review progress, evidentiary assessment, and factual content remain separate dimensions; a review state called “accepted” would otherwise risk conflating several judgments.

For an eventual network binding, specify message correlation, delivery acknowledgment, retry/timeout handling, representation and capability negotiation, concurrency controls, and application errors. Reuse transport semantics where suitable. Keep the procedure implementable through documented human steps or file exchange before requiring a network service.

94.1.5 5. Minimum vertical pilot

Structural role: demonstrate one complete recording-to-revision trajectory across a deliberately small technical surface.

The proposed first pilot uses the programme’s shareable decision history and a synthetic contested institutional case, as described in the governance and pilot plan. A consented research or collaborative inquiry case can extend this work when suitable material and participation are available. One participant records an observation or attributed claim with a source and uncertain time; a second records a competing interpretation; a reviewer examines their stated bases; an author revises an account; a custodian restricts part of the evidence. Before claiming interchange maturity, a separate implementation imports the permitted export and presents both the current account and the accessible history.

The pilot includes one consequential decision, an alternative not pursued, and the stated basis for a later change of direction. Those records test whether the trajectory remains intelligible beyond the final artifact; they are attributed accounts, not measurements of an assumed universal generativity score.

Candidate scope:

- one bounded recording profile and explicit missing/unknown/restricted information;
- stable record/version references and independently attributed assessments;
- one review procedure and one restriction/correction procedure;
- a documented batch package and one human-readable presentation;
- structural validation plus semantic, disclosure, and procedural checks;
- two independently implemented producer/consumer paths before an interoperability claim.

The first prototype can use one implementation to find problems. The two-implementation demonstration is a later readiness gate for the pilot specification, not a claim that the current repository has implementations.

Acceptance scenario	Evidence sought
Round-trip attributed claim and evidence	Import preserves the specified identifiers, target versions, source/assessor distinction, uncertainty, and restriction status; any unsupported content appears in the report.
Competing interpretations	Both accounts remain attributable and discoverable in the authorized view; export/import does not turn disagreement into one proposition.
Corrected and retrospectively reinterpreted account	Reader can distinguish what was recorded at each time, the reason/actor of change, and the current accessible version.
Retried or duplicate submission	A repeat has the specified observable effect without silently creating a second claim or review action.
Stale revision and diverging branches	A conflict is reported or separately represented; existing work is not silently overwritten.
Source missing, restricted, or changed	The result distinguishes the cases at the authorized disclosure level; no fabricated source text or false completeness claim appears.
Rejected, delayed, or disputed challenge	The procedure records receipt, available explanation and review route, without treating silence or rejection as factual refutation.
Restricted export and disposal request	Export contains only the permitted view; receipt distinguishes request, decision, action, and unresolved downstream copies.
Presentation of validation result	Readers can distinguish structural conformance, provenance checks, an assessor's judgment, and institutional decisions. No "truth certified" claim follows from a validator result.
Practical burden and intelligibility	Participants document capture/review effort and whether an uninvolved reader can recover the decision, alternative, evidence limits, and revision. Failures inform smaller or clearer requirements.

Before piloting, agree measurable thresholds for semantic loss, unacceptable disclosure, review completeness, accessibility, and participant burden. Set thresholds from the case and risk context; do not invent programme-wide numerical targets without evidence.

94.1.6 6. History, privacy, and institutional authority

Structural role: preserve a design tension that technical immutability cannot settle.

Historical traceability does not imply indefinite retention or universal access. An append-only public history can preserve corrections while also perpetuating sensitive or harmful material. Deletion can protect people while reducing the evidence available for reconstruction. The programme needs an explicit profile decision about content, metadata, disclosure, retention, and authority in each context.

Evaluate restricted historical access, redacted derivatives, limited disposal metadata, and complete erasure as different operations. Even a tombstone, identifier, hash, or reason can reveal sensitive information; no universal public tombstone is proposed. A deletion receipt describes the actor's action and scope, with stated limits concerning copies beyond its control.

GR-160 owns preservation/access outcomes; GR-310 and GR-400 identify the relevant procedure and decision authority; GR-300 identifies any jurisdictional assertions. Specifications implement that recorded policy choice. They do not create legal rights, decide admissibility, or convert access policy into an epistemic verdict.

94.1.7 7. Sequencing and exit evidence

Step	Deliverable and exit evidence
Governance and scope	Coherent programme procedures; approved work-item scope and accountable maintainers; resolved responsibility for overlapping placeholders.
Requirement discovery	GR-110/200/210 draft requirements, early GR-140/150/160 constraints, and the minimum pilot scenario; explicit specification triggers and initial cross-domain review.
Minimum specification drafting	Bounded GR-SPEC-120/200 model and behavior; GR-SPEC-130 package; source-to-clause traceability, worked examples, and failure cases.
Pilot and independent exchange	Recorded execution of the acceptance scenarios, disclosure review, burden findings and issue dispositions; independent import/export evidence when claiming interchange maturity.
Broader review and revision	Renewed horizontal conceptual, ethical, institutional, accessibility, legal-interface, and security review, building on review during scope formation and before live pilots; traceable revisions to requirements and specifications.
Stabilization and maintenance	Declared edition/profile boundaries, backward-compatibility or migration behavior, conformance evidence, maintainers, and explicit promotion decisions where warranted.

DEFERRED pending demonstrated need: federation/discovery, continuous synchronization, universal identity registries, consensus networks, mandatory signatures, global trust scores, real-time streaming, and automated substantive adjudication. Optional tamper-evidence can be evaluated for a specific threat model without making cryptography the foundation of factual warrant.

External reuse candidates and their limits are documented in the external standards landscape. Evaluation of a source is distinct from adopting it as a normative dependency.

The cross-domain programme supplies substantive review questions; the standards-development comparison informs how proposals, consensus, review and appeals are organized.

94.1.8 8. Decisions still open

- **OPEN:** responsibility and publication class of overlapping GR-120/130 placeholders and the boundaries of the three initial specifications.
- **OPEN:** minimum attributable epistemic unit and its relation to record ontology, without prematurely adding an ontology class.
- **OPEN:** enough common procedural behavior for interoperability while preserving legitimate institutional differences and appeals.
- **OPEN:** which historical metadata survive correction, restriction, or erasure under a scoped profile, and which actors decide.
- **OPEN:** first serialization, validation technology, identifier rules, and offline packaging; decide through the pilot rather than this plan.
- **OPEN:** thresholds and evidence for practical usability and independent interoperability before public review.

Programme-level disposition belongs in open questions and an ADR where architecture changes. This document supplies proposed scope and acceptance evidence for those decisions.

95 standards development comparison

Original source: `docs/planning/standards_development_comparison.md`.
Original source SHA-256: `ba9ff2ef7042be004e253bd2c03dc67da47a67180e39373031ba6f20bdd2adfb`.

95.1 Standards-development approaches and programme tailoring

Document class: Informative comparative planning analysis
Status: PROVISIONAL — proposals for governance development, not adopted procedures
Version: 0.1
Sources checked: 2026-09-22
Related plans: Comprehensive development plan; governance and pilots

95.1.1 1. Purpose and limits

Role: Compare established standards-development mechanisms and identify what this programme has reason and capacity to adopt, adapt, or defer.

The programme's motivation is epistemic and practical: make the grounds of recognition, judgment, classification, contestation, and action inspectable while preserving consequential generative trajectories. Its procedures consequently matter as much as the eventual record model. An inaccessible or unchallengeable development process would undermine the practice the programme seeks to support.

ISO/IEC and IEEE SA provide established approaches to initiating work, preparing drafts, consulting affected interests, handling disagreement, approving publications, and maintaining them. Their organizational structures, constituencies, resources, and authority differ. This comparison does not identify one universal development procedure or propose copying either institution's committees into a small programme.

The labels **ADOPT**, **ADAPT**, and **DEFER** below describe proposed directions for future decisions. None establishes a rule in this document. ISO, IEC, IEEE, and WTO references indicate sources, not affiliation, recognition, accreditation, permission to use institutional marks, or a claim of formal compliance. This analysis does not determine legal obligations or provide legal advice.

95.1.2 2. Source editions and access record

Role: Distinguish verified source content from edition metadata, inaccessible material, and questions needing rechecking before a governance clause relies on them.

Source	Edition or status verified on the check date	Access and use in this comparison
ISO directives and policies index, with its Part 1 resource listing	The official listing includes Part 1:2026 and transition materials.	Listing read. The linked resource interface did not expose a retrievable 2026 PDF in this check; its clause text and transition rules are not represented as verified here.
ISO/IEC Directives Part 1, Consolidated ISO Supplement, accessible HTML	The text identifies itself as **2024, V01/2024**, despite the URL containing `current`.	Text consulted for identified procedural examples. It is an earlier-edition source in this analysis, not evidence of the latest 2026 wording. Current clause-level dependence needs the 2026 text and transition arrangements checked first.

Source	Edition or status verified on the check date	Access and use in this comparison
ISO Part 2 resource listing and directives index	Part 2, ninth edition, **2021**, plus Amendment 1; the directives index identifies a **2026 amendment** concerning management-system drafting.	Edition and amendment listings read; full Part 2/amendment text was not successfully retrieved. The comparison uses ISO's accessible house-style guidance and foreword explanation for the specific drafting principles discussed below.
ISO development overview, stages and resources, and stage codes	Current official webpages accessed; no fixed edition claimed.	Used for the general development approach and stage structure. Their detail is not a substitute for the operative directives during the edition transition.
IEEE SA Standards Board Operations Manual and Bylaws	PDF title pages: Operations Manual approved **January 2026**; Bylaws approved **February 2026**.	Both PDFs accessed. IEEE identifies the PDFs as definitive; linked HTML clauses are convenient reading references. Its policy index also identifies policy-change resources.
IEEE development overview and development quick reference	Official explanatory resources; no rule-edition status inferred from the quick reference.	Used for lifecycle and principles. The 2026 governance documents take precedence for IEEE procedural detail.
WTO TBT Committee's six principles	Official presentation of the Committee's **2000 decision**.	Public text read. Used as a process-design reference; this plan makes no determination of the programme's status under the TBT Agreement.

No external document is copied into the repository. These are selective paraphrases and programme-specific proposals. Public access, free availability, redistribution rights, implementability, and participation rights are separate questions. Full-text access gaps above remain explicit tasks before an adopted procedure cites the affected clauses as its basis.

95.1.3 3. Comparison and proposed tailoring

Role: Separate observed mechanisms from proposed GR programme choices. The right-hand column is new planning analysis, not a statement that the cited organizations prescribe it for this programme.

Topic	Observed mechanism and primary source	Proposed direction for this programme
Motivation and legitimacy of new work	ISO describes stakeholder need, expert contribution, and consultation as foundations of development. ISO development principles	**ADAPT.** A proposal explains the recognition or practice problem, affected people, expected public benefit, alternatives to standardization, and risks of giving a category institutional authority. Market demand is relevant evidence, not the sole motivation. Test the proposal against symbolic-crisis cases, recording burden, and effects on future capacities.

Topic	Observed mechanism and primary source	Proposed direction for this programme
Participation and representation	ISO operates through member-nominated expertise. IEEE distinguishes individual participation from entity representation and prohibits dominance. ISO overview; IEEE Bylaws, 5.2.1	**ADAPT.** Select an explicit participation model from section 5. Include affected people, custodians, implementers, and epistemic, archival, ethical, institutional, and jurisdiction-specific expertise. Record gaps instead of treating a mailing list or one expert as representative of a constituency. Financing and affiliations are visible within justified privacy limits.
Initiation and authorization	ISO uses a scoped new-work proposal; IEEE uses a Project Authorization Request. ISO proposal stage; IEEE initiation guidance	**ADOPT the function; ADAPT the form.** Expand the existing NWIP to include intended conformance subjects, source tensions, non-goals, impacted groups, alternatives, dependencies, review capacity, and maintenance ownership. An approved scope provides the reference against which later expansion is assessed. Formal initiation follows governance launch.
Working-group drafting and oversight	ISO separates expert working drafts from parent-committee progression. IEEE assigns project supervision to a Standards Committee. ISO preparatory stage; IEEE Operations Manual, 5.1	**ADAPT.** One coordinated group with named editors can initially perform several functions. Separate authorship, progression decisions, and conflict-sensitive review in the records. Activate additional working groups when the work and participants justify them; committee names alone provide neither expertise nor independent oversight.
Consensus and voting	The 2024 ISO text distinguishes consensus from unanimity. IEEE combines ballot criteria with comment consideration. ISO Part 1:2024, 2.5.6; IEEE Operations Manual, 5.4	**ADAPT.** Assess whose concerns were heard, which substantial objections remain, and why progression is justified. Record votes separately from grounds and dispositions. A numerical majority does not establish factual truth or remove a material objection. Eligibility, quorum, thresholds, abstention handling, and escalation remain OPEN until the participation model is selected.
Wider review and recirculation	ISO enquiry provides comments through national members. IEEE public review accepts non-balloter comments and requires responses. ISO enquiry stage; IEEE Operations Manual, 5.4.5	**ADAPT.** Offer a direct, accessible comment route suited to the programme's constituency, with versioned drafts, disposition reasons, and notice of material changes. Deliberate outreach complements an open webpage. Significant changes return to affected reviewers. Review duration and outreach adequacy are future governance choices; no ISO or IEEE deadline is imported.

Topic	Observed mechanism and primary source	Proposed direction for this programme
Appeals and independence	ISO's 2024 text provides hierarchical appeals. IEEE's board appeal panels exclude involved or materially affected reviewers and consider procedural matters. ISO Part 1:2024, clause 5; IEEE Operations Manual, 5.8	**ADAPT.** Define standing, grounds, notice, opportunity to reply, conflicts, reasoned remedies, and a neutral review route. Keep technical reconsideration, procedural appeal, misconduct complaint, and requests concerning represented persons distinguishable. A small programme needs available neutral people rather than multiple nominal appeal levels. Section 6 addresses bootstrap capacity.
Openness and transparency	WTO principles address accessible work information, participation opportunities, and consideration of comments. WTO transparency and openness	**ADOPT the aims; ADAPT implementation.** Publish work programmes, draft status, issue dispositions, decision authority, and maintenance notices. Support participation without mandatory travel or proprietary tooling where feasible. Publish sufficient grounds to inspect decisions while protecting confidential evidence, contributors, and complaint participants. Openness does not mean unrestricted release of every record.
Ethics, conflicts, and dominance	IEEE participation rules connect conduct, ethics, affiliations, and non-dominance. IEEE Bylaws, 5.2.1	**ADAPT.** Review funding influence, retaliation risk, exclusion, uncompensated recording work, and whose accounts become authoritative. Establish disclosure, recusal, protected reporting, and corrective actions. Process ethics and assessment of harms from the proposed standard are related but separate reviews; a technically coherent draft can still impose unacceptable burdens.
Intellectual property and contribution terms	ISO publishes a common patent-policy framework and declaration resources. IEEE addresses contributions, copyright, patents, and open-source artifacts separately. ISO patent resources; IEEE Operations Manual, clause 6	**ADAPT.** Decide terms separately for prose, schemas, code, datasets, examples, and foundation material; record third-party permissions and known essential-rights concerns. Compare open implementation, contributor interests, and maintenance needs before selecting licenses. An upstream patent declaration or permissive code license is not assumed to settle all implementation rights. Exact policies remain OPEN for qualified review.

Topic	Observed mechanism and primary source	Proposed direction for this programme
Drafting and testability	ISO's Part 2 explanatory resources distinguish requirement types and assessment neutrality; IEEE distinguishes normative and informative content. ISO house style; ISO foreword explanation; IEEE Operations Manual, 6.4	**ADOPT the distinctions; ADAPT structure.** Use short, identifiable requirements, explicit scope and conformance subjects, examples outside requirements, and versioned dependencies. Locate theory and unresolved mathematics in Technical Reports. For observational or procedural requirements, identify evidence and assessment method without pretending every quality of judgment is machine-testable. Verify Part 2's amendment before taking clause-specific dependencies.
Cross-domain coordination	IEEE includes mandatory coordination during review; ISO supplies drafting guidance beyond formatting. IEEE Operations Manual, 5.4.4; ISO drafting resources	**ADAPT and extend for this mission.** At proposal, pilot, and release review, explicitly examine epistemic warrant, ethics, accessibility, privacy/security, jurisprudential boundaries, governance, political economy, and technical feasibility. A review identifies competence, findings, scope limits, and disposition. This proposed multidisciplinary review is not claimed to be an ISO/IEEE-mandated committee structure.
Adoption versus conformity assessment	IEEE's approval review considers process evidence; its ICAP is a separate conformity-assessment activity. ISO explains assessment against specified requirements. IEEE Operations Manual, 4.2.3; IEEE ICAP; ISO explanation	**ADOPT the separation; DEFER a certification scheme.** Programme adoption establishes a publication's authority under its own procedure. Record or implementation assessment tests a declared subject and profile. Neither certifies truth, legitimacy, or legal validity. Begin with transparent assessment reports; a certification service needs a separately justified scheme, competence, independence, and resources.
Maintenance, revisions, and withdrawal	ISO stage codes distinguish review and withdrawal. IEEE provides revision and inactive-status mechanisms. ISO stage codes; IEEE Operations Manual, clause 9	**ADOPT lifecycle responsibility; ADAPT cadence.** Assign maintainers and review triggers; distinguish correction, substantive amendment, revised edition, supersession, and withdrawal. Coordinate prose, protocol behavior, schemas, and fixtures. Retain public publication history while applying justified protection/deletion to underlying sensitive development records. Review intervals depend on scope and capacity, not borrowed institutional calendars.

Topic	Observed mechanism and primary source	Proposed direction for this programme
Policy and external authority	ISO provides resources for policy use; IEEE controls who speaks for its institutions. ISO public-policy resources; IEEE Bylaws, 5.2.1.6	**ADAPT.** Separate technical conformance from proposals about institutional adoption, legal recognition, funding, or public administration. Name the intended institution, mandate, alternatives, affected interests, and unresolved jurisdictional issues. A liaison or contributor expresses only the authority actually assigned. Policy recommendations enter their own review and authorization route.

95.1.4 4. Development stages: useful correspondence, distinct authority

Role: Relate the programme's existing lifecycle to established practice without relabelling it as an ISO or IEEE process.

ISO's published stage scheme includes proposal, preparatory, committee, enquiry, approval, publication, review, and withdrawal stages. IEEE's explanatory lifecycle covers initiation, group formation, drafting, balloting, final approval, and maintenance. ISO stage codes; IEEE quick reference

Programme work	Useful comparison	Programme-specific consequence
M0/M1: orientation and governance	Institutional procedures precede an authoritative development decision.	Establish founding authority, participation, review, and appeal capacity before formal project approval.
Stages 00/10 and scoped NWIP	Preliminary study and explicit project initiation	Authorize a bounded normative problem; source analysis and exploratory examples remain distinguishable from approved work.
Stages 20/30; M2–M4	Expert drafting and wider technical consideration	Co-develop requirements and only the Specifications/protocols needed to test them; preserve unresolved theoretical differences.
Stages 40/50; M5	Wider review and a recorded approval decision	Public review, horizontal findings, objections, remedies, and maintenance evidence inform adoption. A completed schema does not bypass these steps.
Stage 60; M6 and stage 90	Publication and subsequent maintenance	Declare edition and scope; maintain issues, compatibility, correction, and withdrawal records.

The programme currently groups review/revision/withdrawal under stage 90. ISO's published scheme distinguishes stage 95 for withdrawal. This is an explicit tailoring difference, not a reason to renumber repository documents. Local stages and M0–M6 milestones describe different things: document status and programme work respectively.

95.1.5 5. Participation models to decide

Role: Identify institutional options and their political-economy consequences before selecting voting rules. The contrast between ISO's member-mediated participation and IEEE's individual/entity methods motivates comparison; the options below are programme proposals. ISO development overview; IEEE Bylaws, 5.2.1

Option	Potential fit	Risk and proposed safeguard
Individual contributors acting in their own capacity	Accessible launch; direct epistemic, practical, and affected-person input without needing institutional sponsorship	Professional networks and available unpaid time can dominate. Record affiliations and participation gaps; use asynchronous review, accessible materials, and declared eligibility for decision roles. One employer's several contributors do not automatically demonstrate stakeholder diversity.
Institutional membership and designated representatives	Clear institutional mandates, sustained contributions, and accountable organizational commitments	Large funders or implementers can crowd out affected people and smaller organizations. Distinguish representation from expertise, manage related entities and conflicts, and provide non-member comment and challenge routes. Capacity to administer membership is currently unproven.
Hybrid participation with explicit decision roles	Combines individuals, affected communities, and organizational mandates	Double counting and ambiguous authority are possible. State which capacity each person uses for each decision, separate consultation from formal decision rights, and justify balance arrangements. Avoid creating multiple chambers before participants and administration exist.

The **PROVISIONAL planning preference** is an open individual-contributor launch with affiliation disclosure, deliberate stakeholder outreach, bounded delegated decision roles, and neutral procedural review. Institutional representatives can contribute with their capacity clearly identified. Transition to institutional or hybrid membership remains a later charter decision. This preference does not grant membership or voting rights now.

A participant register records the role and basis of participation, relevant affiliation, declared conflicts, and review competence, with a protected route for information that cannot safely be public. Representation claims need evidence of a mandate or consultation; demographic or geographic breadth alone does not establish that a person speaks for others.

95.1.6 6. Neutral review during bootstrap

Role: Make challenge and remedy possible with a small team while preserving the distinction between procedural authority and substantive truth.

The proposed launch arrangement identifies an editor/coordinator, an authorized progression decision role, and at least an available route to a neutral reviewer outside the disputed decision. These are functions to staff, not assumed existing bodies. Neutrality is assessed through involvement, interests, conflicts, and acceptance of the review procedure rather than asserted by job title. IEEE's conflict-sensitive appeal mechanism provides a useful comparison; its institutional panel size and deadlines are not imported. IEEE Operations Manual, 5.8

Candidate capacity arrangements are an agreed roster of external volunteer reviewers or a later reciprocal review arrangement with another organization. Neither is presently staffed or agreed. A temporary founding steward can coordinate preliminary drafts, but that role alone cannot provide independent review of its own consequential contested decision. Where impartial consideration is unavailable, the proposed response is to retain draft status or defer the disputed progression decision while continuing unaffected research.

The governance package distinguishes:

- **Technical or conceptual objection:** consideration by the responsible drafting/review

group, with source evidence, alternatives, reasons, and recorded remaining disagreement.
- **Procedural appeal:** review of whether the operative process, participation rights, conflicts, and decision authority were respected; available remedies include reconsideration or repeating an affected stage.
- **Ethics or conduct complaint:** a protected route capable of addressing retaliation, harassment, misuse of sensitive records, or domination without making public disclosure a condition of being heard.
- **Record-specific correction or access request:** the route established for the relevant pilot or institution, with the applicable authority and retention conditions identified.
- **Claim requiring an external legal remedy:** identified as outside the programme's adjudicative authority; a contextual review determines the appropriate interface without implying that internal appeal replaces it.

These distinctions prevent one technical chair from becoming a general authority over truth, morality, participation complaints, and legal rights. The relationship between routes, limits on repeated abusive submissions, publication pauses, and available remedies remains governance drafting work.

95.1.7 7. Applying the WTO principles proportionately

Role: Use the six principles as a diagnostic of participation and relevance. The source is a TBT Committee decision about international standardization; the following operationalization is this programme's proposal. WTO six principles

Source principle	Proposed programme question and evidence
Transparency	Can a reader locate proposed work, its motivation, draft status, objections, decision reasons, and maintenance owner? Demonstrate the public decision trail and justified restrictions.
Openness	Can a relevant person learn of the work and contribute before decisions become fixed? Test contact routes, draft access, meeting alternatives, and the handling of unsolicited relevant comments.
Impartiality and consensus	Do funding, affiliation, technical fluency, or control of tools prevent a concern from receiving fair consideration? Review participation, conflicts, and sustained objections as well as votes.
Effectiveness and relevance	Does the practice improve inspectability and contestability at a feasible burden? Use the bounded pilots and report failures, exclusions, and circumstances in which standardization adds little value.
Coherence	Is an existing standard reusable, and where do semantic or authority boundaries differ? Record source editions, gaps, mappings, and tests before compatibility claims.
Development dimension	What resource, language, connectivity, or institutional barriers exclude potential participants? Assess asynchronous options, accessible summaries, translation needs, and support that actual resources can sustain.

Applying these questions does not establish international representativeness or WTO recognition. Limited participation remains a reported limitation of the evidence supporting adoption.

95.1.8 8. Concrete governance-development outputs

Role: Translate the comparison into work under the existing plan rather than adding another layer of nominal institutions.

1. **Source/edition verification note:** obtain and review Part 1:2026 and its transition arrangements, Part 2:2021 with Amendment 1:2026, and recheck IEEE policy updates before adopting source-dependent clauses. Preserve the present access limitation and earlier-edition references in the history.
2. **Charter options memorandum:** compare founding authority, individual/institutional/hybrid participation, decision-role appointment and removal, financial influence, and routes to neutral review. Record the selected option and rationale through the programme's governance process.
3. **Directives Part 1 draft:** define initiation, review, consensus assessment, ballots if selected, disposition, appeal and complaint routes, publication, maintenance, and exceptions. Choose periods and thresholds only after the participation and capacity decisions.
4. **Directives Part 2 draft:** operationalize publication classes, source authority, normative language, testability, cross-references, versioning, and conformance boundaries. Keep GR interpretations traceable to foundation sources and operational decisions.
5. **Horizontal-review record:** for each work item, identify the motivation, affected interests, epistemic assumptions, ethical impacts, legal/institutional boundary, public-policy alternatives, burden distribution, technical evidence, and reviewer competence or gaps.
6. **Contribution and publication policy options:** compare rights for documents, code, schemas, examples, and data; obtain qualified review for the actual organizational and jurisdictional context. No license, patent commitment, or third-party entitlement is established by this plan.
7. **Governance rehearsal:** exercise a contested proposal, minority objection, recusal, neutral appeal, material draft change, correction, and withdrawal using synthetic material or the programme's appropriately shareable history. Revise procedures before treating them as coherent launch infrastructure.

Formal ISO/IEC or IEEE participation, adoption through another standards body, external certification, and international-institution endorsement remain **DEFERRED options**. Each would require its own purpose, eligibility and resource assessment, institutional agreement where applicable, and explicit authorization. The present objective is a credible, usable programme process proportionate to its actual community and mission.

96 drafting models

Original source: `docs/references/drafting_models.md`.
Original source SHA-256: `a079a181ff666a76f19c9bb86fe353de607af7487352bcd483aea3babb850983`.

96.1 External drafting and institutional models

Class: Informative comparative editorial study
Status: PROVISIONAL; supports Working Draft package 0.2
Sources checked: 2026-09-22

The UN system does produce technical standards, but it does not supply one universal standard-writing format. ITU is a UN specialized agency whose ITU-T Recommendations address technical standardization. UN/CEFACT publishes technical specifications and other trade-facilitation instruments. A UN statistical quality manual serves a different purpose. The programme selects practices by function and retains its own publication classes, authority and terminology. ITU institutional description, ITU-T Recommendations, UN/CEFACT catalogue.

This study supplements the earlier development-process comparison. It does not replace the GR foundation corpus with an external ontology or establish compatibility with any external standard. The proposed local decisions are recorded in ADR-0005.

96.1.1 1. Verified sources and access limits

Source and edition	What was inspected	Use in this revision
ISO Model International Standard, third edition, 2023	Official metadata and the 27-page annotated model PDF through the browser; direct download was refused	Document architecture and differentiated normative/ informative material
ISO House Style, web page checked on the date above	Official HTML guidance	Consistent terminology, formal hierarchy, concise impersonal provisions and readable production
IEEE SA Operations Manual, Clause 6, current official HTML checked on the date above	Published provisions on draft status, standard structure, references and verbal forms	Explicit status, normative/ informative separation and reference discipline
ITU Author's Guide for drafting ITU-T Recommendations, June 2023	Official catalogue and 30-page guide PDF through the browser; direct download returned HTML	Technical-document structure, definitions, references, annex roles and editorial review
ITU-T A.1, September 2019	Official catalogue identifies this edition as in force; full operative text was not inspected in this revision	A verified working-methods reference for further institutional study; no detailed rule imported
UN/CEFACT Core Components Technical Specification, version 3.0, 29 September 2009	Official metadata; linked full PDF was inaccessible	Evidence of a UN-system technical Specification class; detailed comparison remains deferred
United Nations National Quality Assurance Frameworks Manual for Official Statistics, 2019	Official metadata and full PDF; a local copy was downloaded from the UN Statistics Division	Institutional, process and output quality as distinct review concerns
UNESCO Recommendation on the Ethics of Artificial Intelligence, adopted 23 November 2021	Official text and adoption metadata	Ethical impact, participation and oversight questions for AI-mediated programme work; not a universal GR technical standard

The machine-readable source register distinguishes browser inspection, catalogue-only verification and successful local retrieval. Only the UN NQAF PDF was successfully cached locally in this revision. The cache is in ignored `build/reference_sources/`; it is not a redistributed programme publication.

The official IEEE drafting page links its Style Manual, editorial checklist and 2026 Word template. Access to the manual/checklist was refused with HTTP 418; the template download was refused with HTTP 403. These files were not read or adopted. The accessible Operations

Manual is the IEEE source actually used. The ISO directives page identifies Part 2 resources, including an amendment; the complete current amended text was not obtained. The model and house-style guidance do not substitute for a claim of full Directives compliance.

96.1.2 2. Differences that matter

96.1.3 Technical structure

The ISO model illustrates a title page, contents, Foreword, Introduction, Scope, Normative references, Terms and definitions, technical clauses, labelled annexes and a bibliography. Its rice example is instructional; its commodity requirements have no relevance to GR conformance. Annotated model PDF.

The ITU guide also separates scope, references, definitions and technical material, but distinguishes integral annexes from supplementary appendices. It is itself author guidance, not an ITU-T Recommendation. The programme uses one alphabetic annex sequence with an explicit normative or informative label. This is a deliberate local choice, rather than an assertion that ISO and ITU structures are identical. ITU guide PDF.

IEEE's accessible rules distinguish normative from informative content, identify the role of references and distinguish mandatory requirements, recommendations, permissions and capabilities. Its own copyright, distribution, committee and approval rules belong to IEEE. The GR programme does not copy those institutional authorities or assert compliance with them. Operations Manual, 6.4.

96.1.4 Institutional quality

The UN NQAF manual addresses official statistics through recommendations, a framework and implementation guidance. Its treatment of institutional environment, statistical processes and outputs makes it useful for asking whether competent responsibility, reliable methods and usable results are all present. It does not define truth for arbitrary factual claims, adjudicate legal disputes or supply a general-purpose provenance schema. UN Statistics Division PDF.

The local adaptation is to assess records and the practices that produce, review and maintain them separately. A well-formed package does not prove that a review was independent, that a notification reached its audience or that a remedy worked. Those are programme design conclusions, grounded also in the GR sources and programme objectives; they are not presented as clauses copied from the statistical manual.

96.1.5 Institutional mandate and policy

UNESCO's AI ethics Recommendation is also relevant to the governance discussion. It treats ethical assessment across an AI system's life cycle and connects values, impacts and institutional action. Its domain and recommendatory form differ from a technical interchange specification. The programme uses it as an informative comparator where AI mediation is involved; the broader GR project includes many processes outside that domain. Official Recommendation.

The existence of UN-system instruments does not identify the appropriate partner for this programme. An ITU technical activity, a UN/CEFACT interoperability activity and a statistical capacity-building initiative have different audiences and mandates. No organization is proposed as sponsor or adopter merely because its publications provided useful examples.

Any later international policy proposal needs a separate mandate analysis, options for voluntary participation and stewardship, participation and resource estimates, risks, safeguards and an evaluation design. It could cite an adopted GR Standard, propose a bounded pilot, or recommend deferral. It would not gain technical conformance authority by adopting the appearance of a UN publication.

96.1.6 3. Local publication model implemented in version 0.2

These are independent programme proposals, implemented in the shared TeX presentation and Directives Part 2:

1. **Front matter:** publication identity, maturity, version and date; contents; Foreword for responsibility and status; Introduction for motivation and relationships.
2. **Numbered clauses:** 1 Scope, 2 Normative references, 3 Terms and definitions, followed by the document's substantive clauses. Parent clauses with subclauses avoid unnumbered hanging text.
3. **Requirements:** stable identifiers retained across rearrangement; the responsible subject, triggering condition, action and evidence expectation are explicit. Editorial numbering and requirement identity remain separate.
4. **Normative schedules:** application conditions and assessment records belong in explicitly normative annexes. Every requirement has an assessment route; an annex's status does not silently turn its examples into obligations.
5. **Informative material:** worked examples, conceptual source maps, external comparisons and unresolved issues remain distinguishable from conformance criteria.
6. **References:** precise draft dependencies are separated from an informative bibliography. A new dependency edition requires reassessment of affected obligations.
7. **Production:** A4, readable serif body text, decimal clauses, restrained monochrome headings, captions, Roman front matter and Arabic main pagination. Annex boundaries have page breaks; ordinary clauses flow continuously. Fonts, code layout and margins are local production choices.
8. **Revision evidence:** the 0.1 source package is preserved; a requirement change register and build hashes identify the revision. Existing IDs are not renumbered to simulate a new origin.

The revision expands procedure and semantic content, rather than imposing a target page count. A useful standard can be short. Here the earlier compression omitted much of the application detail, assessment evidence and failure handling needed to evaluate the proposals. Length is reported as a production result, not as evidence of maturity.

96.1.7 4. Remaining review

The full current ISO directives, IEEE style resources and UN/CEFACT technical text need separate access and edition review before more detailed reliance. Language, accessibility and institutional burden need testing with intended users. Governance adoption, rights terms, actual appointments and independent review remain unresolved. No external source model resolves those local decisions.

97 academia application reference

Original source: `docs/reviews/academia_application_reference.md`.
Original source SHA-256: `269b4c3bc76263d90f44c97e22a350109877ee544bf64ac5fdb40d3baf2c0a01`.

97.1 Academia application reference review

Document class: Informative implementation comparison
Status: Source inspection; proposals are provisional
Reviewed: 2026-09-22
Reference repository: `research/projects/Generative-Relational-Academia-Application`

This review supports the generalized application's graph, recording protocol and record-module design. It compares the academia project's source with its own design documents. It does not establish conformance to the Generativity Standards Program or run the academia application's test suite. No files in that repository were modified and no software source was copied.

> Historical scope: the review below describes the pre-import inspection. ADR-0009 subsequently authorized consolidation; the application is now retained under `application_infrastructure/gr_academia_application/`. Links below resolve to the imported source. Exact original source is recoverable from its verified history bundle; see the migration guide. Earlier statements about work not yet copied or tested describe that original review, not the completed relocation.

97.1.1 1. Reuse the architectural distinction, preserve the different models

The academia application has a useful separation between protocol, host and presentation. Its TypeScript protocol package implements canonical encoding, content identifiers and signatures; its Fastify host stores accounts and a derived SQLite index; its React client presents records. The host delegates substantive record writes to the Python `grrp` command. Plain record files remain available without the host database.

Its semantic kernel is narrower than the programme's six operational record classes. GRRP records changes in understanding as eight acts: `question`, `claim`, `challenge`, `transformation`, `decision`, `connection`, `verification` and `release`. A question starts a trajectory inside a project. Projects are containers; they are not trajectories. A state is content reached through a transition rather than a separate selectable graph subject.

The graph-model draft explicitly refuses person and project nodes and treats occasions as readings of shared cited materials. These are substantive academia-profile choices. They cannot serve as universal restrictions on Entity, State, Event, Process, Relation and Property records in the generalized application.

A shared future kernel can provide stable references, record revisions, explicit relations, attachment digests, protocol versions, transaction integrity and portable storage. Academia can supply its own acts, trajectories, views and policy constraints through a separately declared profile. Mapping GRRP states or transitions directly to generalized State or Event records would require a recorded semantic argument.

97.1.2 2. Actual stored envelope and history

The Python store implementation constructs transition records with:

Group	Fields and treatment
Identity and structure	`id`, `protocol`, `kind`, `trajectory`, `parents`, `prior_state`, `posterior_state`
Factored description	`act`, `target`, `relation`, `trigger`, `disposition`
Attribution and grounds	`performer`, `performed`, `contributions`, `absorption`, `artefacts`
Registration	`registrar`, registration `time`, `attested`, optional `signature` inside `registration`
Administrative operations	`kind: operation`, `operation`, `subject`, `payload`; the common envelope supports these separately from substantive transitions

The three dispositions are `accepted`, `contested` and `unresolved`. Relations include sixteen CiTO bindings and three explicitly local terms. Contributor-role bindings use CRediT. The source preserves the distinction between performing an act and a later party registering it. A distinct registrar's signature is not represented as approval of the substantive content.

State identifiers are SHA-256 digests of stored content bytes. Content is normalized once before initial writing; later readers verify the actual bytes. Transition identifiers cover an explicit, versioned field list, including semantic parents. Registration and disclosure are excluded from that identifier. Registrar signatures cover `{id, registrar, time}`. A cross-language test-vector suite checks Python/TypeScript agreement; it previously exposed different whitespace handling.

Transitions live in append-only `trajectories/<id>/transitions/<hash>.yaml`; state content lives separately in `states/<hash>.md`. Disclosure is a separate sidecar, so its lawful change does not alter the transition identifier. Group-tier proposals live outside the registered-transition directory until registration. Corrections are later transitions. The store topologically orders parent records before descendants; timestamps break ties rather than determine the semantic graph.

The Git adapter stages and commits exactly the paths an operation supplies. It returns a success flag; record files can exist without a successful Git commit. Git history is therefore a substrate, not a one-to-one definition of a semantic transition. This is a useful conceptual distinction, but a generalized application promising Git-backed atomic writes needs stronger failure, locking, rollback and concurrency behavior than this optional adapter supplies.

97.1.3 3. Graph and module patterns worth adapting

The graph canvas already supports selection, neighbor highlighting, dragging, panning, zooming, fit and local layout persistence. Connection transitions with multiple parents appear as selectable capsules on connecting lines. The same connection is thus an edge-like presentation and an inspectable record with its own content.

The subject panel separates Record, Disclosure, Workspace and conditional Calendar tabs. Selecting a graph subject opens relevant components and actions in one place. This is a useful interaction pattern for generalized records: selecting a Relation should expose the same provenance, revision and attachment capabilities as selecting another record class.

The host projection builds graph edges from semantic parents and artifact citations. It distinguishes `follows`, cross-trajectory `crosses`, and `cites`. Repeated references to an artifact become one material node. Structural links and substantive connection records have different authority and affordances; a displayed line need not itself be a record.

The graph-model draft classifies modules by storage and authority:

Module	Intended boundary	Generalized design implication
Record	Protocol-authored semantic content	Persist substantive changes through the recording transaction path.
Disclosure	Protocol operation and sidecar history	Keep permissions and disclosure changes explicit; do not infer them from canvas visibility.
Workspace	Mutable project-shared working material	Distinguish a convenient file collection from a cited, immutable evidence snapshot.
Calendar/layout	Local presentation or planning state	Moving a node or changing a local view need not assert a change in the represented situation.

A workspace upload does not itself become evidence in GRRP. A substantive act deliberately cites a digest. The generalized application can adapt this distinction while offering a clearer attachment workflow: immutable bytes and manifest metadata when attached to a record, with a separately named scratch workspace if later needed.

97.1.4 4. Observed implementation gaps and migration traps

These findings are based on the inspected source, not executed exploit or integration tests.

1. **Disclosure is a placeholder in the node panel.** Its own text says the sidecar is not wired. An attractive tab is not evidence of working access or disclosure controls.
2. **Calendar storage differs from the design.** The draft proposes `.gra/calendar/`; the client stores entries in browser `localStorage`, keyed by project slug. This is not account-scoped persistence or a shared calendar.
3. **The universal workspace is narrower in the UI.** The draft gives every material subject a workspace; the panel enables it for transitions and held `state:` materials, excluding external works. Upload/delete routes allow the project creator, whereas the draft describes project-party sharing.
4. **Visual connection creation is incomplete.** The canvas supports layout interaction, but connections are created with a form containing a typed target identifier. It does not yet implement drawing a connection between selected endpoints. Ordinary act forms also omit the proposed artifact picker and contributor controls.
5. **Missing parents disappear from the graph.** `projectGraph()` skips parent identifiers absent from the current node map. The draft instead calls for explicit "not held here" stubs. The generalized application should preserve restricted, absent or unresolved endpoint information without inventing endpoint content.
6. **Operations need an explicit projection rule.** The trajectory reader maps every YAML file under `transitions/`; the graph builder does not filter `kind: operation` before producing transition-shaped nodes. This differs from the design instruction to keep administrative operations in panels rather than substantive graph nodes.
7. **Authentication and recorded performer are not visibly bound in the web adapter.** The host checks the session party for project access, but calls `runGrrp()` with inherited process environment and no request-specific acting identity. Initializing a project creates a GRRP key in its record directory. The account party and recorded performer therefore need an explicit end-to-end identity check before shared authorship claims. Existing account-database tests alone do not test this binding.
8. **Mutable files are not immutable evidence snapshots.** `writeProjectFile()` can overwrite a path and `removeProjectFile()` deletes it without looking for citations. They do not themselves commit those file changes. The draft's "in Git" and cited-material guarantees should not be inferred from those helpers. Content-addressed storage and a record attachment manifest avoid meaning changing behind a stable record reference.
9. **Bundle import needs separate hardening before reuse.** `bundle.apply()` skips existing target paths without comparing bytes; the draft expects conflicting bytes for an identifier to be refused. It also joins archive names to the target after only a `trajectories/` prefix check. It does not establish safe, atomic, validated import by itself. No importer should be transplanted without path, size, schema, hash, identity-collision and partial-failure validation.
10. **Documentation and types have drift.** The TypeScript grounds list uses `exploratory` where Python uses `vulnerability`; its contribution type is a mapping while Python creates a list. README milestone/test statements are inconsistent. The source and behavior need to govern migration evidence, not a single README status paragraph.

97.1.5 5. Recommended compatibility boundary

Develop the generalized recording kernel and application first, as the user requested. Keep the academia entry point and domain workflow independent. A future adapter can map supported common fields and preserve the original GRRP bytes, identifiers, signatures, profile version and unmapped fields. It should report incomplete mappings explicitly; it should not rewrite signed historical records to make the two models appear identical.

Candidate shared conformance cases include stable record identity across revisions; distinction between Git commit parentage and semantic relations; relation records carrying their own modules; immutable attachment digests; atomic record-plus-relation creation; conflict rejection without losing either submitted revision; explicit missing-reference handling; portable export; and recovery from failed writes. Cross-application compatibility remains unclaimed until such fixtures have been implemented and independently read by both applications.

The reference project's licensing file identifies software as AGPL-3.0-or-later and specifications/documentation as CC BY 4.0 unless separately stated. Its `grrp/README.md` still says MIT. This review transfers design observations only; a later decision to copy software would need to account for the applicable source notices rather than rely on that stale README line.

98 expanded working draft review

Original source: `docs/reviews/expanded_working_draft_review.md`.
Original source SHA-256: `6a26c2ad635d71f5a908fad720815eca344ce3339b27b80ee07ebac5de4f3c3f`.

98.1 Expanded Working Draft 0.2 review

Class: Informative editorial and artifact review record
Status: PREPARATORY; 2026-09-22
Package: Archived nine Working Drafts, version 0.2
Review relationship: AI-assisted drafting and cross-review in the same development session. This is not independent stakeholder review, a formal ballot or a finding of institutional conformance.

98.1.1 1. Scope and source basis

The revision responds to the need for substantive application detail and formal publication structure. It develops all five existing governance drafts and the four initial technical drafts. It does not open additional work items or adopt the instruments. The 0.1 archive preserves original sources and tools with hashes.

The external-source study distinguishes editorial models from quality frameworks and policy instruments. ISO's annotated model, accessible IEEE rules and ITU authoring guidance support publication design; UN NQAF and UNESCO AI ethics materials provide bounded institutional comparisons. Actual access and failed retrievals are recorded. The theoretical basis remains the GR manuscript corpus, with passage-level locators in each technical document.

Particular source attention was given to FM-005's generative attribution, trajectories, evidence survival, reconstruction, uncertainty, epistemic justice, machine mediation and revisability; FM-003's praxis and limits of a fixed intervention sequence; and FM-007's operational roles and conceptual evolution. These readings do not resolve the Property/Attribute question, chronology of Chapter 3 variants or stronger emergence claims beyond the formal assumptions.

98.1.2 2. Substantive changes

Document	Added depth and review purpose
Programme Charter	Actual authority and resources, delegation and reserved decisions, participation barriers, accountability, transitions, readiness and evidence
Directives Part 1	Work-item and stage dossiers, review preparation and disposition, ballots and clocks, independent appeal capacity, emergency action, maintenance and release controls
Directives Part 2	Formal architecture, definition and requirement construction, dependency precision, semantic/protocol boundaries, normative assessment records and editorial completion checks
TC Charter	Assignment, source and decision registers, multidisciplinary review, pilot preparation, failure reporting, handover and maintenance
Ethics/IP Policy	Intake, protection, investigation, response, reasoned findings, proportionate remedies, reconsideration, conflicts, impacts, contribution rights and assessment
GR-100	Numbered terminology, six operational roles with identity and temporal conditions, scale, continuity, mappings, missingness and vocabulary assessment

Document	Added depth and review purpose
GR-110	Purpose and collection planning, generative accounts and evidence, conditions/contributions/alternatives, maintenance and loss, practical effects, custody and assessment
GR-200	Claim decomposition, methods, source dependence, material survival, interpretation, uncertainty, revision, machine mediation, protection and normative semantic schedules
GR-210	Case intake and state transitions, responsible review, competing accounts, response and disposition, corrections and practical effects, review limits and assessment schedules

The requirement change register reports text-level changes against the archived edition. It preserves old and new texts and their normalized hashes. Stable IDs identify provisions independently of their new clause locations. No ID was intentionally removed or reassigned.

98.1.3 3. Cross-review findings and dispositions

Finding	Correction and remaining limit
Sole requirements appeared in Scope while D2 required a declarative scope	Relocated the relevant Charter, D1, TC and EIP provisions into application or authority clauses, preserving their identifiers
Some D2 provisions were under unrelated headings after restructuring	Moved epistemic distinctions, conformance limits, automated checks, bindings and artifact-execution rules to their corresponding clauses
Ethics acknowledgement and determination periods were described collectively as extendible targets	Revised EIP-014 to distinguish mandatory seven-day acknowledgement from the extendible determination target; this is an explicit revision of a 0.1 obligation
Temporary participation restrictions had unclear review/expiry linkage	EIP-067 expressly applies the emergency review and expiry controls, without creating additional institutional authority
Internal conduct threshold and merits reconsideration needed limits and a usable route	EIP-069 states a reasoned criterion, contrary evidence and fairness prerequisites; EIP-099–104 specify scoped reconsideration and assessment. The threshold remains a local proposal under Q-29
Some definition entries blended definitions with examples and implications	Separated explanations into notes in the core vocabulary and epistemic drafts
One result per ID could conceal failure of a component within a grouped requirement	Added component-result rules in the core assessment schedules; every applicable component needs evidence for overall fulfillment
Unknown/restricted values could be read as a waiver of essential record structure	Distinguished required identifiers, content and scope from contextual facts that can be explicitly unknown or protected; an allowed declaration does not prove the fact was examined
A timestamp example overstated proof of recording time	Qualified it by source attribution and clock/integrity/context limits
Repeated long-table headers repeated their caption labels and produced compiler warnings	Separated first-page captions from continuing column headers; checked the revised cross-references and renderings

No review finding establishes beneficial generativity, truth of a claim, legal authority or an operating institution. Shared-session AI cross-review is not the independent human review required by the proposed governance.

98.1.4 4. Artifact verification

The full build report records compiler outcomes, source/preamble/PDF hashes, warnings and tool versions. The check report records structural checks, archive integrity, retained IDs, local

reference resolution, freshness and PDF text coverage. These historical reports were copied before revision to 0.3; current results are recorded in the substantive validation cycle.

All nine documents compiled successfully through WSL/LuaLaTeX. The checker passed with **753 requirement identifiers across 225 PDF pages**, compared with 318 identifiers and 84 pages in 0.1. There were no duplicate or unresolved identifiers, missing requirement text, stale artifact hashes, changed archive hashes, removed historical IDs, overfull boxes, missing glyphs or detected LaTeX/package warnings.

Document	0.1 pages	0.2 pages	0.1 requirements	0.2 requirements
GSP-Charter	9	19	41	85
GSP-Directives-1	13	27	58	95
GSP-Directives-2	8	26	45	95
GR-TC1-Charter	7	17	30	83
GSP-Ethics-IP	8	22	40	104
GR-100	13	30	12	26
GR-110	8	28	34	111
GR-200	11	32	26	49
GR-210	7	24	32	105

All 318 historical IDs remain: 315 requirement texts are unchanged after whitespace normalization, two advance the GR-200 dependency edition, and EIP-014 explicitly corrects the acknowledgement/target distinction. There are 435 new IDs. Clause relocation and non-requirement prose changes are not classified as requirement text changes by the CSV tool.

Formal-structure checks cover opening clauses, front matter, annex status, table captions and local references. The archive and PDF hashes were verified. Local Markdown targets resolved, and `PROJECT_INDEX.txt` lists 108 source/corpus files. These checks are artifact evidence, not fulfillment of all D2 technical and institutional assessment duties.

Visual review sampled each document's cover, opening Scope page and first normative annex, plus D2's assessment schedule, GR-100's record-role and source tables, and GR-200's assessment schedule. The 31-page selection is recorded in `build/review/v02/render-plan.json`; rendered pages and contact sheets are stored beside it. The inspected samples showed readable headings, intact tables and no observed clipping or overlap. One nonblocking underfull-line spacing advisory remains in GR-100's source-map introduction; its rendered page was inspected. No tagged-PDF, screen-reader or affected-user comprehension assessment was performed.

The final toolchain is recorded in the build report: Python 3.12.3, latexmk 4.83 and LuaHBTeX 1.17.0 (TeX Live 2023/Debian) under Ubuntu-24.04/WSL. Builds use shell escape disabled and fetch no external dependencies. Text extraction checks use the Windows Python review environment with pypdf. Source-word counts in the machine report include TeX markup and repeated table headers, and are not represented as prose word counts.

98.1.5 5. Remaining assessment and institutional work

P0 and P1 remain historical 0.1 fixtures. Their arithmetic and authored examples do not assess newly added obligations or demonstrate performance of an actual committee, recording practice, review service or remedy. The initial templates likewise do not substitute for the 0.2 normative schedules.

Before adoption, work remains on actual founding authority, accepted appointments, representation, independent-review capacity, rights terms and a governed rehearsal. Before live operational claims, work remains on contextual legal/ethical review, burden and resource measurement, observed procedure tests, affected-user understanding, accessibility and justified profiles. Current TeX/PDF production does not certify tagged-PDF or screen-reader accessibility.

More detailed drafts expose decisions that can now be reviewed; they do not settle those decisions by their length or typography. ADR-0005 and Q-27–30 retain the proposed choices and alternatives.

99 git layers 2026 09 22

Original source: `docs/reviews/git_layers_2026-09-22.md`.
Original source SHA-256: `b4c7c3260b531bf0a46031c2f627f0a39243a4e0ebf55ffe33f299e591b507bd`.

99.1 Git repository layering verification

Class: Implementation and preservation review
Date: 2026-09-22
Status: Local repositories committed; recursive clone and independent audit passed

99.1.1 Scope

The user's requested structure is implemented by four source repositories: programme, infrastructure, generalized application and academia application. Infrastructure is the programme's submodule; both applications are infrastructure submodules. Common packages remain ordinary infrastructure files. ADR-0010 records authority, alternatives and the selected boundary.

The repositories are local. The user will create hosted repositories after these commits. No remote push, outer-repository commit, application-record mutation or account migration is part of this operation.

99.1.2 Preflight evidence

- The outer repository tracked no programme paths. Its index digest and references were captured privately for an unchanged-state comparison.
- Academia's original source repository was clean at `b98730b46eca5fdf441937aef0180f5b3d4f94dd`, and its preserved bundle matched the recorded SHA-256.
- An independent bounded scan examined 329 reachable academia blob versions for private-key, common token and obvious runtime-path patterns. It found no matches. This is not a comprehensive secret or security certification.
- Source inventories contained no symlinks or junctions requiring an out-of-workspace traversal. The intentionally retained original source-history bundle was identified separately from private runtime history.

99.1.3 Construction and attribution

Boundary-local ignores exclude private runtime, account databases, key files, backups, environments, dependencies and generated builds. Git attributes preserve source bytes, with explicit LF handling for shell scripts and existing academia web sources. Local `core.longpaths` supports the nested Git metadata paths on Windows; no global configuration was changed.

Academia's original main history is imported from the local bundle. Its prior tree is loaded into the new index without checking it out over the relocated working files. The new commit therefore records relocation and current documentation/licensing changes as a continuation of the original history.

All four repository roots have comprehensive READMEs, an MIT licence, scope notes, contributor attribution and contribution guidance. Python packages carry their own copies of the MIT/contributor notices for distribution. Earlier academia notices are retained as dated history. The original bundle, foundation manuscripts and research PDF bytes are preserved; current additional permission for project-controlled material is documented separately from their historical embedded notices.

Historical migration manifests remain evidence of the earlier captured state. They are not refreshed to claim that these later licensing, README or Git-boundary changes occurred during the earlier relocation.

99.1.4 Verification record

Repository	Initial committed revision	Entries in its own index
Programme	`992284aad1798109362edfb784475875103a29d8`	166, including one infrastructure gitlink
Infrastructure	`34878d4149b02a3e4a2672147478e60b2452ffc2`	37, including two application gitlinks
Generalized application	`4df26e7297f4f917bcb879a5ebd9648051cbcf2a`	29
Academia application	`1edbabab28486eeb9994e7298773bb6e7d67bccc`	142

The programme receives a subsequent documentation commit recording this verification; child revisions remain as shown. The initial recursive clone was made from the listed programme commit.

Check	Observed result
Four repository identities and clean trees	Passed in source and fresh recursive clone
Parent `160000` entries and checked-out child revisions	Exact matches for all three submodules
Fresh recursive local clone	Both levels initialized and checked out successfully
Source-to-clone byte comparison	All 371 tracked files identical
Historical publication snapshots	All 30 recorded file digests match in the clone
Private runtime in clone	Absent; ignore probes and bounded tracked-path checks pass
Git object integrity	All four source repositories pass `git fsck`; one harmless unreachable former `.gitmodules` blob in infrastructure
Academia ancestry and original checkout	Original source commit is an ancestor; external checkout remains clean and unchanged
Enclosing repository	HEAD, complete references, index SHA-256 and programme tracked-path inventory unchanged
Python distribution licensing	All three wheels built offline and contain MIT metadata, licence text and contributor files
npm licensing metadata	Four local packages and matching lockfile entries identify MIT; third-party entries unchanged
Retained notices and documents	Earlier licence snapshots, four academia PDFs and source bundle digests preserved
Active Markdown links	All checked current guide targets resolve; historical source snapshots excluded
Hosted remotes	None configured; no push performed

An independent reviewer repeated repository identity, gitlink, clean-tree, object-integrity, ancestry, ownership, privacy and enclosing-repository checks. The recursive clone and byte comparisons were performed separately by the implementing agent. Detailed operator outputs remain in ignored `build/git-layers/`.

Windows initially assigned the newly created repository directories to the sandbox identity. Only the owner field on the new repository/Git directory roots was assigned to the user's Windows account; access-control rules and global trust settings were not changed. Absorption ran under that account. Independent inspection confirmed that repository roots, absorbed Git directory roots and `.git` pointer files belong to the user, and ordinary user Git commands succeed.

Reproduce the structural check with `python tools/check_repository_layers.py` after all four repositories are committed. The check is read-only and does not initialize missing modules or read user records. The previous application regression results remain the dated migration baseline; this task's new verification concerns repository structure, preservation and packaging metadata.

99.1.5 Remaining boundary

Hosted URLs and remote publication remain deferred by the user. Local submodule URLs describe this local nested source layout; they must be updated to actual hosted repositories

before publication. The workflow guide gives the commands and dependency order. Application protocol alignment, existing dependency advisories and operational deployment work remain as previously recorded.

100 initial working draft review

Original source: `docs/reviews/initial_working_draft_review.md`.
Original source SHA-256: `3c56ce2f896a2156e78c8dcaa068ce2bc56376d5178ed7d95979e295bc90976f`.

100.1 Initial working-draft review

Document class: Informative editorial and artifact review record
Status: PREPARATORY; version 0.1; 2026-09-22
Package: Archived nine Working Drafts, draft version 0.1
Review relationship: AI-assisted authoring and cross-review within the same development session. This is not independent stakeholder review, a formal public review, or a competent legal/ethical determination.

100.1.1 1. Scope and evidence

The review examines conceptual distinctions, cross-document requirements, explicit authority, source traceability, synthetic counterexamples, and generated artifacts. It draws on the Programme Brief, repository instructions, seven indexed foundation manuscripts and the prior standards-development comparison. TeX sources contain passage-level source rationale; the manuscript map preserves unresolved differences. External procedures inform comparison, not a claim of ISO/IEEE affiliation or procedural conformity.

Different drafting agents reviewed the governance documents and the recording/epistemic documents; the primary author integrated findings. The P1 example received a separate cross-review. These are useful editorial checks within one AI-assisted process and do not supply the expertise, constituency independence or participation evidence required for actual programme adoption.

100.1.2 2. Findings and dispositions

ID	Finding	Implemented disposition	Evidence
RV-01	Draft R110-012 and some vocabulary metadata mixed occurrence/modality with observational/inferential basis.	Separate them. A realized past event can be inferred retrospectively.	GR-100 Event/Process; E200-005; R110-012; P1-C.
RV-02	“Loss shall be recordable” tested capability but allowed known material loss to be omitted.	Require actual recording or an explicit collection/protection limitation.	R110-017; P1-I.
RV-03	Claim-level GR-200 references could hide its package-scope and assessment obligations.	Identify a bounded material-claim package and require the corresponding dependency results.	R110-005; C210-030.
RV-04	Package/case review and practice/procedure assessment had ambiguous applicability.	Treat documentary-only assessment as partial in this edition; unobserved performance remains not assessed. Condition multi-case rehearsals on procedure assessment.	GR-110 conformance section; C210-030–032; Q-24.
RV-05	D2 amendment language would constrain ordinary draft editing as though every edition were adopted.	Apply formal amendment/revision to adopted normative editions, draft-stage rules to drafts and declared maintenance to released Specifications.	D2-045.

ID	Finding	Implemented disposition	Evidence
RV-06	D1 referenced separate participation/records policies that did not exist.	Cite the Charter, named ethics/rights policy and exact records clauses.	D1-001/008/048 and associated prose.
RV-07	Specification and policy release routes were referenced but underspecified.	Require class-specific review plans, release authority, evidence, objections and appeals; preserve explicit promotion and mandate-specific policy decisions.	D1-056–058; CH-013; TC-022.
RV-08	Charter wording implied every maintenance decision required a substantive ballot.	Refer to applicable ballot/review rules and distinguish substantive changes, corrections and confirmation.	CH-038; D1-029/045/047.
RV-09	Returned-ballot quorum alone could allow one approval plus abstentions.	Require at least three substantive votes in addition to quorum and the two-thirds substantive approval threshold.	D1-031; P0 arithmetic cases. This threshold remains a proposal.
RV-10	Some documents lacked editor/source metadata and governance titles introduced unnecessary codes.	Mark responsibility UNASSIGNED and canonical source; use descriptive governance identifiers and existing GR/TC 1 designation.	Source front matter; manifest build IDs.
RV-11	P1 risked deriving absence from a partial packet, implying an unavailable log had been inspected, overstating adjustment evidence as calibration quality, and treating scheduling as completed reassessment.	Preserve source availability, narrower source content, conditional conclusions and pending actions; include pre-submission antecedents in temporal scope.	P1 inventory, evidence table, procedure and summary.
RV-12	Source prose implied a chronological relationship between two Chapter 3 files.	Describe separately supplied variants and retain unresolved chronology.	GR-110 source rationale; Q-08.
RV-13	The initial GR-110 PDF had a long-path overflow.	Use a breakable source path and recompile the revised package.	Build report and PDF inspection.

No finding resolves the Property/Attribute relationship, full metamodel interpretation, universal generativity measurement, legal jurisdiction, rights licence selection or institutional legitimacy.

100.1.3 3. Artifact checks and reproducibility

The machine-generated build report is the authoritative record of compiler outcomes, source/preamble/PDF hashes and detected warnings for the historical 0.1 full build. The check report records source metadata, unique/resolved requirement identifiers, build freshness and extraction of all source requirement IDs from the PDFs. These historical reports were copied before the 0.2 revision. Current build results belong to the expanded review; they do not replace this record.

The archived build guide explains reproduction of this edition. Compilation uses LuaLaTeX through `latexmk` under WSL with shell escape disabled. No external source material or package dependencies are fetched by these scripts.

The checks discriminate lost identifiers, stale PDFs and unresolved references. They do not

prove that every rendered sentence is correct or assess the substantive warrant of a claim. Visual inspection samples title pages, body text and tables; it is not a full accessibility audit.

Completed artifact results (historical 0.1): all nine documents compiled; all 318 requirement identifiers were found in the historical 84-page PDF package; source, preamble and PDF hashes matched; no duplicate/unresolved requirement identifiers, overfull boxes, missing glyphs or detected unresolved LaTeX references remained. Local Markdown links resolved and the project index matched all 87 source/corpus files. These are artifact checks, not a D2-wide conformance determination.

Draft build identifier	Requirements	PDF pages
GSP-Charter	41	9
GSP-Directives-1	58	13
GSP-Directives-2	45	8
GR-TC1-Charter	30	7
GSP-Ethics-IP	40	8
GR-100	12	13
GR-110	34	8
GR-200	26	11
GR-210	32	7

Toolchain recorded by the final build: Python 3.12.3, latexmk 4.83 and LuaHBTeX 1.17.0 (TeX Live 2023/Debian), running in Ubuntu-24.04 under WSL. The machine report supplies exact versions and hashes.

Visual review covered all nine title pages, PDF page 4 of each document, and assessment/source tables on PDF pages 8 (GR-110), 9 (GR-200) and 7 (GR-210). Additional inspection covered GR-100 role definitions on PDF page 8 and the D1 defaults table on PDF page 11. The samples showed readable layout without observed clipping or overlap. Title-word hyphenation and description-list warnings were corrected in the shared preamble; narrow table columns were changed to ragged-right alignment. The affected samples were inspected again after recompilation. One nonblocking underfull-line spacing advisory remains in the Charter; the build report records it separately from errors and LaTeX/package warnings. Final render samples and contact sheets are in `build/review/`; page numbers here count the title page as PDF page 1. No screen-reader, tagged-PDF or affected-user comprehension assessment was performed.

100.1.4 4. Synthetic evidence and remaining work

P0 checks explicit ballot arithmetic and illustrates comment/disposition logic. It does not perform a real public review, election, recusal, appeal or founding agreement. P1 supplies attributed claims and discriminating defects for review; it does not establish that procedural actions occurred, controls worked, users understood the presentation or harm was repaired.

Use the assessment template to record per-requirement evidence in actual rehearsals. No unqualified conformance claim is made for P0, P1, the programme or an institution. Documentary inspection and arithmetic are only parts of a future assessment.

Before governance adoption and technical initiation, remaining work includes actual founding authority, accepted appointments, neutral-review capacity, participation/representation review, selected rights terms and a real governance rehearsal. Before live institutional claims, work includes contextual legal and ethical review, affected-user participation, disclosure/retention authority, resource and burden measurement, observed procedure tests, accessibility/comprehension evaluation, and a decision on bounded conformance profiles.

M1 and later milestones remain open. Compiled drafts are the first reviewable development output, not evidence that the programme's institutional infrastructure is already operating.

101 remote publication 2026 09 22

Original source: `docs/reviews/remote_publication_2026-09-22.md`.
Original source SHA-256: `c9e6ecc3f59c927c9996e764042455a6287f2395c3b797e4e4e31175297de02c`.

101.1 Hosted source publication

Class: Repository operation and verification record
Date: 2026-09-22
Status: All four repositories published; hosted recursive clone and source comparison passed

101.1.1 Authorization and destinations

The user supplied four GitHub SSH destinations and explicitly requested setup and publication of the local commits. Each repository uses its own `origin` and `main` branch. Both `.gitmodules` files now contain hosted SSH URLs. The repository guide gives clone, identity-selection and maintenance commands.

Repository	Destination
Programme	Generativity-Epistemic-Infrastructure
Infrastructure	Generativity-Relational-Epistemic-Applicative-Infrastructure
Generalized application	Generalized-Generativity-Relational-Social-Science-Application
Academia application	Generative-Relational-Academia-Application

101.1.2 Authentication and publication boundary

Windows OpenSSH authenticated as `huangwanhong-maker` using the user-selected `serendip_id_ed25519` identity. The executable and identity selection are configured locally in each repository. Strict host-key verification remains enabled; noninteractive checks use a temporary batch-mode setting. No global Git or SSH settings were changed, and the private key contents were neither displayed nor added to source.

This operation publishes source repositories. Private account databases, native signing keys, project-record repositories, uploaded material, local backups and environments remain outside source control. An independent bounded preflight checked the repository structure, ignored paths and 638 text blob versions for high-confidence credential patterns without finding a match. This is a limited source audit, not a comprehensive secret or security certification.

101.1.3 Existing remote history

The programme, infrastructure and generalized remotes were empty when inspected. Academia already contained `08590a2e73fd92578e5e75639c09b5815002d7b9`, a README-only commit changing its copyright attribution to all contributors. It and the migrated local branch had diverged from the retained earlier source commit.

The remote commit was fetched and merged with both parents preserved. The README conflict was resolved by retaining the current comprehensive MIT guide and explicitly crediting all contributors listed in `CONTRIBUTORS.md`. The historical README snapshot, import manifest and original source-history bundle retained their earlier bytes. No force push or history replacement was used.

Published application revisions are generalized `19341ae30c6a4f69cb97c424a6a34617a6e8e478` and academia `4e577f2b3f38a3b3c3dcd009804b06182ea4b70b`. Infrastructure `a363e39f51f18734badaabb52eb3740f3063714b` pins those exact commits. Each child was published before its parent pointer.

101.1.4 Verification

The initial hosted programme commit is `d2e5b2398005b2434130c9fc3db00592ae24a175`. A subsequent programme documentation commit records these completed checks; application and infrastructure revisions remain as listed above.

Check	Result
Four remote `main` references	Match the corresponding published local commits
Upstream configuration	Each local `main` tracks its own `origin/main`
Parent/child commit pointers	Programme pins infrastructure; infrastructure pins both published applications
Hosted recursive clone	GitHub supplied all four repositories and all three submodule checkouts
Source comparison	All 372 tracked files in the hosted clone matched the local source bytes
Private runtime	Absent from the hosted clone
Structural checker	Passed in the source workspace and the fresh hosted clone
Academia remote ancestry	Existing remote commit retained through an ordinary merge and non-force push
Frozen academia source evidence	Historical README snapshot, import manifest and original bundle unchanged
Active documentation links	Current local guide targets resolve

The byte comparison used Windows extended file paths for the longest PDF filenames under the disposable clone directory; no machine-wide long-path setting was changed. Detailed command results remain in ignored `build/git-publication/`. The verification clone contains source only and is not a backup of application accounts or user records.

This publication does not adopt a Standard, change application record semantics, resolve the existing dependency advisories or complete cross-application protocol alignment.

102 spacetime projection 2026 09 22

Original source: `docs/reviews/spacetime_projection_2026-09-22.md`.
Original source SHA-256: `55dbe8f5fab113db645daa7ae08a63cc8927351c2cf7b8394f58b2b420a3381c`.

102.1 Event-defined spacetime implementation review

Class: Informative implementation verification record
Status: EXPERIMENTAL; implementation checks on 2026-09-22; preview verification completed 2026-09-27

102.1.1 Scope

This review concerns the additive GR-SPEC-121 implementation selected in ADR-0011: the common Python protocol package, generalized HTTP binding and interface, and the native file chooser styling. It does not adopt a Standard, certify factual warrant, or establish cross-application interoperability. Academia source and native GRRP semantics are unchanged.

The package distribution advances to `gsp-record-protocol` 0.3.0. Its base protocol, schema and profile identifiers remain at 0.2; supported temporal modules and the projection have their own version identifiers. Earlier clients preserve these required modules and refuse unsupported mutations.

102.1.2 Observed automated checks

Check	Observed result and boundary
Combined common protocol, real-Git storage and application API suite	178 passed; five browser tests present at that point were skipped because the browser flag was unset. Isolated runtime; 182.42 seconds.
Shared protocol suite	100 passed, including 47 temporal cases. Covers reverse recording order, incomparable events, predecessor closure, self/multiple cycles, withdrawal, qualifications, unknown/unbounded/unscoped extents, invalid bounds, subject grouping, partial incidence and unsupported module versions.
Bounded scale and cycle review	A 1,000-record, 500-event chain verifies iterative traversal and complete predecessor closure. An independent reachability oracle agreed with cycle component detection for 500 deterministic generated graphs. This is a bounded check, not a throughput benchmark.
New authenticated API tests	Six passed against real isolated Git repositories. Covers cut purity, historical labels/order, retained contradictions and withdrawal, uncertainty, ownership, CSRF, unreachable revisions, ambiguous/excessive JSON and legacy reads without migration. Included in the combined total.
Browser checks	Seven browser tests passed across focused runs: three temporal workflows, three existing application/graph workflows and one topology-layout regression. The temporal workflow run passed in 95.08 seconds. An existing graph journey exceeded its five-second assertion while other browser tests ran; a bounded 20-second assertion allowance and isolated rerun passed in 28.82 seconds. On 2026-09-27 the layout regression and affected temporal workflow passed together in 52.71 seconds. No application assertion was removed.

Check	Observed result and boundary
Script/dependency checks	`node --check` passed for app.js, graph.js and spacetime.js; `pip check` found no broken requirements after the editable package upgrade.
Existing publication dossier	`tools/check_validation_package.py` passed its fixed-baseline identifier/status checks and all 18 arithmetic cases. Historical TeX editions were not changed.

The existing application/API tests retain their scope; passing these cases is not a general security audit. Browser checks use authored accounts and isolated temporary Git repositories. They do not exercise the user's research records.

Together, the completed checks account for **185 passing tests**: 178 non-browser tests and seven browser tests. These were separate runs, not one combined command. The selected-file draft and topology-layout regressions were added after the non-browser run.

102.1.3 Findings addressed during review

- The ordinary unstyled native file button now uses the application palette, a visible focus state and a bounded responsive control. Selection remains a native file input.
- Temporal order is carried by explicit Relation modules. Descriptive dates, Git timestamps, UUID sorting and display columns do not add precedence. An event saved later can occupy an earlier asserted position.
- Contradictory orders remain retained and inspectable. Unsupported ordering versions also prevent a purported complete cut, while unsupported extents keep affected presence indeterminate.
- Active Relation accounts retain their identity when some participants lack active scope. The topology omits those incidences and exposes a partial-relation diagnostic.
- Browser integration exposed a save/refresh race: a closed module dialog could allow a second edit against the previous head. Dialog completion now waits for the accepted snapshot refresh.
- Review required an explicit modality choice for ordering claims, preservation of unseen relation qualifications on revision/rebase, retention of a failed cut selection on retry, and file-aware unsaved-form comparison.
- Final visual review confirmed node overlap in disconnected and mixed-component topology layouts. Edgeless views now use a deterministic grid; connected views retain the force layout when its node boxes are separate and fall back to the grid when needed. All edges are retained. Browser assertions check desktop/mobile separation and a connected pair alongside an isolated node.

102.1.4 Evidence and remaining limits

Ignored local screenshots are under `build/webapp-review/`, including the file picker and desktop/mobile spacetime views. They document the authored test scenario, not a deployed institutional workflow. Tests and reproduction commands are in application TESTING.md and common verification.

On 2026-09-27 the local generalized preview was started on port 8000. Its public capability endpoint returned `gsp.spacetime/1` and both temporal module versions; its page included the temporal interface script. The two existing generalized project heads matched the private pre-refresh capture. No demonstration records or automatic migration were added to those projects. This verification preceded the separately authorized source publication; its findings concern implementation behavior, independently of the later source commits.

The view evaluates retained applicability assertions. It does not execute events to infer later target states, decide between competing chronologies, model extended-event overlap, or prove that two accounts describe the same continuing entity. Unscoped records stay separate from active topology. Event ranks and consistent cuts do not establish physical simultaneity or elapsed duration. These limits and further assessment needs remain in Q-45–48.

Assistive-technology evaluation, measured participant comprehension, scenario-specific interpretation selection and independent implementation interoperability remain OPEN. The

successful bounded tests supply implementation evidence only.

103 README

Original source: `docs/reviews/validation_0.2/README.md`.
Original source SHA-256: `e8d72f9e2bdb9e1b5608b45612bd411d7977813ee81b730c20cf3aab85def9c7`.

103.1 Substantive validation of Working Draft 0.2

Class: Informative review, fixture-assessment and revision record
Status: PREPARATORY; 2026-09-22
Fixed baseline: Archived Working Draft package 0.2
Resulting publication: Coordinated Working Draft 0.3

103.1.1 1. Result and limits

The cycle examined all **753 baseline requirement identifiers through 116 topical review groups**, produced new P0/v2 and P1/v2 fixtures, and identified five supported drafting corrections or clarifications. The current edition advances to 0.3 with **754 identifiers**, including one new conditional requirement concerning recirculation accounts. No publication, governance instrument or institution was adopted or certified by this work.

Editorial review, component assessment, arithmetic execution and institutional readiness are separate evidence categories. The review groups document what was read and compared; they do not mean 753 independent conformance tests passed. The source review is AI-assisted interpretation, not author approval of every operational narrowing or independent stakeholder validation.

The requirement review matrix gives each baseline ID its exact archived source, hash, requirement text, review groups, findings and available P1 results. The 0.2 to 0.3 change register records actual requirement text changes. The matrix continues to describe 0.2; it is not silently relabelled as an assessment of 0.3.

103.1.2 2. Review streams

Stream	Baseline coverage	Evidence and review record
Governance	462 requirements; 58 groups	Review, group register, P0/v2
Conceptual fidelity and generativity recording	137 requirements; 35 groups	Review, group register, actual manuscript passages and source-to-operational distinctions
Epistemic recording and contestation	154 requirements; 23 groups	Review, group register, P1/v2 and assessment register

The conceptual review covers recognition, mediated evidence, metamodel/record distinctions, identity, generative attribution, alternatives, possibility fields, maintenance/loss, recirculation and revision. It preserves the unresolved Property/Attribute relationship, manuscript precedence, formal emergence limits and the broader interpretation of generativity return. Exact manuscript passages and operational narrowings are recorded in that review.

103.1.3 3. Findings and revision dispositions

Finding	Disposition in 0.3	Verification and remaining limit
GOV-F01: invalid/unresolved attempted ballots disappear into nonresponse	D1-032/074 and the ballot dossier distinguish valid returns, attributable unsuccessful attempts and no attributable submission; separate unattributable/ineligible messages	Count partition and replacement cases preserve the original thresholds. Actual identity, validity review and participation remain untested

Finding	Disposition in 0.3	Verification and remaining limit
CF-01: absence of a mapping can incorrectly exempt a general safeguard	GR-100 Annex A separates the general V100-011 distinction from its conditional mapping component	A no-mapping example still receives the general check
CF-02: disputed attribution is mixed into occurrence/modality	R110-012 explicitly separates occurrence/modality, epistemic basis and assessment/dispute disposition	Realized effect, retrospective inference and disputed attribution can coexist without forced selection of one status
CF-03: generic return recording can conceal uncertainty in recirculation links	New R110-112 and the semantic/assessment schedules distinguish initial generation, conversion/transfer, return path and later-condition effect	Applies only when recirculation is asserted. Unknown links remain unresolved; no universal measure, entitlement or complete theoretical definition is introduced
EP-01: GR-210 can accidentally import blanket GR-100 conformity	Clause 2 identifies the incorporated terms, role meanings and result meanings, preserving the complete applicable GR-200 package obligation	No claim-only shortcut and no unstated vocabulary-certification requirement

The revision regression cases make the corrected distinctions inspectable. Their outcomes are authored-text comparisons; they are not live process tests. ADR-0006 records the alternatives, rationale and scope of the new operational requirement.

Of the 753 old requirement texts, 748 remain unchanged after whitespace normalization, three are revised, and two change only the GR-200 dependency edition. One new identifier is added. The GR-100 assessment-row and GR-210 dependency-prose corrections are substantive clarifications outside the requirement macros and therefore appear in this disposition table rather than as changed requirement text in the CSV.

103.1.4 4. What the rehearsals establish

103.1.5 P0: numerical results and procedure design

The checker executed **18 authored count cases: 13 valid-count states and five malformed inputs**. All matched the independently authored expected results. Cases include quorum failure, insufficient substantive participation, approval boundaries, all abstentions, zero/small rosters, hypothetical recusal and invalid count types/totals. An invalid input is distinguished from a valid numerical defeat. These results do not prove participant eligibility, consensus, proper notice, fair review or an adoption decision.

The expanded narrative includes founding readiness, comment/reply/re-review, ballot replacement, recusal, unavailable appeal capacity, ethics reconsideration, source rights, release and maintenance. Its timelines are synthetic. The cycle did not conduct public review, appoint reviewers or wait through institutional deadlines.

103.1.6 P1: documentary results and unperformed practice

The register contains **208 assessment rows**, explicitly divided into 54 selected components and 154 whole-requirement coverage results:

Assessment level	Fulfilled	Not fulfilled	Not assessed	Not applicable
Selected documentary components	53	0	1	0
Whole GR-200/210 requirements in the declared fixture scope	0	0	152	2

QA-01 corrected an initial failure classification under C210-094. P1 contains a proposed retention arrangement, not an identified operative retention/disposal decision; the assessor had inferred the trigger and incorrectly required a fixed period where an event-based timing rule can suffice. Both the component and whole-requirement results are now not assessed with unresolved applicability. The original classification and rationale for correction remain traceable in EP-03 and the fixture. The two inapplicability results concern absent comparison/reproducibility claim triggers under E200-035/041. The fulfilled components establish that identified information or distinctions are present in supplied text, not that fictional events occurred.

P1 now gives explicit scope, source dependence, claim and issue tracks, service periods, attributed grounds, a notice specimen, view limits, action ownership and failure branches. The original application, original log, instrument identity, notification receipts, actual review, funding outcome and effective repair remain unavailable or unperformed. The unresolved retention arrangement remains visible; no operative decision, authority or fixed period is invented to manufacture either a failure or a pass.

No entire GR-200 or GR-210 requirement receives a fulfilled result in this register. GR-100/110 source interpretation is covered separately; the P1 register does not assert full assessment of those documents. The new 0.3 recirculation requirement has a discriminating example and source review, but is not retroactively inserted into the 0.2 assessment totals.

103.1.7 5. Reproducibility and artifact checks

Run from the repository root:

```
python tools/check_validation_package.py
python tools/compare_publication_requirements.py --baseline 0.2
python tools/build_publications.py --wsl Ubuntu-24.04
python tools/check_publications.py
```

The validation checker verifies baseline hashes, coverage membership, identifiers, assessment levels/results, fixture locators and numerical expectations. It writes a generated report and the requirement matrix. The report records the Python version and SHA-256 hashes of the checker, requirement extractor, registers, fixtures and baseline manifest. It does not automatically judge source fidelity, factual warrant or institutional performance. The authored reviews and assessments remain the evidence for those bounded judgments.

Publication builds and source/PDF checks are recorded in the build report and publication check report. Generated files are ignored and need reproduction in a fresh checkout. Historical 0.2 results are preserved separately under `build/archive/0.2/`.

All nine 0.3 PDFs compiled successfully: **226 pages and 754 requirement identifiers**. The publication checker passed with current source, preamble and PDF hashes, retained historical identifiers and intact archives. There were no reported review warnings; GR-100 retains one nonblocking underfull-line spacing advisory. Visual inspection covered 24 rendered pages: the nine covers, nine foreword pages, the revised ballot clause, the GR-100 assessment schedule, three GR-110 return/semantic-schedule pages and the GR-210 dependency clause. No clipping or overlap was observed in those samples. The render plan and images are local generated artifacts under `build/review/v03/`; this sampling does not establish complete rendering or accessibility conformance.

103.1.8 6. Readiness and the next evidence

The readiness and burden record distinguishes available preparation evidence from the actual authority, accepted responsibilities, independent competence, representation, rights and observed practice still needed. No elapsed participant effort, cost, fairness or accessibility measurements are invented.

Reply/ballot overlap and calendar-day boundary conventions remain governance choices requiring explicit treatment before use. Practical burden and proportionate profiles need observed tasks. A future GR-150 draft can use these findings to separate package, practice and procedure claims and state trigger rules, inherited obligations, permitted exclusions and evidence requirements. There is no reduced profile or automatic launch approval in this cycle.

104 conceptual review

Original source: `docs/reviews/validation_0.2/conceptual_review.md`.
Original source SHA-256: `d6087aaaf653718dcb33232dedff6a4bece6b5541609aac254dc0b433d2cb336`.

104.1 Conceptual-fidelity review of GR-100 and GR-110, Working Draft 0.2

Document class: Informative review record
Status: PROVISIONAL; editorial source comparison, not programme adoption or a conformance assessment
Review date: 2026-09-22
Reviewer: AI-assisted documentary review; no independent manuscript-author confirmation obtained
Baseline: Archived GR-100 0.2 and archived GR-110 0.2

104.1.1 1. Review question and result

This review asks whether the operational proposals preserve the distinctions they draw from the foundation manuscripts, where they deliberately narrow the theory, and where their drafting or assessment instructions can lose those distinctions. It examined all **26 GR-100 requirement identifiers and 111 GR-110 identifiers**, their surrounding definitions, and their normative assessment schedules. The machine-readable group register assigns every identifier to exactly one review group. A group's `reviewed` status means that its text was examined; it does not mean that an implementation fulfilled the requirement, that a historical claim is true, or that the author endorses the interpretation.

The central architecture is consistent with the inspected passages: record existence is distinct from factual warrant; relational reality can precede recognition; representations can change later relations; contribution is more demanding than association; historical continuity differs from a chain of contributions; and descriptive generation has no automatic favorable normative sign. The text preserves these distinctions substantially better than a provenance-only or output-only account would.

Three local improvements are proposed. **CF-01** repairs an assessment instruction that can exempt a general safeguard. **CF-02** separates an ambiguous modality example from a claim's assessment disposition. **CF-03** makes the conditional interpretation of a recirculation claim explicit in the return requirements. CF-03 is a precision improvement rather than evidence that version 0.2 contradicts the theory: its general linkage requirements already supply part of the needed discipline. No finding licenses a universal measure of generativity, a compulsory causal method, or a complete ontology.

Source fidelity remains only one part of validation. The number of required declarations, actual recording effort, review competence, comprehension, protected access, and operational correction still need case evidence. Their presence in a well-written clause does not demonstrate a working institution.

104.1.2 2. Sources and limits of examination

Page references below are **one-based PDF pages in the supplied files**, not newly assigned edition dates. Titles, filenames, and source status are indexed in the foundation manifest. The review read the passages themselves through PDF text extraction. Mathematical symbols affected by extraction were not used to certify a proof. The review does not independently verify the external works cited inside those manuscripts.

Source	Passages directly examined for this review	Purpose
FM-001, `GRE_Chapter_01.pdf`	§1.14, pp. 78–83	Symbolic abundance, referential instability, classification effects, provenance and practical trust.

Source	Passages directly examined for this review	Purpose
FM-003, `GRE_Chapter_03.pdf`	§3.12, pp. 129–141; the opening of §3.13, p. 141	Iterative praxis, allocation, downstream effects, feedback, withdrawal, reversal and repair; descriptive/evaluative separation.
FM-004, `GRE_Chapter_04.pdf`	§4.2, pp. 11–19	Reality registers, pre-recognition reality, manifestation, recursive effects, non-necessary comparability.
FM-005, `GRE_Chapter_05_Complete_First_Draft.pdf`	§5.4, pp. 28–29, 32, 34; §§5.13–5.14, pp. 105–122; §5.17, pp. 145–150; §§5.19–5.20, pp. 168, 170, 173–174	Claim-relative evidence, generative attribution, carriers, trajectories, possibilities, uncertainty, return pathways, and revision.
FM-006, Part I metamodel	§§3–4, pp. 5–6; §§6–8, pp. 10–11	Weak formal state/mechanism notions, fixed-carrier limits, and limits on normative readings of collapse.
FM-007, Part II metamodel	p. 2; §§7–8, pp. 26–27, 32–33; §9, pp. 39–41, 43; §10, pp. 43–50; §11, pp. 52–54; §12, pp. 56–57, 60; §§16–17, pp. 76–80	Overlapping roles, identity, incidence, event multiplicity, attributes, state sufficiency, history, classification uptake, and regime change.

These selections support the comparisons below. They are not a fresh complete collation of all seven manuscripts. In particular, FM-002 and FM-003 have not been assigned an editorial precedence, and their full differences have not been resolved by this review.

104.1.3 3. Source-to-operational-requirement matrix

The **source position** column reports the inspected manuscript. The **operational translation** column identifies the programme's drafting choice. Normative metadata duties are new programme proposals, even where their rationale is strongly source-grounded.

Topic and source position	Operational translation in 0.2	What is narrowed, qualified, or left open	Review result and discriminating case
Symbolic crisis. FM-001 §1.14.2–5, pp. 79–83 distinguishes fabricated representations from sincere but outdated categories; authentication, trust, and substantive adequacy differ; correction can arrive after consequential action.	V100-002–004/012/017; R110-003/019/029–030/074/081 distinguish record, warrant, institutional uptake, and later repair.	The draft standardizes inspectability and recording duties. It does not standardize trust, certify a referent, or imply a universal collapse of representation.	Reviewed. An authentic AI-assisted summary can contain an unwarranted inference and still cause a real funding decision. Correcting the summary does not prove restoration of funding or capacity.
Reality and recognition. FM-004 §4.2.2–5, pp. 13–19 allows relational efficacy before recognition and allows a later manifestation to alter the system. Registers are different questions, not stages or exclusive bins.	V100-002/007/012; R110-016/019/050/067–068/074 retain target, access, description, and practical effect separately.	GR-100's operational Manifestation definition selects recording-relevant availability. No philosophical-register field is mandatory; a record role does not confer reality.	Reviewed. A category can reveal an older relation and separately change its future treatment. Record both claims and their distinct grounds.

Topic and source position	Operational translation in 0.2	What is narrowed, qualified, or left open	Review result and discriminating case
Trace and evidence. FM-005 §5.4, pp. 28–29, defines evidence through its inferential role relative to a target; a transcript can support an utterance more strongly than a durable intention.	V100-003/004/017; R110-042–047/051 preserve origin, transformation, claim-relative grounds, and the bounded GR-200 dependency.	The operational Trace definition admits a proposed trace connection whose warrant remains disputed. This broadens recordability relative to a reading requiring the source connection already to be established. It does not redefine every record as evidence.	Reviewed. One log can evidence that a value was entered while remaining insufficient evidence that the represented calibration occurred. Multiple copied reports are not independent corroboration.
Generative attribution. FM-005 §5.13, pp. 105–113, especially Definition 5.93 and Proposition 5.103, treats attribution as a warranted, target-relative claim with plural methods and graded support.	R110-010–014/051–056 records proposed contributions, mechanisms, alternatives, configuration and uncertainty. V100-008 separates attribution from evaluation.	`Generative account` is deliberately more permissive than manuscript `Generative attribution`: a contested or weak account can be recorded without becoming warranted attribution. Completion of a record is distinct from evidential adequacy.	Reviewed, with CF-02 for the status wording. A strongly supported occurrence and weak contributor linkage remain two differently supported claims.
Carriers and delayed contribution. FM-005 §5.13.6–7, pp. 110–112, distinguishes temporal distance, a persisting/transformed carrier, branch opening, selection, and stabilization.	R110-057–059/061 requires carrier accounts, link-specific support and limits of useful attribution. R110-013/062 preserves distributed contribution without compulsory credit allocation.	No new carrier ontology class or mandatory percentage allocation is introduced. A long chain can retain conjectural links rather than receiving one uniform confidence value.	Reviewed. Maintenance can sustain capacity later used by a different contributor; the earlier maintenance does not acquire the whole discovery's attribution.
Relational versus generative trajectory. FM-005 §5.14.1–2, pp. 114–116, distinguishes continuity of a relation under a criterion from a chain in which earlier contributions change later conditions.	V100-005/006/022; R110-006–009/048–050/057–060 distinguish identity, lineage, ordering, carriers, and path dependence.	The broad operational `Trajectory` term is an umbrella for bounded accounts. It is not asserted to be synonymous with either manuscript-defined trajectory. No total temporal order is mandatory.	Reviewed. A training relation can end while an acquired skill contributes later; a continuous filename cannot establish a continuous social relation.
Alternatives and possibility field. FM-005 §5.13.7 and §5.14.4/6, pp. 111–112, 117–118, 120, distinguishes a path becoming feasible, realization, and historically grounded alternatives from retrospective imagination.	R110-015/061/063–066 records whose options, conditions, horizon, practical access, comparative meaning and non-exhaustiveness.	`Possibility-field account` is a bounded representation, not the complete theoretical possibility field. No enumerated tree, probability distribution, or forced common metric is required.	Reviewed. A proposed option that was unavailable under historical resources stays distinct from an available but unchosen option; permission alone does not establish practical access.
Revision and re-epistemization. FM-005 §5.14.7, pp. 121–122, and §5.20.2/5–6, pp. 170, 173–174, distinguishes new evidence, category change, target change, and reflexive observation.	V100-007/015/018; R110-016/020–022/050/067–068/079/082–083/105 retains versions, semantic mapping and propagation limits.	The three-history organization is operational scaffolding; several kinds of change can coincide. It does not claim that changing a label produces a new past object or that every later reading is equally plausible.	Reviewed. New evidence can correct a past assertion while a new eligibility rule changes future access. Reflexive-observation temporal segmentation remains a useful additional pilot question.

Topic and source position	Operational translation in 0.2	What is narrowed, qualified, or left open	Review result and discriminating case
Praxis and consequences. FM-003 §3.12, especially pp. 130–133 and 137–141, treats diagnosis/intervention/feedback as iterative, distinguishes implementation from effects, and separates withdrawal, reversal and repair.	R110-019/074–081 identifies reliance, authority, intended transformation, follow-up, feedback, actual action and residual consequences.	Recording obligations apply when the account or practice includes the relevant activity. An archive does not acquire authority to operate a programme, and the heuristic praxis sequence is not made a universal protocol.	Reviewed. A delivered correction notice, a changed administrative decision, and restored practical opportunity require separate evidence. Unobserved follow-up receives an explicit limitation.
Maintenance, loss and value. FM-003 pp. 130, 133–134, 140–141 and FM-007 §16.7, pp. 77–78, distinguish maintained capacity, descriptive generation and appraisal. FM-005 p. 116 allows a short-run capacity to become long-run dependence.	V100-008/012; R110-017/069–072 records sustaining work, several forms of loss, affected positions, horizon, values and disagreement.	No value ranking is inferred from novelty or formal preservation. Record loss is not identical to destroyed real-world capacity; capacity expansion for one party can coincide with another party's foreclosure.	Reviewed. A quiet year of maintenance can be generatively relevant, and aggregate expansion can coexist with reduced access for an excluded participant.
Generativity return and recirculation. FM-005 §5.17.3, p. 145, distinguishes initial generation, conversion/transfer, return path, and effects of returned value on future generative conditions. Each contributes uncertainty.	GR-100's provisional `Generativity return` topic; R110-018/073 separates asserted concept, recipients, evaluation, quantity, transfer, response and entitlement. R110-058 separately protects link-specific uncertainty.	The programme term is not yet established as equivalent to manuscript `recirculation`. Its presence does not establish a universal return measure or distribution entitlement.	CF-03: clarify the four links conditionally when recirculation or return to future generative conditions is claimed. A promised grant, an observed payment, and an evidenced sustained capacity are different claims.
Metamodel versus record roles. FM-006 pp. 5–6 defines weak states and mechanisms; pp. 10–11 limits the fixed carrier. FM-007 p. 2 makes the six roles selected and overlapping; §§7–12 add identity, incidence, occurrence and history.	V100-009–011/018/021/025; R110-009/048 retains semantic roles, referenceable Relations, criteria, and information losses.	No one-to-one mapping from the carrier to record State, mechanism to Process, or formal action to Event is presumed. Property/Attribute remains unresolved.	CF-01 concerns the assessment row, not the body safeguard. An agreement can be a Relation and an Entity while its negotiation is a Process; these do not create six substances.
Definedness, scale, and sufficiency. FM-007 §§10.4–10, pp. 45–50, and §11, pp. 52–54, separates unknown/inapplicable, numerical codes/meaningful arithmetic, current-report accuracy/predictive sufficiency/history.	V100-019–021/025; R110-026/043/066/070/086/088/090/108 retains missingness reasons, domain/scale, scope and migration loss.	Semantic safeguards are adopted as recording proposals without importing a complete partial-map or quotient construction. `Unknown` remains an epistemic declaration, not an imposed third truth value.	Reviewed. Converting unknown, zero and withheld to one empty cell loses meaning. A correct current flag can still omit a history needed by a later query.

104.1.4 4. Findings and proposed dispositions

104.1.5 CF-01 — Assessment instruction can waive part of V100-011

Location: GR-100 V100-011; normative Annex A, Table A.1, V100-011 row.
Type: Assessment applicability ambiguity; priority: fix before relying on a complete vocabulary assessment.

The body first requires the application to distinguish operational record roles from metamodel concepts. Its second sentence conditions particular identifications on an explicit scoped mapping and argument. The assessment row says that absence of a mapping makes the conditional check not applicable. A reader can interpret that as making the whole requirement inapplicable, even when an application describes record roles and implicitly confuses them with formal primitives.

Proposed disposition: Retain V100-011. Rewrite the assessment row to check the general separation safeguard in the declared application, then assess the mapping-and-argument component only where a mapping or identification is made. A declared absence of mappings can support non-applicability of that component, but cannot exempt an implicit identification found elsewhere. This follows the component-result rule V100-026.

Alternative: Make V100-011 itself entirely conditional. That would weaken the general architectural safeguard and is not recommended.

Discriminating check: An application labels a semigroup mechanism as Process without a mapping document. The assessor finds an implicit identification requiring an argument; absence of the document is not an absent trigger. An application that makes no formal identification still receives review of the general separation component, with only the mapping-specific component excluded.

104.1.6 CF-02 — R110-012 mixes a dispute label into modality examples

Location: GR-110 R110-012; compare GR-100 V100-016 and R110-051.
Type: Terminological ambiguity; priority: local clarification.

R110-012 lists `disputed` alongside realized, intended, possible and unrealized effects. A dispute can concern whether an effect occurred, who contributed, or whether it was beneficial. Its location in the modality list can encourage one status value to carry actuality, knowledge mode and assessment disposition. GR-100 V100-016 expressly separates these three dimensions. FM-005 §5.17.3 p. 145 additionally distinguishes warrant for the relation, target change and connecting attribution.

Proposed disposition: Retain the identifier and its existing purpose. Name actuality/modality, epistemic mode, and assessment disposition separately. Use `unresolved actuality` where the occurrence question itself is unresolved, or qualify the dispute's target. Keep the example that an actual past effect can be retrospectively inferred. Do not make a disputed attribution change a supported occurrence to hypothetical.

Alternative: Retain `disputed` but add an explanatory note that identifies exactly which claim is contested. This is weaker because the normative clause would continue to place an assessment expression among modality examples.

Discriminating check: A maintenance activity is documented; whether it materially enabled a later discovery is contested. The record preserves an actual activity, a retrospectively inferred contribution, and an unresolved attribution assessment without forcing them into one status.

104.1.7 CF-03 — Make recirculation links explicit only when that return claim is made

Location: GR-100 provisional Generativity return definition and source note; GR-110 R110-018/058/073, semantic and assessment schedules.
Type: Conditional recording precision; priority: develop in the next draft without settling the broader return concept.

R110-018/073 correctly avoids inventing a quantity or entitlement. It does not explicitly tell the reader how to distinguish a transfer from its contribution to regenerated conditions. The broader linkage clauses can cover that problem, but their application to a return account is indirect. FM-005 §5.17.3 p. 145 identifies the separate uncertainty in generation, conversion/transfer, return and subsequent effects. An improvement should expose this structure while preserving the open relationship between `generativity return` and `recirculation`.

Proposed disposition: Add a conditional requirement or extend R110-073: where a return account claims recirculation or alteration of future generative conditions, identify those asserted links, relevant subjects/recipients, boundary, horizon, grounds, and link-specific uncertainty, or state that a link is proposed, unobserved, unavailable or unassessed. Cross-reference R110-058. State that completed transfer alone does not establish restored or ex-

panded generative capacity. Add the same discriminating check to the return assessment row and semantic schedule.

Alternatives: Keep only the general linkage clauses and clarify their application informatively; or impose a universal return formula. The first remains possible if pilots show the direct clause unnecessary. The second is unsupported by the reviewed sources and would close an unresolved theoretical and normative question.

Discriminating check: An institution proposes training support following a disputed decision. This is a proposal, not an observed transfer, a legally established entitlement, or evidence of changed future capacity. A later receipt can establish only the transfer claim unless further evidence supports the remaining links.

104.1.8 5. Tensions deliberately preserved

1. **Property and Attribute — OPEN.** FM-007 §10 treats Attribute through a declared domain, interpretation, scale and definedness. GR-100 retains Property as a provisional operational role and expressly denies an established equivalence. Its minimum metadata, numerical-scale rule and missingness rule preserve many relevant distinctions; they do not settle whether the concepts coincide. A future ADR needs comparative examples for a qualitative classification, a partial value, disputed assignment, and a value whose subject changes across descriptive levels.

2. **Fixed carrier, declared regimes, and emergence — OPEN.** FM-006 pp. 10–11 acknowledges that its fixed carrier and congruence do not generate new states or distinctions. FM-007 §17.1–2, pp. 78–80, models transitions within declared regimes and expressly leaves genuinely unrepresented vocabulary development to further work. R110-066 can record changing distinctions without claiming that these formalisms exhaust emergence. Category counts, graph size, and formal collapse are consequently not universal measures of generativity.

3. **Preservation and normativity — OPEN.** FM-006 pp. 10–11 places normative weight on the chosen congruence while acknowledging that not every collapse is wrong. FM-007 §16.7, pp. 77–78, separates formal preservation from reasons to value a distinction. The standards retain explicit evaluations, access limits and justified loss; they do not silently rewrite the earlier formulation or claim that mathematical preservation proves justice.

4. **The two Chapter 3 files — OPEN.** The manifest records a verified eight/nine problem-family difference and unresolved chronology. This review uses FM-003's specified praxis passages. It does not declare FM-003 final, replace FM-002, or claim that the two files have been fully collated.

5. **Return terminology and distribution — OPEN.** The recording topic can hold proposals and disputed accounts. Its relationship to manuscript recirculation, any assessment of beneficial return, recipients' claims, and legally effective allocation remain separate decisions. CF-03 does not resolve those matters.

6. **Proportionality and practical value — OPEN.** Source support for a distinction does not prove that every proposed declaration is necessary at every scale. R110-035–037 allows bounded purposes and acknowledges unmet work; it does not yet establish a lighter conformance profile. Measure actual authoring/review effort and losses before selecting GR-150 profiles.

104.1.9 6. Implications for the P0/P1 exercises

These are review tasks, not reports that institutional actions occurred. Their actual execution and component results belong in the separate pilot assessment records.

The P1 version 2 fixture now supplies stable documentary locators: claims, claim-relative evidence, and revision/action records. `GEN/v2` distinguishes practical access and the retrospectively imagined alternative; `AC6` and the following return statement preserve the absence of an established return chain. These passages were inspected as authored case representations, not as independently established events.

Task	Requirements principally tested	Observable discriminator	Limit to retain
Read the original and revised claim with its evidence	V100-002–004/016/017; R110-005/012/046/047/051	Reader distinguishes a recorded statement, an occurrence claim, a contribution claim, and their different grounds/statuses.	Reading authored fiction cannot authenticate a missing original log or establish a real occurrence.
Reconstruct a historical alternative	R110-015/063–066	Actor-period evidence distinguishes a contemporaneously available option from a later analyst's imagined option; practical access remains separate.	No evidence of an option is not proof that every alternative was absent.
Follow correction into consequences	R110-019/074/077–083	Receipt, reliance, revised judgment, implemented action, and repair have distinct locators or explicit unassessed status.	A pending funding outcome and unverified external spreadsheet correction remain pending/unverified.
Examine a return proposal	R110-018/058/073; proposed CF-03	Proposed support, completed transfer and altered future capacity remain distinct; each asserted link has grounds or its own uncertainty.	The current P1 has no verified return pathway. Recording that limitation does not assess substantive return.
Apply a role and assess its criteria	V100-009–011/025/026; R110-009	Stable structural references remain supplied, uncertain contextual values remain typed, and unmet criteria do not receive fulfillment.	A usable role description is not proof of subject identity; review of the V100-011 general safeguard is not waived.
Re-read after classification change	V100-007/015/018; R110-016/050/067/068/105	Old categories and grounds remain inspectable; correction, new knowledge and rule change are separately located.	A revised account does not give earlier actors later knowledge or establish that practical harm was repaired.

The immediate revision can address CF-01–03 without resolving the open theoretical questions. Subsequent pilots need cases beyond P1: maintenance with delayed effects; conflicting identity criteria after organizational succession; and historical reconstruction with severe preservation gaps. Those cases test whether the present distinctions survive use and whether the required recording effort is proportionate.

105 epistemic review

Original source: `docs/reviews/validation_0.2/epistemic_review.md`.
Original source SHA-256: `4d7f6f4753f6ece719fcb78629b77d575593f7d434f0ff05a5f7a2e97afb06d8`.

105.1 GR-200/210: substantive review and P1 documentary validation

Publication class: Informative review report
Status: PROVISIONAL; author review, 2026-09-22
Baseline: GR-200 WD 0.2 and GR-210 WD 0.2.
Reviewer: Codex assistant performing the repository task; author of the revised P1 fixture, not an independent assessor.
Artifacts: Exact-ID review groups, P1/v2 dossier, P1 component results.

105.1.1 1. Scope and method

This review examines all **49 GR-200 requirements and 105 GR-210 requirements** by bounded topical groups. Every requirement ID occurs in exactly one review group. Group status `reviewed` means its text was compared with the declared conceptual basis and related clauses; it does not mean the requirement was fulfilled by a practice or validated across domains. `finding` identifies a concrete drafting or fixture issue, and `open` identifies a question needing further evidence or a decision.

The work comprised direct reading of both drafts, their normative annexes, the original P1 example, GR-100/110 scope and dated-dependency clauses, and relevant actual foundation PDF passages. P1/v2 was authored to make the existing case's distinctions inspectable, then compared manually with selected components of the requirements. Whole-package and whole-procedure fulfillment was not assessed. There was no actual institutional reviewer, participant, exchange, hearing, signature test, access-control test, timing exercise or outcome observation. No public-policy or legal compatibility determination was made.

The supplied foundation passages were read from FM-005, one-based PDF pp. 28–29, 145, 150–151, 161–162, 169–170 and 172–173. This is focused source review of the relevant distinctions, not a new complete manuscript collation or verification of the manuscript's external citations. The foundation manifest preserves version uncertainty and source differences.

105.1.2 2. Conceptual fidelity

Source distinction actually consulted	Draft treatment and bounded conclusion	P1 discriminator
FM-005 §5.4, Definitions 5.25/ 5.26 and Claim 5.27, pp. 28–29: a trace is not evidence independent of a target and an articulated inferential role.	E200-010/011/012/032/033 and C210-013/014/059/060/061 preserve material, assignment, assessor and grounds. The recording obligations are operational proposals; the source supplies no universal numerical reliability test.	M1 has an extract-content role but cannot establish complete application contents or non-calibration. L1's adjustment report differs from proof of adequate calibration.
FM-005 §5.17.3, Proposition 5.132, p. 145: support for a relation and outcome does not establish the generative linkage; recirculation inherits uncertainty at successive links.	E200-014/028/031/035/039 and C210-063/064 support separate contribution questions. GR-110's fuller return-path scope is reviewed by the companion conceptual review; P1 supplies no completed return chain.	C7a report, C7b causal attribution and C7c prospective risk remain separately examinable. AC6 is proposed support, not observed transfer or return.
FM-005 §5.17, Proposition 5.138, p. 150: confidence is proposition-relative and qualified across several dimensions.	E200-014/035/036 and C210-016/062/067 do not require probability or collapse incompatible judgments. This supports qualitative cases without denying valid domain metrics.	Identity, method, dependence, time, causal linkage, boundary and authority stay distinct in U/ v2.

Source distinction actually consulted	Draft treatment and bounded conclusion	P1 discriminator
FM-005 §5.18, Definition 5.139, pp. 150–151: access, visibility, testimony and contestability matter without replacing evidential warrant.	C210-004/011/012/036/043/053/054/055/057/091/099 address opportunity and barriers. Their practical adequacy needs participant evidence, not merely an authored inclusive declaration.	A technician's testimony is considered in relation to access and scope. Neither low institutional status nor an invitation to speak determines warrant or demonstrates uptake.
FM-005 §5.19, Definitions 5.149/5.150 and Proposition 5.151, pp. 161–162: mediation includes acquisition, selection, classification, transformations and institutional effects, not only generative AI.	E200-022/033/040/041 and C210-018/061/067 retain operations and limits. No inaccessible internal explanation is fabricated.	M1→S1→C1 has shared derivation; S1 output is not an independent observation. No actual execution or reproducibility claim is supplied.
FM-005 §5.20, Definitions 5.159/5.162/5.166/5.167 and Proposition 5.165, pp. 169–170, 172–173: evidential revision, target change, intervention and category revision have different histories.	E200-017/018/019/037/038/039 and C210-023/066/075/076/077/086/087 preserve prior grounds and consequences. The clauses do not mandate one metaphysical account of change.	C1 revision changes current assessment of the past; K2 changes the rule; D2 schedules action; none establishes completed practical repair.

The review found no need to redefine the GR-200 epistemic modes or turn an evidence assignment into a new ultimate ontology class. E200-005 already distinguishes asserted actuality/modality from epistemic basis. P1 labels retrospective inference as a mode concerning an alleged actual occurrence, while dispute and warrant remain assessment matters. The correction proposed for R110-012 in the companion review does not require a corresponding change to E200-005.

105.1.3 3. Findings and dispositions proposed for the next edition

105.1.4 EP-01 — Ambiguous GR-100 incorporation in GR-210

Type: Draft clarification; normative dependency scope. **Priority:** Resolve before publishing the coordinated next edition.

GR-210 Clause 2 says GR-100 supplies operational terms, then says the referenced drafts' relevant requirements remain applicable to the bounded claim package. That sentence can be read to import a separate GR-100 vocabulary-application assessment. GR-200 and GR-110 instead precisely incorporate Clause 3 terms, Clause 5 record-role meanings when used, and result-category meanings in 8.3, while explicitly excluding a separate GR-100 conformity claim. C210-030 invokes the complete applicable GR-200 package obligations, not an independently specified V100 result set.

Alternatives: (a) import every applicable V100 requirement and specify the additional subject/results; (b) adopt the precise terminology incorporation already used by GR-200/110. **Proposed direction:** (b), preserving all GR-200 package-level obligations. It avoids a hidden conformance expansion without weakening the epistemic package. **Affected material:** GR-210 Clause 2 and C210-030's interpretation; dependency declarations in updated fixtures. No new requirement ID is needed solely to clarify this reference.

105.1.5 EP-02 — P1/v1 lacks documentary and performance evidence needed by the expanded procedure

Type: Fixture gap, not a newly discovered event or universal draft defect. **Priority:** Address documentary structure now; rehearse performance later.

P1/v1 has a useful narrative but only two response targets, incomplete issue/action separation and no performed grounds/reply, notice or practical-response evidence. Against C210-035/052/069/071/073/102/104, an overall successful-case label would obscure those differences. P1/v2 adds an explicitly authored service schedule, I1–I6, AC1–AC6, a grounds-notice specimen and component results. All actual performance remains not assessed. The current values are local hypotheses whose feasibility needs resource and participant evidence.

Proposed disposition: retain the v0.1 fixture historically; use the new one as an experimental rehearsal input. Do not manufacture receipts, assignments or completed funding outcomes. Full C210 procedure conformance remains unclaimed.

105.1.6 EP-03 — Protected-source and retention claims remain bounded

Type: Evidential limitation and OPEN contextual design question; corrected author assessment. **Priority:** Resolve contextual policy before a real pilot.

P1's protected original is not supplied, and B's scenario authorization concerns the excerpt only. A statement that B inspected or authenticated the original would contradict E200-023/042 and C210-059/068/095. P1/v2 distinguishes that unavailable source from the actual invented excerpt and preserves the examination limit. Its retention text supplies a proposed arrangement and future Custodian review, not an identified operative retention or disposal decision. C210-094's decision trigger is therefore unresolved for this design, and its result is **not assessed**. Contextual authority, timing and verification remain questions for the proposed arrangement; no fixed retention period is imposed by this review. Actual retention/disposal/enforcement is also **not assessed**.

Review correction QA-01: The initial author assessment marked a C210-094 component and its requirement not fulfilled because contextual authority and a specified retention period were absent. That classification inferred a decision trigger not supplied by P1 and treated a fixed period as necessary when a stated event can define timing. The finding was withdrawn after critique. The register preserves this rationale and now records not assessed with applicability unresolved; no baseline decision or artificial failure case was added.

Proposed disposition: keep the limitation visible and prepare a contextual retention arrangement before collection of real data. No blanket retention period or legal basis is invented. Restriction does not turn an unexamined obligation into fulfillment or make an actual activity inapplicable.

105.1.7 EP-04 — Conformance claim inflation through component results

Type: Assessment design hazard; existing normative safeguards sufficient for this case. **Priority:** Enforce in result tooling and summaries.

E200-049 explicitly requires materially different component results to remain visible. C210-097 similarly distinguishes documentary adequacy from performance. A row showing that C1/v2 states an uncertainty is insufficient to pass E200-014 for every included claim, and a notice specimen cannot pass C210-022's actual notification duty. The P1 register labels each subject, method and coverage; whole-requirement rows remain unassessed unless their whole scope was examined. No new permission to downgrade applicable practice obligations is proposed.

Proposed disposition: retain these clauses; make their aggregation rule explicit in assessment artifacts and later GR-150 work. A fulfilled component never overrides a failed or unassessed applicable component. Even a row with no known failure is not an overall pass when coverage is incomplete.

105.1.8 EP-05 — Proportionality and actual access remain open pilot questions

Type: OPEN empirical/profile question. **Priority:** Measure before fixing reduced profiles or routine service commitments.

The expanded drafts can express a careful case, but this review does not establish a practicable workload for a small project. The number of requirements is not a burden measure: one shared record can support several checks, while a single participation duty can demand significant resources. Independent capacity, user comprehension, protected participation, actual notice recovery and follow-up are still untested. A future proportionate profile needs an explicit decision about its claim and retained protections; describing a small operator does not silently remove current duties.

Proposed disposition: collect preparation time, per-case time, handoffs, support requests, inaccessible material, disputed judgments, comprehension failures and unresolved practical outcomes in a bounded rehearsal. Retain shared-context references where useful, without treating their mere existence as actual performance. No normative burden threshold is selected here.

105.1.9 4. P1 reassessment design and results interpretation

The machine-readable review groups cover every E200/C210 requirement exactly once. The component result register is a different artifact: it records whole-requirement coverage limits and selected inspected components against the fixed 0.2 baseline. Whole-requirement rows are deliberately not promoted from a selected component pass. Conditional absence can produce `not applicable` only with an actual missing trigger; this edition uses that result narrowly for E200-041's absent reproducibility/independent-reviewability claim and E200-035's absent comparison or transfer of confidence grades. Unperformed notification, competent review or user comprehension remains `not assessed`.

Actual review evidence consists of the cited fixture portions and the assessment reasoning recorded in the register. In-world representations are identified as authored synthetic material. Documentary checks locate content/version distinctions, source derivation, reasons, qualifications, action status and view limitations. The failure branches are manually compared variants: no live operator was observed making the expected response.

P1 now exposes the complete intended path from capture through practical response without declaring every step performed: A1→M1→S1→C1→D1→CH1→AS1→C1/v2→K2→D2→pending action. C7 and AC5 preserve unresolved effects rather than ending the inquiry at record correction. A proposed acknowledgment or policy change remains different from replenished monitoring capacity, funding or trust.

105.1.10 5. Next evidence and publication handling

The immediate drafting correction is EP-01. The principal remaining validation work is a participant rehearsal of the documented procedure, followed by independent assessment of the recording and procedural evidence. It needs an ordinary case and the conflict, unavailable-source, missed-target, failed-notice, restricted-view, rule-challenge, propagation and reopening conditions in GR-210 Annex C. The current authored variants prepare those cases but do not discharge their performance tests.

A later edition can reuse an unchanged documentary result only after recording why changed text, dependencies, scope or evidence do not invalidate it. This report remains fixed to archived Working Draft 0.2. Any next-edition fixes belong in a separate disposition record; they do not retroactively change the reviewed baseline or transform an unperformed scenario into empirical pilot evidence.

106 governance review

Original source: `docs/reviews/validation_0.2/governance_review.md`.
Original source SHA-256: `fabd1af9e3c2001b548db8cfd9ddbea63a193f80ec58c22d6beada18a5658941`.

106.1 Governance review of Working Draft 0.2

Class: Informative substantive review record.
Status: PROVISIONAL; authored inspection and synthetic design analysis, 2026-09-22.
Reviewer: AI-assisted repository review; no appointed governance assessor or independent human reviewer is represented.
Baseline: The five governance sources preserved in the 0.2 archive.
Assessment claim: Inspection of all 462 requirement bodies, their document structure and relevant normative schedules. This is a review of proposed rules, not a conformance assessment of an operating institution.

106.1.1 1. Conclusion and boundary

The coordinated governance texts preserve the programme's central distinction between an inspectable account and warranted institutional authority. They provide explicit founding conditions, versioned decisions, review and reply, minority consideration, protected handling, rights clearance and independent challenge. These mechanisms are coherent enough to support continued preparatory drafting and a more demanding rehearsal. They do not establish governance launch readiness.

One concrete ballot-accounting omission needs correction: invalid or unresolved attempted submissions have no explicit place in the required summary partition. Two timing choices need explicit interpretation before a live procedure. Actual personnel, commitments, permissions, protected routes, independent competence, and resource capacity remain unavailable as assessment evidence. Their absence is not a textual defect to be cured by adding fictional names.

This review does not independently establish foundation-manuscript fidelity, applicable law, a rights clearance, accessibility conformance, societal trust, representative legitimacy, or external standards compliance. The root programme review addresses manuscript interpretation separately. No external source has been newly incorporated through this review.

The method was to read the requirement bodies in source order, examine the controlling definitions and schedules, compare cross-document authority and dependencies, and apply normal, failure and boundary scenarios. The grouped register is governance_review_groups.json. Every identifier is listed exactly once. A group marked `reviewed` means its authored text was examined against the stated question; it is not a group pass or individual fulfillment result. `finding` identifies a demonstrated drafting omission; `open` identifies a policy choice or unavailable evidence needed before an institutional conclusion. Requirement-level conformance results would need the component evidence required by D2-054/086/091–095.

106.1.2 2. Findings, alternatives and proposed dispositions

106.1.3 GOV-F01 — Invalid attempted ballots disappear from the tally partition

Classification: Drafting defect; correct before relying on the tally procedure.
Exact baseline: Directives Part 1 0.2, D1-029–032, D1-074, D1-076 and Annex B's Ballots row. Historical P0 0.1 defines nonresponses as `N − R`.

D1-031 correctly defines `R` as valid returns. D1-074 requires clarification of ambiguous or unverifiable submissions and prohibits silently converting them into approval or abstention. D1-032 nevertheless lists valid returns, approvals, disapprovals, abstentions and nonresponses without requiring a separate count for an otherwise eligible participant whose attempted return remains invalid or unresolved. The older P0 formula consequently treats every such attempt as nonresponse. That hides an access, authentication or clarity problem as silence.

The discriminating example is five eligible persons: two approvals, one disapproval, one abstention and one timely but unresolved ambiguous submission. `R=4`; the three numerical

conditions pass. There are zero actual nonrespondents, not one. The unresolved attempt still needs its own validity decision, reasons, challenge route and materiality assessment; a mathematical pass cannot remove that issue.

Alternatives are: (a) classify every excluded attempt as nonresponse, losing a procedurally important distinction; (b) count every attempt as a return, changing the valid-return quorum; or (c) retain valid-return quorum and add explicit submission-state accounting. **Proposed direction: (c).** Record `N=R+I+U`, where `I` counts eligible persons with an attributable excluded or unresolved attempted submission and no counted valid ballot, and `U` counts eligible persons without an attributable submission. Replacement and duplicate handling precede this partition. An individual with a valid replacement contributes to `R`, not also to `I`; the attempt history remains in the protected audit. Count records describe persons, while the audit may contain multiple submissions. Unattributable or ineligible submissions have a separate inventory; their identity is not invented to complete the person partition. An invalid attempted replacement does not by itself erase a preceding valid ballot; withdrawal or invalidation needs an applicable rule and recorded decision.

Affected text: D1-032, D1-074 and the Annex B Ballots row; supporting P0 and tally checks. D1-031's quorum, minimum substantive participation and approval formula remain unchanged. A procedural finding about an excluded attempt can still block progression under D1-028/076 even where the arithmetic passes. Closure requires inspection of the revised clauses and a fixture distinguishing valid replacement, excluded attempt and genuine nonresponse.

106.1.4 GOV-O01 — Reply-window and ballot sequencing

Classification: OPEN implementation choice, not a proved contradiction.
Exact baseline: D1-023, D1-024, D1-027–029, D1-033, D1-073/075 and Annex A stage 50.

The text requires disposition replies before final approval and a completed review dossier at the final-approval stage. It does not state explicitly whether a ballot can open during a final reply window if the package remains frozen. One reading serializes reply, assessment, ballot and appeal. Another allows reply and ballot to overlap but withdraws the ballot if a reply requires substantive change. The latter can save calendar time, while placing greater demands on notification and explaining what the ballot actually considers.

Provisional rehearsal choice: use sequential windows. This is a conservative scenario assumption, not a newly adopted rule. Before a live process, either make sequencing explicit or specify the permitted overlap, reply handling, updated objection record and withdrawal triggers. The effect is calendar time and informed consideration; shortening the 30-day minimum is not proposed.

106.1.5 GOV-O02 — Calendar-day boundary conventions

Classification: OPEN implementation detail.
Exact baseline: D1's calendar-day definition, D1-019/020/023/025/029/034–036/050/059/092; EIP-014/067/100.

Notices must identify exact timestamps and time zones, which makes a chosen deadline observable. The drafts do not fix whether the initiating calendar date is day zero, how an inclusive last date is interpreted, or how a local daylight-saving transition affects the minimum opportunity. A shared convention would prevent two administrators calculating different deadlines from the same receipt.

Alternatives are elapsed hours, local calendar-date arithmetic at the same local time, or a specified close-of-day convention. **Provisional rehearsal choice:** UTC timestamps and addition of 7, 30 or 60 date intervals, with the start as day zero. That avoids daylight-saving assumptions in the fixture. Choose and document the operational convention before live notices; do not retroactively shorten an already announced window.

106.1.6 GOV-O03 — Minimum institutional capacity and independent review

Classification: OPEN launch gate; no evidence of fulfillment.
Exact baseline: CH-021–025/028/029/036–041/055/060/065/078–085; D1-003–005/008/016/035–038/041/051/060/076; TC-011–014/040/054/062/071; EIP-001/010/020/042–046/101.

The documents correctly refuse to let role labels constitute appointments and permit combined functions only with disclosed limits. The minimum three substantive ballots are arithmetic conditions, not evidence of reviewer independence or a sufficient range of perspectives. A single person and several AI assistants cannot supply the independent human functions required for founding, disputed decisions, tally verification or source/render release review.

Options are to obtain accepted bounded roles and competent external review, reduce the formal work scope to actual capacity, or continue preliminary development. **Current direction:** preliminary development, while preparing an appointment and capacity dossier for actual people to consider. No names, commitments, contacts, review independence or rights competence have been invented. Availability needs actual acceptance and an exercised route. An unfilled mandatory function is not `not applicable` merely because the programme is small.

106.1.7 GOV-O04 — Burden, accessibility and concentrated influence

Classification: OPEN empirical question.
Exact baseline: CH-015–020/031/043–045/049–052/064–068/073; D1-007/019/021/060/072/090; D2-060/079/080; TC-040/054/067; EIP-012/045/055/076–081/094.

The texts make unpaid labor, funding, infrastructure control and access barriers visible. They permit shared registers and reuse of still-applicable evidence, which can reduce duplication. The actual cost of administering the full package is unmeasured. A small, cooperative synthetic example cannot establish affordability for a volunteer committee, language accessibility, protected reporting usability or meaningful affected-person participation.

Options are separate forms for each obligation, shared records with explicit views, or reduced scope with bounded claims. **Proposed next experiment:** one shared dossier, with recorded operator time, assistance, failed tasks and reviewer effort; no weakening of requirements is inferred. Test public and protected routes with consenting participants after responsible roles and permissions exist. Numerical targets for acceptable burden remain unset pending those observations.

106.1.8 GOV-O05 — Rights and organizational context

Classification: OPEN adoption and distribution gate.
Exact baseline: CH-034/064/071; D1-033/040/082; EIP-026–038/066/082–090/098.

The policy accurately separates permission to examine material from permission to redistribute or sublicense it, and distinguishes prose, code, schemas, examples, datasets and manuscripts. It does not select contribution terms, establish legal personality or appoint a competent rights reviewer. Those unresolved facts cannot be closed by adding a generic open-source license to the entire repository.

Alternatives are artifact-specific permissions, suitably reviewed common terms with documented scope, replacement of restricted material, or narrower distribution. **Current direction:** preserve source terms and record actual intended uses; prepare a rights register and obtain competent contextual review before the affected public distribution or operative agreement. This report supplies no legal opinion or clearance.

106.1.9 3. Cross-document results

Topic	Inspected provisions	Textual result and consequence
Founding authority	CH-001/002/036–038/058–060; D1-003/004	Express commitments and founding review precede operation; a repository revision cannot adopt the package. Actual founding evidence remains absent.
Formal project activation	CH-014/028; D1-009–014/060; TC-001/032/033	Standards-first drafting can continue preliminarily; launch, mandate and accepted resources still gate formal projects.

Topic	Inspected provisions	Textual result and consequence
Review and minority objection	D1-019–028/068–072; CH-027; EIP-058	A vote does not dispose of an objection, and conduct handling does not suppress a technical concern. Replies and material changes retain separate records.
Ballot and recusal	D1-029–032/073–076; CH-039/040/053; EIP-053/054	Numerical thresholds are internally consistent; a material roster change requires a new ballot. GOV-F01 concerns submission-state accounting.
Procedural appeal	D1-034–039/078–081; CH-029	Independent review, stay where specified, reasons and remedy verification are explicit. Absence of capacity prevents contested progression.
Conduct and merits reconsideration	EIP-014/016–020/064/067/069/099–104	The internal evidence criterion is explicit and separate from fair response; scoped substantive reconsideration is distinct from procedural appeal. Contextual acceptability still needs human review.
Emergency protection	D1-049–051/088; EIP-067/068/103	Seven-day independent review and 30-day expiry apply to temporary participation restrictions as well as publication safeguards. A late remedy does not erase an earlier failure.
Release and maintenance	D1-040–048/082–087; D2-042–045/082–084; TC-072–075	Exact source, authorization and substantive change control remain distinct. An editorial correction cannot alter an outcome merely because it is a small edit.
Protection and public reasons	CH-069/070; D1-021/052/053/080/095; EIP-039/091/092	Safe public accounts can expose limitations without exposing protected existence or identity. Restricted access does not establish evidential adequacy.
Assessment and publication classes	D2-001–005/026–032/068–071/085–095; TC-026/051/052	Per-subject and per-component evidence is required. This grouped authoring review does not satisfy full conformance or institutional performance claims.

The JSON register supplies the complete 462-identifier matrix rather than treating the selected identifiers in this table as exhaustive.

106.1.10 4. Updated P0 and completion conditions

P0 for Working Draft 0.2 expands arithmetic boundary cases, malformed-input cases and synthetic procedural traces. The old P0 remains historical. An executable fixture's mathematical result has a different evidence status from a fictional notice, appointment, appeal, or behavior.

The next institutional rehearsal needs an actual mandate limited to rehearsal, willing participants, declared interests, safe synthetic input, tested public/protected routes, assigned custody, accessible assistance, a non-conflicted reviewer and an agreed record of observed effort. It can test mechanisms over compressed time only if it says so; compressed time cannot fulfill elapsed 7/30/60-day obligations.

Before governance launch, the dossier still needs actual founding review and dispositions, accepted appointments and commitments, independent assessment, rights and contribution arrangements, records/recovery capacity, release authority and a neutral procedural review

route. Completed prose and successful arithmetic do not discharge these conditions. The recommended drafting repair can advance to 0.3 while these institutional gates remain pending.

106.1.11 5. Complete grouped inspection matrix

Each row is an authored-text review group. Exact identifiers and immutable source locators are in the JSON register; the counts are coverage counts, not passed conformance obligations. Open findings can affect only part of a group.

Group	Document and topic	Requirements	Review state	Inspection basis
GOV-R001	GSP-Charter: Normative references	1	reviewed	Exact adopted editions are fixed explicitly; later drafts cannot acquire authority by replacement.
GOV-R002	GSP-Charter: Mission and programme commitments	10	reviewed	Mission evaluation distinguishes intended benefit, measured practice and broader trust claims; layers and operational narrowing stay separate.
GOV-R003	GSP-Charter: Publication authority	8	reviewed	Reserved decisions, editorial custody and publication class are distinguished; pre-adoption drafting does not authorize work items.
GOV-R004	GSP-Charter: Participation and consideration	13	open	Contribution, representation, endorsement and eligibility are separated; alternative access and anti-dominance duties require observed capacity.
GOV-R005	GSP-Charter: Organization and accountable appointments	10	open	Accepted bounded appointments, recusal, vacancy and handover control authority; combined roles cannot supply neutral self-review.
GOV-R006	GSP-Charter: Founding and decision accountability	16	open	Founding review and express commitments avoid self-authorizing drafts; independent capacity and effective conditions remain launch gates.

Group	Document and topic	Requirements	Review state	Inspection basis
GOV-R007	GSP-Charter: Resources and infrastructure	7	open	Support conditions, essential-resource control, staffing and exercised recovery are identified; actual resources are not yet evidenced.
GOV-R008	GSP-Charter: Records and external relations	6	open	Public decision history is bounded by protection; external agreements and representation require actual mandate and assent.
GOV-R009	GSP-Charter: Oversight, transition, and closure	6	reviewed	Annual review, prospective amendments, transition and custody preserve earlier decisions without pretending external uses disappear.
GOV-R010	GSP-Charter: Assessment	3	reviewed	The subject, period, relationships and evidence are declared; blank forms and unobserved routes do not establish performance.
GOV-R011	GSP-Charter: Annex A: Minimum governance evidence records	5	reviewed	Authority, decision and continuity records retain evidence and limits; sampling cannot imply observation of inaccessible routes.
GOV-R012	GSP-Directives-1: Founding, responsibilities, and participation	8	open	Founding basis, appointments, access and recusals precede consequential operation; unassigned mandatory functions defer progression.
GOV-R013	GSP-Directives-1: Project initiation and scope control	8	open	NWIP scope, normative problem, Specification need and resource acceptance are explicit; proposal receipt is not project approval.

Group	Document and topic	Requirements	Review state	Inspection basis
GOV-R014	GSP-Directives-1: Stages and progression evidence	10	reviewed	Stage labels require actual evidence; source decisions, missing expertise, synthetic tests and shared dependencies remain visible.
GOV-R015	GSP-Directives-1: Public review and comment disposition	14	open	60-day intake, 7-day acknowledgement, 30-day disposition target/reply and substantive re-review are distinct; access failures affect progression.
GOV-R016	GSP-Directives-1: Consensus, ballots, and final approval	12	finding	Valid-return quorum and substantive thresholds are consistent; invalid attempts lack a required separate tally category, while recusal can require restart.
GOV-R017	GSP-Directives-1: Procedural appeals and separate complaint routes	10	open	Accessible notice, independent assignment, replies, scoped stay, reasons and implemented remedy differ from substantive disagreement.
GOV-R018	GSP-Directives-1: Publication and release integrity	5	open	Authorization, rights, exact artifacts and non-editor source/render review are prerequisites; successful compilation does not authorize release.
GOV-R019	GSP-Directives-1: Maintenance, review, and withdrawal	10	reviewed	Correction, amendment, confirmation and withdrawal have different effects; prior editions and existing users are not retroactively relabelled.

Group	Document and topic	Requirements	Review state	Inspection basis
GOV-R020	GSP-Directives-1: Emergency safeguards and continuity	4	reviewed	7-day independent review and 30-day expiry constrain temporary safeguards; emergency action cannot make permanent normative changes.
GOV-R021	GSP-Directives-1: Records, transparency, and external liaison	9	open	Records, review cycles and external liaison are bounded; Specification technical requirements retain the full technical review route.
GOV-R022	GSP-Directives-1: Annex A: Stage evidence and procedural schedule	3	open	Stage records reuse evidence only when still applicable; clocks need explicit start, zone, deadline and failure effects.
GOV-R023	GSP-Directives-1: Annex B: Registers and minimum decision records	2	finding	Shared registers preserve specific record content; ballot accounting needs a distinct attempted-but-not-valid category.
GOV-R024	GSP-Directives-2: Normative references	1	reviewed	Bounded internal dependencies identify invoked subjects and edition; incompatible or unavailable material blocks the affected result.
GOV-R025	GSP-Directives-2: Publication identity and document architecture	15	reviewed	Class, status, title, front matter, scope, annex role and leaf hierarchy distinguish publication functions and controlling requirements.
GOV-R026	GSP-Directives-2: Formulation of provisions	16	open	Actor, trigger, criterion, modality, component results and exceptions are specified; unknown declarations do not resolve underlying facts.

Group	Document and topic	Requirements	Review state	Inspection basis
GOV-R027	GSP-Directives-2: Terminology and conceptual sources	9	reviewed	Operational definitions and manuscript interpretation retain scope and source differences; no formal-to-archival equivalence is presumed.
GOV-R028	GSP-Directives-2: References and dependency management	7	reviewed	Verified primary provisions, precise dependencies and access gaps are distinguished from informative bibliographic motivation.
GOV-R029	GSP-Directives-2: Conformance and assessment provisions	11	reviewed	Record structure, practice, interoperability, warrant and authority have separate subjects and evidence; partial claims stay bounded.
GOV-R030	GSP-Directives-2: Information models, protocols and technical artifacts	10	reviewed	Semantic need precedes encoding; protocol delivery, acceptance, retry and institutional outcome differ; artifact conflicts need disposition.
GOV-R031	GSP-Directives-2: Presentation, accessibility and contextual statements	9	open	Accessible structure, formulas, synthetic examples and contextual claims require evidence beyond successful rendering.
GOV-R032	GSP-Directives-2: Versioning and publication production	7	reviewed	Canonical sources, hashes, build tools and archived editions support traceability; semantic changes trigger the appropriate review.
GOV-R033	GSP-Directives-2: Assessment of a publication package	4	reviewed	Declared competence and per-requirement evidence precede overall results; correction closure needs a revised artifact and recheck.

Group	Document and topic	Requirements	Review state	Inspection basis
GOV-R034	GSP-Directives-2: Annex A: Structural schedule for programme publications	2	reviewed	Structural presence is not substantive completeness; unresolved topics need exclusion, development or a blocking status.
GOV-R035	GSP-Directives-2: Annex B: Requirement assessment record	3	reviewed	Requirement records retain applicability, method, component results, assessor and limits; missing evidence cannot become fulfillment.
GOV-R036	GSP-Directives-2: Annex C: Publication self-assessment schedule	1	reviewed	Discriminating checks are meaningful prompts; grouped schedule rows explicitly do not authorize undifferentiated passes.
GOV-R037	GR-TC1-Charter: Normative references	1	reviewed	Exact coordinated governance editions are recorded before committee reliance; external text cannot amend obligations by implication.
GOV-R038	GR-TC1-Charter: Mandate and work programme	17	reviewed	Mandate, work authorization, dependencies and protocol scope remain distinguishable from preliminary technical authoring.
GOV-R039	GR-TC1-Charter: Organization and conduct of work	11	open	Editors and reviewers accept bounded roles; asynchronous work, disclosed self-review, capacity shortfall and handover retain separate records.
GOV-R040	GR-TC1-Charter: Source interpretation and requirements	14	reviewed	Foundation interpretation, alternatives, edge cases and assessed requirements are traced; independent exchange evidence is required for interoperability.

Group	Document and topic	Requirements	Review state	Inspection basis
GOV-R041	GR-TC1-Charter: Multidisciplinary review	11	open	Domain competence, affected perspectives, conflicts and reasons are retained; technical agreement does not create a legal mandate.
GOV-R042	GR-TC1-Charter: Pilot preparation and authorization	8	open	Baseline, questions, permissions, protection and stop/restart conditions precede real pilots; authored scenarios remain synthetic.
GOV-R043	GR-TC1-Charter: Pilot evaluation and implementation evidence	6	open	Failure, assistance, burden, excluded perspectives and later unobserved effects qualify outcomes; independence is a scoped evidenced relationship.
GOV-R044	GR-TC1-Charter: Progression, maintenance, and publication	7	reviewed	Progression includes rights, findings, source/render agreement and maintenance; an informal implementation update cannot amend requirements.
GOV-R045	GR-TC1-Charter: Committee assessment	3	reviewed	Committee performance is assessed for a declared activity, edition and period; a problem-to-decision trace reveals missing evidence.
GOV-R046	GR-TC1-Charter: Annex A: Committee dossier and record content	5	reviewed	Dossier records link baseline, sources, findings, pilot limits and progression; reuse can avoid duplication without erasing distinctions.
GOV-R047	GSP-Ethics-IP: Normative references	1	reviewed	Material cross-policy timing, authority or protection conflicts are resolved before consequential dependent determination.

Group	Document and topic	Requirements	Review state	Inspection basis
GOV-R048	GSP-Ethics-IP: Responsibilities and readiness	7	open	Contacts, alternates, protected custody and independent review require actual acceptance and tested routes before operation.
GOV-R049	GSP-Ethics-IP: Conduct and evidential integrity	9	reviewed	Disagreement is not misconduct; claims, errors and AI assistance retain sources and accountable review without exposing protected material.
GOV-R050	GSP-Ethics-IP: Interests and influence	10	open	Disclosure alone does not manage conflicts; recusal preserves relevant evidence and retrospective discovery can require renewed procedure.
GOV-R051	GSP-Ethics-IP: Report intake and triage	8	open	Intake, triage and determinations differ; acknowledgement remains due in 7 days even if the 30-day determination target is extended.
GOV-R052	GSP-Ethics-IP: Inquiry and fair response	7	open	Adverse findings need safe grounds and reply; missing evidence and limited participation do not prove conduct or non-occurrence.
GOV-R053	GSP-Ethics-IP: Protective measures and determinations	18	open	Protection is time-limited; more-likely-than-not criterion does not override fair review; scoped merits reconsideration has independent assignment.
GOV-R054	GSP-Ethics-IP: Ethical impact assessment	11	open	Impacts distinguish observed effects, predictions and values; operational mitigation and practical repair require evidence.

Group	Document and topic	Requirements	Review state	Inspection basis
GOV-R055	GSP-Ethics-IP: Contribution intake and permission	12	open	Rights to examine, incorporate, modify and distribute are separate, versioned and use-specific; source custody is not relicensing.
GOV-R056	GSP-Ethics-IP: Terms, implementation rights, and publication	10	open	Artifact-specific terms need contextual competent review and actual assent; known implementation-rights issues cannot be cleared by an empty register.
GOV-R057	GSP-Ethics-IP: Records, oversight, and assessment	6	open	Safe public summaries and retention duties avoid exposure; assessment and recurring-failure review do not assume effective remedies.
GOV-R058	GSP-Ethics-IP: Annex A: Handling records and state transitions	5	open	Case states, conflicts, rights and timing records preserve unfinished performance; specimen completeness is distinct from observed handling.

107 readiness and burden

Original source: `docs/reviews/validation_0.2/readiness_and_burden.md`.
Original source SHA-256: `b786fa68f47ee6c7c2b6829a54fb12bff41d0552b3e55860d20da31b86ba3bdf`.

107.1 Readiness and burden assessment

Class: Informative assessment design and evidence-gap record
Status: PROVISIONAL; Working Draft 0.2 validation cycle
Boundary: Repository evidence and synthetic exercises; no external institution assessed

107.1.1 1. What the available evidence establishes

The programme has authored governance and technical drafts, preserved their earlier editions, compiled review artifacts and performed bounded editorial and arithmetic checks. These are preparation activities. They do not establish accepted appointments, stakeholder representation, legal authority, rights clearance, independent review, operational accessibility or successful repair of a real consequence.

The following are evidence gaps in this dossier, not assertions that the relevant people or capacities cannot exist.

Readiness question	Evidence in this cycle	Present conclusion	Next evidence needed
Can a founding authority adopt and resource the programme?	Proposed Charter and unsigned founding template	Not established by the dossier	Identified authority, applicable mandate, accepted responsibilities and resource commitments
Can separate and competent review actually be supplied?	D1, TC and ethics requirements; fictional reviewer reassignment	Not assessed	Accepted reviewers, conflicts record, availability and an observed handling exercise
Are affected interests able to participate?	Participation requirements and synthetic access barriers	Not assessed	Recruitment and access evidence, actual contributions, missing perspectives and response records
Are contribution and publication rights usable?	Proposed rights-clearance procedures	Not established by a procedural draft	Artifact-specific terms, authority to grant them and resolved source restrictions
Can a practice capture a meaningful history at reasonable cost?	Authored P1 record inventory and selected component assessment	Expressibility examined; operational burden not measured	Repeated capture/review tasks with time, assistance, omission and interruption records
Can the challenge and correction routes work?	Declared synthetic routes and failure branches	Real procedure not assessed	Observed receipt, assignment, response, decision, notification and downstream correction
Can intended users understand the result?	Editorial PDF inspection and authored public view	User understanding not assessed	Task-based sessions with intended users and suitable access arrangements
Does the infrastructure improve outcomes?	Proposed causal accounts and unresolved practical repair in P1	No observed effectiveness finding	A bounded outcome question, comparison, time horizon, alternate explanations and follow-up evidence

107.1.2 2. Burden dimensions to measure

Counting clauses, records or fields does not measure minutes of work, cognitive effort or institutional cost. The 753 baseline identifiers are a review inventory; they are not 753 mandatory

independent entries in every record. Conditional obligations, reusable package-level declarations and overlapping evidence need explicit treatment.

A future observed rehearsal can record the following without inventing a universal acceptable threshold:

Dimension	Observation record	Interpretation limit
Initial setup	Roles involved, declaration work, configuration and review time	Separate reusable setup from each subsequent claim or case
Capture	Active task time, material available, fields requiring judgment, assistance and interruptions	Missing historical evidence is not necessarily a usability failure
Assessment	Time to locate grounds, understand source dependence, identify an uncertainty and apply a criterion	Fast assessment can still be wrong or superficial
Contestation	Steps and effort to submit, clarify, respond and obtain a reasoned disposition	Successful submission is not successful remedy
Protection	Work to prepare permitted views, inspect access, manage retention and document limitations	Reduced effort does not justify exposing protected content
Revision	Dependent records located, transformations checked, notifications attempted and verified	An uncontrolled external copy can remain uncorrected
Participation	Language/access assistance, preparation burden, unavailable perspectives and withdrawal	Attendance alone does not establish effective influence
Maintenance	Recurring custody, review, migration, incident and training effort	One initial build does not establish sustainable capacity

Each observation identifies the task, actual participant role, experience level, scenario/version, start/end convention, excluded idle time, interruptions, assistance, result and limitation. Thresholds or comparison criteria are selected before interpreting measurements and remain purpose-specific. This cycle has no such participant measurements and reports none.

107.1.3 3. Profile decisions informed by the cycle

Three assessment subjects need separate consideration in GR-150 development: a retained documentary package, the practice that creates and maintains it, and a procedure handling challenges and practical responses. Version 0.2 permits partial documentary assessment but supplies no reduced profile that turns it into complete practice or procedure conformity.

Candidate simplifications include reusing an unchanged package declaration, referencing controlled material rather than duplicating it, providing explicitly permitted unknown historical context, and omitting a conditionally required feature when its trigger is absent. They do not permit dropping known material loss, concealing an unassessed component, or calling an unperformed action inapplicable.

A profile proposal records parent obligations, intended users, trigger rules, retained safeguards, additional obligations, exclusions, evidence methods and its exact claim. Alternatives are assessed against the same scenario. There is no adopted profile in this cycle and no requirement to use a particular database or schema.

107.1.4 4. Readiness consequence

The current evidence supports a traced drafting revision and more precise rehearsal materials. Formal governance adoption and claims about institutional performance remain pending the evidence above. Preparatory drafting can continue, with its status and assumptions explicit, while those capacities are developed.

108 README

Original source: `examples/README.md`.

Original source SHA-256: `7dba5b56c2fba85eab8e3696550702e76a752ca44b8fab9b2a5d1f9afe04fefb`.

108.1 Examples

Current informative fixtures: P0 governance arithmetic and design rehearsal and P1 contested decision. These are synthetic authoring/review material, not live pilot results or conformance certification.

Planned example datasets:

1. Individual research idea development
2. Human–AI assisted manuscript development
3. Collaborative research project
4. Institutional decision process
5. Historical reconstruction from incomplete records

Examples are informative unless explicitly incorporated into a conformance test suite.

109 p0 governance rehearsal

109.1 P0 — Governance arithmetic and procedure design rehearsal

Document class: Informative synthetic example and evaluated arithmetic fixture
Status: EXPERIMENTAL; version 0.1; 2026-09-22
Related drafts: Directives Part 1, Programme Charter, and Ethics, Conflict-of-Interest, and Contribution Rights Policy, Governance Working Drafts 0.1
Assessment boundary: Five finite numerical states were evaluated in PowerShell. The comment, disposition, recusal, and later procedure examples are synthetic design exercises. No actual ballot, review notice, appointment, complaint, appeal, adoption, or elapsed review period is represented.

109.1.1 1. What was exercised

The arithmetic evaluation checks the three simultaneous conditions in proposed D1-031:

- Returned-ballot quorum: `R >= ceiling(2 × N / 3)`.
- Minimum substantive participation: `Y + D >= 3`.
- Approval: `Y >= ceiling(2 × (Y + D) / 3)`.

`N` is the number of eligible non-recused participants; `Y` approvals; `D` disapprovals; `A` abstentions; `R = Y + D + A`. Nonresponses are `N − R`. These are synthetic counts, not participant identities or representation claims. A numerical pass checks only D1-031 arithmetic. Consensus assessment, legitimate appointments, notices, timing, conflict management, comment disposition, and independent appeal capacity require other evidence.

The formula above records the precise rule used in this exercise even if a later revision of draft 0.1 changes D1-031. The values are local proposed defaults, not ISO or IEEE thresholds.

109.1.2 2. Evaluated results

The following results were produced by an executed PowerShell calculation on 2026-09-22. The execution also checked that the five numerical outcomes, in order, were `true, false, false, false, true`; the check completed without an error.

Case	N	Y	D	A	R	Required R	Y + D	Required Y	Numerical result
P0-B01	5	2	1	1	4	4	3	2	Pass all three conditions
P0-B02	6	3	0	0	3	4	3	2	Fail returned-ballot quorum
P0-B03	3	1	0	2	3	2	1	1	Fail three-substantive-vote minimum
P0-B04-before	5	2	2	1	5	4	4	3	Fail approval threshold
P0-B04-after-hypothetical	4	2	1	1	4	3	3	2	Arithmetic passes; an actual decision still requires a new ballot

P0-B01 exercises the proposed two-approval, one-disapproval, one-abstention case with one nonresponse. Its two approvals meet the ceiling of two-thirds of three substantive votes. It does not establish that the objection has been considered or that three voters adequately represent affected interests.

P0-B02 shows that unanimous approval among three respondents does not overcome the missing fourth return required for a six-person roster. P0-B03 shows that two abstentions cannot supply the minimum substantive participation needed alongside one approval.

P0-B04 models a later discovery requiring recusal of one disapproving participant. Removing that person's eligibility and ballot changes the arithmetic from fail to pass. Under **D1-030**, the material electorate and result change requires a new ballot; the hypothetical recalculation cannot turn the original failed ballot into adoption. The original roster and result remain in

the record, with the recusal assessment and a new ballot identifier. Actual recusal, notice, and reballoting have **not** been performed here.

109.1.3 Reproducing the numerical evaluation

The following PowerShell code reproduces the evaluated formula and inputs. It creates no appointment, ballot, or decision record beyond the displayed calculation.

```
$p0Cases = @(
    @{ Case='P0-B01'; N=5; Y=2; D=1; A=1 },
    @{ Case='P0-B02'; N=6; Y=3; D=0; A=0 },
    @{ Case='P0-B03'; N=3; Y=1; D=0; A=2 },
    @{ Case='P0-B04-before'; N=5; Y=2; D=2; A=1 },
    @{ Case='P0-B04-after-hypothetical'; N=4; Y=2; D=1; A=1 }
)
$p0Results = foreach ($p0Case in $p0Cases) {
    $p0Returns = $p0Case.Y + $p0Case.D + $p0Case.A
    $p0Substantive = $p0Case.Y + $p0Case.D
    $p0Quorum = [math]::Ceiling(2 * $p0Case.N / 3)
    $p0Approval = [math]::Ceiling(2 * $p0Substantive / 3)
    [pscustomobject]@{
        Case = $p0Case.Case
        N = $p0Case.N; Y = $p0Case.Y; D = $p0Case.D; A = $p0Case.A
        R = $p0Returns
        QuorumRequired = $p0Quorum
        QuorumMet = ($p0Returns -ge $p0Quorum)
        Substantive = $p0Substantive
        MinimumMet = ($p0Substantive -ge 3)
        YesRequired = $p0Approval
        ApprovalMet = ($p0Case.Y -ge $p0Approval)
        NumericPass = (($p0Returns -ge $p0Quorum) -and
            ($p0Substantive -ge 3) -and ($p0Case.Y -ge $p0Approval))
    }
}
$p0Results | ConvertTo-Json
if ($p0Results[0].NumericPass -ne $true -or
    $p0Results[1].NumericPass -ne $false -or
    $p0Results[2].NumericPass -ne $false -or
    $p0Results[3].NumericPass -ne $false -or
    $p0Results[4].NumericPass -ne $true) {
    throw 'P0 ballot arithmetic differs from the stated expected outcomes.'
}
```

This bounded calculation does not test malformed inputs, participant identity, duplicate ballots, eligibility evidence, record protection, notification delivery, or arbitrary roster sizes. It is not an implementation of a voting service.

109.1.4 3. Synthetic comment, disposition, and re-review

The invented example below concerns a draft challenge-submission Specification. It is not an actual GR publication, received comment, or decision. Scenario versions `FICT-P0/0.1` and `FICT-P0/0.2` are local fixture labels without programme publication authority.

Record	Synthetic content
Draft provision FICT-P0-007 in 0.1	A submission is accepted only if the sender supplies a proposed replacement clause.
Comment P0-C01	An affected person can identify a misleading classification without knowing how to draft a technical clause. Accept an explanation in ordinary language and provide formatting assistance.
Commenter and recipient	Fictional Commenter A and fictional Review Chair B; neither represents an actual appointment or submission.
Initial disposition P0-CD01	Accepted. Making drafting expertise a condition of intake defeats the intended affected-person challenge route. Preserve the substance of the concern and offer assistance with technical formatting.

Record	Synthetic content
Revised provision FICT-P0-007 in 0.2	The challenge route accepts a free-text explanation of the concern without requiring a replacement clause. The operator offers assistance when structure is needed for processing.
Change classification P0-CC01	Substantive: the accepted inputs and operator obligations change. The intended conformance subject and affected constituency remain the same in this scenario.
Proposed review consequence	Under D1-025/026, show the changed text, rationale, and effects in at least 30 calendar days of public re-review. Notify prior commenters and relevant affected interests; consider consequences for unchanged validation rules.
Alternative scope consequence	If the change instead expands the original purpose, affected constituency, or conformance subject substantially, D1-025 calls for renewed scope approval and a full 60-day review. A "minor edit" label cannot determine that question.
Reply and later disposition	No actual reply or later disposition exists. D1-023/024 require disposition notice, the reply opportunity, and assessment of continuing disagreement before final approval.

The design exercise identifies the expected transition: comment → reasoned disposition → changed provision → substantive-change classification → re-review → further disposition and reply → possible progression. It does not advance a real document through that sequence. No fictional dates stand in for elapsed mandatory periods.

A chair's answer to the comment would not itself establish consensus. The approval package would still need the participation and objection assessment in D1-027/028. A protected procedural complaint about exclusion would use the separate appeal or conduct route appropriate to its grounds, with an actual independent reviewer.

109.1.5 4. Procedure exercises still to perform

The following are uncompleted tasks. Actual function holders, contacts, and independent reviewers remain **UNASSIGNED**. The required evidence concerns observable actions and accepted responsibilities, not merely completed templates.

- ☐ **Founding basis and commitments:** Identify actual prospective signatories, their capacities, reviewed texts, scope of commitment, dissent, and succession route under CH-036–038. No adoption instrument has been executed by this fixture.
- ☐ **Notice and accessible intake:** Staff and test public and protected contact routes; deliver a real test notice and acknowledgement; check asynchronous and assisted submission. Record actual timestamps and access failures under D1-006/018–021.
- ☐ **Participant roster and conflicts:** Apply published selection criteria, obtain accepted roles, assess concentrated interests, and exercise a recusal with a legitimate substitute. Verify D1-008/030 and CH-039–041 using consenting participants.
- ☐ **Comment and reply:** Have someone other than the draft's author try the submission route, receive a reasoned disposition, reply, and locate the resulting change. Record barriers without treating a self-review as independent review.
- ☐ **Material re-review:** Publish an appropriately labelled rehearsal change and test notification and version access. A compressed demonstration can test mechanics; it cannot establish compliance with elapsed 30- or 60-day minimums.
- ☐ **Independent appeal:** Identify an available, non-conflicted reviewer; test a process objection, access to grounds, opportunity to reply, stay, remedy, and restoration. Repeat the unavailable-reviewer case and show that consequential progression remains pending under D1-034–038.
- ☐ **Protected conduct report:** Exercise the distinct ethics route using synthetic material; verify contact and alternate, confidentiality limits, response, fair consideration, and remedy monitoring under EIP-013–020.

- ☐ **Publication integrity:** Independently compare an exact approved rehearsal source with its render, detect an intentionally omitted requirement, and record release deferral. Check D1-040–042 without representing the draft as adopted.
- ☐ **Maintenance and exceptional procedure:** Distinguish editorial correction from a changed conformance outcome; exercise revision, withdrawal, emergency expiry, role vacancy, and protected-record disposition under D1-043–053.
- ☐ **Rehearsal assessment:** Record time, effort, failures, unfilled roles, remedies, remaining objections, and proposed clause changes in a D1 requirement/evidence register. Obtain independent assessment of the actual founding process before declaring governance ready.

109.1.6 5. Limits and programme status

The arithmetic evidence supports the stated results for five finite input states. The comment fixture makes one design consequence explicit. Neither supplies actual participation, represented consent, independent review, rights clearance, notice delivery, elapsed review time, or procedural adoption.

M1 — Governance launch remains pending. This file contributes a limited rehearsal artifact to the governance and pilot evidence plan; it does not complete that gate, approve GR/NWIP-001, activate a committee, or publish an adopted Standard.

110 p1 contested decision

Original source: `examples/p1-contested-decision.md`.
Original source SHA-256: `447987aaa52b9ce73f28b4a442aeea66abbc30a5fbc8658e4595d4c052072eef`.

110.1 P1 — Contested funding decision and generative trajectory

Document class: Informative synthetic example and design fixture
Status: EXPERIMENTAL; version 0.1; 2026-09-22
Related drafts: GR-100/110/200/210 Working Draft 0.1
Assessment boundary: A fictional dossier and expected review behavior. No real people, institution, law, hearing, submission or remedy is represented.

110.1.1 1. Purpose and boundary

Package `P1/v1` examines how a fictional research fund classified a community water-monitoring application, how contrary material changed its assessment, and what changed for future monitoring capacity. Intended readers are participants, reviewers, custodians and designers of the recording procedure. The decision and response horizon is synthetic days 0–40, with relevant antecedent activity before day 0 included where identified. Dates below are ordered scenario labels, not claims about actual elapsed work.

The retained inventory comprises the following attributed records. It is not a complete history. Raw measurements, personal identities, vendor internals and subsequent environmental outcomes are outside the supplied material. A fictional Secretariat records receipt and custody; an initial Panel makes the funding decision; Reviewer B handles the later evidence review; a distinct Review Contact handles procedural reconsideration. These are scenario roles, not programme appointments. No actor has an asserted mandate beyond this fictional fund's internal procedure.

The purpose-based collection rule selects claims relied on for eligibility, evidence assessment, contribution and practical response. The material-claim set is C1–C7 and their assessments, with D1/D2 and rule versions K1/K2 as consequential dependencies. This is the bounded GR-200 package for R110-005 and C210-030. The fixture does not assert fulfillment of every applicable requirement.

110.1.2 2. Inventory and three distinguishable histories

Reference	Attributed content and role	Time and availability
A1	Community team application reports an operating sensor network. This is a report, not independent verification of every measurement.	Submitted day 0; only this content summary is supplied, not the full packet or an independently inspectable application extract.
M1	Intake extract omits the calibration attachment. It establishes the extract's contents, not whether calibration occurred.	Created day 2 from A1; intake scope excludes other channels.
S1	Fictional `SummaryTool/demo-v0` output: "The sensors were not calibrated." Input: M1 only; transformation: generated summary. Internal reasoning unavailable.	Day 3; taken up by Panel; output is generated, not independent evidence.
K1	Panel's rule category "documented calibration" requires an attachment in the application packet. Source of authority: fictional fund's internal rule only; no asserted legal effect.	Version 1 effective in scenario days 0–20.

Reference	Attributed content and role	Time and availability
C1/v1	Panel repeats S1 as a factual conclusion that calibration did not occur. Epistemic mode: inference from missing metadata; actuality claim: non-occurrence.	Recorded day 4; concerns equipment before submission; disputed.
D1	Panel excludes the application, relying on C1/v1 and K1. The exclusion and its factual warrant are different questions.	Day 5; institutional action in the story.
T1	Technician testimony reports calibration before submission. The technician also contributed maintenance labor omitted from A1's attribution.	Statement recorded day 7; retrospective report of pre-submission activity.
L1	Maintenance log records adjustments; fictional protected original includes contact details. Only the invented nonpersonal excerpt is supplied here: "Day −2: station S adjusted against reference instrument."	Original described as restricted; excerpt supplied day 8; no genuine protected data.
CH1	Team challenges C1/v1 and the suitability of K1, citing T1/L1 and requesting reconsideration and attribution review.	Received day 8; two distinct issues.
C1/v2	Reviewer B assesses that calibration activity has support from testimony, while L1 supports the narrower report of adjustment. Whether that adjustment met the intended calibration method, its quality and the chain of measurement remain unresolved.	Day 12; evidence/assessment revision, not a new calibration event.
K2	Panel changes its rule to permit assessed maintenance testimony and controlled log inspection as possible evidence. Adequacy remains case-relative.	Announced day 20; effective from day 21. A rule/category change.
D2	Panel schedules a renewed assessment under K2; it does not yet award funding.	Day 22; scheduling is recorded, while reassessment and its outcome remain pending.
C7	Team reports that the exclusion delayed equipment replacement and interrupted training; no independent outcome follow-up is supplied.	Day 30; reported practical effects and possible future constraint.

The first history concerns claimed calibration activity, maintenance, exclusion and possible effects on monitoring capacity, with their respective evidential qualifications. The second includes the creation, use and revision of claims about them. The third includes K1/K2 and changing evidential categories. The case does not identify a changed category with a changed past event. Historical use of K1 stays visible after K2 is introduced.

Record references identify representations and versions. They do not settle whether two sensor names denote the same physical instrument. An unresolved match stays unresolved. The maintenance relation can have its own participants, interval, contribution dispute and history; it need not disappear into an edge without attributes. Event, Process and Relation roles can describe different aspects of the same maintenance episode without asserting three different underlying episodes.

110.1.3 3. Claim-relative evidence and assessment

Claim	Grounds and method	Assessment and limits
C1/v1: no calibration occurred	Panel infers non-occurrence from M1. The method assumes all calibration would appear in that extract.	Unsupported inference in the fixture: expected recording coverage is unestablished. Preserve "attachment absent from M1." Do not automatically infer the opposite factual conclusion.
C1/v2: calibration activity occurred	Reviewer B considers T1's calibration testimony and L1's narrower adjustment report. The excerpt does not independently establish every part of the testimony.	Activity receives qualified support; instrument identity, method, reference quality and adequacy remain unresolved. Two sources do not establish independence if the testimony derives from the log.
C2: application met K1	Proposed rule comparison against complete packet contents; only M1's limited extract is represented here.	Compliance remains unresolved from the supplied material. Missing attachment can matter to K1's application, but its absence from M1 alone does not establish absence from the full packet. Even a correct rule application would not resolve the rule's legitimacy or procedural suitability.
C3: exclusion was unfair	Team applies stated values of accessible participation and recognition of maintenance labor, citing differing access to formal documentation.	Attributed ethical judgment. Panel's competing value of consistent evidence requirements remains identified. No universal value ordering is imposed.
C4: D1 violated a legal duty	Team's asserted legal objection.	Jurisdiction, legal source, competent authority and applicability are UNSPECIFIED in this fiction. The case records the allegation and routes it outside the reviewer's claimed competence. No legal finding follows.
C5: maintenance enabled continued monitoring	Technician's account connects adjustments and ongoing operation, compared with the earlier condition of drift.	Attributed generative account; causal sufficiency and longer-term effects unestablished. Maintenance can matter without a new output.
C6: granting the application would have preserved training	Proposed alternative raised during challenge, with team estimates of cost and availability.	Counterfactual, not observed outcome; feasibility is only partly examined. Other funding and scheduling constraints remain unknown.
C7: exclusion constrained later capacity	Team reports delayed replacement and interrupted training; reviewer identifies D1 as one possible contributing condition.	Reported realized effects and inferred contributions remain separate from predicted future loss. No complete causal attribution or remedy is established.

Reviewer B's method is qualitative comparison of claims, source scope, derivation and alternative explanations. No probability is invented. M1, S1 and C1/v1 share a derivation path; they do not constitute three independent observations. Authenticity of an excerpt and the strength of its support for calibration quality are separate assessments. This fixture has no actual signature or authenticity test.

Generativity return is not quantified. Attribution review can acknowledge maintenance contribution while leaving ownership, payment, entitlement and fair distribution unresolved. Any future assessment would need recipients, evaluative criteria, grounds and context. A funding award would not itself settle that inquiry.

110.1.4 4. Proposed procedural trace

The fictional operator declares the covered decisions, accessible text/oral submission routes, protected-contact option and a review contact distinct from the original Panel. Local fixture targets are acknowledgement within two scenario days and initial disposition within ten; extensions require notice before the target, reasons and a revised date. These values illustrate C210-003 and are not programme-wide service requirements. No actual contact channel has been created or tested.

1. **Receipt:** CH1 receives a distinguishable reference and day-8 receipt entry. An acknowledgement on day 9 identifies the two issues, review function and target. Receipt is not acceptance of the challenge's merits.
2. **Conflict:** Initial proposed Reviewer A authored S1's uptake note. The scenario identifies this conflict and reassigns to B; it does not label A independent. If no suitable reviewer is available, the record stays pending with notice and a declared alternative, rather than inventing independence.
3. **Participation:** Panel and team can respond to the grounds used. The technician can submit through protected contact. The short, nonpersonal L1 excerpt and B's assessment of that excerpt support response while the original remains restricted. B's described authorization covers the excerpt only; no examination or authentication of the unavailable original is represented. Missing perspectives and limits of that substitution remain visible.
4. **Assessment:** B separately considers factual calibration claims, K1 application, K1 adequacy, contribution attribution and the asserted legal objection. The legal matter is recorded outside B's competence. Silence by a party is not consent.
5. **Disposition:** On day 12, B replaces the unqualified C1 conclusion with C1/v2, preserves the earlier inference and its use, records remaining uncertainty, and refers reconsideration of D1 and K1 to the Panel. No funding award is represented as accomplished.
6. **Action:** D2 schedules reassessment. The action owner is the fictional Panel; completion evidence would be a dated assessment/decision record and notice. These are absent at the fixture boundary. Correction of C1 is complete within the supplied text; practical repair is pending.
7. **Notification and propagation:** A case notice is described as sent to the team and Panel. The public summary can be changed; a prior exported spreadsheet is a known dependent copy whose correction remains unverified. The fixture includes no delivery receipts, so sending and receipt are unverified procedural assertions.
8. **Further review:** The declared Review Contact can consider new evidence, an incorrect correction or a procedural failure. Reopening links CH1 and the prior disposition. The operator cannot promise external court review or exercise legal authority it lacks.

110.1.5 5. Restricted material and reduced presentation

The fictional custody rule authorizes B to examine the nonpersonal excerpt; public readers receive the excerpt and a scope statement, not personal contact details. Retention decisions separate claim history, testimony content, contact information and permitted audit evidence. Proposed contact-data disposal after closure needs a declared authority, executor and permitted confirmation; it does not require keeping the removed content to prove removal. No deletion is claimed to have been performed.

A suitable public summary reads:

> An earlier finding of no calibration relied on a missing attachment in a limited intake extract. Subsequent testimony supports calibration activity; a maintenance-log excerpt reports adjustment, with method, quality and identity limits remaining. The fund has scheduled reassessment under a revised internal rule. Funding, correction of external copies and reported losses remain unresolved. This summary omits personal contact information and does not provide full inspection of the described original log.

The summary preserves the difference among attributed assertion, assessment, institutional action and pending repair. Reader comprehension is an empirical question that has not been tested with users.

110.1.6 6. Discriminating cases and expected results

These are review expectations applied to authored variants, not passed live operational tests.

Case	Deliberately defective variant	Expected finding and relevant clauses
P1-A	Replace “no attachment in M1” with “no calibration occurred,” without a coverage argument.	Unsupported missingness inference; E200-013, C210-015.
P1-B	Count M1, S1 and C1 as three independent sources.	Shared derivation exposed; E200-012/022.
P1-C	Label calibration “unrealized” because its occurrence is retrospectively inferred.	Confuses modality with epistemic basis; E200-005, R110-012.
P1-D	Overwrite K1 with K2 and represent the earlier Panel as using K2.	Historical regime distinction lost; E200-017/018, R110-016/021.
P1-E	Mark D2 “funding restored” when only reassessment was scheduled.	Proposed action mistaken for completed remedy; C210-021/023, R110-022.
P1-F	Describe Reviewer A as independent without disclosing prior involvement.	Conflict and independence misrepresented; C210-009/024.
P1-G	Miss the stated review target with no notice; declare the case rejected by timeout.	Timing and disposition failures; C210-003/026.
P1-H	Publish contact details merely to make L1 inspectable.	Disclosure exceeds scenario authority; E200-023, R110-025/026, C210-027–029.
P1-I	Omit reported training loss from a supposedly complete account of capacity changes.	Material loss missing without collection/protection explanation; R110-002/017.
P1-J	Call the public summary conforming because its formatting validates.	Structural result overstated; E200-002/026, R110-030/034.
P1-K	Demand all history remain public forever, or claim an outside spreadsheet was deleted without evidence.	Retention and propagation limits ignored; R110-025/028, C210-028.

110.1.7 7. Assessment limits and next evidence

This fixture supplies concrete content and counterexamples for clause review. It does not provide a complete conformance dossier. Required operational evidence such as actual assignments, acknowledgements, delivery, reviewer performance, access enforcement, deletion results, comprehension and resource burden remains **not assessed**. Unavailable original material limits evidential examination; restriction alone does not convert an unassessed requirement into fulfillment.

Next, designated participants can rehearse the procedure with this fictional material, record what actually occurs, maintain a requirement-by-requirement result register, and revise the draft where burden or ambiguity appears. A live pilot would additionally need a real institutional mandate, contextual legal/ethical analysis, participation arrangements, protection decisions and a scoped profile. No jurisdiction or external partner is selected by this example.

111 p0 governance rehearsal

Original source: `examples/validation_0.2/p0-governance-rehearsal.md`.
Original source SHA-256: `9f5cc36dd050f84e2c4ea97618fff817d6198a8dd51a1cb027a544ab71a4260e`.

111.1 P0 — Governance rehearsal against Working Draft 0.2

Class: Informative synthetic rehearsal and finite arithmetic fixture.
Status: EXPERIMENTAL; authored 2026-09-22.
Baseline: The five Governance Working Drafts 0.2, preserved in the source archive.
Relationship: Extends historical P0 0.1, which remains unchanged.
Responsible exercise roles: UNASSIGNED. Scenario role names below are fictional functions, not actual appointments.

111.1.1 1. Purpose and evidence boundary

This rehearsal asks whether the proposed governance rules lead to distinguishable outcomes when a process succeeds, fails, receives an objection, or lacks capacity. It covers founding, proposal intake, review and reply, ballot arithmetic and submission handling, recusal, procedural appeal, conduct review, temporary protection, rights, publication and maintenance. It exercises rule interpretation on synthetic inputs; it does not constitute an operating governance service.

There are three distinct evidence kinds:

1. **Authored expected results:** The finite count inputs and their expected numerical results are in p0_ballot_cases.json. They are inspectable assertions awaiting or linked to a recorded execution; the JSON itself does not prove they were executed.
2. **Actual arithmetic execution:** A validator run can compare those expected values with recalculation, record its tool and fixture versions, and report disagreements. Its conclusion is limited to the selected finite count states and malformed-input handling. The execution record produced by the repository checker is the evidence of that run.
3. **Synthetic procedural traces:** Fictional notices, dates, persons, reports and actions below are authored scenarios. None is an observation of actual receipt, notice delivery, review, independence, elapsed institutional time or remedy. No procedural fulfillment is inferred from the prose.

The governance review records GOV-F01 and GOV-O01–05. The fixture uses the conservative timing choices described there. It does not create adopted timing rules, a reduced conformance profile or authority over anyone's rights.

Executed arithmetic result: The repository validator was run for this cycle; all 18 authored cases matched their expected results (13 valid-count states and five malformed inputs). The generated execution record records the run. This executes the numerical exercise only; the institutional sequences below remain synthetic.

111.1.2 2. Count domain and discriminating arithmetic cases

The four-count fixture accepts nonnegative integers `N`, `Y`, `D`, `A`, excluding Boolean values and requiring `Y+D+A <= N`. `N` counts eligible, non-recused persons; `Y`, `D` and `A` count their valid approval, disapproval and abstention ballots. `R=Y+D+A` is the valid-return count. The fixture assumes attempted submissions are valid; cases concerning invalid attempts have a separate record partition in section 5.

The three simultaneous conditions from D1-031 are:

```
returned-ballot quorum:   R >= ceil(2N/3)
substantive minimum:      Y+D >= 3
substantive approval:     Y >= ceil(2(Y+D)/3)
numeric_pass:             all three conditions hold
```

Integer recalculation can use `(2*N+2)//3` and `(2*(Y+D)+2)//3` on this nonnegative domain. A malformed input has no ballot result; it is not a procedurally valid defeated ballot. A zero-person input is mathematically valid for this finite fixture but fails the substantive minimum and says nothing about actual constitution of an electorate.

Case	N	Y	D	A	R	Required R	Y+D	Required Y	Authored expected result
P0-02-B01	5	2	1	1	4	4	3	2	Numerical pass; dissent remains to be addressed
P0-02-B02	6	3	0	0	3	4	3	2	Fail quorum
P0-02-B03	3	1	0	2	3	2	1	1	Fail substantive minimum
P0-02-B04-before	5	2	2	1	5	4	4	3	Fail approval threshold
P0-02-B04-after	4	2	1	1	4	3	3	2	Arithmetic passes; changed roster requires a new ballot
P0-02-B05	3	2	1	0	3	2	3	2	Numerical pass; breadth and independence unassessed
P0-02-B06	2	2	0	0	2	2	2	2	Fail substantive minimum
P0-02-B07	7	3	1	1	5	5	4	3	Numerical pass at both ceiling boundaries
P0-02-B08	7	2	2	1	5	5	4	3	Fail approval threshold
P0-02-B09	8	4	2	0	6	6	6	4	Numerical pass
P0-02-B10	8	3	2	1	6	6	5	4	Fail approval threshold
P0-02-B11	4	0	0	4	4	3	0	0	Fail substantive minimum; `Y>=0` alone proves nothing
P0-02-B12	0	0	0	0	0	0	0	0	Fail substantive minimum

Cases P0-02-I01–I05 respectively supply more valid returns than eligible persons, a negative count, a fractional count, a numeric string and a Boolean. All expect `valid_input=false` and `numeric_pass=null`. These validation choices are a bounded fixture convention; they do not specify an interchange format or a general voting-service contract.

The fixture does not authenticate persons, evaluate interests, receive ballots, observe a deadline, determine consensus, ensure accessibility, make a recusal or supply the independent tally verification required by D1-076.

111.1.3 3. Trace P0-02-G0 — Founding and proposal gate

Controlling provisions: CH-001/002/014/021/028/029/036–040/058–060; D1-003–005/009–014/059–061; TC-001/032/033; EIP-001/042/044.

Record	Synthetic input or operation	Expected state and discriminating consequence
P0-02-G0-01	An author has compiled all five governance documents and entered proposed role names in a form.	Prepared documents exist; appointments, acceptance, authority and adoption do not follow. Formal roles remain UNASSIGNED.
P0-02-G0-02	The form proposes a founding signatory who can control a repository but has no mandate to represent a university.	Only the actual resource commitment can be considered; the university representation assertion lacks a basis.
P0-02-G0-03	A fictional founding-review package identifies exact editions, prospective signatories, their capacities, proposed appointments, contribution terms and public/protected routes.	Ready for assessment of the proposed founding review; publishing this scenario does not open that review or start a clock.
P0-02-G0-04	No non-conflicted independent reviewer has accepted a bounded role.	Founding-process independence remains unavailable; formal initiation is pending. Preliminary drafting may continue.
P0-02-G0-05	A hypothetical proposal for a correction protocol supplies purpose, scope, affected interests, interfaces, assessment plan and resource estimate.	Register and acknowledge a proposal within seven days in an actual process; registration remains distinct from acceptance.

Record	Synthetic input or operation	Expected state and discriminating consequence
P0-02-G0-06	The proposal assumes a maintenance owner and protected-record custodian will be found later.	Essential accepted roles are missing. Revise scope or defer; do not describe assumed future capacity as present.

The real repository can supply source versions and this scenario. It cannot currently supply the synthetic signatory, notice, accepted roles or observations. The missing launch evidence is an institutional action list, not an invitation for an assistant to assign people.

111.1.4 4. Trace P0-02-G1 — Accessible comment, disposition, clocks and re-review

Controlling provisions: CH-015/017/018/049–052; D1-018–028/068–072/091–093; EIP-058.

A fictional protocol draft `FICT-P0/0.2-A` accepts a challenge only if the sender provides a replacement technical clause. An affected person submits an ordinary-language explanation that the entry identifies the wrong contributor and describes a practical consequence. A second part of the submission alleges that an administrator dismissed previous comments because of the person's affiliation.

The intake trace has separate but linked records: `P0-02-G1-C01` for the technical objection, `P0-02-G1-E01` for protected conduct handling, and `P0-02-G1-P01` for the access/protection decision. The technical record retains the person's actual concern; converting it into structured fields records any interpretive assistance. A safe summary omits identifying conduct details. An unsupported conduct allegation does not dispose of the technical objection.

The proposed technical disposition accepts ordinary-language challenge submissions and identifies assistance requirements. The record preserves the replacement-clause-only alternative, its exclusion risk and the resulting proposed change. The change affects accepted inputs and operator obligations, so it is substantive. Within the same purpose, constituency and conformance subject, it needs at least 30 days of re-review. If it changes those boundaries substantially, renewed scope approval and 60-day review apply. A label such as "minor wording" cannot select the shorter route.

The following is a separate **unchanged-text timing branch**, used only to make successive periods inspectable. It assumes UTC, start as day zero, effective notice at the stated timestamp, no delivery/access failures, no substantive replies and sequential reply/ballot windows. Those assumptions have not been observed.

Fictional event	Scenario timestamp	Meaning
Initial review opens	2026-10-01 09:00 UTC	Identified fixed draft and notice
Review closes	2026-11-30 09:00 UTC	60-day opportunity; intake closure is not disposition completion
Initial dispositions delivered	2026-12-30 09:00 UTC	30-day target after close; delivery assumed only in this scenario
Reply window closes	2027-01-29 09:00 UTC	30 days after disposition notice
Ballot opens after assessment	2027-01-30 09:00 UTC	Frozen package and completed review dossier assumed
Ballot closes	2027-03-01 09:00 UTC	30-day ballot
Decision notice accessible	2027-03-02 09:00 UTC	Starts ordinary appeal opportunity; not immediate release permission
Ordinary appeal period ends	2027-04-01 09:00 UTC	Release can be considered after the period only if remaining conditions are met

The substantive-change branch does **not** inherit this unchanged-text schedule. It inserts the applicable re-review, dispositions, reply and reassessment before a new frozen approval package. A later material reply cannot be ignored to preserve a planned publication date.

Failure injections make the obligations observable in a future live rehearsal:

Injection	Expected response	Evidence still needed
Comment arrives 2026-10-02 09:00 UTC; acknowledgement occurs 2026-10-10	Record a missed seven-day duty; explain effect and correction. A determination-target extension cannot make acknowledgement timely.	Actual received/sent logs, delivery limits and handling reason
Essential supporting material is inaccessible for affected reviewers	Assess material access failure and extend review sufficiently to restore opportunity.	Access incident, affected scope, extension reasons and revised notice
A disposition email is known to have failed	Offer a workable route or extend the affected reply window; do not count failed delivery as silence.	Delivery record, permitted alternative, effective opportunity and progression decision
A late reply identifies a material rights defect	Assess before adoption irrespective of receipt date.	Grounds, competent review, disposition and any blocking consequence
The 30-day disposition target cannot be met	Notify reasons, interim state and a new target before expiry. A missed target remains historical if already missed.	Actual notice and revised target; no deemed resolution

111.1.5 5. Trace P0-02-G2 — Ballot validity, replacement and recusal

Controlling provisions: D1-029–033/073–076; CH-039/040/053; EIP-053/054.
Related finding: GOV-F01. The explicit `I/U` summary partition below is a proposed repair to 0.2, not a claim that 0.2 already specifies that partition completely.

Five fictional eligible persons are designated A through E. Their proposed receipt ledger is:

Person	Submission history at closing	Final count state
A	Attributable approve	Y
B	Attributable approve, followed by an unverifiable purported replacement	Earlier valid approve remains the latest valid ballot unless an applicable withdrawal or validity decision changes that; unresolved attempt stays in audit
C	Attributable disapprove with a material procedural objection	D; grounds require disposition independently of the arithmetic
D	Attributable abstain	A
E	Attributable but ambiguous “possibly”; clarification not completed	Attempted but not counted valid; record clarification, exclusion/review grounds and challenge route

The candidate person partition is `N=5, R=4, I=1, U=0`, with `Y=2, D=1, A=1`. Here `I` counts otherwise eligible persons with an attributable excluded or unresolved attempt and no counted valid ballot; `U` counts eligible persons without an attributable submission. A naive `N–R` nonresponse formula would falsely count E as silent. Unattributable and ineligible submissions need a separate inventory; no identity is invented to force them into the roster partition. The numeric quorum passes; the actual effect of E’s handling and C’s objection still needs reasoned assessment. If exclusion reflects a material failure of participation or administration, D1-028/076 prevents progression even though the numerical rule passes.

If E supplies a valid approval before close, the candidate partition becomes `R=5, I=0, U=0`, with `Y=3, D=1, A=1`. E is not counted twice. The ambiguous earlier attempt remains in the protected audit. A duplicate transmission from A does not add a person or vote. No unknown message is silently converted to an abstention.

For recusal, use B04-before and B04-after from the count fixture. Removing one disapproving person’s eligibility after a material conflict discovery changes both the electorate and apparent result. Preserve the first frozen roster and failed tally, record the conflict decision, and start a new ballot if the matter proceeds. Recalculating the old tally is diagnostic; it cannot transform the old failed ballot into adoption.

The real exercise still needs identity and acceptance evidence, announced validity rules, conflict handling, protected audit controls, actual notice/receipt, an independent tally check and a reasoned consensus assessment. A script supplies none of these.

111.1.6 6. Trace P0-02-G3 — Procedural appeal and unavailable capacity

Controlling provisions: CH-023/029/061; D1-034–039/078–081/093; EIP-010/020.

Step	Synthetic case state	Expected action and failure boundary
P0-02-G3-01	A commenter alleges exclusion from a changed review package and supplies the earlier notice.	Log receipt and relevant decision; acknowledge within seven days; distinguish alleged failure from a finding.
P0-02-G3-02	The original chair offers to determine whether their own notice was adequate.	Do not treat that chair as independent; obtain a non-conflicted appointed reviewer or keep consequential disputed progression pending.
P0-02-G3-03	Review cannot proceed because no independent reviewer is available.	Record the capacity gap, action owner and review point; preserve appropriate protection and affected publication stay. Silence is not rejection.
P0-02-G3-04	In an alternative staffed branch, a reviewer accepts a bounded mandate, discloses interests, explains admissibility, access and timetable.	Provide meaningful reply to the appellant and decision maker. Record how protected grounds can be assessed fairly.
P0-02-G3-05	The reviewer establishes that a material delivery failure prevented reply and remits the decision for renewed opportunity.	Identify the affected stage, remedy, owner and evidence needed to lift the stay. The finding addresses procedure, not factual truth.
P0-02-G3-06	The appeal file is marked closed, but no corrected notice has been delivered.	Remedy implementation remains open; file closure does not establish restored participation.
P0-02-G3-07	A new notice is actually delivered and the required opportunity is restored in a future exercise.	Verify the actual evidence before renewed progression; cite the appeal and repeated stage in the new decision.

An ordinary appeal is filed within 30 days of accessible notice. Ineffective notice or newly discovered concealed failure can support a reasoned extension by the independent reviewer. That flexibility is not an excuse to omit notice or make the original decision maker determine their own appeal.

111.1.7 7. Trace P0-02-G4 — Conduct, temporary protection and reconsideration

Controlling provisions: EIP-013–020/056–075/095/096/099–104; D1-035/036/050.

The synthetic report concerns alleged retaliatory exclusion from a working discussion. It uses no actual person’s information. The handler logs the report and requested protection, checks conflict and immediate risk, and separates factual allegations from their assessment. Acknowledgement has a seven-day deadline; a complex inquiry may need a reasoned extension of its 30-day initial-determination target, notified before expiry. The extension affects that target only.

An authorized temporary access restriction, if justified, records evidence, scope, safer alternatives, impact, challenge route and notice limits. It needs independent review within seven days and expires within 30 days unless the authority records a justified extension, next review date and remedy plan. Relabelling it “temporary” every month cannot substitute for reasons and review. An immediate protective measure is not a concluded conduct finding.

Three outcome branches are deliberately distinct:

- **Unresolved evidential balance:** Two plausible accounts remain equally supported after fair examination. The allegation is not substantiated under EIP-069. This does not establish that the report was false or permit retaliation.
- **Unsafe grounds:** The information cannot be disclosed or tested sufficiently for a meaningful response. EIP-016/020/064 prevents an unsupported adverse finding even if the author feels confident. The record identifies limitations and feasible non-punitive improvements within authority.
- **Material assessment error identified later:** A reporter or reported person submits a scoped substantive reconsideration request. A competent, non-conflicted reviewer who did not determine the finding handles admissibility and any admitted grounds under EIP-099–102. Mere repetition without grounds can receive a reasoned refusal; an identified error cannot be treated as misconduct for being raised.

Ordinary reconsideration filing is within 30 days of accessible disposition notice, with the stated extension grounds. Acknowledgement is within seven days and an initial admissibility or substantive determination has a 30-day target. The existing remedy gets an explicit stay/modification/continuation decision under EIP-103; neither automatic continuation nor automatic suspension is inferred from the request alone. Temporary restrictions remain subject to EIP-067. A revised finding preserves the earlier decision and records changed practical effects.

These branches exercise the specified criterion and procedural distinctions. They establish neither actual fair treatment nor contextual acceptance of the programme's proposed internal evidence criterion.

111.1.8 8. Trace P0-02-G5 — Rights, publication integrity and maintenance

Controlling provisions: CH-047/048/071; D1-040–053/082–088; D2-042–045/075/076/082–084; EIP-026–038/082–090/098.

Synthetic condition	Expected distinction and disposition
A foundation manuscript can be read within the project, but public redistribution is unverified.	Preserve source terms; do not infer permission from the manifest or citation. Obtain a reviewed basis, remove the attachment, or restrict the affected distribution. New independent drafting within actual permission can continue.
A contributor assents to code terms, while a submitted example contains a third-party dataset.	Code assent does not clear the dataset. Separate artifacts, versions, intended uses and authority evidence.
Source is approved in a fictional record, but the rendered PDF omits a requirement.	Block release; resolve the source/render discrepancy and obtain review by someone other than the final editor. Compilation success alone is insufficient.
A proposed one-character edit changes `30` to `3` days.	Substantive change: it changes permitted outcomes and needs the relevant review route. Character count does not define editorial status.
A real error can be corrected without altering intended meaning or valid outcomes.	Use a documented corrigendum only after the required non-editor review; retain the original publication and effect interval.
An exchange dependency becomes unavailable or changes incompatibly.	Assess affected versions, implementation rights, users and migration losses; narrow scope, revise or defer rather than claim interoperability by citation.
A serious protection incident requires immediate warning or distribution suspension.	Use bounded emergency authority, review and expiry; permanent amendment or withdrawal retains the ordinary procedure.
The maintenance contact leaves and no alternate accepts custody.	Record the vacancy and loss of capacity. Reassign within mandate or defer dependent decisions; an unchanged email address is not an accepted duty.
A recovery test restores files but loses protected-access restrictions.	Record a failed material part of continuity; successful copying does not establish preserved custody or safe service restoration.

Synthetic condition	Expected distinction and disposition
A withdrawal is proposed.	Give at least 60 days' public notice, dispositions, reply and formal approval; preserve historical edition identity and avoid retroactive claims about earlier users.

111.1.9 9. Actual work remaining and measurement plan

The substantive review and authored fixtures are preparatory evidence. The following remains **NOT ASSESSED** as institutional performance:

Activity	Observable evidence needed	Responsible function
Founding process and commitments	Actual authority, reviewed texts, signatory assent, dispositions and independent assessment	Prospective founders; UNASSIGNED
Public/protected intake and assistance	Real test deliveries, failure logs, assistance requested and supplied, access controls	Secretariat and protected custodian; UNASSIGNED
Eligibility, interests and tally verification	Accepted roles, declared capacities, conflict decisions, per-person audit, separate verifier	Chair and non-conflicted verifier; UNASSIGNED
Reply, appeal and reconsideration	Observed notices, meaningful response, independent competence, reasons and actual remedy verification	Independent reviewers; UNASSIGNED
Rights and release	Competent use-specific review, identified permissions, exact source/render examination, authorization	Rights reviewer and release owner; UNASSIGNED
Recovery, maintenance and remedy	Exercised recovery including access restrictions, accepted handover and demonstrated correction	Custodian and maintenance owner; UNASSIGNED
Practical burden and accessibility	Operator/reviewer time, waiting time, repeated entry, failed tasks, assistance, missing perspectives and user findings	Pilot evaluator; UNASSIGNED

For a future staffed rehearsal, record time separately for preparation, interpretation, record entry, assistance, review, correction and waiting. Track one shared dossier instead of copying the same facts into every form, while retaining each required distinction and locator. Report actual measurements and population limits; do not fabricate person-hours or assume a compact scenario scales to a live institution.

The stop conditions are unavailable authority for the attempted action, unsafe disclosure, unresolved material conflict, failure of independent capacity, material exclusion, and an unhandled substantive change. A stop leads to a recorded limitation and response; it does not prohibit unrelated authorized drafting.

Governance launch remains pending. A successful arithmetic run establishes only the finite mathematical results it reports. This document does not approve a work item, create a committee, constitute public review, or adopt a Standard.

112 p1 contested decision

Original source: `examples/validation_0.2/p1-contested-decision.md`.
Original source SHA-256: `d614093324a7caecfe0b6fd2a56ad0064dc4a5406d2b44a0bd527366b1a9ec84`.

112.1 P1/v2 — Contested decision: bounded validation dossier

Publication class: Informative synthetic example and assessment fixture
Status: EXPERIMENTAL; fixture version 2; 2026-09-22
Assessment baseline: GR-100/110/200/210 Working Draft 0.2, preserved in the dated archive.
Predecessor: P1/v1, retained unchanged.
Assessment: Component result register; epistemic review.

112.1.1 1. Boundary, authorship and evidence status

Package `P1/v2` records an invented community water-monitoring funding case, using synthetic days −2 through 40. Its purpose is to examine whether a narrative package preserves the distinction among a missing attachment, a claim of non-calibration, an exclusion decision, challenge, evidential revision and practical consequences. The recording role is the **fixture author, a Codex assistant acting for this repository task**. The assessment role is the same assistant; this is author review, not independent review. The date of this actual documentary review is 2026-09-22. Synthetic day labels express scenario chronology, not elapsed real activity.

The collection rule includes claims C1–C7, their identified versions, material invoked for them, rule versions K1/K2, decisions D1/D2, challenge CH1, and the downstream dependencies named below. Shared context `CTX-P1/v2` consists of this section and the declared method in section 4. All those records inherit it unless a row states otherwise. The unit of inquiry is one fictional application and a claimed maintenance relation; no population-wide inference is attempted. The judgment horizon ends at day 40; the pre-submission maintenance target is day −2 or otherwise explicitly unknown. Claims about later durable environmental or social benefit fall outside the supplied evidence.

The **actual supplied evidence** is the text of this file, the historical P1/v1 text, the archived draft clauses and the linked assessment register. Every in-world actor, submission, notice, receipt, review, authority and action is fictional. The dossier supplies authored representations of them, not evidence that such procedures occurred. Text inspection can establish that a specified field or distinction is present; it cannot establish actual receipt, fair participation, competent review, enforcement, deletion or repair. Such performance remains **not assessed**.

This edition adds explicit scenario declarations, issue tracks and component assessments. These additions are authoring choices, not newly discovered historical facts. It does not fill the absent original application, original maintenance log, calibration method, instrument identity, contact details, delivery receipts or funding outcome. No real restricted material is held. The claimed protected original exists only as a scenario premise; the current file is a fully public authored demonstration of differentiated views.

The package is a **partial documentary assessment subject**. It does not claim full GR-110, GR-200 or GR-210 conformance. Its assessment register contains selected components and explicitly identified unassessed whole-requirement results. GR-200's package obligations remain applicable; nothing is removed because this is a small example. No reduced conformance profile is assumed. Neither this fixture nor its checks establish truth, legal rights, institutional legitimacy or beneficial generativity.

112.1.2 2. Scenario declaration and service schedule

`P1-PROC/v2` is a **proposed synthetic procedure**, effective for this fixture only. The fictional Fund is the operator. Secretariat records and routes submissions; Panel applies the fictional internal eligibility rule and alone can authorize funding reassessment; Reviewer B assesses the scoped evidential questions; Review Contact handles procedural reconsideration; Custodian controls the described original log. No role is an actual appointment or an available external service. The fixture supplies no jurisdiction or external legal mandate.

Covered users are the team, technician and Panel for this case. No fee is proposed. Text and assisted oral submissions, protected contact and representative submission are designed routes, not deployed channels. An issue description and target sufficient to identify a concern are the proposed minimum intake content; technical clause numbers and public identification are unnecessary. English is the authored fixture language. Translation, disability support and safety arrangements require participant needs assessment in a rehearsal; availability is not presumed. Known barriers are unequal documentation resources, possible exposure of a technician's contact details and inability to inspect a protected original. Actual experience of those barriers and adequacy of assistance have not been measured.

The following illustrative periods are local design choices. Their rationale is a small case needing prompt status communication while allowing a protected evidence request and a reply. No resource study validates their adequacy. They do not replace any external deadline. All clocks use elapsed scenario days; day of receipt is day 0 of each local clock. The proposed extension rule is one reasoned extension, authorized by Review Contact before the current due time and communicated with a new date; missed targets stay in the record. Any further extension requires a capacity review and reasoned alternative. A hold preserves pending status and receives a review point; it does not decide the merits.

Service event	Proposed owner; start → period	Notice, pause or escalation
Receipt/acknowledgement	Secretariat; receipt → 2 days	Identify case, issues and next step; failed contact recorded and protected alternative attempted if available.
Clarification/scoping	Secretariat; missing-information request → 3 days for reply, then review	Explain why information matters and available assistance; no automatic factual rejection on silence.
Urgent triage	Review Contact; identified urgent risk → 1 day	Limited temporary protection only within fictional internal authority; review after 2 days.
Reviewer assignment	Review Contact; scoped case → 2 days	Record accepted questions, competence and conflicts; unavailable reviewer triggers notice and deferral.
Grounds/reply	B; provision of usable grounds → 2 days	A material new ground restarts the relevant reply period; protection barriers can require adjustment.
Initial disposition	B; receipt of sufficiently scoped challenge → 10 days	Status notice if extension needed; refer matters outside B's competence.
Disposition notice	Secretariat; disposition → 1 day	Identify exact notice version, recipient and known delivery status.
Further-review request	Review Contact; confirmed receipt of disposition → 10 days to request	Where receipt is unknown, no expiry is inferred; acknowledge within 2 days and decide scope within 5 days.
Further review	Review Contact; accepted further-review scope → 10 days	Conflict screening and stay consideration; unavailable independence disclosed.
Action follow-up	Panel; action assigned → 5 days to first status report	Identify action-specific due/review point and completion evidence; unresolved action prevents a completed-remedy claim.
Closure	Review Contact; proposed closure → 2 days for record check	Closure distinguishes outstanding actions and their owners; reopening on new evidence or defect remains available.

Protection/continuity	Custodian/Review Contact; incident or handover concern → 1 day to triage	No onward disclosure beyond declared purpose; retention and transfer require separate documented authority.

No hearing, appointment, capacity test, acknowledgement, notice transmission or clock performance was executed. The schedule's completeness is a documentary question; its feasibility and actual fulfillment remain unassessed. It deliberately exposes a resource question: an institution with only the original decision maker cannot honestly advertise independent further review.

112.1.3 3. Inventory and temporal trace

Reference/version	Supplied representation, provenance and availability	Target / acquisition / recording / assessment time
A1/v1	Author-supplied summary of a team's application asserting an operating sensor network; full application **not supplied**.	Pre-submission operation / scenario submission day 0 / author representation in this edition / contextual review day 12.
M1/v1	Author-supplied description of an intake extract omitting a calibration attachment; extraction from A1 asserted in the scenario, not reproduced from an available packet.	Packet contents / day 2 / day 2 / day 12. Other channels and completeness unknown.
S1/v1	Exact fictional output, "The sensors were not calibrated." `SummaryTool/demo-v0`, input M1 only, task summary; no runtime, configuration, internals or reproducibility evidence.	Pre-submission calibration / M1 acquired day 3 / generated expression day 3 / reviewed day 12.
T1/v1	Authored testimony summary attributed to a protected technician: calibration before submission and maintenance labor. Original utterance and independent interview **not supplied**.	Pre-submission activity; exact interval unknown / day 7 / day 7 / day 12.
L1-excerpt/v1	Entire supplied fictional excerpt: "Day −2: station S adjusted against reference instrument." It is an invented nonpersonal excerpt, not an authenticated copy.	Adjustment day −2 / excerpt available day 8 / original entry time **unknown** / day 12.
L1-original/unknown-version	Described protected original; **not supplied**, identity/contact information imagined but not entered. Custodian's asserted protection premise is a fictional confidentiality arrangement.	Original creation/acquisition time unknown. No original examination represented.
K1/v1	Fictional internal rule: "documented calibration" requires an attachment in the application packet.	Effective scenario days 0–20; used in D1. No external authority asserted.
K2/v1	Fictional internal revision permits assessed maintenance testimony and controlled log inspection as possible evidence; does not guarantee sufficiency.	Announced day 20, effective day 21. Earlier application not silently reevaluated as if K2 existed.
D1/v1	Authored representation of Panel excluding the application using C1/v1 and K1.	Decision/action day 5; actual delivery and execution not observed.

Reference/version	Supplied representation, provenance and availability	Target / acquisition / recording / assessment time
CH1/v1	Authored challenge from team, receipt label day 8, challenging C1/v1, rule application/adequacy, attribution and consequences; legal allegation separately routed.	Concerns D1 and pre-submission conditions; entered day 8. No actual submission occurred.
AS1/v1	Authored qualitative assessment by B, day 12; examined representations M1, S1, T1 and L1-excerpt, not originals.	Evidence state limited to those items as represented by day 12.
D2/v1	Authored representation of Panel scheduling renewed assessment under K2 on day 22.	Reassessment date **unspecified**; completion/outcome **not supplied** by day 40.
X1/v1	A prior exported spreadsheet is a known scenario dependency; actual file, custodian contact and corrected version **not supplied**.	Creation/dispatch time unknown; correction unverified.

The three histories are distinct: alleged maintenance and institutional actions; recording, inference and assessment; and the K1→K2 change in admissible documentation. Record identifiers do not settle physical sensor identity. The station named S and the equipment described in A1 are an **unresolved match**, not a verified equivalence. A maintenance Relation can retain participants, duration and contribution history while the same episode also receives Event/Process descriptions. No one-to-one mapping to ultimate reality is claimed.

112.1.4 4. Claims, evidential roles and uncertainty

Assessment method `METHOD-P1/v2` is author inspection of stated claim content, source scope, derivation, alternative explanations and reasons. The in-world assessment `AS1/v1` uses qualitative claim-relative comparison, with no numerical confidence scale or assertion of independent source verification. Criteria distinguish testimony about calibration, a log of adjustment, compliance with an attachment rule, and proof of calibration quality. No combination of the supplied material establishes the last of these.

All claim assertions below are entered by the fixture author; the source column names their represented in-world origin. Each assertion concerns the single application/maintenance episode unless stated otherwise. No cross-person or cross-period aggregation is supplied. AS1's criterion and date do not silently transfer to the Panel's earlier assessment. The domain criterion for adequate calibration remains unavailable; the author's documentary judgment is that the dossier states that limit.

Claim/version; origin; target time	Assertion, epistemic mode and relevant modality	Grounds, assessment and material uncertainty
C1/v1; Panel adopting S1; before day 0	"Calibration did not occur." Inference asserting actual non-occurrence, recorded day 4.	M1→S1→Panel assumes all calibration would appear in the intake extract. Coverage unestablished; **historical unsupported conclusion**, retained as such.
C1/v2; B; before day 0	"Testimony supports calibration activity; the supplied excerpt supports reported adjustment." Retrospective assessment, day 12, of an alleged actual occurrence.	T1 and L1-excerpt support different components. Method, quality, instrument identity, source independence and actual occurrence remain qualified. Preferred present assessment within AS1's limited evidence scope, not a factual certification.
C2/v1; Panel's implied eligibility judgment; day 0	"Application met K1" is the question under review, not an established assertion of compliance. Normative rule application with unresolved factual premises.	Complete A1 unavailable; absence from M1 does not establish absence from A1. K1 application **unresolved**. The rule's adequacy is separate.

Claim/version; origin; target time	Assertion, epistemic mode and relevant modality	Grounds, assessment and material uncertainty
C3/v1; Team; D1 and effects through day 40	“Exclusion was unfair.” Ethical judgment under accessible participation and recognition of maintenance labor.	Documentation burden and omitted contribution are asserted grounds; Panel’s consistent-evidence value retained. No universal ordering or numerical net benefit. Actual burdens and other applicants’ circumstances not measured.
C4/v1; Team; D1	“D1 violated a legal duty.” Party allegation, not a determination.	Legal concept: alleged duty of fair treatment. Source, jurisdiction, competent authority, temporal applicability and procedural avenue **unresolved**. B has no asserted legal competence.
C5/v1; Technician; maintenance before day 0	“Maintenance enabled continued monitoring.” Attributed generative inference, not direct observation of the causal linkage.	Reported adjustment and continuing operation compared with reported earlier drift. Maintenance may stabilize capacity; competing equipment/operator conditions and duration of effect not examined.
C6/v1; Team; alternative to D1	“Granting the application would have preserved training.” Counterfactual proposed in CH1, not observed outcome.	Proposed costs and availability are unverified; allocation authority, funding sufficiency and feasible timing remain unknown. An available request route does not establish practical access to support.
C7/v1; Team; days 5–30 and prospective period after day 30	“Replacement was delayed and training interrupted; exclusion contributed.” Reported effects plus causal inference and prospective concern.	Split for examination into C7a/v1 (reported delay/interruption), C7b/v1 (inferred contribution of D1), C7c/v1 (possible future capacity loss). No independent follow-up or exclusion of other causes.

Assignment	Material → claim; assigned by/date	Reasoning, dependence and result
EA1/v1	M1→C1/v1; Panel/day 4	Panel’s missingness inference is preserved as its historical assignment, not adopted by author review. No demonstrated capture coverage.
EA2/v1	M1→limited statement “attachment absent from M1”; B/day 12	Supports the extract-content representation only; actual A1 coverage and channel selection remain unknown.
EA3/v1	S1→C1/v1; Panel/day 4; qualified by B/day 12	Generated restatement inherits M1’s limitation. M1, S1 and C1 are one derivation chain, not three observations. No internals invented.
EA4/v1	T1→C1/v2; B/day 12	Testimony supports a report of calibration by someone with alleged situated access. Access, memory, method and identity not independently established. Institutional status alone neither accepts nor rejects testimony.

Assignment	Material → claim; assigned by/ date	Reasoning, dependence and result
EA5/v1	L1-excerpt→C1/v2; B/day 12	Supports the narrower represented adjustment report. “Adjustment” is not automatically adequate “calibration.” Authored excerpt authenticity and actual occurrence are not verified.
EA6/v1	T1+L1-excerpt→C5/v1; B/day 12	Relevant to maintenance account; source independence unknown because testimony may derive from the log. Connection to durable monitoring remains unestablished.
EA7/v1	Team’s day-30 report→C7a/b/c; recorded by Secretariat/day 30	Reported realized effects, causal attribution and prospective risk separated. No outcome survey or causal analysis performed.

Alternative register `ALT/v2`: **retained** explanations include calibration outside the intake channel, adjustment short of adequate calibration, and identity mismatch. The inference “no attachment anywhere because none appears in M1” is **rejected as unsupported under current coverage**, not proof of the contrary. Selective preservation is a known possibility; deliberate concealment is **not examined and not alleged as established**. Independent confirmation, instrument matching, calibration-method inspection and sensitivity to another eligibility rule were **not performed**. Contradictory sources are not assigned equal weight merely to preserve pluralism.

Uncertainty register `U/v2`: identity (which instrument); observation (what occurred and was captured); method (calibration meaning and quality); dependence (T1/L1); timing (original log entry, original transmission); causal linkage (maintenance→capacity and D1→loss); boundary (other channels, funding and operating conditions); and legal/authority context. Confidence in one component supplies no universal confidence score for the others. Zero, false, unknown and unexamined retain different meanings.

112.1.5 5. Issue tracks and represented transitions

The authored receipt record `REC-CH1/v1` distinguishes receipt on day 8 from acceptance of grounds. The proposed reviewer A authored the initial uptake note; this disclosed relationship prevents an independent-review description. The fiction routes evidential review to B, whose relevant role is comparison of claim/source scope. No actual competence, availability, acceptance of appointment or independence was verified. The Review Contact is likewise a declared fictional route, not an operating appeal body.

Track	Questions and competent scenario recipient	Represented day-12 disposition; status at day 40
I1	C1/v1 warrant and missingness inference; B	Replace unqualified present reliance with C1/v2; earlier assertion and D1 use retained. Documentary correction supplied, real procedure not performed.
I2	Whether A1 complied with K1; Panel, informed by B	Cannot decide from M1; complete packet sought but absent. **Unresolved**, Panel owns follow-up.
I3	Adequacy of attachment-only rule; Panel	Rule question retained separately; K2 authored as later scenario change. Review of transition effects and meaningful response not demonstrated.

Track	Questions and competent scenario recipient	Represented day-12 disposition; status at day 40
I4	Maintenance contribution and attribution; B/Panel	Include C5 with limits; credit/payment/return decision **pending**. No entitlement follows from attribution.
I5	Asserted legal duty; outside B's competence	Allegation retained with missing legal context. **Referral proposed**, recipient/acceptance unavailable; not "legal claim resolved."
I6	Practical consequences and possible response; Panel	D2 is scheduling only. C7 remains attributed; repair and funding outcome **pending**.

State trace `STATE/v2`: received (REC-CH1) → scoped (I1–I6) → assigned in the scenario → under review (AS1's described examination) → issue dispositions (above) + action pending. The file provides no actual grounds-delivery or reply event. It therefore does **not** attest that an operative transition into a valid consequential disposition satisfied all prerequisites. A real procedure cannot skip that evidence by applying these labels. Overall case closure is not claimed, and no expiry or agreement is inferred from silence.

Proposed grounds notice `GND/v1` identifies M1, S1, T1 and L1-excerpt, the separate I1/I2/I3 questions, intended scope limitations, a two-day reply period after usable provision, protected contact and adjustment route. It is an authored specimen only; dispatch, delivery and response opportunity remain **not assessed**. A later material ground or changed criterion would need a new response opportunity under the declaration.

112.1.6 6. Revision, dependencies, actions and generative conditions

Revision `REV1/v1` links C1/v1→C1/v2, attributed to B on day 12, reason **evidence/assessment change**. It changes the current warrant and formulation, not the alleged calibration event. Revision `REG1/v1` links K1→K2, attributed to Panel, announcement day 20/effective day 21, reason **category/rule change**. The mapping is partial: an absent earlier attachment cannot be converted into a demonstrated testimony assessment under K2. Earlier D1 retains K1 and its actual represented grounds. D2's future reassessment does not retroactively supply those grounds.

Dependency register `DEP/v2` links C1/v1 to D1, S1's uptake note, the public summary and X1. The present authored summary changes to PS/v2; D1 is retained with current qualification and pending action review. X1 is outside the supplied file/control boundary: correction is **unverified**, not presumed performed. No universal downstream propagation or external recall is claimed.

Action	Scenario owner/authority; status; next review point	Evidence required and present limit
AC1 — correct current account	B within AS1 scope; documentary C1/v2 supplied day 12	This text demonstrates changed wording and linked reasons. Actual institutional correction unobserved.
AC2 — reassess application	Panel under K2; **scheduled**, D2 day 22; first proposed status review day 27	Dated reassessment, reasons and notice needed; absent at day 40. Proposed review target itself not evidence of a performed review.
AC3 — notify team and Panel	Secretariat; **notice specimen available**, dispatch/delivery unknown	Exact notice, recipient, route, dispatch and receipt evidence absent. No assertion that deadlines began.
AC4 — address X1	Secretariat; external custodian/contact unknown; **unverified**	Located copy and correction/receipt evidence needed. The unknown is not permission to declare propagation complete.

Action	Scenario owner/authority; status; next review point	Evidence required and present limit
AC5 — investigate reported capacity loss	Panel; **proposed**, authority/ resources and follow-up date unresolved	Participant account, alternative causes and actual capacity observations needed; C7 alone does not establish complete loss attribution.
AC6 — recognition and training support	Team's proposed response to contribution and loss; **not authorized or performed**	Decision, eligible recipients, transfer, return pathway and changed future conditions would need separate evidence. No numeric return, payment right or completed repair asserted.

GEN/v2 records the maintenance account's capacity (continued operation), alleged prior drift, candidate stabilizing relation, uncertain mechanism, and short observation horizon. The exclusion account identifies possible reduced practical access to replacement and training, while C7 remains a report. The possibility-field account is actor-relative and incomplete: the team could request review under the proposed route; whether it had usable resources, safety and time to exercise it was not observed. Later grant support remains counterfactual, and an alternative of a regional instrument-sharing programme introduced by this fixture's author is **retrospectively imagined only**; no evidence makes it available to the team at day 5.

No generativity-return chain is established. Generation, conversion/transfer, any return to contributors or enabling conditions, and any changed capacity require distinct support. Acknowledged contribution does not prove recirculation, an equitable distribution or entitlement. No completed restoration of training, monitoring or trust is claimed.

112.1.7 7. Views, protection and retention

View AS-VIEW/v2 is this public assessment dossier, including the invented L1 excerpt, source limitations and case tracks. View PS/v2 below is a reduced public summary derived from AS-VIEW/v2 by selecting the current assessment and action limits. The described **protected source arrangement** is a scenario design: Custodian would hold L1-original, B is authorized only for the nonpersonal excerpt, and no author or actual reviewer has examined an original. A future controlled assessment could be reported with its own reviewer, scope and limits; it could not become the present author's direct examination.

No actual personal data, restricted originals, access controls or deletion service are supplied. The proposed schedule separates substantive claims/history, testimony, contact data, protected original, reviewer working material, notices and permitted audit metadata. Custodian would review retention at closure and after any reopening; no deletion is represented as performed. Retaining an audit statement need not retain content barred from continued storage. The proposal does not identify an operative retention or disposal decision. A contextual arrangement would identify its authority, timing by a stated date, period or event, and permitted verification. These details remain design questions; their present absence does not by itself establish failure of the decision-level requirement C210-094 or permit indefinite retention.

PS/v2, produced by the fixture author on 2026-09-22:

> In this fictional case, an earlier conclusion of no calibration relied on a missing attachment in a limited intake extract. Testimony supports a report of calibration activity; the supplied maintenance excerpt reports adjustment. Instrument identity, calibration method and quality remain unresolved. A revised internal rule permits broader evidence, and reassessment is scheduled, without an evidenced funding outcome. Reported training and replacement losses, practical repair, delivery of notices and correction of an external copy remain unverified. The described original log is not supplied or independently inspected. This summary omits scenario contact information and is a partial view, not a truth or conformance certificate.

Both views preserve dissent, qualification and uncertainty without displaying a protected person's identity. Their comprehensibility, adequacy for contestation and actual access enforcement have not been tested with participants.

112.1.8 8. Failure branches and documentary checks

These are authored variants examined by comparing their text with the archived clauses. They are **not additional events in the baseline narrative** and not exercised institutional procedures. The result below concerns detectability of a documentary defect; expected procedural responses remain rehearsal tasks.

Variant	Injected change	Documentary finding and expected response
FB1	Replace C1/v2 with “Calibration definitely did not occur; three sources confirm it,” counting M1/S1/C1.	Coverage and derivation objections remain recoverable in EA1–EA3. E200-012/013 and C210-015/061 would be contradicted by adopting this result.
FB2	Label alleged calibration “unrealized” because its description is retrospective.	C1/v2 distinguishes asserted actuality from inferential access; E200-005 applies. Retrospective is not counterfactual.
FB3	Present Reviewer A as independent and close I5 as a legal ruling.	Assignment relationship and missing legal authority contradict the labels; C210-051/082 and E200-025 expose separate defects.
FB4	Announce “funding and training restored” on the basis of D2.	AC2/AC5 disclose missing implementation and outcome evidence; C210-071/077 and R110-077/081 are discriminating.
FB5	A specimen acknowledgement due day 10 is dated day 11 with no explanation.	The specimen is late against its stated target. Record a missed event, cause/limits, notice and escalation under C210-088; no merits rejection follows. No real clock was exercised.
FB6	A notice specimen has “sent” but no recipient or delivery state; then starts the further-review expiry clock.	C210-073 documentation is incomplete; receipt-start assumption unsupported. A new opportunity or alternative route would need actual performance evidence.
FB7	Replace K1 by K2 in D1, hide C1/v1 and omit X1.	REV1/REG1/DEP preserve the history and unresolved propagation; E200-017/018/019/038 and C210-075/076 address the loss.
FB8	Declare L1-original verified because B was permitted to inspect an excerpt; publicize imagined contact data.	Examination and disclosure scope are overstated; E200-023/042 and C210-090/091/095 apply. A restriction never establishes unseen examination.

The authored checks establish that these contrasts can be described and located. They do not establish inter-reviewer agreement, a functioning user interface, field burden or independent comprehension. The fixture needs a real rehearsal before any performance result changes.

112.1.9 9. Assessment boundary and next work

The linked JSON records exact requirement IDs, component, subject, applicability, result, evidence, rationale and locator. Each row also identifies method, assessor, assessment date, baseline and whether it covers an entire requirement. A **fulfilled component** means the specified documentary content was inspected and found present in that subject; it is not a fulfilled whole requirement where other claims/components are outside the check. Whole-requirement rows remain not assessed when examination is incomplete. C210-094 remains not assessed with applicability unresolved because no operative retention/disposal decision

is identified. Unperformed actions are not relabeled not applicable. During author review, C210-094 was initially marked not fulfilled by inferring a decision trigger from the proposed arrangement and treating a fixed period as mandatory. Review correction QA-01 withdrew that finding: an event-based timing condition can suffice, and an unmade decision is not invented to supply the trigger. The corrected result is recorded in the component register.

Next evidence is a bounded rehearsal with separate participants: locate the route; submit and scope CH1; handle a conflict; communicate grounds and receive a response; miss a target and recover; restrict an original; decide each issue; notify; revise dependencies; and follow an action. Retain what participants actually did, resource/time measurements and comprehension failures, with their consent and protection arrangements appropriate to that rehearsal. No current finding validates the service periods or operational capacity.

This edition changes the fixture and its documentary assessment only. A future normative edition requires a changed dependency declaration and targeted reassessment; successful 0.2 component results do not automatically transfer to 0.3.

113 revision regressions

Original source: `examples/validation_0.2/revision_regressions.md`.
Original source SHA-256: `4dfd59dbecaa8a035b58929951a3f06041339aa5ae3df04a41ff5af6c7db5443`.

113.1 Discriminating cases for the 0.3 corrections

Class: Informative synthetic review fixture
Status: EXPERIMENTAL; 2026-09-22
Basis: 0.2 findings and 0.3 dispositions

These cases distinguish the intended interpretation of the revised clauses. The comparison is an authored-text review. It does not report a real election, institutional action, transfer, historical occurrence or observed user performance. The separate P0 numerical results are recorded by the executed arithmetic checker.

113.1.1 RG-01 — An attempted ballot is not silence

Five eligible participants are represented. Two have valid approvals, one a disapproval, one an abstention, and one only an attributable unresolved attempted submission. The tally has `Y=2`, `D=1`, `A=1`, `R=4`, `I=1`, `U=0`, `N=5`.

The numerical conditions pass, but an unresolved validity/handling issue still needs disposition. Calling the fifth person a nonrespondent loses the attempt; treating the attempt as an abstention changes the valid return count. Revised D1-032 preserves `N=R+I+U` and D1-074 preserves the clarification and challenge history. A valid replacement moves that person into `R` and out of `I`. Multiple submissions from one person do not become multiple persons. An unattributable message remains separately inventoried.

Text-review result: the revised provisions express these distinctions without changing D1-031. Actual verification, participant identity and challenge handling remain untested.

113.1.2 RG-02 — No mapping does not remove a general safeguard

Candidate account A states that the six recording roles are ultimate constituents of reality and provides no metamodel mapping. Candidate B preserves operational roles separately and makes no mapping claim.

Both lack a mapping, but that fact concerns only the conditional mapping component of V100-011. Candidate A still violates the general separation. The revised Annex A assessment row asks the general question before considering whether a mapping-specific check is applicable.

Text-review result: the revised assessment instruction no longer permits the whole requirement to be skipped because a mapping is absent. This result does not settle any metaphysical thesis.

113.1.3 RG-03 — An actual effect can have disputed attribution

An account represents an effect as realized, its evidence as retrospective inference, and the proposed contributor's attribution as disputed. These are three distinct statements. A single exclusive list containing `realized`, `inferred` and `disputed` would make the combination impossible or obscure its meaning.

Text-review result: revised R110-012 permits the combination and separately requires explicit unresolved actuality where applicable. The case tests representational distinctions; it does not establish the effect or the contributor's actual role.

113.1.4 RG-04 — A transfer does not establish recirculation

A proposed return account contains the following authored components:

Stage	Supplied assertion	Grounds and uncertainty
Initial generation	A maintenance collaboration is reported to have sustained monitoring	A participant's account; extent and alternatives unresolved
Conversion/transfer	A sponsor proposes returning resources to the collaboration	A fictional proposal; no delivery evidence
Return path	The proposal names a recipient route	Feasibility and actual receipt unverified
Later generative conditions	Continued maintenance capacity is an intended effect	No follow-up evidence of realization

Candidate A summarizes the proposal as proof that regenerative capacity was restored. Candidate B retains the four stages, their connections and the stated uncertainty, and presents capacity renewal as intended and unverified.

Text-review result: R110-112 and the revised semantic/assessment schedules require these distinctions when recirculation is asserted. Candidate A's conclusion is not supported by the represented stages. Candidate B supplies a bounded, uncertain account; this is not a finding that recirculation occurred or that every GR-110 obligation is fulfilled. If no recirculation claim is made, R110-112's trigger is absent while other applicable return requirements remain assessable.

113.1.5 RG-05 — A definition reference does not import an unstated certification

A GR-210 case uses GR-100 meanings and supplies a bounded GR-200 claim package. It makes no independent claim of GR-100 vocabulary-application conformity. The revised GR-210 reference identifies exactly the imported meanings, while C210-030 continues to require the applicable GR-200 package obligations.

Text-review result: the dependency scope is explicit. Neither a claim-field-only check nor the absence of a separate GR-100 conformity declaration substitutes for assessment of the required GR-200 package.

114 MANIFEST

Original source: `foundation_manuscripts/MANIFEST.md`.
Original source SHA-256: `20b3f6b0999847d1c4f2a8c548d7560dfc840748664a47b73cd5b174817e5e26`.

114.1 Foundation Manuscript Manifest

Document class: Informative source register
Status: PROVISIONAL; initial indexing of the seven locally supplied PDFs
Indexed: 2026-09-22

114.1.1 1. Scope and source handling

This register identifies the project-local foundation corpus. FM identifiers identify particular files, not an adopted doctrine or a claim of publication precedence. Both Chapter 3 files remain separately identifiable. No PDF has been renamed or replaced.

Titles below come from the opening pages. Author attribution for the GRE chapters comes from their PDF metadata; the two metamodel papers name the author on their opening pages. Publication dates and formal publication status have not been verified. PDF creation timestamps are build metadata, not evidence of publication or approval. A filename containing `fir st_draft` is identified as a filename label rather than treated as independently verified editorial status.

Section references and page numbers refer to the supplied PDF, using one-based PDF pages. These entries provide a planning-oriented source map, not a complete collation, mathematical review, or verification of the manuscripts' external references. An external work cited inside a manuscript has not thereby been independently verified for use in a programme publication.

The companion foundation traceability map connects passages to candidate requirements, unresolved questions, and prospective pilot evidence. Those operational translations remain proposals.

114.1.2 2. Indexed manuscripts

114.1.3 FM-001 — Historical Conditions of the Contemporary Economy

- **File:** GRE_Chapter_01.pdf, 180 pages.
- **Author:** Wanhong Huang, as recorded in PDF metadata.
- **Date:** Publication/manuscript date unknown; not inferred from PDF build metadata.
- **Version/status:** Chapter 1 of *Generative Relational Economics*; formal publication and revision status unknown.
- **Primary concepts:** Historical formation of economic categories; relational production; symbolic abundance; representational instability; classification; authenticity; provenance; epistemic trust; access to generative conditions.
- **Important passages:** Section 1.14, "Symbolic Abundance and Representational Crisis," pp. 78–83; especially symbols and referents (§1.14.2), administrative classification (§1.14.3), authenticity/provenance/trust (§1.14.4), and coordination under representational instability (§1.14.5).
- **Terminology and notation:** The section title uses "representational crisis." The user's programme motivation uses "symbolic crisis"; this is a motivation-level connection, not an alteration of the manuscript title or terminology. The cited section develops conceptual distinctions rather than a record encoding.
- **Relevant programme documents:** Programme Brief; GR-100/110/140/150/200/210/400; epistemic and institutional work planning.
- **Supersedes / revised by:** No verified supersession relationship.
- **Known tensions or ambiguities:** Authenticity, provenance, trust, and truth are distinct. Representational crisis includes sincere category mismatch as well as fabricated representations. Verification infrastructure can itself concentrate power; provenance alone does not settle the represented claim.

- **Notes for contributors:** Use the chapter for motivation and problem framing. Its historical account does not itself supply adopted recording requirements or establish compatibility with external standards mentioned in the text.

114.1.4 FM-002 — Constitution and Research Programme of Generative Relational Economics — `complete_first_draft` file

- **File:** GRE_Chapter_03_complete_first_draft.pdf, 241 pages.
- **Author:** Wanhong Huang, as recorded in PDF metadata.
- **Date:** Publication/manuscript date unknown.
- **Version/status:** "Complete first draft" is the filename label; independent editorial/publication status unknown.
- **Primary concepts:** GRE's relation to broader GR theory; four primitive distinctions; plural methods; generative effects; epistemic commitments; praxis; evaluation; power; research programme revision.
- **Important passages:** Primitive structure (§3.3, pp. 22–34); praxis (§3.12, pp. 128–139); evaluation and normative orientation (§3.13, pp. 139–151); competing accounts of generativity (§3.19.8, p. 206 onward).
- **Terminology and notation:** Change, structure, constraint, and difference are a minimal analytical vocabulary under ontological suspension. These are not six record classes or four required database fields. Generativity has several related formulations whose equivalence is not presumed.
- **Relevant programme documents:** Programme Brief; GR-100/110/200/210/400; praxis, evaluation, and policy-proposal planning; technical reports.
- **Supersedes / revised by:** Related to FM-003; formal supersession is OPEN. Retain separate citations.
- **Known differences:** This file's §3.2 has eight problem families; its summary on p. 22 says so. FM-003 contains an additional subsection on access to generative capacity and conditions. Section pagination differs throughout.
- **Notes for contributors:** Preserve this formulation when tracing conceptual development. A complete comparison of the two Chapter 3 files remains OPEN; the identified difference is not asserted to be the only difference.

114.1.5 FM-003 — Constitution and Research Programme of Generative Relational Economics — unqualified filename

- **File:** GRE_Chapter_03.pdf, 243 pages.
- **Author:** Wanhong Huang, as recorded in PDF metadata.
- **Date:** Publication/manuscript date unknown.
- **Version/status:** Chapter 3; no verified edition or formal publication status. The shorter filename does not establish finality.
- **Primary concepts:** Disciplinary constitution; access to generative capacity and conditions; four primitive distinctions; orientations of generation; epistemic commitments; praxis; normative evaluation; internal pluralism.
- **Important passages:** Access to generative capacity and conditions (§3.2.3, p. 15); primitive structure (§3.3, pp. 23–34); orientation of generation (§3.9, pp. 94–104); praxis (§3.12, pp. 129–141); evaluation (§3.13, pp. 141–152); competing accounts of generativity (§3.19.8, p. 208 onward).
- **Terminology and notation:** The four primitive distinctions remain analytical dimensions. Praxis identifies iterative diagnosis, intervention, tracing, feedback, revision, and possible withdrawal, reversal, or repair; it explicitly does not impose one mandatory sequence on every practical problem.
- **Relevant programme documents:** Programme Brief; GR-100/110/200/210/400; praxis and evaluation work; policy and institutional proposals.
- **Supersedes / revised by:** Related to FM-002; formal supersession is OPEN.
- **Known differences and limits:** Section 3.2 contains nine problem families, including the access subsection absent from FM-002's corresponding list. Generation is not intrinsically beneficial (§3.10, p. 115; §3.13). Access to outputs and access to the conditions of generation are distinguishable concerns.

- **Notes for contributors:** Cite the precise file and section. Treat the additional access emphasis as an observed variant, while leaving authorial precedence and wider editorial differences unresolved.

114.1.6 FM-004 — The Ontological View of Generative Relational Theory

- **File:** GRE_Chapter_04.pdf, 183 pages.
- **Author:** Wanhong Huang, as recorded in PDF metadata.
- **Date:** Publication/manuscript date unknown.
- **Version/status:** Chapter 4; formal publication/revision status unknown.
- **Primary concepts:** Ontological, relational, and manifestational reality; ontological suspension; manifestation relations; non-invertibility; symbolization; recursive effects of representation; scale and historical categories.
- **Important passages:** Three registers (§4.2, pp. 11–19); ontological suspension (§4.3, pp. 19–27); manifestation and its mappings (§§4.6–4.9, pp. 43–74); symbolization and recursion (§§4.10–4.11, pp. 74–89); reality, access, and epistemic reconstruction (§4.22, pp. 172–180).
- **Terminology and notation:** `M_C: X ↠ Y` (Equation 4.1, p. 65) denotes a general manifestation mapping under conditions `C`. Deterministic, stochastic, partial, multivalued, and historically variable realizations remain open. It is not a universal single-valued function or proposed interchange syntax.
