This intersection permits a broad empirical range while limiting conceptual inflation. A study of a labor platform can belong to GRE when it investigates how contractual, algorithmic, reputational, and infrastructural relations shape workers' future bargaining capacity, subject positions, dependence, or access to opportunity. A study of agricultural credit can enter GRE through the way financing relations reorganize production choices, ecological risk, household vulnerability, and later credit dependence. A study of education can become economically relevant to GRE when it examines the generation and distribution of capabilities, knowledge, credentials, networks, and future participation in production or exchange. A study of artificial intelligence can enter through changing productive capability, ownership of computational infrastructure, knowledge concentration, labor transformation, or new asymmetries in the capacity to generate economically consequential outputs.

The same objects can also be studied outside GRE, and that coexistence is expected. A legal analysis may focus on doctrinal validity, a sociological analysis on status relations, a psychological analysis on cognition, and a GRE analysis on the economic generation and distribution of capacities through the same institution. Domain boundaries therefore concern the primary research problem rather than exclusive ownership of empirical objects. Interdisciplinary work becomes especially important when the economic mechanism cannot be understood without juridical, cultural, ecological, technological, or political relations.

Scope also varies by temporal depth. GRE can examine immediate relational mediation, medium-term capability formation, long-run institutional reproduction, intergenerational effects, or transformations in the conditions that govern later change. The appropriate horizon depends on the generative claim. A microcredit intervention may require months or years to evaluate changes in debt dependence and productive capacity. An infrastructure investment may reorganize settlement, land value, ecological conditions, and institutional expectations over decades. Knowledge and educational processes can generate effects whose later manifestations are difficult to attribute to a single intervention. GRE therefore treats temporal horizon as part of research design rather than assuming that the period convenient for measurement is identical to the period relevant to generation.

The programme is similarly multiscalar. Generative effects can occur within persons, households, organizations, communities, markets, institutions, states, ecosystems, or transnational systems, and they can propagate across these levels. A policy that expands aggregate productivity can simultaneously weaken a local community's bargaining capacity; a household intervention can change community norms; an institutional classification can alter individual access to credit; a technological standard can reorganize international production networks. GRE does not presume that effects observed at one scale aggregate straightforwardly into effects at another.

A useful boundary follows from this scope. Relational complexity alone is insufficient to define a GRE contribution. Many systems contain numerous relations. GRE becomes relevant when the inquiry identifies an economically meaningful process through which relations contribute to generation, reproduction, transformation, distribution, or foreclosure. The analytical burden is therefore positive: the researcher

should specify the relation, the generated object or capacity, the mechanism or interpretive pathway connecting them, the relevant scale and horizon, and the evidence appropriate to the claim.

This scope allows GRE to remain broad without becoming synonymous with social science. It welcomes interdisciplinary objects while retaining an economic center of gravity. It also leaves neighboring GR domains available for questions whose primary object lies elsewhere. The breadth of the programme is therefore an architecture of interfaces rather than a claim of disciplinary absorption.

3.1.3 Economics as the Primary Domain

GRE is constituted within economics because its motivating questions concern the organization of material and symbolic conditions through which economic life is produced and reproduced. Production, distribution, allocation, exchange, labor, care, investment, credit, ownership, technological capability, ecological dependence, institutions, and value formation remain central. The relational and generative vocabulary changes the analytical emphasis placed on these objects; it does not dissolve the obligation to engage economic mechanisms, evidence, and established economic explanations.

This primary-domain commitment has several consequences. First, GRE should be able to state what is economically at stake in an inquiry. A sophisticated relational description does not automatically become economic analysis. The researcher must connect the relational configuration to economically consequential capacities, constraints, valuations, flows, institutions, or distributions. Second, GRE remains answerable to existing economics. When a conventional model explains the relevant outcome more parsimoniously and with adequate empirical support, GRE has no disciplinary privilege that exempts it from that result. The programme earns analytical space by identifying dimensions that established representations omit or by connecting findings that remain separated across existing literatures.

Third, economics as the primary domain does not imply a narrow definition of economic value. Market prices, income, productivity, and output are indispensable in many inquiries, but economic life also depends on capabilities, care, ecological conditions, knowledge, institutional trust, infrastructure, social reproduction, and forms of relational value whose significance may be incompletely priced. GRE therefore studies how multiple forms of value enter economic processes, while preserving the distinction between economic relevance and universal commensurability.

Fourth, the economic domain contains both descriptive and normative questions. GRE can describe how a platform generates dependency or how an institution concentrates productive capacity without thereby deciding whether the arrangement is just. Normative inquiry enters when evaluative criteria are made explicit: distribution, capability, recognition, participation, ecological sustainability, generative justice, or other justified standards. Economics supplies part of the descriptive object; ethical and political reasoning remain necessary where evaluation exceeds positive explanation.

Fifth, the primary-domain commitment helps distinguish GRE from the wider GR framework. GR can investigate generative relations in history, law, education, epis-

temology, aesthetics, governance, or other domains without reducing those domains to economics. GRE concerns those interfaces when they materially affect economic processes or when economic arrangements shape the neighboring domain. A legal rule governing property, for example, is relevant to GRE because it constitutes ownership relations, allocative authority, collateral possibilities, and future investment conditions. The same rule can simultaneously require independent jurisprudential analysis concerning legal validity, interpretation, or rights. The interface is real while disciplinary identity remains differentiated.

This differentiation is important for the future development of the research programme. Without it, GRE could expand until every relational phenomenon becomes an economic phenomenon and the term loses discriminative value. With an explicit economic center, interdisciplinary expansion becomes more rigorous: each borrowing must show what economic problem it helps explain and what aspects remain better handled by another domain.

Economics also offers GRE a demanding test environment because economic systems combine formal institutions, strategic behavior, material constraints, symbolic valuations, historical change, quantitative data, and normative controversy. A viable GRE research programme must therefore interact with several established modes of economic reasoning rather than relying on a single philosophical language. The field's disciplinary identity is strengthened when relational and generative claims produce better questions, better explanations, better empirical distinctions, or more adequate evaluations within this demanding domain.

3.1.4 Relation and Generativity as Organizing Commitments

Relation and generativity provide GRE with its two principal organizing commitments. Neither concept functions as a universal explanation. Relation directs attention to the possibility that economic entities, capacities, positions, and values are partly constituted through connections, dependencies, institutions, recognitions, and repeated interactions. Generativity directs attention to the possibility that present relations alter what becomes possible later. Their conjunction gives GRE its characteristic analytical movement.

The relational commitment begins from specification. A relation should be identified with enough precision to distinguish it from mere co-presence or statistical association. Depending on the inquiry, the relevant relation may involve ownership, exchange, debt, employment, care, authority, information, recognition, technological dependence, ecological dependence, legal standing, platform access, infrastructural connection, or another structured linkage. Relations can be direct or mediated, durable or episodic, formal or informal, symmetric or asymmetric, cooperative or exploitative, visible or weakly represented in available data. GRE does not require these differences to be collapsed into a common relational metric.

Relations can also be constitutive at different levels. A contractual relation may connect already recognized legal persons while simultaneously contributing to their later capacities. Other relations help constitute the relevant economic subject or object itself. Employment relations can stabilize occupational identities and access to social insurance; credit relations can create debtor positions and classifications; plat-

form rules can constitute categories of worker or seller; property institutions can define the objects over which exchange rights are recognized. Relational analysis therefore includes both interaction among entities and the relational production of entityhood.

The generative commitment adds temporal and counterfactual depth. A relation matters not only through its current state but through the capacities, constraints, structures, values, and subsequent relations it helps produce. Generation can involve accumulation, learning, reproduction, institutionalization, path formation, trust, dependence, lock-in, ecological change, innovation, subject formation, or the creation of new option spaces. Some generative effects amplify later agency; others narrow the range of feasible action. Many do both for different actors or at different scales.

GRE consequently treats generativity as descriptive before it becomes evaluative. A relation can be highly generative because it reliably produces further structures or capacities while remaining normatively objectionable. Monopoly power can generate entry barriers; surveillance infrastructures can generate behavioral control; debt can generate productive investment and also dependency; extractive institutions can reproduce themselves. The strength of a generative mechanism does not determine its justice. Normative orientation must be supplied through explicit evaluative argument.

The two commitments become especially distinctive when the generated effects alter the conditions of further generation. A subsidy can increase productive capacity; the expanded capacity can change market structure; the changed market structure can alter bargaining power and investment incentives; those changes can influence the design of subsequent policy. A technology can alter productivity while also reorganizing skills, ownership, infrastructure, and standards in ways that change which technologies can be developed later. At this point, economic analysis concerns more than a sequence of outcomes. It concerns transformations in the field of future possibility.

This recursive feature explains why GRE pays attention to what later chapters call generative conditions and effective rules of change. The language should remain modest. Many cases can be modeled adequately with fixed rules and changing state variables. Stronger claims about rule transformation require stronger evidence and clearer specification. GRE does not infer meta-level transformation merely because a system changes. It asks whether the mechanisms through which future states are produced have themselves been altered and what observations would support that inference.

Relation and generativity therefore organize research without dictating a single ontology or method. A historical study may reconstruct how property relations generated institutional persistence. A causal design may estimate how access to credit changes later productive capacity. A network model may represent diffusion through relational structure. An ethnography may identify meanings and recognition processes omitted by administrative data. A formal model may examine self-reinforcing dependence under specified assumptions. These inquiries share an orientation while preserving different evidential objects and standards.

The disciplinary identity of GRE resides in this organized plurality. Relation speci-

fies the mediating architecture through which economic processes occur; generativity specifies the downstream production of capacities, constraints, values, structures, and possibilities. Their conjunction turns attention from isolated possession toward economically consequential histories of formation.

3.1.5 Openness, Revisability, and Disciplinary Development

An emerging research programme requires mechanisms for changing itself. GRE therefore treats openness and revisability as constitutive commitments rather than temporary concessions made during an early phase. Its concepts, categories, methods, and boundaries should remain corrigible through empirical failure, theoretical criticism, comparison with competing explanations, normative disagreement, and changes in the historical economy it attempts to understand.

Revisability begins with ontological suspension. GRE can use relational, processual, dynamical, network, field, geometric, or computational representations while leaving open the question of whether any one representation captures the ultimate ontology of economic reality. This stance permits formal development without transforming modeling convenience into metaphysical certainty. A network can be an excellent representation for one mechanism and an inadequate representation for another. A field model can capture distributed conditions while obscuring actor interpretation. A qualitative reconstruction can identify constitutive meanings that are difficult to parameterize while remaining unable to estimate population-level magnitude. Openness protects the programme from identifying one mode of access with reality itself.

Revisability also concerns the programme's own categories. Economic subjects, institutions, technologies, forms of labor, ownership arrangements, and modes of value production change historically. A research language adequate to one economic formation can become less adequate as new infrastructures and relations emerge. Artificial intelligence offers an obvious contemporary example: rapid changes in productive capability, knowledge generation, labor substitution and complementarity, compute ownership, and human-machine interaction may require categories that were less salient in earlier economic analysis. GRE's emphasis on historical generation would be inconsistent if GRE treated its own conceptual vocabulary as historically exempt.

The programme should therefore preserve records of theoretical change. When a category is revised, the earlier formulation should remain intelligible enough for researchers to understand what changed and why. This matters for cumulative inquiry. A field that silently changes the meaning of its central terms can create an appearance of agreement while losing comparability across studies. Explicit versioning of definitions, assumptions, measures, and model classes can make theoretical evolution a source of knowledge rather than a source of confusion.

Openness further requires external correction. GRE should remain answerable to mainstream economics, heterodox economics, economic history, sociology, anthropology, political theory, law, ecology, philosophy, computer science, and other relevant fields. The appropriate correcting discipline depends on the claim. A causal claim can fail under econometric scrutiny; a historical claim can fail under archival

evidence; a legal claim can misunderstand doctrine; an ecological model can omit biophysical constraints; a normative argument can rely on undefended values. Interdisciplinarity is therefore not only a source of concepts. It is a structure of accountability.

Internal pluralism performs a related function. Researchers working within GRE may prefer different ontologies, causal accounts, measures, formal systems, or normative theories. The field should permit such disagreement when the competing formulations remain explicit enough to compare. Productive pluralism differs from unrestricted eclecticism. Competing accounts should specify their domains, assumptions, explanatory targets, evidential support, and points of incompatibility. A programme grows when disagreement creates sharper tests and better distinctions.

Disciplinary development also depends on negative results and limits. A proposed generative mechanism may fail to replicate, operate only under narrow institutional conditions, or add little beyond an existing model. A relational representation may become computationally intractable without improving explanation. A broad concept of value may prove impossible to operationalize for a particular decision. Such findings belong inside GRE rather than outside it. A research programme that records only cases where its preferred vocabulary succeeds would gradually lose contact with the conditions under which that vocabulary is useful.

Finally, GRE should remain historically revisable in its normative orientation. The programme can state commitments to transparency, participation, non-domination, capability, ecological viability, generative justice, or other evaluative principles only by making their justification available for criticism. Historical change can reveal conflicts among values or forms of exclusion that an earlier framework failed to perceive. Normative learning therefore requires both continuity and openness: continuity sufficient to make commitments accountable, and openness sufficient to correct them.

The disciplinary identity proposed in this section is consequently provisional by design. GRE is an emerging economic research programme organized around relational constitution and generative consequence, committed to economics as its primary domain, open to methodological and formal plurality, and structured for revision through evidence and criticism. This identity is strong enough to distinguish a problem-space while remaining incomplete enough to learn from the research it enables. The next section can therefore move from the identity of the programme to the concrete classes of economic problems that give it substantive necessity.

3.2 The Problem-Space of Generative Relational Economics

The role of this section is to delimit the class of economic problems for which Generative Relational Economics (GRE) is intended to provide additional analytical leverage. Its objective is not to claim that these problems belong exclusively to GRE, but to identify the recurring situations in which analysis becomes incomplete when it stops at the immediate recipient, current output, present ownership, or a fixed description of economic actors. The section proceeds through eight problem families: relational effects of allocation, downstream generation, value beyond possession and

exchange, persistent asymmetry and power, changing economic subjecthood, symbolic abundance and representational instability, heterogeneous subjects and value structures, and transformation of future generative possibilities. The method is constitutive and problem-oriented. Each subsection identifies an analytical difficulty that already appears within economic life and states the additional questions that a generative-relational perspective places around it.

The problem-space of GRE begins from a simple observation with wide consequences: an economic intervention rarely terminates at the point where it is administratively recorded. A payment reaches a recipient, a loan enters a balance sheet, an educational opportunity is allocated to a student, infrastructure is installed in a locality, compute is assigned to an organization, legal recognition is granted to a category of actor, or information becomes available to a community. Each event can be represented as an allocation. Yet its economically consequential effects depend on the relations through which the allocated object becomes usable, convertible, reproducible, contestable, shareable, or restrictive. The immediate transfer is therefore one moment within a potentially longer generative process.

This does not make conventional measures irrelevant. Recipient-level outcomes, prices, quantities, income, productivity, ownership, expenditure, and welfare indicators remain indispensable where they answer the question at hand. GRE instead focuses attention on cases in which these measures capture only one layer of the economic transformation. The programme asks what new capacities, dependencies, relations, subject positions, institutional routines, representations, and later possibilities are generated after the administratively visible event. It also asks which possibilities are weakened, foreclosed, extracted, or displaced. The resulting problem-space extends economic analysis temporally, relationally, and across scales without presuming that every problem requires maximal complexity.

The eight problem families below are connected but analytically distinct. An allocation can alter future capability without changing formal ownership. A productive process can generate symbolic standing without generating transferable wealth. A capability asymmetry can remain benign in one relational configuration and become power in another. An artificial system can become economically consequential before its legal or moral subjecthood is settled. Symbolic abundance can expand expressive possibility while making evidence, attribution, and scarcity harder to stabilize. Heterogeneous actors can participate in one economic process while valuing its outcomes through partially incommensurable standards. GRE treats these differences as reasons to preserve a plural problem-space rather than compress them into one master variable.

3.2.1 Allocation beyond the Administrative Recipient

Many economic interventions are administratively organized around identifiable recipients. A household receives a transfer, a firm receives credit, a student receives a scholarship, a municipality receives infrastructure funding, a laboratory receives equipment, or a community receives access to a service. Administrative legibility requires such attribution because institutions must identify who qualifies, who receives, how much is transferred, and whether the transfer conforms to a rule. This

recipient-centered representation is operationally necessary, yet it can be analytically narrower than the economic effects that follow.

An allocation enters a pre-existing relational environment. A monetary transfer can alter bargaining positions within a household, reduce dependence on one employer, enable mobility, change creditworthiness, or increase the capacity to support others. A scholarship can generate knowledge, recognition, networks, migration opportunities, future income, or new asymmetries between the recipient and those who remain excluded. Infrastructure can alter land values, mobility, ecological pressure, political expectations, and patterns of settlement. Access to compute can enable research, automation, surveillance, artistic production, or organizational concentration depending on surrounding capabilities and institutions. The economically relevant object is therefore often larger than the administratively named recipient.

GRE treats the recipient as an important entry point rather than the presumed boundary of analysis. The analytical task is to identify which relations are activated, weakened, or reorganized by an allocation and which downstream effects are sufficiently connected to the intervention to warrant inclusion. This requires boundary discipline. Expanding the field indefinitely would make attribution impossible and turn relational analysis into a description of everything connected to everything else. A GRE inquiry therefore needs to justify why particular relational pathways are economically material to the problem under study.

The extension beyond the recipient also changes how incidence can be understood. Formal receipt and effective benefit can diverge. A subsidy assigned to one actor may partly accrue to landlords, intermediaries, suppliers, creditors, family members, or platforms through price adjustment, contractual dependence, or relational obligation. Conversely, an allocation formally directed at one person can generate benefits for a wider group through care, knowledge sharing, network access, or local demand. Recipient-level accounting remains informative, while the relational incidence of an intervention can require a different map.

This problem becomes especially important where institutions evaluate success shortly after delivery. Immediate uptake can coexist with longer-term dependence, capability loss, market concentration, ecological degradation, or institutional displacement. The reverse is also possible: modest immediate output can generate durable capabilities whose value becomes visible only later. GRE therefore places the administrative recipient inside a wider temporal-relational field and asks how the intervention changes the conditions under which later economic action becomes possible.

The resulting problem is not simply one of externalities. Externality language often begins from a focal transaction and asks which effects fall outside the prices or decisions of the transacting parties. GRE can include such effects, but its concern is broader. Some downstream consequences are constitutive of the recipient's own future capability; others alter the identities and relations through which the original economic categories remain meaningful. The issue is therefore not only what spills outward from a transaction, but how an allocation participates in the production of a subsequent economic configuration.

3.2.2 Generation beyond Immediate Output

Economic analysis frequently evaluates a process through an observable output: units produced, income generated, services delivered, learning achieved, emissions reduced, jobs created, patents filed, or profits realized. Such outputs matter, yet a process can also alter the capacity to produce later outputs. GRE distinguishes these two analytical moments. Immediate output concerns what is produced within a defined interval or activity. Generative effect concerns how the process changes the capacities, relations, constraints, orientations, infrastructures, or rules through which subsequent outcomes may be produced.

The distinction is visible in ordinary economic life. Training can produce a credential while also changing confidence, professional networks, problem-solving capacity, and access to later institutions. A research grant can produce papers while also creating laboratories, datasets, collaborations, techniques, reputations, and future questions. A platform can produce convenience while also establishing standards, behavioral routines, data assets, dependency relations, and barriers to entry. Care can meet an immediate need while also maintaining the bodily, emotional, and social capacities through which later participation remains possible. A failed project can produce little immediate output while still generating knowledge about constraints, new alliances, or institutional learning.

These examples show why generativity cannot be inferred mechanically from output volume. High output can consume the capacities on which future production depends. A firm can raise short-run productivity by exhausting workers, degrading equipment, externalizing ecological costs, or eliminating slack needed for adaptation. An institution can increase publication counts while narrowing intellectual diversity. A resource boom can raise current income while weakening alternative productive capacities. Conversely, a process can appear inefficient in a short horizon because it invests in capacities whose effects are delayed or uncertain.

GRE therefore treats the temporal relation between present production and future productive possibility as a central economic problem. This includes positive generation, maintenance, regeneration, reproduction, depletion, and foreclosure. The relevant question is not whether every activity has downstream consequences; that proposition would be trivial. The research problem is to identify which downstream changes are economically consequential, through what mechanisms they occur, how durable they are, who can access them, and whether they remain reversible.

Generation also differs from simple multiplication. A process is generative in the stronger GRE sense when it changes the conditions under which later states can be produced. Replicating an identical output can matter economically, but repetition alone does not establish transformation of generative capacity. A production system becomes analytically interesting to GRE when participation, accumulated resources, learned practices, institutional recognition, or altered relations change what can subsequently happen. The generated object may be material, organizational, epistemic, symbolic, ecological, juridical, or relational.

This distinction creates a problem of attribution. Later capacities usually have multiple antecedents. A newly capable organization may have received funding, benefited from favorable regulation, recruited skilled members, inherited prior infras-

tructure, and learned from failed experiments. GRE should therefore avoid attributing the whole later capacity to one relation merely because the relation preceded it. Generative claims require mechanism-sensitive reasoning and calibrated scope. The field's interest in downstream effects increases rather than relaxes the burden of specifying how generation is believed to occur.

3.2.3 Value beyond Possession and Exchange

Possession and exchange provide powerful ways of organizing economic value. Ownership establishes claims over resources; exchange reveals willingness to trade under particular conditions; prices coordinate decisions and permit aggregation across many activities. GRE retains these objects while addressing situations in which economically significant value depends on participation, relation, access, recognition, continued circulation, ecological condition, or future capability rather than possession alone.

A resource can have little value to an actor who lacks the relations required to use it. Data require interpretive and computational capacity. Credit requires institutional access and future repayment possibilities. Land depends on legal recognition, infrastructure, ecology, community relations, and permitted uses. Knowledge can gain value through dissemination and recombination rather than exclusion. Membership in a trusted network can create opportunities that cannot be transferred as a discrete owned object. Public infrastructures and commons can generate value through reliable shared availability. Care, reputation, cultural meaning, and institutional legitimacy similarly resist complete description through possession.

Value can also change form as it moves through relations. Economic resources can become educational capability, political access, symbolic standing, health, time, security, knowledge, or ecological resilience. These conversions are neither automatic nor necessarily commensurable. The same monetary amount can generate very different capacities under different institutional, bodily, geographical, or relational conditions. Conversely, forms of value that appear qualitatively different can sometimes be converted into economic advantage through mechanisms such as credentialing, collateralization, monetization, platform visibility, or legal recognition.

GRE treats these conversions as part of the economic problem because they influence who can participate in subsequent generation. The possession of a resource at time one may matter less than whether it can be converted into durable capability at time two. A person may formally possess information without possessing the literacy or authority required to act on it. A community may possess land while lacking political protection against dispossession. A researcher may possess an idea while lacking access to laboratories, collaborators, or publication channels. An organization may own technology whose value depends on ecosystems maintained by others.

This perspective also creates a problem of value trajectories. Value can circulate, recirculate, dissipate, be extracted, be destroyed, or become embedded in relations that outlast the originating exchange. An intervention that appears beneficial at one point may produce a later value transfer away from the original participants through debt service, rent, licensing, platform fees, intellectual-property claims, or unequal bargaining. Conversely, a resource can generate distributed value through open stan-

dards, shared knowledge, community infrastructure, or repeated reciprocal use.

The purpose of GRE is not to replace price with a universal alternative measure. Doing so would reproduce the commensuration problem in another form. The programme instead asks which forms of value are relevant to the generative process, how they are recognized or obscured, which conversions occur, and what is lost when heterogeneous values are forced onto one scale. Some studies may use monetary valuation; others may require capabilities, ordinal comparison, qualitative description, multidimensional indicators, or explicit acknowledgement of incommensurability.

The problem-space therefore includes a distinction between current value realization and future value generation. An actor can possess valuable assets while occupying relations that reduce future autonomy or capability. Another actor can possess few assets while participating in institutions that generate durable access, learning, security, or collective capacity. GRE does not assume that future generativity should replace present welfare as the evaluative objective. It instead treats the relation between present value and future generative conditions as an economic question requiring explicit normative and empirical analysis.

3.2.4 Persistent Asymmetry and Economic Power

Economic relations routinely contain asymmetries. Actors differ in wealth, productive capability, knowledge, computational capacity, institutional access, bargaining position, vulnerability, mobility, legal recognition, and ability to exit a relation. Difference alone does not establish domination. A doctor and patient, teacher and student, infrastructure provider and user, or advanced technical system and ordinary user can possess highly unequal capabilities while participating in relations that remain mutually beneficial. The analytical problem is to understand when persistent asymmetry becomes economic power and how that power affects later generative possibilities.

GRE approaches power through the conversion of asymmetry into the capacity to shape another actor's options, dependencies, classifications, resources, risks, or future relations. Resource asymmetry can become power when one party controls access to necessities. Knowledge asymmetry can become power when one party can define the relevant evidence or obscure the consequences of a transaction. Institutional asymmetry can become power when one actor controls eligibility, procedure, or recognition. Exit asymmetry can stabilize dependence even where formal participation appears voluntary. Computational or informational asymmetry can allow one actor to predict, rank, personalize, or intervene in another's behavior at a scale the other cannot reciprocate.

This problem is generative because power can reproduce or deepen the conditions from which it arises. Control over capital can generate further capital; control over data can improve prediction and attract further users; institutional authority can shape the categories through which later authority is exercised; reputational advantage can increase access to opportunities that generate additional reputation. Such processes are not inevitable. Competition, law, collective organization, technological change, public infrastructure, and countervailing institutions can interrupt them. GRE is interested in the mechanisms that determine whether an asymmetry decays,

persists, becomes self-reinforcing, or changes form.

Persistent asymmetry also complicates simple strategies of equalization. Some differences in skill, knowledge, role, or capability are produced by specialization and may be beneficial. Other differences may be difficult to eliminate or may arise continually through innovation. The problem for GRE is therefore not reducible to making actors identical. It concerns the relational conditions under which unequal capabilities remain compatible with meaningful participation, non-domination, contestability, access to alternatives, and the preservation of future capacity.

This issue becomes especially important under radical capability asymmetry. An actor may rely on another whose productive, predictive, cognitive, financial, or infrastructural capacity is orders of magnitude larger. Traditional bargaining models can become insufficient when one party cannot meaningfully evaluate the other's capabilities, reproduce the service independently, or exit without severe loss. GRE treats such situations as economic problems of relational architecture. Governance may need to address access, reversibility, auditability, representation, fallback options, common infrastructure, or limits on conversion of capability into control.

The programme also distinguishes power from observable coercion. A relation can shape behavior through dependence, standards, defaults, classification, architecture, or anticipated exclusion without direct commands. Conversely, strong influence can sometimes arise from trust, expertise, or voluntarily delegated authority without amounting to domination. GRE therefore requires local analysis of mechanisms rather than treating every asymmetry as evidence of one universal power relation.

3.2.5 Subjecthood under Changing Productive Relations

Economic theories require some account of the actors who produce, exchange, consume, invest, work, own, decide, cooperate, and bear risk. These actors are often represented as given units for analytical purposes. That representation is frequently useful. Yet productive relations can also change the capacities, roles, identities, and recognition through which an actor counts as an economic subject. GRE treats this instability of subjecthood as part of its problem-space.

Industrialization transformed relations among workers, firms, households, professions, and states. Corporate forms created collective economic actors with legal capacities distinct from their members. Welfare institutions established categories of claimant, beneficiary, dependent, contributor, and protected person. Digital platforms reorganized relations among user, worker, producer, advertiser, seller, and data source. Contemporary artificial systems further complicate the picture by performing economically consequential tasks that were previously associated with human expertise, agency, authorship, coordination, or judgment.

The GRE problem is not to settle the metaphysical status of every possible subject before economic analysis can begin. It is to examine how economic systems assign, stabilize, contest, and transform subject positions. Legal status, contractual capacity, ownership, accountability, recognition, access to institutions, technological mediation, and productive participation can all affect who is treated as an actor and which consequences attach to that treatment.

Changing productive relations can also alter human subjectivity without replacing human subjects. A worker who collaborates with automated systems may become responsible for supervision rather than direct production. A creator working through generative tools may occupy changing relations to skill, attribution, originality, and ownership. A consumer can simultaneously become a source of behavioral data, content, training material, reputation signals, and network effects. A household member can become an economically visible care provider when institutions change the classification of care. Subject positions are therefore partly produced through the categories and relations of economic organization.

This creates problems for models that assume stable preferences, capabilities, roles, or boundaries of agency across the period being analyzed. Participation in an economic relation can change what an actor knows, wants, can do, expects, or is permitted to become. These changes do not imply that subjecthood is infinitely fluid. Bodies, histories, institutions, legal status, material constraints, and persistent identities provide continuity. GRE's task is to identify which aspects of subjecthood are sufficiently transformed by economic relations to matter to explanation.

The problem also has distributive consequences. When productive systems redefine valued participation, some actors gain recognition while others lose it. Automation can reduce the market value of an existing skill while increasing the value of complementary judgment or coordination. Credential systems can open access while excluding actors whose competence is not institutionally legible. New categories can create rights and protections while also fixing identities in ways that become restrictive. GRE therefore studies subject formation together with the institutional conditions under which recognition generates capability or constraint.

3.2.6 Symbolic Abundance and Representational Instability

Contemporary economies increasingly operate through symbolic objects: data, classifications, scores, rankings, credentials, financial representations, software, models, digital identities, synthetic media, generated text, virtual assets, and machine-produced predictions. Symbolic production has become inexpensive in many domains, while attention, verification, trusted interpretation, and institutional recognition remain scarce. GRE treats this divergence between symbolic abundance and representational stability as a distinct economic problem.

A representation can influence economic reality even when it is incomplete. Credit scores affect access to lending; rankings affect applications and funding; metrics shape organizational behavior; maps and categories determine eligibility; recommendation systems alter visibility; forecasts influence investment; labels affect trust; and digital profiles mediate access to platforms or services. These representations do more than describe pre-existing actors. Once institutions act on them, they can change the relations and opportunities through which those actors subsequently develop.

Symbolic abundance intensifies this process because the cost of producing plausible representations can fall faster than the cost of verifying them. When text, images, claims, reports, credentials, signals, or forecasts can be generated at high volume, scarcity shifts toward provenance, attention, adjudication, trusted institutions, and

the ability to distinguish meaningful variation from noise. Economic value can then accumulate around infrastructures that organize visibility and credibility rather than around content production alone.

Representational instability also arises when the underlying object changes faster than the categories used to represent it. Occupational classifications can lag behind new forms of work. Legal categories can lag behind technological capability. Statistical indicators can retain the same name while their social meaning changes. A model trained on historical data can continue producing stable outputs after the relations that made the historical pattern informative have shifted. The representation may remain technically consistent while its relation to the target becomes weaker.

GRE is concerned with this problem because representations participate in generative processes. A classification used to allocate resources can alter behavior, incentives, identities, and institutional structure. A ranking can change the population it was designed to rank. A predictive system can influence the outcome it predicts by affecting who receives attention or opportunity. A narrative about economic risk can alter investment and thereby change the risk environment. Representation is therefore both epistemic and potentially causal.

This does not mean that symbols possess autonomous power outside institutions and practices. Their effects depend on recognition, enforcement, infrastructure, interpretation, and material consequence. A score ignored by all relevant actors remains economically weak; the same score embedded in lending, hiring, insurance, or governance can become highly consequential. GRE therefore studies the relation among symbolic objects, institutional uptake, material allocation, and downstream generation.

The contemporary problem of symbolic abundance also raises questions about knowledge capital. If the production of codified knowledge becomes much cheaper, advantage may shift toward actors who control data, evaluation systems, distribution channels, trusted identities, proprietary infrastructure, or the capacity to convert symbolic output into institutional action. The economic structure of knowledge can therefore change even when information becomes more abundant. GRE treats this as a problem of changing generative conditions rather than assuming that abundance automatically produces equal access or equal capability.

3.2.7 Heterogeneous Subjects and Value Structures

Many economic models gain tractability by representing actors through a common set of variables or a shared metric of preference and welfare. Such representations can be highly informative when the relevant differences are commensurable. GRE also addresses situations in which subjects differ more deeply: in embodiment, cognition, temporal horizon, vulnerability, institutional status, ecological dependence, forms of agency, or the values through which outcomes are interpreted. Heterogeneity then becomes a constitutive feature of the problem rather than a residual variation around one common type.

Heterogeneous subjects can still enter economic relations. A child and guardian, patient and care institution, local community and multinational firm, present generation and future generation, human user and artificial system, or human econ-

omy and ecological system may be connected through exchanges, dependencies, constraints, and value creation even where their capacities and evaluative structures differ sharply. The analytical challenge is to represent the relation without pretending that the parties are equivalent or completely mutually intelligible.

Value heterogeneity intensifies this challenge. Economic decisions can involve income, autonomy, cultural continuity, ecological integrity, security, dignity, recognition, knowledge, aesthetic significance, collective identity, and future possibility. Some of these values can be monetized for particular purposes; others resist stable conversion or lose important meaning when reduced to price. Conflict can therefore arise not only over the distribution of one value but over which values should count, how they should be represented, and who has authority to decide.

GRE approaches heterogeneous value through explicit pluralism. A study may compare several value dimensions, trace conversions among them, identify institutional priorities, or describe conflicts that remain partially incommensurable. The aim is not to prohibit aggregation. Aggregation can be indispensable for decision and coordination. The requirement is to distinguish the practical need for a decision rule from a claim that the underlying values are intrinsically reducible to one scale.

Heterogeneity also affects generative relations because the same intervention can expand one subject's capabilities while narrowing another's. Infrastructure can increase mobility while degrading an ecosystem or displacing a community. Automation can reduce routine labor while expanding organizational capability and concentrating control. Open information can increase public access while exposing vulnerable individuals. A generative process therefore needs to be indexed to subjects, scales, and value dimensions rather than described as generative in an unqualified sense.

The GRE problem-space consequently includes coexistence under incomplete commensurability. Economic relations often need to continue even where actors do not share one ontology, one value function, one time horizon, or one conception of flourishing. Governance then concerns the design of relations that preserve participation, contestability, translation, and revisability under difference. This is an economic issue whenever resources, capabilities, risks, and future possibilities are allocated through those relations.

The problem should also be distinguished from simple diversity. Diversity describes variation among actors or values. Heterogeneity in the stronger GRE sense becomes analytically significant when the differences affect what can be compared, exchanged, represented, or jointly generated. A heterogeneous relation may require several descriptive languages at once. Economic analysis must then resist both premature unification and the opposite conclusion that comparison is impossible.

3.2.8 Transformation of Future Generative Possibilities

The deepest extension in the GRE problem-space concerns interventions that change not only current states or future outcomes, but the space of possibilities from which later economic processes can unfold. An intervention can create new capacities, remove constraints, alter institutions, establish standards, transform expectations, reorganize infrastructures, generate new subject positions, or change the relations through which subsequent innovation and coordination occur. GRE refers to this

family of problems as the transformation of future generative possibilities.

The distinction can be illustrated through capability formation. Education does not merely raise an output variable at the moment instruction occurs. It can change which problems a person can recognize, which institutions can be entered, which collaborations become possible, and which future learning can be undertaken. Infrastructure does not merely deliver a service. It can alter settlement patterns, market access, technological adoption, and the feasibility of later investments. Legal reform can change not only current entitlements but the range of organizations, contracts, claims, and collective actors that can subsequently exist.

Technological platforms provide another example. A platform may begin as an intermediary and later become infrastructure on which other actors build businesses, identities, communities, data practices, and standards. At that point, changes to the platform's architecture affect a wide field of downstream possibilities. The economically relevant question extends beyond current user surplus or firm revenue toward the distribution of capacity to create, exit, interoperate, and develop alternatives.

Future possibility can also be narrowed. Debt can finance productive investment while creating obligations that restrict later choices. Monopoly can generate efficient infrastructure while reducing the space for alternative innovation. Environmental degradation can increase present output while eliminating future ecological options. Surveillance infrastructures can improve prediction while normalizing forms of control that become difficult to reverse. Educational standardization can improve comparability while reducing curricular diversity. These processes are generative in the sense that they shape future conditions, even where what they generate is constraint or foreclosure.

GRE therefore distinguishes generation from desirable expansion of possibility. More possibilities are not automatically better, and some constraints are constitutive of valuable order. Legal prohibitions can protect persons and ecosystems; technical standards can make cooperation possible; professional norms can sustain trust; ecological limits can preserve future viability. The analytical problem is to identify which possibilities are enabled or foreclosed, for whom, at what scale, through what mechanism, and according to which evaluative commitments.

Transformation of future possibilities also makes reversibility important. Two interventions with similar current benefits can differ greatly if one preserves exit and revision while the other creates lock-in. Reversible experimentation can support learning under uncertainty. Irreversible infrastructure, ecological change, institutional centralization, or path-dependent standards require stronger attention to long-horizon effects because later actors inherit conditions they did not choose. GRE therefore treats temporal asymmetry between present decision and future revisability as economically significant.

At the strongest level, an economic process can alter the effective rules through which later change occurs. A new legal form can change what organizations may be created. A communication infrastructure can transform how markets and communities coordinate. Artificial intelligence can alter the cost and distribution of cognitive tasks, thereby changing which activities are scarce and which forms of expertise remain economically valuable. Political-economic reforms can change not only alloca-

tions but the procedures through which future allocations are decided. The system's later transformations then occur under conditions partly generated by earlier transformations.

This does not imply that future possibility can be mapped exhaustively. Novelty, uncertainty, reflexivity, and incomplete knowledge place limits on prediction. GRE therefore treats generative possibility as an object of inquiry under uncertainty rather than as a fully enumerable state space. Researchers can identify enabling conditions, constraints, path dependencies, option structures, mechanisms of lock-in, and observed capability formation without claiming complete knowledge of the futures that may emerge.

The eight problem families together delimit the initial problem-space of GRE. Allocation can propagate beyond its administrative recipient; production can transform future productive capacity; value can depend on relations and conversion rather than possession alone; asymmetry can become self-reinforcing power; productive relations can reshape economic subjecthood; symbolic abundance can destabilize representation and shift scarcity toward verification and institutional recognition; heterogeneous subjects can remain economically connected without complete commensurability; and interventions can reshape the future conditions under which generation itself occurs. These problems share no single mechanism and should not be collapsed into one model. Their common feature is that economically consequential change exceeds the immediate state that conventional accounting or transaction-level description may record.

The next step is therefore conceptual rather than empirical. If GRE is to investigate these problems without presupposing a fixed ontology of entities, agents, relations, or values, it requires a minimal vocabulary from which richer economic objects can later be constructed. The next section introduces that primitive structure through change, structure, constraint, and difference, while retaining ontological suspension regarding their ultimate metaphysical status.

3.3 Primitive Structure for Ontological Emergence

The problem-space specified in the preceding section requires GRE to speak about entities, subjects, relations, capacities, institutions, values, and fields. Treating those objects as unquestioned primitives would, however, reintroduce many of the assumptions that a generative-relational analysis is intended to examine. The role of this section is therefore to establish a weaker conceptual starting point from which richer economic objects can become analytically available. Its objective is to specify four primitive distinctions—change, structure, constraint, and difference—and to explain how their interaction can support the emergence and stabilization of more determinate configurations. The discussion proceeds from each primitive separately to their interaction, the emergence of relative stability, ontological suspension, and multiple realization. Its method is constitutive and minimal: the section states the weakest commitments currently required by GRE while leaving stronger metaphysical claims open.

The term *primitive* is used here in a methodological sense. A primitive is a dis-

tinction that the present analytical framework takes as available before introducing more articulated objects. It is not thereby asserted to be metaphysically fundamental, indivisible, timeless, or ontologically prior in every possible theory. Another formalism may decompose one of these primitives further, replace it with a different basis, or represent the same empirical problem through another ontology. GRE's purpose in selecting a primitive structure is practical and epistemic: to begin with concepts weak enough to avoid presupposing the entities and relations whose emergence the programme may later wish to explain.

This choice also prevents a common circularity. If an economic subject is defined first and its relations are then studied, the analysis can miss processes through which subjecthood itself depends on recognition, law, infrastructure, classification, productive organization, or repeated participation. If a relation is defined first as a link between already constituted nodes, the analysis can miss cases in which the relation contributes to the differentiation or persistence of the nodes. If an institution is treated as a fixed background, the analysis can miss how repeated practices maintain or transform the institution. A minimal primitive structure postpones these commitments. It asks first what changes, what organization makes those changes intelligible, what conditions restrict or enable possible transformations, and what differences become consequential within the configuration.

The four primitives should not be imagined as four substances or four separable components of an economic system. They are analytical dimensions that become meaningful through one another. Change without structure is difficult to identify because change requires some organization within which a transformation can be distinguished. Structure without change becomes analytically inert because structure is known through persistence, variation, reproduction, or transformation. Constraint presupposes a space of possible differences or transitions whose accessibility is conditioned. Difference becomes economically consequential when a structure renders it perceptible, operative, classifiable, or capable of altering later possibilities. Their interaction supplies a minimal grammar for describing ontological emergence while leaving the ontology itself under suspension.

3.3.1 Change

Change is the first primitive because GRE studies economic processes in which later conditions differ from earlier ones. The minimal concept is deliberately broad: change designates a transformation that can be distinguished between configurations, positions, capacities, relations, classifications, rules, or other analytically relevant conditions. This formulation does not presuppose that the thing changing is already an entity with a fixed identity. It permits the identity, boundary, or kind of the relevant object to become part of the change being studied.

Several levels of change should therefore remain distinct. A variable can change while the relations among variables remain similar. A relation can form, intensify, weaken, reverse, or dissolve while the participating terms remain sufficiently stable for the relation to be tracked. A structure can change when patterns among multiple relations are reorganized. A constraint can change when possibilities previously unavailable become accessible, or when previously accessible transitions become costly,

prohibited, or practically unreachable. A classificatory or representational regime can change when actors are newly recognized, grouped, valued, or rendered visible. At a still stronger level, the effective rule through which later transformations occur can itself be modified. GRE eventually requires all of these possibilities, yet the primitive concept of change remains weaker than any one of them.

Change is therefore not synonymous with movement along a pre-specified coordinate. Many economic models legitimately represent change in exactly that way: price changes, employment changes, output changes, wealth changes, or probabilities change within a stable variable system. GRE retains such representations wherever they answer the research question. Its additional interest appears when the variable system itself is historically unstable. A category such as employment may change in prevalence while retaining a stable legal meaning, or the legal and organizational meaning of employment may itself be transformed by platform work, contracting arrangements, automation, or new institutional classifications. The first case can be represented as change within a category; the second includes change in the category's constitutive conditions.

This distinction also separates state change from generative change. A state can differ at two times without the transition altering the capacity to produce later states. By contrast, a generative change modifies some condition through which subsequent possibilities are produced, selected, stabilized, or foreclosed. Training that raises a measured skill level is a state change; when the training also alters future access to occupations, networks, credentials, confidence, or learning capacity, the economic significance includes a generative dimension. A regulation that changes a current price is one kind of intervention; a regulation that changes entry conditions, bargaining institutions, or the incentives through which future market structure develops reaches a different level of change.

The concept must also accommodate maintenance. Persistence across time can require continuous activity. A bridge remains usable because inspection and repair occur; a currency remains accepted through continuing institutional and social practices; an organization persists through recruitment, routines, accounting, authority, and repeated recognition; a relation of trust can remain stable because encounters repeatedly confirm expectations. In such cases, apparent sameness at the level of an outcome is produced through ongoing change at other levels. GRE should therefore avoid equating observable stability with absence of process.

Change also carries no intrinsic normative direction. Transformation can enlarge capability, reduce vulnerability, create knowledge, or regenerate ecological conditions. It can equally generate dependency, exhaustion, exclusion, concentration, ecological loss, or irreversible foreclosure. Even a change described as innovation is not thereby beneficial to all affected subjects. The primitive records transformation; the normative evaluation of that transformation requires additional criteria developed later in the programme.

Finally, change is always specified relative to an analytical resolution. A firm may appear unchanged because it retains the same legal identity while its workforce, technology, ownership, dependencies, and internal authority are transformed. A person may appear occupationally unchanged while the meaning and security of the occupation are altered. A market may display stable aggregate shares while the underly-

ing network of suppliers becomes more concentrated. GRE therefore requires the researcher to state which differences count as changes for the local question and which dimensions are being held provisionally constant. This dependence on resolution will become important when the programme later treats scale, boundary selection, and representation.

3.3.2 Structure

Structure provides the organization within which changes and differences become intelligible. In its minimal GRE sense, a structure is a pattern of organization that relates distinguishable components, positions, transitions, or conditions with sufficient regularity to support analysis. The term does not require a single formal representation. A structure may be institutional, relational, spatial, temporal, legal, organizational, symbolic, ecological, computational, or represented through several of these descriptions at once.

This minimal definition matters because structure is often confused with rigidity. GRE instead treats structure as compatible with extensive internal change. A labor market can preserve a recognizable structure while workers and firms enter and exit. A legal system can preserve institutional continuity while rules are amended. A network can preserve a degree distribution or community pattern while particular ties change. A household can remain an administratively recognizable unit while roles and resource flows are reorganized. Structural persistence therefore concerns patterned organization at a selected resolution, not immobility of every constituent.

Structure can also exist at several analytical levels. A local structure may concern the arrangement of a small number of actors or resources. A higher-order structure may concern patterns among relations, institutions, or categories. Structures can be nested, overlapping, or partially incompatible. The same economic subject may simultaneously occupy a workplace hierarchy, a household division of care, a credit relation, a legal status, a platform ranking system, and an ecological dependency. No single structure necessarily exhausts the subject's economic position.

For GRE, structure becomes especially important when it shapes how an intervention propagates. The same allocation can have different effects under different structures because access, conversion, visibility, bargaining, and recirculation differ. A cash transfer received within a predatory debt relation may partly flow to creditors. A research grant enters a university structure that conditions hiring, procurement, intellectual-property ownership, publication, and career recognition. Access to compute can generate different capacities depending on whether technical knowledge, electricity, data, institutional permission, and collaborative networks are available. Structure therefore mediates the relation between an initial resource and the later configuration it helps produce.

Structure also helps distinguish a merely repeated occurrence from a stabilized pattern. Repetition alone can result from coincidence or independent causes. A structural claim is stronger: it proposes that the recurrence reflects an organization of relations, positions, rules, or constraints that makes certain patterns more likely, durable, or reproducible. Such claims require evidence appropriate to the domain. GRE should not infer structure from visual regularity alone; qualitative mechanisms,

institutional rules, historical evidence, statistical relationships, network organization, formal models, or combinations of evidence may be needed.

Importantly, structure can itself be an outcome of prior generation. Infrastructure, property regimes, professional categories, organizational routines, standards, market conventions, and technical architectures are historically produced. Once established, they can condition later behavior and appear to subsequent actors as part of the environment. This temporal layering is central to GRE because generated structures can become conditions of future generation. The analytical movement is therefore recursive: processes generate structures; structures condition later processes; later processes may reproduce, erode, or transform those structures.

Structure should consequently be treated as relative to both scale and time. A relation that looks transient at one temporal scale may contribute to a stable pattern at another. A structure that appears fixed during a short intervention study may be historically recent. A national institution can function as background in a firm-level analysis while becoming the primary object in a comparative institutional study. GRE's minimal concept of structure supports these shifts without requiring that one level be declared ontologically fundamental.

3.3.3 Constraint

Constraint concerns the conditioning of possible transformation. A constraint limits, channels, raises the cost of, delays, redirects, or otherwise modifies which changes are available to a configuration under specified conditions. This definition is intentionally broader than prohibition. Constraints can be hard or soft, formal or informal, material or symbolic, local or distributed, immediate or historically accumulated. They can reduce some possibilities while enabling others by stabilizing expectations, protecting boundaries, supplying standards, or coordinating action.

The enabling dimension is important. A legal rule constrains conduct while also making contracts, organizations, ownership claims, or collective action more reliable. A technical standard restricts admissible designs while enabling interoperability. A professional norm narrows acceptable practice while supporting trust. A budget constraint restricts expenditure while helping define feasible planning. Physical infrastructure limits movement to available routes while making high-volume movement possible along those routes. GRE therefore treats constraint as a transformation of an option space rather than as a synonym for oppression or deprivation.

Constraints differ in the mechanisms through which they operate. A material constraint may arise from energy, time, geography, bodily capacity, or resource availability. An institutional constraint may arise from law, organizational authority, eligibility criteria, property rights, or administrative procedure. A relational constraint may arise from dependence on another actor, obligations, network position, reputation, or bargaining asymmetry. A cognitive or epistemic constraint may arise from limited knowledge, inaccessible information, uncertainty, interpretive categories, or attention. A technological constraint may be embedded in interfaces, protocols, platforms, or computational architectures. These forms can interact, and the same observed limitation can often be generated through several different mechanisms.

Constraint is therefore relational in a weak but important sense: a condition con-

strains only relative to some possible transformation of a specified configuration. The absence of advanced compute does not constrain a task that requires none. A licensing rule may constrain an unlicensed entrant while enabling established professionals to coordinate around a recognized standard. A language barrier can constrain access in one institution and become irrelevant in another with translation infrastructure. The researcher must specify whose possibilities are conditioned, which possibilities are at issue, and through what mechanism the conditioning occurs.

Constraints can also be inherited. Present actors confront conditions generated by earlier processes that they did not choose: debt structures, infrastructures, ecological degradation, historical exclusions, educational systems, legal categories, standards, and accumulated concentrations of capital or knowledge. Such inherited constraints can be highly durable even when no current actor intends their continuation. GRE's concern with generation therefore includes the production and transmission of constraints across time.

At the same time, constraints are often transformable. Actors can acquire resources that relax a constraint, organize collectively to alter a rule, invent technologies that change material limits, reinterpret categories, create new infrastructures, or exit relations that previously restricted them. An intervention can also exchange one constraint for another. Credit can relax a liquidity constraint while introducing repayment obligations. Digital platforms can reduce search costs while increasing dependency on ranking systems or data infrastructures. Automation can relax labor bottlenecks while creating new capital, compute, energy, or skill dependencies. Analysis should therefore trace transformations of the constraint structure rather than classify interventions simply as constraint-reducing.

GRE also distinguishes constraint from deterministic closure. A constraint can make a transition improbable without making it impossible, and it can make a transition formally possible while rendering it practically inaccessible. Conversely, the absence of a known constraint does not imply that a possibility will be realized. Capacities, orientations, coordination, chance, and additional conditions also matter. This distinction will later be important for economic power: asymmetry can influence option spaces and the conditions under which choices are made without reducing action to mechanical determination.

3.3.4 Difference

Difference supplies the discriminations through which change, structure, and constraint can be described. In its minimal GRE sense, a difference is a non-equivalence, contrast, distinction, gradient, or differentiation that is relevant to a specified analysis. The primitive does not assume that every observable variation is economically meaningful. A difference becomes analytically consequential when it participates in identification, interaction, selection, valuation, constraint, or subsequent generation.

This distinction between variation and consequential difference is central. Two actors can differ in height without that difference affecting a particular credit relation. They can differ in legal status in a way that radically alters eligibility, bargaining, mobility, or vulnerability. Two firms can differ in size without that difference determining market power in one industry, while in another industry scale can transform

access to data, compute, distribution, or finance. GRE therefore asks how a difference enters the relational configuration and what later effects follow from its recognition or operation.

Difference can be prior to a relation, produced through a relation, or amplified by a relation. Participants may enter an exchange with different resources or capabilities. The exchange may itself create new differentiation through learning, reputation, debt, ownership, or access. Repeated interactions can amplify an initially small difference through cumulative advantage or self-reinforcement. Conversely, institutions can reduce the economic consequences of a difference through insurance, universal provision, accessibility design, anti-discrimination rules, redistribution, or shared infrastructure. The economic significance lies in the generative trajectory of the difference, not merely in its presence.

Difference also participates in the constitution of categories. Economic systems routinely classify workers, firms, borrowers, residents, consumers, citizens, dependents, owners, professionals, risks, assets, and forms of labor. Such classifications make some differences institutionally salient while suppressing others. A category can convert a continuous variation into a discrete administrative distinction, or combine heterogeneous cases under one label. Once institutionalized, the classification can affect access, rights, prices, obligations, visibility, and self-understanding. Representational differences can thereby become causally effective within economic life.

The primitive must remain distinct from inequality. Inequality is a more specific relation involving unequal quantities, positions, opportunities, burdens, capabilities, recognition, or powers. Difference is logically weaker. Heterogeneity can be economically valuable, neutral, complementary, conflictual, or unjust depending on how differences are organized and evaluated. GRE's later treatment of heterogeneous subjects depends on preserving this distinction; a plural economy need not aim at eliminating difference, while justice may require intervention when particular differences are converted into avoidable domination or exclusion.

Difference is also scale-relative. Two configurations can be equivalent for one analytical purpose and different for another. Two households may have the same income while differing in care burdens, health needs, legal status, housing security, social networks, or exposure to environmental risk. Two firms may have identical revenue while differing in ownership, dependence on a platform, ecological footprint, or accumulated knowledge. An economic representation always selects which differences to preserve. GRE therefore treats the choice of relevant difference as part of the epistemic architecture of inquiry rather than as a transparent property of the world.

This point prevents the primitive from becoming an unlimited invitation to complexity. A research design cannot preserve every difference. The analytical task is to justify which distinctions matter to the proposed generative mechanism and to test whether omitted differences undermine the explanation. Difference thus supports pluralism while remaining disciplined by the local research question.

3.3.5 Interaction among the Four Primitives

The analytical value of the primitive structure lies primarily in interaction among its terms. Change, structure, constraint, and difference should rarely be interpreted as

independent explanatory variables. Each modifies the meaning and operation of the others. A difference can alter a transition; repeated transitions can stabilize a structure; a structure can convert some differences into effective constraints; a constraint can preserve a structure by narrowing available transitions; and structural change can create new differences and remove old ones.

Consider a simple economic sequence. Two actors begin with a difference in access to finance. An institutional structure determines which forms of collateral are recognized. That structure constrains borrowing possibilities differently across the actors. The resulting difference in investment capacity alters later income, asset ownership, reputation, and access to finance. Repetition can stabilize a configuration in which the original difference is amplified and incorporated into a more durable structure. The example does not require the researcher to declare wealth, creditworthiness, institutions, or even the actors themselves to be ontological primitives. It can begin from transformations, patterned organization, conditioned possibilities, and consequential distinctions, then introduce richer objects as the analysis becomes empirically specific.

The same primitive structure can describe generative expansion. Shared infrastructure may reduce a constraint on participation. Increased participation can create new differences in specialization and knowledge. Those differences can support a more complex division of labor. The emerging structure can generate additional resources, standards, and coordination capacities, which further relax some constraints while creating new ones. Generativity therefore need not mean monotonic liberation from constraint. New capabilities often depend on newly stabilized structures whose operation introduces obligations, dependencies, standards, or maintenance requirements.

The interaction among primitives also permits recursive analysis. A structure can constrain change, while changes can transform the structure. A difference can be produced by a constraint, while the resulting difference can later modify the constraint through political organization, market power, technological innovation, or institutional recognition. Constraint structures can become objects of economic investment; differences can become commodities, credentials, rankings, or legal statuses; structures can be deliberately designed; and change itself can be governed through procedures that determine how rules may be revised.

This recursion provides a bridge to the stronger GRE question concerning transformation of effective rules of change. At an initial analytical level, a researcher may ask how a configuration changes under a specified structure and set of constraints. At a second level, the inquiry can ask how those structures and constraints themselves change. At a third level, the procedures or mechanisms through which structures and constraints are transformed may become objects of inquiry. The primitive vocabulary can therefore support increasingly reflexive analysis without assuming that a single immutable law governs every level.

A useful discipline follows from this interaction: explanations should specify which primitive role a concept is playing at a given moment. The same institution can be treated as structure when its internal organization matters, as constraint when it conditions an actor's options, as difference when membership distinguishes eligible from ineligible actors, and as an object of change when reforms alter its

operation. These descriptions are compatible because they answer different analytical questions. Confusion arises when movement among them occurs without being stated.

The primitive framework is therefore better understood as a grammar than as a taxonomy. It organizes questions about transformation without assigning each empirical object to one permanent category. This flexibility is important for economic inquiry because the same phenomenon can change analytical status across scale and time. Money can be a resource in one analysis, a relation of credit in another, an institutional structure in a third, a symbolic representation in a fourth, and a constraint through liquidity requirements in a fifth. The primitives do not replace these richer categories; they clarify how such categories can be introduced without assuming their universality in advance.

3.3.6 Emergence of Stable Configurations

GRE requires relatively stable objects because economic inquiry cannot proceed by treating every moment as ontologically unique. Contracts, firms, households, states, currencies, property rights, professions, platforms, resources, and subjects must often be tracked across time. The primitive framework therefore needs an account of how stability can become analytically legitimate without turning stability into primordial substance. The concept of *stable configuration* supplies that bridge.

A stable configuration is a patterned organization whose continuity is sufficient for a specified analytical purpose across a relevant interval, scale, or set of transformations. Stability can arise through several mechanisms: material durability, repeated interaction, institutional recognition, legal enforcement, habit, technical standards, ecological reproduction, feedback, coordinated expectations, memory, documentation, or continual maintenance. These mechanisms need not produce permanence. They produce enough persistence or recurrence for the configuration to function as an identifiable object within the inquiry.

The phrase *sufficient for a specified analytical purpose* is crucial. A corporation can be treated as the same legal entity across changes in personnel and assets, while an organizational ethnography may treat those same changes as constitutive transformations. A currency can remain nominally the same while inflation alters its purchasing power and institutional reforms alter its governance. A household can persist administratively while membership changes. Entityhood is therefore resolution-dependent. GRE treats an entity as analytically real where the stability of a configuration supports explanation, measurement, interpretation, intervention, or coordination at the chosen scale.

Relations can stabilize in the same way. A relation need not be continuously active in order to persist. A debt relation remains operative between payments; a property relation persists while the owner is absent; a professional relation can survive periods without interaction; an institutional hierarchy can remain in force outside moments of explicit command. Persistence can depend on documents, expectations, enforcement, memory, infrastructure, or recognized roles. A stable relation is therefore more than repeated contact, yet it need not be a metaphysically independent object.

Stable configurations can also acquire causal and generative efficacy. Once a classification is institutionalized, it can govern eligibility. Once a platform becomes infrastructure, it can condition market access. Once a professional credential stabilizes, it can shape labor-market sorting. Once a norm becomes widely expected, deviations can become costly even without formal enforcement. An emergent configuration can thus become part of the structure and constraint environment faced by later actors. Ontological emergence and generative recursion meet at this point: what was produced through earlier processes becomes a condition of later processes.

Stability should also be distinguished from desirability, efficiency, and equilibrium. A configuration can persist because exit is costly, alternatives are suppressed, coordination failure prevents change, or power reproduces the relevant conditions. Another configuration can be beneficial yet fragile because its maintenance depends on scarce resources or voluntary cooperation. GRE therefore treats persistence as an empirical property requiring explanation rather than as evidence of optimality.

The emergence of stable configurations gives GRE a principled basis for introducing richer objects in the next section. Entities, subjects, relations, resources, values, fields, institutions, and symbolic objects can be treated as first-class economic objects when their organization is sufficiently stabilized and their distinctions matter to the research problem. Their status remains historically and analytically conditioned. Stability licenses local objecthood; it does not establish final ontology.

3.3.7 Ontological Suspension

Ontological suspension is the discipline that keeps this primitive framework from becoming a dogmatic metaphysics. It means withholding claims about the ultimate constitution of economic reality when stronger ontological commitments are unnecessary for the local inquiry. Suspension permits the researcher to use entities, relations, processes, fields, networks, states, events, or other representations where they are analytically productive while keeping open the possibility that another representation may reveal different aspects of the same empirical configuration.

Suspension differs from ontological denial. GRE does not claim that entities are unreal because they are relationally constituted, that relations are unreal because they are represented through models, or that institutions are mere descriptions because they depend on recognition. A bank account, legal status, debt, organization, or technical standard can have robust economic consequences. Ontological suspension concerns the level of metaphysical assertion attached to those consequences. The researcher can treat an object as real and causally relevant within an inquiry without claiming that its current representation exhausts what the object is.

This position also differs from unrestricted constructivism. Economic objects can resist interpretation, produce unexpected effects, and impose material constraints regardless of the researcher's preferred description. A bridge has load limits; an ecosystem can be degraded; a debt contract can be enforced; a platform can deny access; a person can become exhausted. Ontological suspension does not dissolve these realities into discourse. It requires the analyst to distinguish the empirical resistance of a configuration from the categories used to describe it.

The discipline is especially important when formal methods are used. A graph

can represent relations among nodes, a state space can represent possible configurations, a field can represent distributed conditions, and a simulation can explore consequences of specified rules. Each representation can be rigorous within its assumptions. None acquires metaphysical authority merely from mathematical precision. GRE therefore asks what distinctions the representation preserves, what it suppresses, which mechanisms it assumes, and whether alternative representations change the substantive conclusion.

Ontological suspension also supports interdisciplinary communication. Economics, law, sociology, history, ecology, computer science, and philosophy can represent the same situation through different objects. A platform worker can appear as a labor supplier, contractual party, legal claimant, network node, data-generating user, organizational participant, or historically situated subject. These representations can conflict in specific claims while remaining jointly informative. GRE should compare their explanatory consequences before treating one vocabulary as universally privileged.

Finally, suspension creates a condition for theory revision. If entities, relations, and categories were fixed as final primitives, evidence that their boundaries change would threaten the coherence of the framework. A suspended ontology permits categories to be reconstructed when historical change reveals their limits. This revisability is particularly important to a programme concerned with the generation of new economic objects, technologies, institutions, and forms of subjecthood.

3.3.8 Multiple Realizations and Ontological Plurality

A minimal primitive structure also allows economically meaningful objects to have multiple realizations. The same functional or institutional role can be sustained through different material, organizational, legal, or relational configurations. Payment systems can be realized through cash, bank deposits, cards, mobile platforms, or other infrastructures. Collective production can be organized through firms, cooperatives, public institutions, households, commons, or loosely coordinated networks. Credentialing can be performed by universities, professional bodies, states, platforms, or community institutions. What counts as the same economic object therefore depends partly on the level at which equivalence is being claimed.

Multiple realization should not be confused with identity. Two configurations can perform similar functions while differing in power relations, vulnerability, ecological cost, accessibility, governance, or downstream generativity. A public payment infrastructure and a proprietary platform may both enable transactions while generating different dependencies and data relations. Two educational systems may produce comparable test scores while differing in social networks, institutional recognition, stress, curiosity, or future opportunity. GRE consequently treats functional equivalence as one possible relation among configurations rather than as proof that their broader economic consequences are equivalent.

The converse problem also occurs: similar manifestations can arise from different generative structures. Two workers can report the same income while one depends on a stable employment relation and the other on volatile platform work. Two firms can display the same output while one relies on durable local capabilities and the

other on fragile external supply chains. Two communities can exhibit similar consumption while differing in debt burdens, ecological dependencies, public infrastructure, or informal care. Observable similarity therefore does not guarantee generative similarity.

Ontological plurality follows from these possibilities. GRE can permit several ontologies or representational schemes to coexist when they preserve different distinctions relevant to the research question. An entity-centered model may be adequate for one task, a network representation for another, a process account for a third, and a field-like description for a fourth. Plurality is disciplined by explanatory and evidential adequacy rather than by an assumption that every representation is equally useful.

This pluralism has limits. Representations can contradict evidence, conceal relevant mechanisms, or impose categories that systematically misdescribe the subjects they classify. A plurality of possible descriptions does not eliminate standards of criticism. GRE should ask whether a representation preserves the differences relevant to the claim, whether its boundaries are justified, whether its entities remain stable enough for the inference being made, and whether alternative representations produce materially different conclusions. Ontological plurality therefore increases the burden of comparison rather than removing it.

Multiple realization also matters normatively. Policies often target administratively standardized objects such as households, firms, jobs, schools, or regions. If those categories have heterogeneous realizations, identical interventions can generate unequal effects. A household with the same measured income can face different care obligations; a firm of the same size can possess different network dependencies; a school with similar resources can operate within different linguistic, social, or infrastructural conditions. GRE's later analysis of heterogeneous subjects and values depends on recognizing that categorical sameness can coexist with generatively consequential difference.

The primitive structure developed in this section therefore establishes a deliberately modest ontological foundation for the programme. Change identifies transformation without presupposing a fixed bearer. Structure identifies patterned organization without requiring stasis. Constraint identifies the conditioning of possible transformation without implying deterministic closure. Difference identifies relevant non-equivalence without equating difference with inequality. Their interaction can generate relatively stable configurations that become legitimate objects of economic inquiry at specified scales and times. Ontological suspension prevents these objects from hardening prematurely into universal primitives, while multiple realization and ontological plurality preserve the possibility that comparable economic functions can be sustained through different configurations and that similar observations can arise from different generative histories.

This architecture is intentionally incomplete. It supplies the minimal conceptual conditions under which richer objects can be introduced; it does not yet specify which objects GRE should study. The next section can therefore move from primitive structure to the heterogeneous economic objects that become available once relative stability, analytical scale, and ontological suspension have been established.

3.4 Objects of GRE Inquiry

The primitive structure developed in Section 3.3 allows GRE to introduce richer objects without treating their present boundaries as metaphysically final. The role of this section is to specify the principal classes of objects that GRE may take as economically relevant once relative stability, analytical scale, and ontological suspension have been established. Its objective is taxonomic rather than exhaustive: to identify a working repertoire of objects through which relational and generative economic processes can be investigated. The discussion proceeds from emergent entities and subjects to relations, resources and capacities, value, conditions and constraints, fields, temporal objects, institutions, and symbolic or representational objects. Its method is constitutive and pluralist. Each category is defined by the analytical work it can perform, while overlap among categories remains permissible where an empirical configuration supports several descriptions.

An *object of inquiry* in GRE is therefore an analytically stabilized referent around which a research question, body of evidence, mechanism claim, comparison, or intervention can be organized. Objecthood in this sense is local to an inquiry. A firm may be treated as an entity when the question concerns ownership or output, as a relational configuration when the question concerns authority and contracting, as an institutionally recognized subject when the question concerns legal responsibility, and as a trajectory when the question concerns organizational transformation. These descriptions are compatible when they preserve different economically consequential distinctions. GRE does not require a single vocabulary to carry every explanatory burden.

The admissibility of an object depends on several disciplines. Its boundary should be sufficiently explicit for the claim being made. Its persistence should be adequate to the temporal resolution of the inquiry. The evidence used to characterize it should correspond to the dimensions under discussion. Its role in a mechanism should be distinguished from the representation through which that role is inferred. Finally, the analyst should remain attentive to whether the object itself changes through the processes being studied. A category useful at the beginning of an inquiry can require revision if its constitutive relations, internal heterogeneity, or practical meaning change during the relevant history.

The categories below are therefore best understood as a research grammar. They help determine what GRE can study without implying that economic reality is naturally partitioned into ten mutually exclusive classes. Many of the most important GRE questions arise precisely where an object moves across categories: a resource becomes a capability, a repeated relation stabilizes into an institution, a symbolic classification becomes a material constraint, an event redirects a trajectory, or a distributed field of conditions contributes to the emergence of a new economic subject. The taxonomy is designed to preserve those transformations rather than eliminate them through premature classification.

3.4.1 Emergent Economic Entities

Economic analysis routinely refers to persons, households, firms, states, markets, sectors, technologies, assets, platforms, infrastructures, and other entities. GRE retains these objects while treating their entityhood as historically and analytically conditioned. An emergent economic entity is a relatively stabilized configuration that can be tracked as a distinguishable unit because some combination of boundary, continuity, recognition, organization, or causal coherence persists across the interval relevant to the inquiry.

Relative stability is central. A corporation can remain the same legal entity while employees, ownership shares, technologies, contracts, products, and internal authority change. A household can remain administratively recognizable while membership, dependency relations, income sources, and care obligations vary. A market can persist as a named domain while its technologies, participants, rules, and geographic reach are transformed. GRE can treat each as an entity when the continuity is sufficient for the local question, while preserving the possibility that another question requires decomposition of the apparent unit.

Entity boundaries can arise through several mechanisms. Law creates juridical boundaries around corporations, contracts, property, and public authorities. Accounting creates reporting boundaries around organizations and transactions. Technical architectures distinguish users, devices, accounts, services, and platforms. Social recognition can stabilize occupations, communities, or organizational identities. Material organization can generate boundaries through infrastructure, geography, or ecological dependence. These boundaries differ in durability and authority. A legal boundary may remain stable while operational relations cross it extensively; an informal organization may have no independent legal personality while displaying strong internal continuity.

The economic significance of entityhood therefore depends partly on what the boundary permits the entity to do. Recognition can make ownership, contracting, taxation, liability, borrowing, representation, or participation possible. Entity formation can pool resources, concentrate decision rights, create collective capabilities, or separate responsibility. It can also obscure internal asymmetries by presenting a heterogeneous configuration as a single actor. Treating a firm, household, state, or community as one unit can be analytically efficient while suppressing differences in who decides, who bears risk, who receives value, and who remains unrepresented.

Entity emergence can itself become an object of explanation. A group of workers can become an organization; a technical project can become a firm; a loose exchange environment can become a recognized market; a digital protocol can acquire institutional governance; a collective practice can become a sectoral standard. GRE is interested in the conditions through which such configurations become sufficiently stable, recognized, resourced, and reproduced to acquire economic consequences as entities. The transition from diffuse activity to recognized entity can alter access to finance, law, infrastructure, legitimacy, and bargaining power.

Entities can also dissolve, fragment, merge, or migrate across classifications. Insolvency can dissolve a firm while parts of its productive capacity survive elsewhere. A public service can be privatized while its infrastructure remains materially continu-

ous. A platform can reclassify workers without changing the practical dependence through which labor is organized. These cases show why GRE treats entity identity as a question of maintained distinctions rather than a self-evident fact.

The category of emergent economic entity consequently supplies a practical unit of analysis while keeping three questions open: which relations stabilize the entity, which boundaries make the entity economically actionable, and which transformations would make the existing entity description inadequate. These questions connect entity analysis to the remaining object classes rather than isolating entities from them.

3.4.2 Subjects and Subject Positions

Subjects form a distinct class because economic participation involves more than the persistence of an entity. A subject occupies positions from which action, claim-making, evaluation, vulnerability, responsibility, recognition, or experience becomes economically consequential. GRE therefore distinguishes the existence of an entity from the constitution of a subject position. A corporation can be a juridical subject for some purposes without possessing human experience; a person can exist as a biological and social individual while being denied effective recognition as a worker, claimant, owner, borrower, resident, or political participant.

A *subject position* is a relationally and institutionally organized location from which rights, expectations, obligations, opportunities, exposures, or forms of agency become available. Employment status, citizenship, tenancy, creditor status, professional accreditation, platform membership, consumer classification, and eligibility for public support are examples of positions that configure economic possibilities. Such positions are often produced jointly by law, organizational rules, records, classifications, infrastructures, and recognition by other actors.

Subject positions can therefore change without the underlying person or organization disappearing. A worker can move from employee to contractor; a resident can gain or lose eligibility for a service; a borrower can be reclassified by a credit system; a community can become formally recognized as an eligible governance unit; a software agent can be delegated limited transactional authority. Each change modifies what the subject can do, what others may demand from it, and which relations become economically available.

GRE is especially interested in the generative consequences of these positions. A position can enable access to income, credit, education, information, legal remedies, social networks, or institutional voice. It can also create dependency, surveillance, liability, exclusion, or constrained exit. Because positions mediate later capacities, subject formation is not merely a descriptive question about identity. It can become part of the economic mechanism through which future options are generated or foreclosed.

This perspective also preserves the difference between subjecthood and agency. A subject can be strongly constrained while remaining economically consequential. Children, persons under guardianship, refugees, patients, dependents, or algorithmically classified users can occupy economically important positions even where their formal decision authority is limited. Conversely, an actor with substantial op-

erational agency can remain weakly recognized within a legal or moral order. GRE should therefore specify which dimension of subjecthood matters to the inquiry: capacity to act, capacity to experience, standing to claim, institutional recognition, representation, accountability, or exposure to consequences.

Heterogeneity within subject categories is equally important. Administrative categories such as household, worker, consumer, student, patient, migrant, or firm can contain subjects with markedly different capacities and dependencies. Treating category membership as sufficient description can obscure differences in language, disability, care obligations, wealth, access to networks, legal status, technical literacy, or exposure to institutional power. A GRE analysis can preserve the usefulness of the category while examining how its practical realization varies among subjects.

Subject positions can also be collectively constituted. A union, cooperative, community association, indigenous polity, professional body, or informal collective can acquire forms of representation and bargaining capacity that are unavailable to isolated members. Collective subjecthood can reorganize the field of negotiation, create shared resources, and alter the conversion of individual grievances into actionable claims. The relevant object is then neither a simple aggregate of persons nor a timeless collective substance. It is a stabilized configuration of representation, recognition, organization, and capacity.

The category will later support GRE's more detailed inquiry into human and artificial economic subjects. At the constitutional level, the key point is narrower: subjecthood is an economic object whenever the positions from which actors participate, experience consequences, make claims, or become governable are themselves generated, maintained, or transformed through economic relations.

3.4.3 Relations and Relational Configurations

Relations are central objects of GRE because economic consequences frequently depend on how actors, resources, institutions, and conditions are connected. A relation can involve exchange, authority, dependence, care, credit, ownership, recognition, information, obligation, trust, competition, cooperation, representation, access, or other structured forms of connection. GRE treats the relation itself as analytically available when its persistence, terms, or consequences matter to the research question.

Relations vary in their constitution. Some are formally specified through contracts, law, accounting, organizational rules, or technical protocols. Others depend on repeated practice, trust, custom, shared expectations, social proximity, or tacit coordination. Some are symmetric in a relevant dimension; others distribute authority, information, risk, or exit options asymmetrically. A relation can remain formally unchanged while its practical content shifts because one party's outside options, dependence, knowledge, or institutional protection changes.

Dyadic representation is useful for many questions, yet GRE also recognizes relational configurations that cannot be adequately decomposed into independent pairs. Supply chains, families, teams, communities, standards ecosystems, financial systems, platform markets, and public infrastructures often involve higher-order or multilayer dependencies. The significance of one tie can depend on the presence of

several others. A credit relation, for example, can depend on legal enforceability, informational infrastructure, collateral arrangements, reputational systems, and monetary institutions. A labor relation can depend on household reproduction, immigration status, local labor demand, professional credentials, and collective bargaining institutions.

A *relational configuration* therefore refers to an organized set of relations whose joint structure has economically consequential properties. Concentration, brokerage, segregation, reciprocity, redundancy, hierarchy, mutual dependence, and network closure can arise at the configuration level. These properties may affect bargaining power, diffusion, resilience, access, vulnerability, and capacity formation even when no single relation carries the full explanation.

GRE also distinguishes relations that connect already stabilized objects from relations that contribute to the constitution of those objects. A contract between two established firms may primarily coordinate exchange. Repeated recognition relations can help constitute a professional status. Care relations can contribute to the maintenance of persons' capabilities. Membership relations can constitute an organization. Legal relations can create ownership or corporate personality. The analytical question is therefore whether the relation is external to the identity relevant for the model, partly constitutive of it, or generative of a new stabilized object.

Relations can persist through material and symbolic infrastructures. A debt relation may be maintained through records and enforcement institutions; a platform relation through accounts, interfaces, ranking systems, and data; a professional relation through credentials and reputational networks. These mediating objects matter because they can change the relation without changing its nominal category. Digitization, automation, or legal reform can intensify monitoring, alter bargaining positions, reduce transaction costs, or enable new forms of exclusion within an apparently familiar relationship.

Relation formation and relation removal are themselves economically consequential events. Access to a mentor, lender, market, transport system, care network, professional community, or knowledge infrastructure can transform later opportunity. Loss of a relation can destroy capability even when material possessions remain unchanged. GRE therefore studies relational portfolios and configurations alongside stocks of individually held resources.

This category supplies the most direct bridge between the programme's relational commitment and ordinary economic inquiry. GRE does not require every explanation to be relation-first. It requires the analyst to make relation-dependent mechanisms visible where they materially alter economic outcomes, value trajectories, subject positions, or future generative conditions.

3.4.4 Resources and Capacities

Resources and capacities are distinct objects because possession or access does not by itself determine what an economic subject can do. A resource is something that can be mobilized, accessed, consumed, transferred, invested, preserved, or combined within an economic process. A capacity concerns an ability or practical possibility to act, produce, learn, adapt, participate, maintain, transform, or generate further pos-

sibilities. The relation between the two is mediated by context, institutions, skills, relations, infrastructure, bodily conditions, ecological conditions, and other conversion factors.

Resources can be material, financial, informational, institutional, social, technical, ecological, or symbolic. Land, equipment, money, time, data, legal rights, public infrastructure, credentials, reputation, access to a network, and environmental quality can each function as resources under appropriate conditions. Their resource character is relational because usefulness depends on what a subject can access and convert within a particular configuration. A database inaccessible to a community, a credential unrecognized by employers, or capital without complementary infrastructure can have limited practical value despite nominal possession.

Capacities likewise occur at several levels. Individuals can possess capacities for work, learning, judgment, mobility, communication, care, and political participation. Organizations can possess capacities for production, coordination, innovation, maintenance, adaptation, compliance, or collective learning. Communities can possess capacities for mutual support, governance, cultural reproduction, ecological stewardship, and collective action. Infrastructures can support capacities by making transport, communication, payment, identification, or knowledge access possible across many subjects.

GRE gives special attention to *generative capacity*: the ability of a configuration to produce or support further economically consequential possibilities. Education can generate later learning capacity; institutional trust can reduce coordination costs and enable cooperation; a research infrastructure can generate future knowledge; public health can preserve productive and participatory capacity; ecological regeneration can sustain future material possibility. Generative capacity is therefore temporally extended and often distributed across relations rather than located wholly inside a single actor.

The distinction between resource and capacity also clarifies why equal allocation can produce unequal outcomes. Subjects receiving identical monetary transfers can face different housing markets, care obligations, health conditions, legal statuses, network access, or local infrastructure. The same nominal resource can therefore generate different effective possibilities. Conversely, subjects with different resource bundles can sometimes realize comparable capabilities through different conversion arrangements. GRE is interested in the relational conditions that mediate these transformations.

Resources and capacities can also be depleted, captured, transferred, or rendered obsolete. Skill can lose market value after technological change; social capital can erode through displacement; ecological capacity can be exhausted; institutional capacity can decay through underinvestment; a public infrastructure can become inaccessible through privatization or pricing. These processes matter even when short-run output or consumption remains stable because they alter the future space of action.

Collective and relational capacities deserve separate attention. Some capacities exist only through coordination among several subjects. A payment system, scientific community, emergency-response network, common resource regime, or democratic

institution cannot be reduced to the sum of individual skills. Their capability depends on maintained relations, standards, trust, interoperability, authority, and shared infrastructures. Disruption of those relations can destroy a collective capacity while leaving individual resources physically intact.

GRE therefore treats resources and capacities as related but non-equivalent economic objects. Resource analysis asks what is available and under whose control. Capacity analysis asks what actions or transformations become practically possible. Generative analysis adds a further temporal question: how does the use, distribution, or transformation of present resources and capacities alter the production of later capacities?

3.4.5 Value and Forms of Value

Value is an object of GRE inquiry whenever economic relations create, recognize, transform, circulate, convert, preserve, capture, dissipate, or contest something treated as valuable. The category includes monetary price while extending beyond price to forms of value whose realization depends on use, relation, recognition, institutional standing, ecological condition, cultural meaning, capability, or future generativity. GRE therefore studies both valued objects and the processes through which value becomes intelligible, actionable, and convertible.

Forms of value should remain differentiated. Market value can be expressed through exchange prices under specified institutional conditions. Use value concerns usefulness relative to purposes and users. Social and relational value can depend on participation, belonging, trust, recognition, reciprocity, or the quality of continuing relations. Cultural and symbolic value can depend on meaning, status, heritage, identity, or collective recognition. Ecological value can concern the maintenance of living systems and material conditions that support present and future activity. Generative value concerns the production or return of capacities, resources, relations, knowledge, infrastructures, or other conditions that enable further generation.

These forms can interact without becoming automatically commensurable. A forest can carry market value as timber, ecological value as habitat and water regulation, cultural value for a community, and generative value through the capacities it sustains over time. A university can generate wages and patents while also producing credentials, knowledge, networks, civic capacity, and symbolic standing. A care relation can involve paid labor, emotional significance, capability maintenance, and institutional responsibility. GRE's task is to track these dimensions with enough separation to avoid converting plurality into a single metric before the research question justifies such conversion.

Valuation is therefore as important as value. Institutions, markets, professional communities, households, algorithms, legal systems, and cultural practices establish procedures through which some properties become visible and comparable. Accounting standards recognize certain assets and liabilities; credit systems assign risk categories; rankings convert heterogeneous characteristics into ordered representations; markets translate bids and offers into prices; communities maintain values that remain outside formal exchange. These valuation processes can affect the objects being

valued by changing access, incentives, recognition, or behavior.

Value conversion creates a particularly important object of inquiry. Economic processes frequently transform one form of value into another: knowledge into income, reputation into access, public infrastructure into private profit, ecological resources into commodities, care into labor-market participation, or symbolic recognition into political and economic influence. Conversion interfaces distribute power because actors differ in their ability to authorize, measure, appropriate, or resist conversion. The same relation can generate value for several parties while allowing only some of that value to be captured or monetized.

Value can also propagate beyond the initial transaction. Education provided to one person can contribute to household well-being, organizational capability, future teaching, or community knowledge. A technological standard can create value for complementary producers. A public transport investment can alter labor-market access and land values. These effects need not be reducible to externalities in a narrow sense; GRE can examine the pathways through which value becomes distributed across relational configurations and time.

Normative value requires additional care. Something can be economically valued without being normatively desirable, and a normatively important condition can remain weakly priced or administratively invisible. Profitability, efficiency, social importance, justice, and generativity are separate evaluative dimensions. Later normative sections of the programme can specify how such dimensions are assessed. At the object level, GRE preserves their distinction so that descriptive value processes do not silently determine normative conclusions.

Value thus enters GRE as a heterogeneous and dynamic object. The central questions concern which form of value is at issue, who recognizes it, through which relations it is produced or realized, how it moves or converts, who can capture it, what is lost in conversion, and how present valuations alter future generative conditions.

3.4.6 Conditions and Constraints

Economic action unfolds within conditions that shape which transitions are feasible, costly, legitimate, intelligible, or sustainable. GRE treats these conditions as objects when their distribution or transformation materially affects economic possibility. A *constraint* is a condition that restricts, redirects, or differentially prices possible action; an enabling condition expands or stabilizes practical possibility. The same configuration can perform both roles for different subjects, actions, or timescales.

Conditions can be material, ecological, institutional, legal, technical, social, epistemic, temporal, or spatial. Transport infrastructure affects geographic access; legal status conditions eligibility and enforceability; technical standards condition interoperability; language affects participation in institutions and markets; ecological limits shape production possibilities; time scarcity constrains care and learning; data access conditions computational capability; public safety affects mobility and investment. These conditions often operate before any explicit transaction occurs.

Constraints vary in strength. Some prohibit action through law or physical impossibility. Others increase cost, uncertainty, delay, or risk. Still others operate probabilis-

tically by making some pathways easier to reproduce than others. A weak broadband connection, lack of childcare, inaccessible documentation, reputational stigma, or absence of collateral may not formally prohibit participation, yet each can substantially reduce practical access. GRE therefore studies the topology of feasible action rather than equating freedom with formal permission alone.

Constraints can also be relationally generated. Bargaining dependence can restrict exit; debt can condition future income allocation; platform design can constrain visibility; organizational hierarchy can restrict decision rights; social obligations can direct resource use; network position can limit access to information or opportunities. These constraints arise through relations and can persist even where no single actor consciously designs them.

Enabling conditions deserve equal analytical standing. Public infrastructure, trust, open standards, education, legal protection, care systems, stable ecological conditions, and interoperable institutions can make action possible across broad populations. Their economic contribution may be difficult to assign to individual transactions because they operate as background capacities. GRE can bring such enabling structures into view by asking which later activities depend on their continued reproduction.

Conditions can become endogenous to the processes they condition. Industrial activity can degrade ecological conditions; investment can improve infrastructure; repeated discrimination can reshape expectations and network access; successful coordination can build trust; institutional reform can alter transaction costs and enforcement. A condition that is treated as fixed in one local model can therefore become an outcome in a wider temporal or system boundary.

This category is especially important for intervention analysis. Policies frequently act by changing conditions rather than directly producing final outcomes. A guarantee changes perceived risk; a public option changes outside alternatives; a legal recognition changes standing; a subsidy changes relative cost; an information system changes observability. GRE can study these interventions by tracing how modified conditions alter relations, capacities, subject positions, and later trajectories.

Conditions and constraints thus provide the connective tissue between current configuration and future possibility. Treating them as first-class objects allows GRE to examine why identical resources or formal rights can generate different practical outcomes across subjects and contexts.

3.4.7 Fields and Distributed Structures

Some economic conditions are best represented as distributed structures rather than as possessions or pairwise relations. GRE uses the term *field* cautiously for configurations in which opportunities, pressures, meanings, incentives, risks, or capacities vary across a domain and affect actors partly through their position within that distribution. The field concept is an analytical resource rather than a commitment that social reality literally instantiates a physical field.

A distributed structure can be spatial. Land prices, transport access, pollution exposure, labor demand, public services, broadband quality, and ecological condi-

tions vary across geographic space. It can also be institutional or social. Prestige, professional opportunity, credit access, political influence, or informational visibility can vary across positions in a social or organizational configuration. Digital environments add further domains in which ranking, recommendation, search visibility, platform rules, and data access are unevenly distributed.

Field-like representation is useful when the relevant condition cannot be assigned cleanly to a single actor or relation. A local labor market exerts pressures that emerge from many employers, workers, institutions, transport networks, regulations, and expectations. A scientific field distributes prestige and attention through journals, institutions, funding systems, peer networks, and disciplinary categories. A financial environment shapes borrowing conditions through monetary policy, risk assessment, regulation, liquidity, and market expectations. No isolated tie carries the entire condition.

GRE can therefore study how distributed structures affect the formation and transformation of local relations. A person entering a region with abundant public transport and dense employment opportunities faces a different opportunity structure from an otherwise similar person in a poorly connected region. A small firm operating within an interoperable technical ecosystem faces different generative possibilities from one locked into a proprietary infrastructure. A researcher positioned in a highly visible institutional environment encounters different pathways for recognition and collaboration.

Fields can also be produced by accumulated local actions. Residential sorting can generate spatial concentrations; repeated investment can create technological clusters; platform participation can generate data advantages; institutional prestige can become self-reinforcing through hiring, funding, and citation. The distributed condition then feeds back into later local decisions. GRE is especially interested in these recursive situations because a field generated by past relations becomes a condition for future relation formation.

Boundaries of a field require explicit justification. The relevant domain may be a neighborhood, labor market, profession, platform ecosystem, jurisdiction, linguistic community, supply network, or ecological region. Different boundaries can reveal different gradients and dependencies. The researcher should therefore state what is distributed, across which domain, how position is measured, and which mechanism links the distributed structure to observed outcomes.

Field representations also help avoid attributing every effect to intentional action by identifiable actors. Unequal opportunity can arise through distributed historical structures even when no single current actor controls the whole configuration. At the same time, distributed structure does not imply absence of power. Some actors may possess disproportionate capacity to shape the field through infrastructure ownership, rule setting, investment, standardization, or control of classification systems.

Fields and distributed structures therefore enter GRE as meso- and macro-level objects that connect local relations with wider conditions. They prepare the transition to the next section's analysis of levels and scales by showing that the same economic process can be experienced locally while depending on structures distributed across a much larger domain.

3.4.8 Processes, Events, and Trajectories

GRE requires temporal objects because generation is inherently concerned with how present configurations produce later conditions. Processes, events, and trajectories provide three complementary ways of organizing temporal analysis. A process is an extended pattern of transformation or reproduction; an event is a temporally localized occurrence that changes or reveals a configuration; a trajectory is an ordered history through a sequence of states, positions, relations, or regimes.

Processes can include accumulation, learning, institutionalization, technological diffusion, ecological degradation, care, maintenance, financialization, organizational growth, migration, professionalization, or the reproduction of inequality. Their identity depends on a pattern that persists through time even though the participating entities and local actions can change. Process analysis asks which mechanisms sustain the pattern, what inputs and relations it requires, and under which conditions its direction or intensity changes.

Events are analytically useful when temporally concentrated occurrences reorganize later possibilities. A bankruptcy, legal judgment, policy reform, infrastructure failure, technological release, merger, protest, disaster, discovery, or institutional recognition can redirect relations and expectations. The significance of an event is relational to its surrounding history. The same formal event can have different effects depending on preparedness, institutional capacity, network structure, or prior accumulation.

Trajectories preserve ordered history. Two subjects can arrive at similar present outcomes through different paths that leave different capacities, obligations, networks, expectations, or vulnerabilities. Equal current income can follow stable professional advancement, volatile gig work, inherited wealth, debt-financed education, or recent displacement. A cross-sectional measure can therefore conceal generatively important histories. GRE uses trajectory analysis to ask how sequences of relations and events shape present and future possibility.

Path dependence can arise through several mechanisms. Earlier choices can create switching costs, complementary investments, habits, classifications, reputational effects, or network structures that condition later choices. Institutional arrangements can make some transitions progressively easier and others harder. Learning can create cumulative capability. Trauma or depletion can reduce future adaptability. These mechanisms differ, so trajectory dependence should be specified rather than invoked as a generic explanation.

Temporal objects also allow GRE to distinguish maintenance from change. A stable institution or capacity may require continuous process. Public infrastructure must be repaired; professional competence maintained; ecosystems regenerated; trust reproduced; data updated; organizations staffed. A snapshot can therefore make a dynamically maintained condition appear static. Process analysis reveals the labor, resources, relations, and constraints required for persistence.

The timescale of a trajectory matters. A policy can improve short-run consumption while weakening long-run fiscal capacity; a technology can raise output while generating ecological or skill dependencies; a cost-cutting strategy can increase current profit while degrading organizational knowledge. GRE consequently studies tra-

jectories across timescales rather than treating the immediate effect as a sufficient description of economic consequence.

Processes, events, and trajectories can themselves interact. An event can initiate a process; a process can accumulate conditions that make an event consequential; a trajectory can cross a threshold that changes the process governing subsequent evolution. These temporal objects therefore provide the language needed to connect current intervention with future generative structure.

3.4.9 Institutions and Social Facts

Institutions and social facts are objects of GRE because economic possibilities are stabilized through rules, roles, classifications, expectations, conventions, recognized statuses, and recurring practices that exceed isolated transactions. Institutions organize who may act, under what authority, through which procedures, with which forms of recognition, and under which expectations of continuity. Social facts include collectively sustained realities whose economic consequences depend on shared recognition, repeated practice, or institutional support.

An institution should be distinguished from an organization. An organization is a relatively bounded collective entity; an institution is a stabilized pattern of rules, roles, norms, or practices that can operate across many organizations. A university is an organization, while credentialing practices, academic tenure, disciplinary review, or degree recognition are institutional arrangements. A bank is an organization, while money, deposit insurance, accounting standards, or secured lending involve wider institutions. The distinction matters because organizational change can occur within persistent institutions, and institutional change can reorganize many organizations simultaneously.

Institutions stabilize expectations. Contract law affects the expected consequences of agreement; property regimes organize control and transfer; professional licensing structures entry; welfare systems define eligibility; labor law configures employment relations; standards coordinate interoperability. This stabilization can reduce uncertainty and make complex cooperation possible. It can also preserve historically produced asymmetries by assigning differential rights, burdens, recognition, or access.

Social facts can become economically real through collective recognition and practical enforcement. Currency, credentials, corporate status, property claims, rankings, occupational categories, and reputations depend partly on recognition while producing material consequences. Their socially constituted character does not weaken their reality. A person denied a credential, account, license, or legal status can face direct material exclusion even though the relevant object exists through institutional and representational practices.

GRE is interested in how institutions are generated and reproduced. Repetition can stabilize conventions; law can formalize existing practices; administrative categories can create new subject positions; technical infrastructures can embed rules into routine action; organizations can reproduce institutions through hiring, reporting, and compliance. Institutional persistence therefore requires material, symbolic, and relational supports that can themselves become objects of economic analysis.

Institutions also transform the value and meaning of other objects. A dwelling becomes mortgageable property under specific legal and financial institutions. Data become tradable or restricted through regulatory and contractual regimes. A skill becomes economically valuable when recognized by employers or credentialing systems. A relationship becomes taxable, insurable, or legally protected when institutional categories recognize it. Institutions thus participate in converting material and social differences into economically actionable distinctions.

Institutional change can produce generative effects that extend far beyond the immediate rule modification. A new legal status can enable contracting, borrowing, inheritance, representation, or access to public support. A new technical standard can create markets for complementary products. A revised accounting rule can alter investment behavior. Because institutions condition many later relations simultaneously, their generative reach can be large even when the initiating intervention appears administrative.

The institutional object category therefore links GRE's analysis of stable social reality with its interest in historical transformation. Institutions provide continuity while remaining generated, maintained, contested, and revisable. Their durability makes them analytically powerful; their historical production prevents their present form from being treated as timeless.

3.4.10 Symbolic and Representational Objects

Economic life increasingly depends on symbolic and representational objects: prices, money, accounts, contracts, rankings, scores, categories, models, forecasts, identities, records, credentials, tokens, indices, dashboards, and algorithmic classifications. GRE treats such objects as economically consequential when representations mediate access, coordinate action, allocate attention, stabilize expectations, or alter the behavior of the subjects represented.

A representation should be distinguished from its referent. A credit score is not identical to a borrower's full financial condition; a ranking is not identical to institutional quality; a market price is not identical to every form of value; a model is not identical to the system modeled. The distinction matters because economic action often responds to the representation. A lender can deny credit because of a score, investors can respond to a rating, students can choose universities through rankings, managers can reorganize work around performance indicators, and public agencies can allocate resources through administrative categories.

Representations can therefore become performative or generative. Once a category is used for allocation, subjects may adapt behavior to satisfy it. Once a metric determines funding, organizations may reorganize activity around the metric. Once a risk model affects pricing, the resulting prices can alter the behavior on which future risk estimates are based. Representation enters the causal structure because institutions and actors use it to make decisions.

Symbolic objects also permit coordination across distance and scale. Money represents transferable claims; contracts encode obligations; accounting records organize complex organizations; technical standards encode compatibility; credentials communicate institutional recognition; databases preserve histories that can be acted

upon by subjects who never directly observed the original events. These symbolic infrastructures expand economic coordination while creating dependencies on classification, record integrity, interpretability, and institutional trust.

The production of representations is therefore itself an economic process. Data must be collected, categories designed, models trained, records maintained, standards negotiated, and interpretations authorized. These activities require labor, infrastructure, expertise, and institutional power. Actors controlling representation systems can shape which differences become visible and which forms of value become actionable. In data-intensive economies, control over classificatory and representational infrastructure can become a major source of economic power.

Representations also have error structures. Measurement can be noisy; categories can be incomplete; models can be misspecified; historical records can be biased; proxies can drift as behavior changes. A representation can remain administratively stable while becoming less adequate to the underlying configuration. GRE therefore treats representational validity as historically revisable. The question is not only whether a representation was accurate when introduced, but whether the relations between indicator, referent, and institutional use remain sufficiently stable for current decisions.

Symbolic objects can move across contexts and acquire new effects. A credential issued for educational recognition can become a labor-market filter. A social-media metric can become an advertising asset. A legal category can become a database field used in automated decision systems. A scientific indicator can become a policy target. Such movements can alter the meaning of the representation and the incentives surrounding it.

GRE's interest in symbolic and representational objects is consequently broader than a study of information. It concerns the economic relations through which representations are created, authorized, circulated, interpreted, converted into decisions, and recursively connected to the realities they describe. The distinction between relation and representation remains central: a representation can reveal a relation, simplify it, distort it, or participate in generating a new one.

The ten object classes developed in this section provide GRE with a plural repertoire for empirical and theoretical inquiry. Emergent entities supply relatively stable units; subjects and subject positions identify locations of participation, standing, experience, and exposure; relations and relational configurations make interdependence explicit; resources and capacities distinguish what is available from what can practically be done; forms of value identify heterogeneous objects of production, recognition, conversion, and evaluation; conditions and constraints organize feasible possibility; fields capture distributed structures; processes, events, and trajectories preserve temporal organization; institutions and social facts explain stabilized collective realities; and symbolic or representational objects make visible the classificatory infrastructures through which economic action is coordinated.

These categories should remain permeable. A corporation can simultaneously be an entity, a juridical subject, an institutional configuration, a bundle of capacities, a node in relational fields, and a trajectory. Money can be a resource, an institutionally stabilized social fact, a symbolic object, and a medium through which value is repre-

sented and converted. A platform can be an organization, technical infrastructure, field, relation-generating environment, classificatory system, and economic subject under different legal arrangements. GRE gains explanatory power from selecting the representation that preserves the distinctions relevant to the local question, while comparing alternative representations when conclusions depend on that choice.

Object selection is therefore inseparable from scale. An object stable at one level can decompose into heterogeneous relations at another; a relation local to one scale can appear as a distributed field at another; an event for one subject can be part of a long institutional process at a wider temporal resolution. The next section turns explicitly to these levels and scales of inquiry, establishing how GRE can move among individual, organizational, collective, institutional, ecological, and transnational domains without assuming that the same objects retain identical boundaries across them.

3.5 Levels and Scales of GRE Inquiry

The objects identified in the preceding section become analytically meaningful only relative to a level and scale of inquiry. A household can be treated as an economic subject in one analysis, as a field of interpersonal relations in another, as a node in a credit or welfare network in a third, and as part of a larger demographic, ecological, or transnational configuration in a fourth. Generative Relational Economics therefore requires an explicit account of scale selection. The role of this section is to specify the principal levels at which GRE inquiry can be organized and to clarify how movement among levels affects what counts as an entity, relation, condition, mechanism, and consequence. Its objective is neither to impose a fixed micro–meso–macro hierarchy nor to deny the usefulness of scalar distinctions. It is to make scale an explicit analytical choice whose adequacy depends on the research question, the generative mechanism under study, and the evidential resolution available to the researcher.

Scale in GRE has several dimensions. A *spatial scale* concerns the geographic or material extent of a configuration. A *temporal scale* concerns the duration over which formation, persistence, transformation, or consequence is observed. An *organizational scale* concerns the level at which coordinated action is stabilized, from interpersonal relations to firms, states, transnational institutions, or distributed infrastructures. A *juridical scale* concerns the reach of rights, duties, jurisdictions, and recognized authority. An *ecological scale* concerns the material and living systems within which economic activity is embedded. An *analytical scale* concerns the resolution at which a researcher constructs objects and causal or generative claims. These dimensions can align, but they often diverge.

The distinction between *level* and *scale* is useful even when their boundaries remain context-dependent. A level identifies a position within a layered description, such as person, organization, institution, or transnational system. Scale identifies the extent or resolution of the phenomenon being observed. An organizational process can have a local spatial scale but a long temporal scale; an interpersonal relation can be embedded in a global platform infrastructure; a juridical rule can operate nationally while being produced through transnational negotiation. GRE therefore

treats levels as analytical locations within an inquiry and scales as dimensions of extent, duration, or resolution. Neither should be assumed to map onto a single natural hierarchy.

This section proceeds across six recurrent domains of analysis—individual and interpersonal, organizational, community and collective, institutional and juridical, ecological and more-than-human, and inter-system and transnational—before turning to two cross-cutting issues: scale-relative entityhood and cross-scale generative effects. The method is constitutive rather than classificatory in a rigid sense. The purpose is to define a usable architecture for GRE research while preserving the possibility that empirical cases require different or additional levels.

3.5.1 Individual and Interpersonal Scales

Individual and interpersonal scales concern persons, households, dyads, small groups, and recurrent relations whose immediate organization is accessible at the level of situated interaction. At this scale, GRE can study how economic capacities, constraints, expectations, obligations, identities, and values are generated through relations among concrete subjects. The focus is wider than individual choice in isolation. Choice remains important, but the inquiry asks how the conditions under which choices become available, intelligible, affordable, legitimate, or sustainable are relationally formed.

An individual can be analyzed as an economic subject with resources, preferences, capabilities, legal standing, knowledge, vulnerabilities, and temporal commitments. Yet these attributes frequently depend on relations that exceed the individual. Income can depend on employment relations; credit access can depend on institutional classification and social history; capability can depend on care, education, infrastructure, or recognition; preference formation can depend on social learning and available categories of action. GRE therefore treats individual-level observations as legitimate without treating the individual as analytically self-sufficient.

Interpersonal relations can themselves generate economic effects. Trust can reduce monitoring costs and make cooperation feasible. Care can maintain or expand another person's practical capacities. Advice can alter information, confidence, or opportunity. Repeated exchange can create expectations of reciprocity. Family relations can redistribute resources across time and persons. Friendship and professional ties can provide access to information, employment, finance, or institutional navigation. These effects can be valuable without being fully priced, and they can generate dependency or unequal obligation as well as support.

Households illustrate the importance of distinguishing the administrative recipient from the relational field. A transfer formally delivered to one household member can alter bargaining power, care allocation, educational investment, consumption, savings, mobility, or future exit options for several people. A wage increase can change household time allocation and dependency patterns. Debt undertaken by one member can constrain future resources of others. The relevant unit therefore depends on the mechanism being studied rather than on the administrative unit through which a programme or transaction is recorded.

Temporal scale is especially important at the interpersonal level. Some effects are

immediate, such as payment, consumption, or access. Others accumulate through repeated interaction. Trust, skill, reputation, dependency, and caregiving capacity are often generated through histories rather than single encounters. A relation that appears beneficial over one month can create vulnerability over several years; a costly educational investment can generate capabilities whose effects become visible much later. GRE inquiry should therefore specify the time horizon over which an interpersonal relation is being evaluated.

The individual and interpersonal scale also reveals the difference between formal equality and relational position. Two persons may hold the same legal right while facing different exit costs, knowledge, network access, or dependence. Equal monetary transfers can have different generative effects because subjects occupy different relational configurations. This does not imply that every analysis must reconstruct the full social history of each person. It means that the scale of analysis should be broad enough to capture the relations necessary for the specific generative claim.

At this level, evidence can include interviews, ethnography, surveys, administrative records, experiments, transaction histories, diaries, social-network data, or mixed-method designs. The appropriate evidence depends on whether the claim concerns subjective meaning, observed behavior, resource flow, causal effect, relational structure, or long-horizon change. Individual-scale data do not automatically support interpersonal or institutional claims, just as aggregate data can conceal mechanisms operating through concrete relations.

The individual and interpersonal scale is therefore a legitimate entry point rather than a privileged foundation. GRE can begin with persons and direct relations when that resolution is adequate, while remaining prepared to enlarge the analytical boundary when the observed capacities, constraints, or trajectories depend on organizational, institutional, ecological, or transnational structures.

3.5.2 Organizational Scales

Organizational scales concern coordinated configurations that stabilize roles, procedures, decision rights, resource pools, routines, information flows, and boundaries of participation. Firms, public agencies, universities, hospitals, cooperatives, nongovernmental organizations, platforms, laboratories, and project teams can all become objects at this scale. The relevant question is not simply whether an organization exists as a legally recognized entity. GRE asks how organizational arrangements generate capacities and constraints for participants and how those arrangements reproduce or transform their own conditions of operation.

Organizations can pool resources that individuals cannot mobilize alone. They can create specialized roles, accumulate knowledge, establish infrastructure, coordinate long production processes, and distribute risk. They can also concentrate decision authority, create informational asymmetries, and determine access to opportunities. An organization therefore appears simultaneously as an emergent entity and as a relational architecture through which people, technologies, rules, and resources become coordinated.

Organizational boundaries are analytically important because many contemporary production processes extend beyond formal employment or ownership. A plat-

form can rely on independent contractors, users, complementors, cloud providers, advertisers, moderators, data-labeling workers, and public infrastructure. A manufacturing firm can depend on suppliers distributed across jurisdictions. A university can rely on temporary researchers, publishers, funders, accreditation systems, and digital services. The legal boundary of the organization is one relevant boundary, but it may not coincide with the generative boundary of the economic process.

GRE can therefore distinguish between organizational membership and organizational dependence. A person may depend economically on an organization without being an employee. A community may bear environmental or infrastructural consequences of organizational activity without participating in governance. A supplier may become technologically locked into a dominant buyer. A public institution may depend on proprietary software whose provider sits outside its formal hierarchy. These relations affect the organization's generative reach and the distribution of benefits, risks, and future options.

Organizational scale also makes internal heterogeneity visible. Departments, teams, occupational groups, and technical systems can operate under different incentives and temporalities. A firm can appear coherent at the market level while containing conflicts over investment, labor conditions, safety, innovation, and accounting. An organization can therefore be treated as a unit for one research question and decomposed into internal relational configurations for another. The adequacy of aggregation depends on which mechanisms matter to the inquiry.

Organizational learning is one important generative process. Routines, archives, training systems, informal norms, and technological infrastructures can preserve knowledge beyond individual tenure. Conversely, turnover, outsourcing, or fragmentation can dissipate capabilities even when short-term financial indicators improve. Investment in organizational capacity can therefore generate future possibilities that are not visible in current output, while extraction from organizational knowledge or trust can reduce later adaptability.

Governance within organizations is similarly generative. Decision procedures determine whose information enters deliberation, which risks become visible, how conflict is resolved, and who can revise rules. Participation can create knowledge and legitimacy; concentrated authority can accelerate decisions in some contexts while suppressing local information in others. GRE does not presume one organizational form to be normatively superior across cases. It studies how specific governance architectures shape the production, distribution, and transformation of future capacities.

Organizational scale thus mediates between interpersonal relations and wider institutional structures. Organizations translate law, markets, technologies, and cultural expectations into local procedures, while their actions can reshape sectors, communities, standards, and political economies. Their analysis requires attention both inward to internal relational architecture and outward to the fields in which they operate.

3.5.3 Community and Collective Scales

Community and collective scales concern forms of coordination and shared dependence that do not necessarily coincide with formal organizational boundaries. Neighborhoods, professional communities, scientific fields, cultural groups, commons, mutual-aid networks, open-source communities, social movements, informal markets, and distributed publics can exhibit patterns of collective action without constituting a single organization. GRE includes these formations because economically consequential capacities can emerge through repeated participation, shared norms, common infrastructures, and distributed recognition.

A community can generate resources that are difficult to assign to individual producers. Shared knowledge, reputation systems, linguistic conventions, safety expectations, informal credit, professional standards, and norms of reciprocity can enable action across many participants. Their value often depends on continued collective reproduction. If participation declines, trust erodes, common infrastructure deteriorates, or knowledge ceases to circulate, the resource itself can weaken even when no discrete asset has been destroyed.

Collective scale also matters for the formation of economic subjects. Membership in a professional, cultural, or local community can provide categories through which people understand opportunities and obligations. Collective narratives can shape expectations about work, entrepreneurship, education, debt, care, or acceptable risk. These processes need not imply homogeneous values. Communities can contain disagreement, hierarchy, exclusion, and multiple overlapping memberships. GRE therefore treats collective identity as an empirical configuration rather than an assumption of unity.

Commons provide a particularly useful illustration. A resource can be collectively used and governed through rules that define access, contribution, monitoring, sanction, and adaptation. The relevant economic object is then neither only the resource nor only the individual user. It includes the relation among resource conditions, user practices, governance arrangements, and external pressures. Changes in any of these can alter the viability of the collective system.

Digital communities extend these issues beyond geographic proximity. Open-source projects, online knowledge communities, creator networks, and platform-mediated groups can generate software, information, cultural value, reputation, and social support through dispersed participation. Their infrastructures can nevertheless remain privately owned or technically centralized. A community can therefore be distributed at the level of participation while depending on concentrated control at the infrastructural level. This asymmetry becomes visible only when multiple scales are analyzed together.

Collective action can also produce public or quasi-public capacities. Community organizing may improve bargaining power; professional associations may establish standards; neighborhood networks may coordinate disaster response; scientific communities may produce shared methods and repositories. These capacities can benefit participants unevenly and can create boundaries around membership or recognition. GRE can study both the generative contribution of collective organization and the distribution of access to what is collectively generated.

The temporal scale of communities often exceeds individual participation. Institutions of memory, ritual, documentation, mentorship, and repeated practice can transmit norms and capacities across cohorts. At the same time, a community can transform rapidly under migration, technological change, political conflict, or economic restructuring. Analyses that treat collective structure as fixed can miss the processes through which membership, meaning, and governance are continually reproduced.

Community and collective scales therefore provide a middle range in which distributed relations acquire partial stability without necessarily becoming formal organizations. They are especially important for GRE because generation frequently occurs through participation that is economically consequential yet only partially represented in contracts, prices, or administrative categories.

3.5.4 Institutional and Juridical Scales

Institutional and juridical scales concern relatively stabilized systems of rules, recognized roles, procedures, classifications, rights, duties, jurisdictions, and authorized decisions. At this scale, GRE studies how economic possibility is structured through the formal and informal arrangements that determine what can be owned, exchanged, licensed, enforced, recognized, taxed, subsidized, inherited, represented, or contested. Institutions are not merely background conditions. They actively generate categories of action and subject positions.

Law provides one especially explicit architecture of economic possibility. Corporate law makes certain collective entities legally actionable. Property law organizes claims over resources. Contract law structures enforceable commitments. Labor law defines employment relations and protections. Bankruptcy law redistributes consequences of failure. Immigration law can shape access to labor markets and public support. Intellectual-property law conditions the circulation and appropriation of knowledge. These arrangements alter incentives, but they also constitute the legal identities and relations through which economic action proceeds.

Juridical scale should not be reduced to national legislation. Municipal regulations, administrative agencies, courts, professional licensing bodies, treaty regimes, private arbitration systems, technical standards, and organizational rules can each exercise authority over different domains. Jurisdictions overlap, and actors can move or strategically position activity among them. GRE therefore asks which authority is operative for the relation under study and how jurisdictional boundaries affect the distribution of rights, risks, and generative opportunities.

Institutional categories can have constitutive effects. Eligibility rules determine who counts as a beneficiary. Accounting standards determine which assets and liabilities become visible. Educational credentials authorize access to professions. Credit classifications influence borrowing conditions. Statistical categories shape policy populations. Once institutionalized, such classifications can alter behavior and resource flows, thereby contributing to the reality they purport to describe.

Institutional scale also introduces temporal depth. Rules inherit prior conflicts and compromises; administrative routines accumulate; precedents stabilize expectations; legal categories outlive the conditions under which they were formed. Economic actors adapt to these structures, and repeated adaptation can create constituencies

that support their continuation. Institutional persistence can therefore be generated through feedback among rules, investments, expectations, and organized interests.

Change at this scale can be discontinuous. A legal recognition, regulatory decision, court judgment, or policy reform can rapidly transform the feasible set of actions for many actors. Yet implementation remains relational. Formal change can produce uneven effects when local administrative capacity, information, infrastructure, or social recognition differs. GRE consequently distinguishes institutional rule change from the distributed processes through which a rule becomes effective in practice.

Institutional and juridical scales also mediate normative questions. Rights, procedural protections, and public obligations can constrain economically efficient arrangements for reasons of justice, dignity, or political legitimacy. Conversely, legal authority can stabilize extractive or exclusionary relations. GRE does not infer normative validity from institutional existence. It treats institutions as economically generative structures whose consequences and justification require separate evaluation.

This scale is indispensable whenever the relevant causal or generative mechanism depends on recognized authority. A transaction between two persons may appear interpersonal, yet its enforceability, tax treatment, property consequences, and admissible terms can be institutionally constituted. The juridical environment therefore enters GRE inquiry whenever it materially changes what relations can exist and what they can generate.

3.5.5 Ecological and More-than-Human Scales

Ecological and more-than-human scales concern the living, material, energetic, climatic, and technological systems through which economic activity becomes possible and consequential. GRE includes these scales because economic relations are embedded in conditions that are neither produced solely by human exchange nor adequately represented as passive inputs. Soil fertility, water systems, biodiversity, atmospheric conditions, energy infrastructures, animal populations, computational systems, and built environments can shape and be transformed by economic processes.

Ecological scale complicates conventional boundaries around the economic unit. A factory can be analyzed as an organization, but its production may depend on watersheds, energy grids, mineral extraction, transport corridors, and waste sinks distributed across large regions. Agricultural production can depend on pollination, soil microbiomes, climate patterns, seed systems, and water availability. The relevant generative configuration can therefore extend far beyond the spatial boundary of the producing organization.

Temporal scale becomes especially consequential here. Ecological regeneration, depletion, contamination, and climate effects can unfold over decades or generations. Short accounting periods can therefore classify an activity as productive while externalizing degradation of the conditions that make later production possible. GRE can address this mismatch by treating ecological conditions as part of the generative system rather than only as exogenous constraints encountered by economic actors.

More-than-human inquiry also raises questions about agency and subjecthood.

GRE need not resolve a general metaphysics of non-human agency in order to study how animals, ecosystems, technical systems, or artificial agents participate causally in economic configurations. A river can constrain settlement and transport; a disease vector can alter labor and health systems; an algorithm can allocate visibility or credit; an automated system can modify production decisions. The analytical status of these participants should be specified relative to the claim being made rather than predetermined by a universal hierarchy of subjects.

Technological systems illustrate the overlap between ecological and organizational scales. Energy networks, communication infrastructures, logistics systems, and machine-learning platforms have material footprints, operational dependencies, maintenance requirements, and failure modes. Their economic effects emerge through coupled human and technical relations. Treating technology as a neutral tool can obscure how technical architecture redistributes practical capacities and how its maintenance depends on resource extraction, labor, standards, and institutional support.

Ecological relations also generate value that can resist simple monetization. A wetland can support flood protection, habitat, cultural practice, recreation, and future ecological resilience. Assigning a price to one service can assist a particular decision while leaving other forms of value unrepresented. GRE therefore permits multiple valuation registers at ecological scales and requires transparency about which dimensions are included in a given economic representation.

More-than-human scales also expand the population affected by economic decisions. Future people, non-human organisms, and ecosystems can bear consequences without participating in present transactions. This creates a temporal and representational problem: current subjects make decisions under institutions that may weakly represent distant or non-speaking affected parties. GRE can study the mechanisms through which those absences become economically consequential without assuming that a single metric resolves the normative problem.

Ecological and more-than-human scales thus prevent the research boundary from stopping where conventional organizational or market boundaries stop. They make visible the material conditions, distributed dependencies, and long-duration transformations through which present economic generation can either sustain or erode future possibility.

3.5.6 Inter-System and Transnational Scales

Inter-system and transnational scales concern relations that cross organizational fields, institutional orders, jurisdictions, sectors, infrastructures, or national boundaries. Contemporary economic processes frequently operate through such crossings. Finance, migration, supply chains, digital platforms, scientific collaboration, humanitarian assistance, trade, energy systems, taxation, and data governance can connect actors governed by different rules and situated within different value structures. GRE therefore requires a scale at which interactions among systems become objects in their own right.

A transnational supply chain illustrates the problem. Production may involve design in one jurisdiction, components from several others, assembly elsewhere,

finance through global institutions, shipping through international logistics, and consumption in distant markets. Labor rights, environmental rules, currencies, tax regimes, and political risks differ across locations. The economic relation cannot be understood fully through the bilateral transaction between buyer and seller because value generation and vulnerability are distributed across the chain.

Inter-system analysis is broader than geographic internationalization. Health systems can interact with labor markets; education systems with migration regimes; financial systems with housing; scientific systems with intellectual-property institutions; humanitarian systems with border governance. Each system can maintain its own classifications, objectives, and evaluative criteria. Their coupling can create gaps, contradictions, or conversion points through which subjects gain or lose access.

Conversion across systems is therefore a central object. A qualification recognized in one jurisdiction may not convert into professional standing elsewhere. Financial capital can cross borders more easily than labor. Data can be generated in one legal environment and processed in another. Carbon emissions can be produced locally while their climatic effects are globally distributed. Humanitarian categories can determine access to assistance but interact imperfectly with immigration categories. GRE can study these interfaces as generative sites where differences among systems produce new capacities or constraints.

Transnational scale also changes the distribution of governance capacity. Some actors can choose jurisdiction, route investment, relocate data, restructure ownership, or negotiate directly with states. Others remain territorially or institutionally fixed. Mobility itself therefore becomes an economic capability. The ability to cross boundaries can alter bargaining power even when formal rules are equal within each jurisdiction.

Distributed infrastructures further complicate territorial analysis. Payment networks, cloud computing, communications, shipping, and digital identity systems can operate across many jurisdictions while being controlled by a limited number of organizations or standards bodies. Failure or policy change at one infrastructural node can propagate across distant systems. The relevant scale is then neither purely national nor simply global; it follows the architecture through which dependence and coordination are organized.

Transnational processes also operate across heterogeneous temporalities. Trade agreements, infrastructure investments, migration histories, debt contracts, and climate commitments can bind actors over long periods. Short-term political cycles may interact with long-term obligations. GRE can therefore examine how institutional time horizons become coupled and how present decisions distribute future adjustment costs across places and populations.

Inter-system and transnational scales are consequently necessary whenever the generative relation crosses the boundary of the system in which the initial action is recorded. They direct attention to interfaces, conversions, jurisdictional differences, infrastructural dependencies, and the unequal capacity to move among systems.

3.5.7 Scale-Relative Entityhood

The preceding scales reveal a central constitutional principle of GRE: entityhood is often scale-relative. A configuration that functions as a coherent entity at one analytical level can become a field of heterogeneous relations at another. A household can be a unit in a national survey and a contested relational configuration in an ethnographic study. A corporation can be a market actor in industrial analysis and a network of departments, contracts, algorithms, workers, and investors in organizational analysis. A state can be treated as an actor in international negotiation and decomposed into agencies, courts, political coalitions, infrastructures, and administrative practices in institutional analysis.

Scale-relative entityhood does not imply that entities are unreal. It specifies the conditions under which treating a configuration as an entity is analytically productive. Relative stability, boundary persistence, coordinated action, recognized identity, and causal integration can justify entity-level analysis. The same configuration can nevertheless be decomposed when internal structure becomes relevant to the question. Ontological suspension therefore supports practical realism: the analyst can work with entities while remaining open to changing the level of resolution.

Aggregation is one mechanism through which entities appear. Individual transactions can produce market-level regularities; organizational decisions can produce sectoral patterns; local ecological changes can accumulate into regional effects. Yet aggregation alone does not guarantee that the higher-level object has independent explanatory value. GRE asks whether higher-level patterns feed back into lower-level behavior, constrain possible transitions, or stabilize classifications and expectations. When they do, the higher-level configuration can become causally or generatively relevant in its own right.

Decomposition likewise requires care. Explaining an organization through individuals alone can omit rules, infrastructures, and emergent coordination. Explaining a legal order through statutes alone can omit administrative practice and social recognition. Explaining a market through transactions alone can omit standards, network effects, and institutional conditions. Reduction to a finer scale can therefore lose structure just as aggregation can conceal heterogeneity.

The choice of scale also affects attribution. If a worker acquires a skill, the generative contribution may involve individual effort, teachers, organizational training, public education, family support, digital infrastructure, and prior scientific knowledge. Different scales reveal different contributors. GRE should therefore match attribution to the level of the claim and avoid converting a multi-scale generative process into a single-agent narrative without justification.

Scale-relative entityhood also matters for normative evaluation. Benefits and harms can reverse appearance across scales. A firm-level efficiency gain can impose community-level unemployment; a household-level coping strategy can reproduce gendered burdens; a national growth policy can create ecological costs elsewhere; a local conservation rule can restrict livelihoods while sustaining long-run regional resilience. Evaluation should therefore state the population, temporal horizon, and scale to which a conclusion applies.

Remark 3.1 (Scale-relative entityhood)*.* Treating a configuration as an entity is a mod-

eling and evidential commitment justified by the local inquiry. It does not require the same configuration to remain indivisible, homogeneous, or equally salient at other scales.

This principle gives GRE a disciplined way to move among levels without declaring one level ultimately fundamental. The research question determines the initial resolution, while empirical anomalies, mechanism evidence, or downstream effects can require expansion or decomposition of the analytical boundary.

3.5.8 Cross-Scale Generative Effects

Cross-scale generative effects occur when processes organized at one level alter capacities, constraints, structures, or possibilities at another. These effects are central to GRE because economic generation often propagates beyond the scale at which an intervention, transaction, or decision is initially observed. A scholarship allocated to one person can affect a household, professional network, organization, or future community. A local technological innovation can reshape industry standards. A national regulation can reorganize firm behavior and interpersonal opportunities. A transnational platform rule can alter the visibility and income of individual creators.

Cross-scale effects can move upward through accumulation, coordination, diffusion, or institutionalization. Repeated individual behavior can create market conventions. Local experiments can become organizational routines. Collective practices can become recognized standards. Distributed demand can support an industry. Social expectations can become politically salient and eventually codified. The relevant mechanism should be specified rather than assumed from the observation that lower-level and higher-level change occur together.

Effects can also move downward. Institutional classifications shape individual eligibility; organizational rules structure team behavior; market concentration alters bargaining conditions; national monetary policy changes borrowing costs; ecological degradation constrains household livelihoods. Higher-level patterns can therefore become conditions of lower-level action even when they originated historically from distributed processes.

Horizontal propagation across scales is equally important. A change in one sector can alter another through labor, finance, infrastructure, or regulation. A technological standard adopted by one industry can create complementary markets elsewhere. A health crisis can transform education, transport, employment, and care. These processes are not captured adequately by a single vertical hierarchy because the relevant systems can be partially autonomous yet strongly coupled.

Cross-scale generation can also involve delayed effects. Investment in early childhood can influence educational trajectories years later; infrastructure can shape settlement and productivity over decades; ecological damage can accumulate before crossing thresholds; institutional reforms can alter expectations gradually. A local analysis may therefore be accurate within its immediate horizon while incomplete for longer generative consequences.

Feedback among scales creates additional complexity. An organizational policy can alter worker behavior; aggregated behavior can change organizational perfor-

mance; performance can lead to a revised policy. A legal reform can change market practices; those practices can generate new political coalitions; the coalitions can reshape subsequent law. In such cases, scale is part of the mechanism because causal influence circulates among levels rather than traveling in one direction.

Cross-scale effects also create attribution difficulties. When value or harm propagates across several levels, assigning the outcome to the initial actor alone can overstate individual contribution, while attributing it only to structure can erase situated agency. GRE therefore treats generative attribution as potentially distributed. The relevant task is to identify the relations through which capacities or constraints were produced and the points at which different actors or structures materially altered the trajectory.

Measurement should reflect this distributed character. Data collected at one scale can miss effects at another. Firm-level productivity data may not reveal household care burdens; household income data may not reveal ecological depletion; national statistics may not capture transnational tax shifting; platform-level engagement metrics may not capture community-level cultural effects. Multi-level designs, linked data, comparative cases, qualitative tracing, and simulation can each contribute where appropriate, provided the relation between evidence and claim remains explicit.

Cross-scale analysis finally has a governance implication. Interventions aimed at one level can generate consequences elsewhere, so institutional responsibility may need to follow generative reach rather than administrative jurisdiction alone. This does not imply unlimited responsibility for every remote consequence. It creates a research question about which downstream effects are sufficiently connected, foreseeable, material, or governable to enter evaluation and design.

The architecture established in this section therefore gives GRE a way to specify where an inquiry begins, how far its analytical boundary extends, and when movement among scales becomes necessary. Individual, organizational, collective, institutional, ecological, and transnational levels are recurrent sites of inquiry rather than a closed hierarchy. Entityhood remains relative to analytical scale, and generative effects can propagate upward, downward, horizontally, and across time. With these levels clarified, the next task is to state the characteristic questions through which a GRE inquiry can interrogate a concrete economic situation.

3.6 Illustrative Questions in Generative Relational Economics

The preceding sections have specified the disciplinary identity, problem-space, methodological primitives, objects, and scales of Generative Relational Economics. Those elements define a field of possible inquiry, but they remain abstract until translated into questions that can organize empirical, historical, formal, interpretive, and normative research. The role of this section is therefore illustrative. It identifies recurrent question-forms that make the distinctive concerns of GRE operational without turning them into a mandatory sequence or a closed checklist. The objective is to show how a researcher can move from a conventional economic problem toward

a generative-relational formulation by asking what relations constitute the situation, what is generated through them, how value and capacity travel, where asymmetries are converted into power, and how present arrangements alter later conditions of possibility.

These questions are intentionally broader than particular methods. A question concerning value propagation might be studied through administrative data, interviews, network analysis, accounting records, historical archives, ethnography, simulation, or some combination of these. A question concerning subject formation may require interpretive evidence that differs from the evidence required to identify a resource flow. GRE therefore treats the question-form as analytically prior to method selection. Methods are chosen according to the object, scale, mechanism, and evidential problem rather than according to a presumption that one technique defines the field.

The questions are also non-exclusive. A single research project may begin with one and encounter several others. An analysis of a training subsidy may ask who formally receives the subsidy, which household or organizational relations mediate its use, what capacities are generated, how those capacities propagate through employment networks, which forms of value are realized or lost, and whether the programme changes the future bargaining position of workers. The value of the GRE perspective lies partly in making these connections available for investigation while preserving distinctions among them.

The twelve question families below should consequently be read as an open repertoire. They do not exhaust GRE inquiry, and they do not imply that every project must answer all twelve. Their function is to reveal characteristic directions of attention: constitution, displacement beyond the administrative recipient, generation, propagation, conversion, recirculation, capacity transformation, subject formation, power formation, orientation, foreclosure, and recursive transformation of the conditions of change.

3.6.1 Which Relations Constitute the Economic Situation?

A GRE inquiry can begin by asking which relations make the observed economic situation possible and intelligible. The question directs attention away from treating visible entities as analytically self-sufficient. A worker, firm, household, platform, loan, public service, or market transaction enters an already organized field of legal, infrastructural, contractual, social, technical, ecological, and symbolic relations. Some of these relations are proximate and observable; others operate as background conditions. The task is to identify which of them materially affect the phenomenon under investigation.

This question is selective rather than totalizing. GRE does not require reconstruction of every relation surrounding an object. The relevant relations are those whose inclusion changes explanation, evaluation, or intervention. A study of household energy insecurity, for example, may need to include income, housing quality, tenancy status, energy pricing, family composition, climate exposure, and access to public support. The entire history of the household is unnecessary unless some part of that history affects the mechanism under study. Relational analysis becomes useful when

it improves the adequacy of the inquiry rather than when it simply multiplies context.

The question also encourages distinctions among kinds of relation. A legal relation of entitlement differs from an interpersonal relation of trust; a supply relation differs from an ownership relation; a technical dependency differs from a political authorization; an ecological dependency differs from a contractual obligation. Several may intersect in one case without being reducible to one another. Mapping constitution therefore requires enough conceptual resolution to preserve the mechanism carried by each relation.

Relational constitution can also be asymmetric. One party may depend on another without reciprocal dependence of the same magnitude or kind. A small supplier can depend heavily on a dominant buyer whose dependence on that supplier is negligible. A migrant worker can depend on an employer for income, legal sponsorship, housing, or information. A municipality can depend on a private platform for an infrastructure it does not control. Asking which relations constitute the situation therefore prepares later analysis of bargaining position, exit, capture, and power.

The practical result is a boundary decision. Once the constitutive relations have been identified, the researcher can justify why some actors, institutions, infrastructures, temporal histories, or ecological conditions are inside the analytical frame and others remain outside it. The boundary remains revisable as evidence accumulates. GRE thus treats relational mapping as a disciplined way to construct the object of inquiry rather than as a demand for unlimited contextual description.

3.6.2 What Changes beyond the Administrative Recipient?

Economic programmes and transactions are frequently recorded through an administrative recipient: the person receiving a transfer, the firm receiving a subsidy, the borrower named on a loan, the patient receiving a service, or the organization holding a grant. GRE asks what changes beyond that formally designated unit. The question matters because economic effects often propagate through relations that administrative data do not treat as recipients.

A cash transfer received by one person may alter household consumption, bargaining power, care responsibilities, debt repayment, education, mobility, or support to relatives. A grant to a small firm can affect employees, suppliers, clients, landlords, local tax revenue, or competing firms. A scholarship can transform not only the student's education but household expectations, future remittances, professional networks, and the aspirations of younger family members. The administrative recipient remains an important object, but it does not automatically define the boundary of effect.

This question is not equivalent to measuring conventional spillovers alone. GRE is interested in the relational pathways through which effects move. Two programmes with similar average indirect effects can operate through different mechanisms. One may propagate through knowledge sharing, another through household redistribution, another through changes in bargaining position, and another through infrastructure created for the initial recipient. Identifying the pathway helps distinguish incidental correlation from generated consequence.

The question also exposes burdens that move beyond the recipient. A policy that expands employment for one group can transfer unpaid care to another group. Debt relief for a firm can preserve jobs while imposing losses on pension funds or public budgets. Digital convenience for consumers can shift risk and time costs onto gig workers. The analysis therefore follows both enabling and constraining consequences beyond the administrative unit.

A useful GRE design can make this boundary extension explicit at the outset. The researcher can specify the formal recipient, identify connected subjects and systems likely to be affected, determine which effects are theoretically relevant, and select evidence capable of observing those pathways. The resulting analysis does not reject administrative categories; it treats them as one layer within a wider relational field.

3.6.3 What Is Generated through an Economic Relation?

A central GRE question asks what an economic relation produces beyond its immediate exchange or recorded output. The relevant generated objects can include income, knowledge, capability, trust, dependency, reputation, infrastructure, organizational routine, institutional legitimacy, ecological burden, expectations, data, symbolic standing, or new relations. Generation concerns the production of later conditions and possibilities, not merely the transfer of an already existing object from one holder to another.

Consider employment. A wage relation transfers income in exchange for labor, but it can also generate skill, professional identity, social networks, credentials, routines, health effects, dependence, bargaining experience, or exclusion from alternative opportunities. Which of these effects matters depends on the research question. A GRE analysis does not assume that every employment relation generates the same bundle. It asks which outputs are produced in this case, through which mechanisms, for whom, and with what temporal persistence.

The distinction between output and generation is especially useful where the immediate output is easy to measure but longer-term transformation is economically important. A training programme can produce a certificate immediately while generating later confidence, network access, occupational mobility, or employer recognition. A public library can provide books and space while generating study routines, weak ties, civic participation, or access to digital services. An open technical standard can coordinate present interoperability while generating an ecosystem of future complementary production.

Generated effects can be intended or unintended. Organizations can deliberately build capability, loyalty, or infrastructure, while other consequences emerge from repeated interaction without centralized design. Some generated effects become visible only retrospectively. GRE therefore distinguishes the existence of a generated consequence from claims about intention. The question concerns the causal or constitutive production of a later condition, not whether an actor planned that condition.

Generation can also be negative in practical or normative terms. A predatory credit relation may generate debt dependency and reduced future exit options. Repeated precarity may generate risk aversion or the erosion of professional capacity. An extractive production process may generate ecological degradation that constrains later

economic activity. The category of generation is therefore descriptive before it is evaluative. Evaluation requires additional criteria concerning whose capacities, values, or futures are affected.

3.6.4 How Does Value Propagate?

Value produced or realized in one relation can travel through a wider configuration. GRE asks how that propagation occurs, which pathways carry it, where it amplifies or decays, and who becomes able to use or capture it. The question begins from the observation that valuable effects rarely remain confined to the site at which they first appear.

Knowledge provides a clear example. A skill acquired by one worker can improve team performance, be taught to colleagues, contribute to organizational routines, support innovation, or become embodied in a product used elsewhere. Public infrastructure can raise the productivity of many firms and households. Trust accumulated through repeated cooperation can reduce coordination costs for later projects. A scientific result can enable downstream technologies, standards, or educational materials. The original site of value generation and the later sites of value realization can therefore be separated in space, time, and institutional ownership.

Propagation has a topology. Some value moves through direct exchange; some through imitation, learning, standards, networks, public goods, reputation, or price changes. Some pathways require institutional authorization. A professional qualification becomes valuable partly because employers and regulators recognize it. A digital protocol becomes valuable as adoption expands. A neighborhood amenity can propagate into land prices through property markets. Mapping the pathway helps determine whether value is widely distributed, locally concentrated, or captured at a bottleneck.

Propagation can also be blocked. Intellectual-property restrictions, incompatible standards, discriminatory networks, lack of infrastructure, language barriers, licensing rules, organizational secrecy, or geographic isolation can prevent generated value from reaching potential users. A GRE analysis can therefore investigate not only how value travels but which relations determine its transmissibility.

This question does not require that heterogeneous forms of value be collapsed into a common unit. Monetary gains, capability expansion, ecological support, recognition, and relational trust can propagate through different mechanisms and may require different measurements. The analytical task is first to identify the form of value and its pathway. Comparison or aggregation comes later, if the research purpose justifies it.

3.6.5 How Does Value Convert across Forms?

Economic life contains interfaces at which one form of value becomes convertible into another. GRE asks how those conversions occur, which institutions authorize them, whose valuations determine the rate or terms of conversion, and what is lost or created in the process. Conversion is analytically distinct from propagation. Propagation concerns movement of value through a relational configuration; conversion

concerns a change in the form through which value is recognized or realized.

Education can be converted into credentials, credentials into employment access, employment into income, income into housing security, and housing security into educational opportunity for another generation. Reputation can become credit access. Cultural attention can become advertising revenue. Publicly produced knowledge can become private intellectual property. Ecological capacity can be converted into commodity production, while financial resources can sometimes be converted into restoration or conservation capacity. Each conversion requires a specific institutional and relational interface.

Conversion interfaces are often sites of asymmetry. Actors differ in their ability to define categories, certify equivalence, set prices, control access, or refuse conversion. A platform may convert user attention into advertising income while users lack a comparable mechanism for realizing the monetary value of their data. A credentialing institution can translate learning into recognized status. A financial system can translate property into collateral and collateral into borrowing capacity, thereby privileging subjects who already possess assets recognizable by that system.

Conversion can be lossy. Meaning, context, ecological complexity, or relational quality can disappear when translated into a scalar metric. Conversely, conversion can create new practical possibilities by making heterogeneous resources interoperable. Monetization can enable exchange across distance; standardized credentials can enable mobility; technical standards can connect previously incompatible systems. GRE therefore treats conversion neither as inherently exploitative nor as inherently beneficial. Its consequences depend on the forms involved, the terms of translation, and the distribution of authority over the interface.

Research can make these interfaces explicit. Instead of asking only how much value exists, it can ask which forms are recognized, which remain invisible, who can perform conversion, what conversion costs arise, who captures the resulting surplus, and whether repeated conversion changes the source form itself. Such questions are especially important when policy seeks to make previously unrecognized value legible to markets or administrative systems.

3.6.6 What Recirculates, Dissipates, or Is Extracted?

Generated resources and value can return to the relations that produced them, spread elsewhere, decay, or be extracted by actors positioned to capture them. GRE therefore asks what recirculates, what dissipates, and what leaves the generative configuration. This question focuses on reproduction through time. A relation can remain productive only if enough of the conditions supporting it are replenished, repaired, or renewed.

Recirculation occurs when generated value or capacity contributes to the maintenance or expansion of the relations that produced it. A cooperative can reinvest surplus in shared infrastructure. A university can use research income to support laboratories and training that enable later research. A community enterprise can return part of its income to local services and networks. Trust generated through successful cooperation can make later cooperation easier. Recirculation can therefore create self-reinforcing dynamics without implying that the resulting configuration is

socially desirable.

Dissipation concerns loss through time, friction, obsolescence, leakage, neglect, or ecological degradation. Skills can decay when unused; infrastructure can deteriorate without maintenance; trust can erode; institutional knowledge can disappear through turnover; ecological capacity can be depleted; attention can fragment. Some dissipation is unavoidable, while some reflects institutional choices about maintenance and renewal. An analysis focused only on gross production can miss the cost of replacing dissipated conditions.

Extraction occurs when generated value or capacity is appropriated in ways that weaken the configuration from which it arises or concentrate its benefits elsewhere. Rent extraction from a local economy, uncompensated appropriation of community knowledge, financial distributions that undermine productive investment, or platform capture of user-generated value can all become candidates for investigation. The concept requires mechanism evidence. The fact that one actor gains more than another does not by itself establish extraction; the analysis must identify the relation through which value is captured and the effect on the generative configuration.

Recirculation, dissipation, and extraction can coexist. A profitable firm can reinvest some surplus, distribute some to workers or suppliers, lose some through depreciation, and transfer some to distant owners. A public programme can generate local capacity while trained workers later migrate. The question is therefore compositional: what proportion or form of generated value follows each pathway, and how do those pathways alter future capability?

3.6.7 How Are Future Capacities Transformed?

GRE places particular emphasis on the transformation of future capacity. An economic arrangement matters not only because of what it produces now but because it changes what subjects and systems can do later. This question links present allocation and relation to the future space of feasible action.

Capacity transformation can occur through learning, infrastructure, health, care, institutional reform, ecological change, debt, technological dependency, network formation, or depletion. A loan can expand productive capacity by financing equipment, while repayment obligations can constrain future cash flow. Employment can build skill and reputation while narrowing alternative career paths. A subsidy can help an industry acquire capabilities that persist after the subsidy ends. Environmental degradation can generate present income while reducing the future productive capacity of an ecosystem.

The temporal profile matters. Some interventions impose immediate costs in order to generate later capacity. Others create immediate gains by drawing down capacities that become scarce only later. A short evaluation window can therefore reverse the apparent ranking of alternatives. GRE does not prescribe one universal horizon, but it requires the horizon to be explicit and adequate to the mechanism claimed.

Capacity is also subject-specific and relational. The same infrastructure can expand the capacity of one group while reducing another's control over land or resources. A technology can increase organizational capacity while deskilling particu-

lar workers. A regulatory change can expand consumer choice while increasing compliance burdens for small producers. Asking whose future capacity changes prevents aggregate improvement from automatically standing in for distributed capability.

The question also creates an interface with uncertainty. Future capacities cannot always be observed directly at the time of intervention. Researchers may need intermediate indicators, historical comparison, simulation, qualitative evidence, or repeated observation. GRE therefore treats claims about future generativity as evidentially demanding. The more distant the claimed effect, the more explicit the mechanism and uncertainty should become.

3.6.8 How Are Economic Subjects Generated and Stabilized?

Economic analysis often begins with subjects already defined as workers, consumers, owners, borrowers, firms, entrepreneurs, citizens, beneficiaries, or investors. GRE asks how such positions are generated, recognized, stabilized, and transformed. The question concerns practical economic subjecthood rather than a final theory of personhood.

Subject positions can be produced through legal categories, contracts, organizational roles, technologies, data systems, professional standards, markets, and social expectations. A person becomes a borrower not simply by possessing an individual preference for credit but through eligibility rules, identity documentation, scoring systems, collateral conventions, and lender recognition. A platform worker occupies a subject position shaped by contract classification, algorithmic management, customer ratings, payment infrastructure, and labor regulation. A firm becomes an investable object through legal incorporation, accounting practices, governance arrangements, and financial representation.

Stabilization requires continuity. Roles persist because institutions recognize them, records maintain them, counterparties respond to them, and subjects often organize their own expectations around them. This continuity can enable planning and rights while also producing path dependence. A classification that initially facilitates coordination can later restrict access or define subjects in ways that no longer fit their circumstances.

Economic subjects can also be generated through participation. Repeated saving can produce a recognized credit history; apprenticeship can produce professional identity; membership in a cooperative can develop capacities for collective decision-making; long-term unemployment can alter institutional classification and self-expectation. Subject formation is therefore partly an economic process because access to resources, roles, and relations can reshape practical identity and future action.

The question becomes especially important under technological change. Artificial agents, automated systems, platforms, and hybrid human-machine arrangements can perform functions previously associated with human economic subjects. GRE can ask which dimensions of subjecthood are relevant in each domain: productive agency, control over resources, capacity to enter recognized relations, continuity across time, liability, representation, or normative standing. These dimensions need not coincide, and functional capability does not settle moral or legal status.

3.6.9 How Does Asymmetry Become Economic Power?

Differences in resources, knowledge, capability, network position, or technical capacity are ubiquitous. GRE asks when such asymmetries become economic power. The question prevents a simple equation between difference and domination. Power arises when asymmetry is connected to relations through which one actor can shape another's feasible actions, terms of participation, exposure to risk, access to resources, or future capacities.

A firm with superior technology does not automatically hold power over every other actor. Power emerges when that capability is linked to ownership, market position, contractual authority, infrastructure control, legal privilege, dependency, standard-setting, or capture of a bottleneck. Likewise, information asymmetry becomes power when one party can use informational advantage to determine terms, classify others, restrict alternatives, or impose costs that the other party cannot readily avoid.

Exit and dependence are therefore central. A relation can be formally voluntary while one side faces much higher exit costs. Workers may be able to leave an employer in principle but lose legal sponsorship, health insurance, housing, or accumulated benefits. Users may be free to leave a platform but face network effects, data lock-in, or loss of professional visibility. Suppliers may be free to reject a dominant buyer while lacking alternative markets. Power analysis asks how these relational conditions transform nominal options into practical constraints.

Power can also be infrastructural and impersonal. No single actor may intentionally dominate others, yet standards, algorithms, payment systems, zoning rules, or inherited property structures can distribute capacities asymmetrically. GRE can therefore examine power embedded in relational architectures as well as direct command. Identifying power does not require attributing malicious intention; it requires showing how a configuration systematically shapes the options or capacities of differently positioned subjects.

The question naturally leads to generative consequences. Power can reproduce itself by generating the resources, information, legitimacy, or dependency that sustain the original asymmetry. It can also erode its own conditions when extraction undermines cooperation or when concentrated authority produces institutional resistance. GRE therefore studies power not only as a present relation but as a potentially self-reinforcing or self-transforming generative configuration.

3.6.10 What Orients the Direction of Generation?

Generation has direction because economic systems selectively develop some possibilities while leaving others unrealized. GRE asks what orients that selection. Markets, institutions, professional communities, public policy, cultural expectations, metrics, aesthetic judgments, scientific questions, organizational goals, and individual aspirations can all influence which objects receive attention and investment.

The question is broader than incentive analysis while remaining compatible with it. Prices and expected returns orient activity, but so do legal mandates, research agendas, rankings, reputational systems, narratives of desirable futures, and perceptions

of what is interesting or feasible. A research organization can direct resources toward questions regarded as scientifically significant even when immediate commercial returns are uncertain. A city can prioritize mobility, housing, tourism, or environmental restoration according to institutional and political judgments that structure later investment.

Orientation can operate before explicit choice by shaping salience. Subjects do not evaluate every imaginable possibility. They encounter a selected field of options made visible by institutions, technologies, language, education, and social experience. Recommendation systems, professional curricula, funding categories, procurement rules, and media attention can influence which possibilities become thinkable or practically available. GRE can therefore study the production of the option field as well as selection within it.

Orientation is also heterogeneous. Different subjects can pursue incompatible forms of value or imagine different desirable futures. Economic coordination then involves negotiation, conflict, coexistence, or institutional procedures for selecting among directions. The presence of plural orientations means that generativity alone cannot supply a normative criterion. A system can be highly generative while producing futures that some affected subjects reject.

Research on orientation can ask who participates in defining goals, which signals are amplified, which possibilities are rendered invisible, what feedback modifies priorities, and how orientation changes after new capacities or knowledge emerge. These questions prepare the more systematic treatment of orientation later in Chapter 3 while showing why the direction of generation is already an economic question.

3.6.11 Under What Conditions Does Generation Produce Foreclosure?

Generation can expand future possibility, but it can also close alternatives. GRE therefore asks under what conditions the production of one pathway forecloses others. Foreclosure can arise through irreversible investment, ecological depletion, institutional lock-in, debt, standardization, network effects, path-dependent learning, spatial development, or the concentration of control over key resources.

A technology can create new capabilities while making older infrastructures uneconomic to maintain. An urban development project can generate housing and commercial value while eliminating community uses of land that cannot easily be reconstructed. A standardized platform can enable broad interoperability while reducing space for alternative technical architectures. Specialized education can generate high competence in one domain while increasing the cost of changing fields later. These examples show why generation and foreclosure can occur together.

Foreclosure is not identical to constraint. Every realized choice excludes some alternatives simply because resources and time are finite. The analytical question concerns consequential closure of future possibilities, especially where the closure becomes difficult to reverse or is imposed unevenly across subjects. The degree of reversibility, distribution of exit costs, and availability of alternative pathways therefore become relevant indicators.

Some foreclosure can be justified or desirable. Safety regulation intentionally elim-

inates dangerous production methods; environmental rules can close destructive extraction pathways; technical standards can reduce costly incompatibility. GRE does not treat openness as an unconditional good. It asks which possibilities are being closed, for whom, by what authority, with what reversibility, and in pursuit of which values.

The question is particularly important for policy evaluation. An intervention can appear successful according to immediate outcomes while narrowing later adaptability. Conversely, a policy that preserves optionality can look inefficient in a short horizon because it maintains redundant capacity or multiple institutional pathways. GRE can therefore include future option structure as part of economic evaluation when the case warrants it.

3.6.12 How Do Relational Structures Transform Their Own Conditions of Change?

The final illustrative question concerns recursive transformation. Economic relations can generate outcomes that alter the mechanisms through which later change occurs. A market can produce firms that reshape regulation; a platform can generate network effects that change entry conditions; a labor arrangement can produce new worker organizations; a financial innovation can change the infrastructure through which future credit is allocated. The object of inquiry is therefore not only change within a structure but change in the conditions that organize subsequent change.

This question requires careful separation among levels of transformation. A system can move from one state to another while its basic rules remain stable. Parameters can change while the form of the mechanism remains intact. Institutions can revise rules while preserving their authority structure. More strongly, actors, categories, boundaries, or mechanisms can be reconstituted so that the previous model of change no longer describes the later situation adequately. GRE is especially interested in the transition among these cases because historical economic development often involves several simultaneously.

Recursive transformation can be deliberate. Legislators can redesign institutions, firms can alter governance, communities can create new property arrangements, and regulators can modify market rules in response to observed outcomes. It can also emerge without centralized design as repeated practices create new conventions, standards, expectations, or dependencies. In either case, the researcher should identify the pathway through which earlier relations modify later generative conditions.

Reflexivity intensifies the problem. Economic subjects can observe models, policies, forecasts, and classifications and respond to them. A credit score changes behavior because actors know that the score affects access. A policy target can reorganize organizational reporting. A market forecast can affect expectations and transactions. Representation can therefore enter the causal field it describes. GRE treats such reflexive loops as empirically investigable rather than as a reason to abandon formal or causal analysis.

The evidential standard should remain demanding. Claims that a system has transformed its own rules can easily become rhetorical if the relevant rule, boundary, or mechanism is left unspecified. A strong analysis identifies what changed, which

earlier relations contributed to that change, how the new arrangement differs operationally from the previous one, and what consequences follow for later possibilities. The concept is useful precisely when it distinguishes ordinary state change from transformation in the organization of change itself.

Taken together, these twelve question families define a characteristic style of GRE inquiry without establishing a closed doctrine. They invite researchers to move beyond the immediate recipient, transaction, or output when doing so materially improves explanation; to track generation, propagation, conversion, and recirculation across heterogeneous relations; to examine future capacities, subject formation, power, orientation, and foreclosure; and to remain alert to recursive changes in the conditions of change. A project can enter this problem-space through any one of these questions and combine them according to the object and evidence at hand.

The next section converts this repertoire of questions into a more explicit analytical sequence. It distinguishes allocation, relational mediation, generation, propagation, conversion, recirculation, extraction, structural transformation, and changes in generative conditions. That sequence is not intended as a universal causal chain. Its role is to provide GRE with a reusable perspective for deciding which stages of an economic process require attention in a particular inquiry.

3.7 The Distinctive Analytical Perspective of GRE

The preceding sections have specified the problem-space, primitive structure, admissible objects, scales, and illustrative questions of Generative Relational Economics (GRE). The role of the present section is to state more explicitly the analytical perspective that organizes those elements into a characteristic mode of economic inquiry. Its objective is to describe a sequence of analytical moves through which an allocation, transaction, policy, institution, or other economic event can be followed beyond its immediate recipient and immediate output into the relations, generated capacities, value pathways, structural changes, and altered conditions of future change that it helps produce. The sequence is presented as a research grammar rather than a universal causal law. A concrete study may enter at any point, omit stages that are irrelevant, distinguish several parallel pathways, or discover feedbacks that make the ordering recursive. The analytical value of the sequence lies in keeping distinct processes that conventional evaluation can easily compress into a single outcome measure.

The perspective begins from allocation because allocation remains a central economic operation. Resources, rights, attention, credit, land, labor, data, infrastructure, authority, and institutional recognition are distributed through decisions and arrangements that place something somewhere under particular terms. GRE treats that placement as an initial intervention into a relational configuration. The allocation changes access, bargaining positions, expectations, dependencies, opportunities for coordination, and sometimes the identities or capacities of the participants. Those changes can generate new resources and forms of value, which may propagate through a wider configuration, convert across forms, recirculate into the relations that produced them, dissipate, or become subject to extraction. Repeated or

sufficiently consequential processes can alter institutional and relational structure, transform the conditions that enable future generation, and in some cases change the effective rule through which subsequent transformations occur.

This perspective therefore extends the temporal and relational horizon of economic analysis without prescribing one metric of success. Monetary return, productivity, capability, recognition, ecological capacity, knowledge, trust, security, autonomy, and other forms of value can remain heterogeneous. GRE asks how they are generated and connected before deciding whether comparison, aggregation, or normative judgment is warranted. It also keeps mechanism claims separate from moral evaluation. A self-reinforcing process can be economically powerful while normatively objectionable; a process that dissipates one form of value can generate another; a structural transformation can expand some future possibilities while foreclosing others. The following subsections develop the ten analytical moments in this perspective.

3.7.1 Allocation as an Initial Intervention

Allocation is the analytical point of departure because many economic processes become administratively visible at the moment when a resource, entitlement, burden, opportunity, or authority is assigned. Public budgets allocate funds to programmes. Firms allocate capital and labor. Banks allocate credit. Households allocate time and care. Platforms allocate visibility. Legal institutions allocate rights and liabilities. Educational institutions allocate credentials and access. These operations remain central to GRE, yet GRE reads them as interventions into already structured relations rather than as terminal distributions among self-contained recipients.

An allocation changes more than possession. Receiving credit can alter a firm's bargaining position with suppliers, its ability to hire, its exposure to debt service, and the confidence of other financiers. A housing subsidy can change household security, neighborhood demand, landlord expectations, and local land values. Allocation of research funding can change laboratory composition, collaboration networks, training capacity, and the future distribution of expertise. Even an apparently simple transfer enters a field of existing institutions, expectations, power relations, and conversion mechanisms.

The analytical unit is therefore the allocation-in-context. A useful GRE study specifies what is allocated, under which institutional conditions, to whom or to which configuration, at what time, with what duration, and through which rights or obligations. It also identifies the baseline relations into which the allocation enters. These relations determine what the allocation can become. The same monetary amount can have different generative effects when recipients possess different infrastructure, debt burdens, social recognition, legal status, network access, or ecological conditions.

Allocation can also concern non-scarce or symbolically abundant objects. Attention, rankings, reputational signals, software, information, and institutional recognition can be allocated through procedures that differ from the allocation of rival material goods. Their economic significance often arises from the relations that make them consequential. A search ranking matters because users, advertisers, platforms,

and firms respond to it. A credential matters because institutions recognize it. A dataset matters because actors possess complementary computational and organizational capacities. GRE therefore treats allocation as a broad intervention category whose meaning depends on the relational conditions of use.

Starting from allocation preserves continuity with established economic analysis while widening the subsequent inquiry. The initial question remains who receives what, under which conditions. GRE then asks what relations are activated or reconfigured by that placement, what becomes possible because of it, and which downstream effects remain outside the administrative boundary of the allocation itself.

3.7.2 Relational Mediation

An allocation acquires practical significance through relational mediation. Resources rarely produce identical effects independently of the relations through which subjects can use, interpret, exchange, protect, combine, or transform them. Relational mediation names the set of pathways through which an initial intervention becomes economically operative. These pathways can include contractual relations, kinship and care relations, organizational routines, infrastructures, legal recognition, technical standards, reputational systems, financial arrangements, ecological dependencies, and informal networks of trust or exclusion.

Mediation can enable use. A loan becomes productive when a borrower can purchase equipment, hire workers, obtain permits, reach customers, and sustain repayment. A public dataset becomes generative when users have the skills, computational infrastructure, legal permission, and institutional incentives required to employ it. A school meal programme can affect educational participation through household budgets, health, attendance routines, and parental expectations. The intervention therefore passes through a configuration of relations whose structure conditions the realized effect.

Mediation can also redirect or neutralize an intervention. A subsidy intended for tenants can be partly captured through rent increases. A wage increase can produce limited household security when debt obligations absorb the gain. New infrastructure can intensify land speculation and displace the population whose mobility it was intended to improve. These outcomes do not imply that the allocation itself is analytically irrelevant. They show that its effect is co-produced by the relations through which it travels.

GRE therefore distinguishes administrative recipient from relational incidence. The person or organization named in a programme may be only one node in a larger set of affected relations. Suppliers, creditors, family members, competitors, property owners, workers, public institutions, ecosystems, or future participants can experience consequential effects. The boundary of relevant incidence should follow the mechanism under investigation rather than the accounting category alone.

Relational mediation also includes interpretation. Economic subjects respond to signals through historically and institutionally formed meanings. A tax incentive can be interpreted as temporary or durable. A guarantee can change perceived risk. A government purchase can signal future market demand. A platform rule can alter expectations about visibility and participation. Such interpretive mediation affects

behavior without requiring that every actor hold the same belief.

The analytical task is to identify which relations materially condition the pathway from intervention to effect. GRE does not require exhaustive mapping of an entire social world. It requires enough relational specification to explain why the intervention produced the observed or anticipated consequences and why those consequences differ across subjects, sites, or periods.

3.7.3 Generation

Relational mediation can produce new capacities, resources, meanings, institutions, practices, identities, expectations, and forms of value. GRE uses *generation* for this productive moment. Generation concerns the emergence or augmentation of economically relevant possibilities through a relation or configuration. The generated object may be material, symbolic, institutional, ecological, epistemic, or relational. Its significance lies in the fact that later action becomes possible, easier, harder, or differently organized because the configuration has changed.

Production and generation overlap in many cases, yet their analytical emphases differ. Production commonly directs attention toward an output: goods, services, income, knowledge, or measurable performance. Generative analysis asks what further capacities and conditions are created in producing, using, distributing, or maintaining those outputs. A training programme produces instruction and credentials; it can also generate professional networks, self-confidence, recognized status, organizational routines, and future learning capacity. A transport project produces mobility services; it can generate new patterns of settlement, commercial access, land valuation, and ecological pressure. A cooperative produces goods or services while potentially generating shared governance capability and durable norms of reciprocity.

Generation can occur without an intended designer. Repeated market exchange can generate conventions. Repeated platform participation can generate data and reputational histories. Shared exposure to risk can generate mutual-aid institutions. Competitive pressure can generate organizational routines or technological standards. Conversely, deliberate interventions can fail to generate the capacities they target because the necessary relational conditions are absent.

Generated outcomes are frequently distributed unevenly. A technology can generate organizational productivity while reducing the bargaining power or skill development of particular workers. A financial instrument can generate liquidity for one group while creating systemic exposure elsewhere. Public infrastructure can generate collective access while simultaneously generating private land rents. The generative question therefore includes the location and distribution of newly created capacities and constraints.

A GRE analysis should identify the mechanism through which generation occurs. The presence of a later capacity after an intervention does not establish that the intervention generated it. Competing pathways, background trends, selection effects, and independent causes remain relevant. Historical, qualitative, quantitative, comparative, causal, formal, and computational methods can each contribute depending on the problem. Generative language becomes analytically useful when it sharpens mechanism and temporal structure rather than merely redescribing change.

Generation also includes the production of constraints. Debt can generate purchasing capacity and repayment obligations. Digital infrastructure can generate access and dependency. Standardization can generate interoperability and exclusion of incompatible practices. Institutional recognition can generate rights and categories that narrow alternative forms of identity. GRE therefore treats generativity as directionally open: what is generated may expand, stabilize, redirect, or constrain future possibility.

3.7.4 Propagation

Generated effects can move beyond the relations in which they first appear. Propagation concerns the transmission, diffusion, amplification, attenuation, or replication of resources, capacities, constraints, meanings, and forms of value through a wider relational configuration. It extends the analysis from local generation to the pathways through which generated effects become consequential elsewhere.

Propagation can occur through exchange, learning, imitation, network contact, infrastructure, standards, prices, legal precedent, organizational replication, migration, ecological flows, media, or technical interoperability. A skill acquired within one workplace may spread through labor mobility. A protocol developed by one organization may become an industry standard. A reputation produced in one network may affect credit access in another. An innovation can diffuse through suppliers and competitors. Pollution can propagate across ecological and jurisdictional boundaries.

The structure of the pathway matters. Dense networks can accelerate some forms of diffusion while creating redundancy. Centralized networks can enable rapid dissemination while producing bottlenecks or concentrated control. Institutional filters can privilege particular carriers and suppress others. Spatial distance can be reduced by digital infrastructure for information while remaining decisive for housing, care, logistics, or ecological impact. A GRE account therefore asks through which relations the effect propagates and how topology, access, and institutional authority condition that movement.

Propagation is also selective. An intervention that generates knowledge may propagate technical information more easily than tacit practice. Monetary gains may cross organizational boundaries through payments while trust remains locally embedded. Recognition can travel across institutions only when credentials or reputational signals are mutually accepted. Ecological damage can propagate physically even when financial liability does not. The form of what moves and the medium through which it moves should therefore be distinguished.

Amplification and attenuation are important possibilities. A small innovation can become economically large when network effects, complementary investment, or standardization amplify adoption. A substantial local intervention can dissipate as effects pass through weak or incompatible connections. The magnitude observed at the origin gives limited information about the magnitude realized elsewhere.

GRE also considers the distribution of access to propagation pathways. Actors positioned at interfaces, platforms, logistics hubs, standards bodies, financial intermediaries, or institutional gateways can influence what travels and under which terms. Propagation can therefore become a source of power as well as a mechanism of dif-

fusion. The relevant inquiry concerns the relational architecture through which generated effects acquire reach.

3.7.5 Conversion

Propagation frequently encounters interfaces at which one form of resource or value is translated into another. Conversion concerns these transformations among forms. Income can become education, housing security, political access, or health. Knowledge can become credentials, intellectual property, technical standards, or market advantage. Attention can become advertising revenue. Reputation can become creditworthiness. Land can become collateral. Ecological capacity can become commodity output, while financial resources can sometimes become restoration capacity.

Conversion differs from movement within a single form. A payment transferred between accounts remains monetary propagation. A credential used to obtain employment converts recognized educational achievement into labor-market access. A public research result licensed into proprietary technology passes through an institutional conversion interface that changes the rights and forms through which its value can be realized. The distinction helps identify where commensuration, authorization, pricing, certification, or institutional recognition becomes necessary.

Conversion interfaces are rarely neutral. Actors differ in their ability to define categories, establish equivalence, set prices, issue credentials, certify quality, recognize claims, or deny access. A bank decides which assets count as acceptable collateral. A university determines which learning qualifies for a degree. A platform determines which forms of attention can be monetized and by whom. A legal system determines which interests can become enforceable rights. Control over conversion can therefore become a source of economic power.

Conversions can be partial or lossy. Rich forms of knowledge can be reduced to a credential or score. Ecological complexity can be translated into a carbon metric. Care can be monetized without preserving every relational quality attached to unpaid care. Standardization may sacrifice contextual detail while enabling interoperability across institutions. GRE therefore keeps the source form and converted form analytically distinguishable and asks what information, capacity, meaning, or control is gained or lost in translation.

Conversion can also generate additional value. A technical standard can make separate systems interoperable. A recognized qualification can enable geographic mobility. Monetization can permit resources to be exchanged across otherwise disconnected contexts. Legal incorporation can allow a collective project to contract, borrow, or hold assets. The normative significance of conversion depends on the terms, distribution, reversibility, and consequences of the transformation rather than on conversion as such.

Because heterogeneous values may resist full commensuration, GRE does not assume a universal conversion metric. Some forms may be partially convertible, institutionally incomparable, or normatively protected from exchange. The analytical task is to identify the interface, the actors who govern it, the terms under which conversion occurs, and the effects of repeated conversion on both the source and destination forms.

3.7.6 Recirculation

Generated and converted value can return to the relations and capacities that helped produce it. Recirculation concerns this return and the possibility that an economic configuration reproduces or expands its own generative conditions through the value it creates. Recirculation provides a bridge from one-time effects to recurrent economic dynamics.

A firm may reinvest earnings in productive equipment, worker training, research, or supplier development. A cooperative may return surplus to shared infrastructure. A university may use research income to support laboratories and students who enable later research. A community institution may reinvest revenue in local services and networks. Trust produced through successful collaboration can reduce the cost of subsequent collaboration. In each case, an output contributes to the maintenance or enlargement of a condition that supports later generation.

Recirculation is broader than financial reinvestment. Knowledge can return through teaching and mentorship. Institutional capacity can return through improved procedures. Ecological value can return through restoration. Recognition can return through strengthened membership and participation. Data generated by users can be used to improve a service that then attracts further users. The relevant object is the pathway by which generated value reconnects to a generative configuration.

The rate, distribution, and governance of return matter. An organization can generate large value while returning little to the workers, communities, infrastructures, or ecosystems that sustain it. Another can deliberately allocate returns to maintain those conditions. The existence of some recirculation does not by itself establish sufficiency or justice. A system can remain self-reinforcing while distributing benefits unequally or depleting unmeasured conditions outside its accounting boundary.

Recirculation can create positive feedback. Additional capability increases later generation, which supplies further resources for capability formation. Such loops can support cumulative development, institutional persistence, or technological lock-in. Their effects depend on the underlying configuration. A virtuous cycle for one group can become an exclusionary barrier for another when access to the loop is restricted. Self-reinforcement is therefore a dynamical property to be analyzed separately from normative desirability.

GRE uses recirculation to ask whether generated value contributes to the reproduction of the capacities and relations on which future generation depends. This question is especially important where conventional accounts register output or profit while leaving maintenance, care, learning, ecological renewal, and institutional reproduction analytically peripheral.

3.7.7 Dissipation and Extraction

Generated value does not necessarily return to its generative configuration. Some of it dissipates through depreciation, obsolescence, friction, neglect, entropy, institutional turnover, loss of trust, or ecological degradation. Some is extracted by actors positioned to appropriate value without proportionately sustaining the conditions

from which it arises. GRE treats dissipation and extraction as distinct pathways because their mechanisms and policy implications differ.

Dissipation can occur without an appropriating beneficiary. Infrastructure decays when maintenance is deferred. Skills weaken when unused. Organizational memory disappears through turnover. Trust erodes after repeated coordination failures. Ecological capacity can decline through cumulative pressure. Data lose relevance. Knowledge becomes obsolete. These processes imply that the maintenance of a generative configuration often requires recurrent inputs rather than a one-time investment.

Extraction involves a relational mechanism of capture. Rent can be appropriated because ownership or control over a bottleneck allows an actor to claim part of the value generated elsewhere. A platform can capture value from user activity through control of infrastructure and monetization interfaces. A financial arrangement can transfer returns away from productive reinvestment. A firm can rely on public education, care work, or ecological capacity while externalizing part of the cost of reproducing those conditions. The analytical claim requires evidence of the pathway through which value is captured and of its relation to the generative configuration.

Unequal distribution alone does not establish extraction. A participant can receive a large return because it supplies scarce capital, bears risk, contributes specialized knowledge, or performs coordination. GRE therefore asks what relation supports the claim, what alternative arrangements are feasible, whether the captured value weakens or sustains the source configuration, and how bargaining power and institutional rights shape the terms of appropriation.

Dissipation and extraction can interact. Deferred maintenance can make an organization dependent on external financing, which can increase opportunities for future extraction. Extractive arrangements can reduce resources available for training or ecological renewal, accelerating dissipation. Conversely, some forms of external appropriation can finance infrastructure that improves the source configuration. Mechanism and temporal sequence matter more than categorical labeling.

The analytical purpose is to account for where generated value goes. A process that appears productive at one accounting boundary may look fragile once maintenance requirements, externalized costs, and captured returns are traced over time. This wider accounting remains plural: GRE need not translate every dissipated or extracted form into money in order to analyze its economic significance.

3.7.8 Structural Transformation

Repeated allocations, mediations, generation, propagation, conversion, recirculation, dissipation, and extraction can alter the relational structure within which later economic action occurs. Structural transformation concerns changes in relatively persistent configurations of access, authority, dependency, coordination, classification, ownership, infrastructure, and institutional recognition. The analytical horizon therefore moves from flows through a structure to changes in the structure itself.

A credit programme can gradually create new financial histories that alter who is considered bankable. Platform adoption can reorganize market access and bar-

gaining relationships. Public infrastructure can change settlement patterns and land values. Repeated outsourcing can transform organizational boundaries and labor relations. An educational expansion can change occupational competition and credential requirements. Long-term extraction can concentrate ownership sufficiently to reshape political and market power. These effects persist because the relations through which later actors operate have changed.

Structural transformation can be cumulative. Small changes in network access, standards, expectations, or institutional categories may become mutually reinforcing. Once a technical standard reaches broad adoption, complementary investments increase switching costs. Once a legal category becomes embedded in administrative systems, data structures, and organizational routines, later decisions may reproduce it. Such persistence does not imply irreversibility, yet reversal can require interventions different in kind from those that produced the initial change.

Structure is scale-relative. A transformation that appears structural for a household may be local from the perspective of a national economy. A regulatory change can be structural for an industry while leaving broader institutional arrangements intact. GRE therefore specifies the scale and boundary at which structural transformation is claimed. The term should signal a change in the organization of relations relevant to the inquiry rather than function as a synonym for any large effect.

Structural transformation can redistribute generative capacity. New infrastructure can enable some actors to participate while making others dependent on centralized systems. Consolidation can create investment capacity and reduce diversity of organizational forms. A new property regime can make resources legible and tradable while displacing customary claims. GRE asks how the changed structure reorganizes the possibilities available to different subjects and which later pathways become easier, harder, visible, or inaccessible.

At this stage, the analytical perspective begins to become recursive. Structures mediate later allocations and generation, while those processes can further transform structure. The economy is therefore approached as historically layered: present relations carry residues of earlier allocations, conversions, institutions, conflicts, and generative cycles.

3.7.9 Transformation of Generative Conditions

Structural change becomes especially significant when it alters the conditions that make later generation possible. Generative conditions include capacities, infrastructures, ecological resources, legal permissions, institutional trust, knowledge bases, standards, networks, interpretive categories, and other background arrangements through which new economic possibilities can emerge. Transformation of generative conditions concerns changes in this enabling and constraining environment.

The distinction between generated output and generative condition is temporal and relational. A research project can produce a paper as an output while training researchers who become a condition for later inquiry. A transportation system can provide current mobility while also changing the accessibility structure through which future firms and households choose locations. A legal reform can resolve a present dispute while changing the institutional expectations that shape later con-

tracting. Restoration can generate present employment and rebuild ecological capacity that supports future livelihoods.

Conditions can become more or less diverse. An economy can accumulate specialized capabilities that deepen productive potential within one technological trajectory while reducing adaptability to alternative trajectories. Standardization can create broad interoperability while narrowing variation. Concentrated infrastructure can generate scale economies while increasing dependency on a small number of providers. GRE therefore examines the composition of generative capacity, including redundancy, diversity, reversibility, and dependence.

Generative conditions are distributed. The capacity to innovate may depend on public education, care systems, research institutions, finance, standards, migration regimes, energy infrastructure, social trust, and ecological stability. No single actor needs to own these conditions for them to shape economic possibility. This distributed character makes attribution and governance difficult: benefits may be privatized while maintenance costs remain collective, or collective institutions may fail to recognize contributions occurring outside formal accounting systems.

Changes in generative conditions can also alter who counts as an economic subject. Digital identity systems can enable participation for some subjects and exclude others. New organizational forms can recognize collective actors. Artificial systems can acquire delegated decision capacities that change the distribution of agency in markets and institutions. Educational and technical infrastructures can transform the capacities through which persons become able to participate in particular forms of production or exchange. These questions prepare the more focused treatment of economic subjecthood in the following section, while the present subsection keeps attention on the background conditions through which such subject positions become possible.

The GRE perspective therefore evaluates interventions partly by their effects on future generativity. Immediate welfare or output remains important, yet an intervention can also be assessed by whether it expands, concentrates, diversifies, depletes, or forecloses the conditions from which later value and action can emerge. Such evaluation requires an explicit temporal horizon and awareness that future uses cannot be fully specified in advance.

3.7.10 Transformation of the Effective Rule of Change

The deepest analytical extension concerns situations in which economic processes transform the effective rule through which subsequent change occurs. A structural configuration can change while the basic mechanisms governing adjustment remain similar. In other cases, the mechanisms themselves are reorganized: new institutions redefine permissible transactions, technologies create new categories of action, collective learning changes how actors respond, platforms redesign market matching, legal reforms alter rights and enforcement, or artificial systems introduce new forms of automated selection and adaptation. GRE treats such cases as transformations of the effective rule of change.

The phrase *effective rule* is deliberately modest. It does not imply that an economy possesses one literal master equation. It refers to the locally relevant mechanisms, in-

stitutional procedures, response functions, selection environments, and constraints through which changes in the studied configuration are produced. Different methods can represent these rules differently. A historian may reconstruct them through institutional sequences, an economist through behavioral or equilibrium relations, a network analyst through evolving topology, an ethnographer through changing practices, and a computational model through explicit update procedures.

Rule transformation occurs when later dynamics cannot be adequately described by holding those mechanisms fixed. A market governed by bilateral bargaining can become a platform-mediated market in which ranking algorithms and platform rules shape matching and price formation. A monetary system can acquire new instruments that change transmission mechanisms. A labor process can move from human supervision to algorithmic allocation, altering how performance is measured and how workers adapt. A regulatory reform can change the criteria through which organizations become eligible, compliant, or sanctionable. The later system is connected historically to the earlier one while operating through modified mechanisms.

Rule transformation is especially important under reflexivity. Economic subjects learn, anticipate policies, reinterpret categories, and adapt to models used to govern them. Institutions respond to observed behavior. Firms redesign strategies when competitors imitate them. Regulators revise rules when existing rules generate unintended effects. The object of analysis can therefore react to the representations and interventions applied to it. A stable rule may remain a useful local approximation, yet GRE keeps open the possibility that repeated interaction changes the mechanisms on which the approximation depended.

The transformation of effective rules also raises a governance problem. Interventions can influence more than outcomes within a given system; they can shape the procedures through which future outcomes will be produced. A procurement rule can determine which organizational forms survive long enough to compete later. A data standard can define what becomes measurable and therefore governable. Intellectual-property rules can influence the future distribution of innovation incentives and knowledge access. Educational assessment can alter what institutions teach and what learners treat as valuable. These interventions operate partly at the level of the future change process itself.

This final analytical moment does not make every economic change a case of rule transformation. The claim requires evidence that the mechanisms generating later transitions have materially changed. Maintaining this threshold preserves the distinction among movement within a structure, transformation of structure, transformation of generative conditions, and transformation of the effective rule of change.

Taken together, the ten moments of the GRE perspective provide a layered way to follow economic action through time and relation. Allocation identifies an initial placement of resources, rights, burdens, or attention. Relational mediation specifies the configuration through which that placement becomes operative. Generation identifies newly produced capacities, constraints, values, subjects, or possibilities. Propagation follows their movement; conversion follows changes of form; recirculation follows return to generative configurations; dissipation and extraction account for loss and capture. Structural transformation asks how persistent relations are reorganized. Transformation of generative conditions asks how the capacity for later gen-

eration changes. Transformation of the effective rule of change asks whether the mechanisms producing future transitions have themselves been altered.

The sequence remains a heuristic research architecture. Empirical cases can contain loops, branching pathways, simultaneous processes, and multiple scales whose temporal order is only partially recoverable. GRE's distinctive perspective lies in making these layers available for explicit inquiry while preserving the possibility that a narrower established economic analysis may be sufficient for a particular question. The next section turns from this analytical architecture to one of its most consequential objects: the economic subject itself, whose identity, recognition, capacities, and persistence can be treated as historically and relationally generated rather than analytically fixed in advance.

3.8 GRE and the Economic Subject

Generative Relational Economics (GRE) requires a conception of the economic subject that is sufficiently stable for analysis and sufficiently open to account for historical transformation. The role of this section is to specify that conception after the preceding sections have established GRE's objects, scales, problem families, and distinctive analytical sequence. Its objective is to explain how persons, organizations, artificial systems, and other configurations can occupy economically consequential subject positions without assuming that subjecthood is a timeless property given prior to economic relations. The discussion proceeds through eight connected problems: the movement from given agents to relationally situated subjects; institutional recognition; relational persistence; the coexistence of human and artificial economic subjects; heterogeneity among subjects; capability asymmetry and ontological distinction; participation under conditions in which productive necessity may decline; and subject formation itself as an economic process. The method is constitutive rather than taxonomic. GRE does not attempt to settle the metaphysics of personhood, consciousness, or agency. It specifies a working analytical conception of subjecthood adequate to economic inquiry while preserving ontological suspension and explicit normative separation.

Within this framework, an *economic subject* is a relatively stabilized locus of economically consequential participation that can be identified within a relational configuration. Such participation may include choosing, claiming, producing, consuming, owning, borrowing, contracting, coordinating, representing, interpreting, allocating, governing, bearing risk, receiving recognition, or being made answerable for an economic event. Different forms of subjecthood need not contain the same capacities. A human worker, a household, a corporation, a public agency, and an automated trading system can occupy very different kinds of economic subject position. Their inclusion within a common analytical vocabulary records their participation in economic relations; it does not establish metaphysical, experiential, juridical, or moral equivalence among them.

This distinction is especially important because economic theory often gains tractability by beginning with an already individuated agent. GRE can use such models when the research question warrants them, yet its broader programme keeps

open the prior question of how the agent became recognizable, durable, capable, and economically situated. The economic subject can therefore be treated both as a participant in economic dynamics and as a possible product of those dynamics. Wage relations, property regimes, credit systems, organizational membership, legal classifications, technical infrastructures, educational institutions, platforms, and systems of representation can all help constitute which subjects exist for an economic process, what they can do, how they are recognized, and which futures become available to them.

3.8.1 From Given Agent to Relationally Situated Subject

A large class of economic models begins with agents whose identities, preferences, feasible actions, and relevant resources are specified before the modeled interaction begins. This abstraction can be highly productive. It makes possible clear analysis of choice, exchange, strategic interaction, allocation, and equilibrium. GRE retains these analytical resources while adding a complementary question: under which relations did the modeled agent become the kind of subject for whom those preferences, capacities, resources, and feasible actions are available?

The move from a given agent to a relationally situated subject changes the analytical starting point. A worker enters a labor market with skills formed through education, family relations, health, language, migration status, credentialing, and previous employment. A firm enters a market through legal incorporation, ownership arrangements, financing, supplier relations, infrastructure, standards, and accumulated organizational routines. A consumer appears in a platform economy through accounts, payment systems, identity verification, recommendation systems, device access, and categories through which demand is represented. In each case, the subject remains a meaningful analytical unit, while its capacities and boundaries are understood as relationally conditioned.

Relational situatedness does not imply that a subject is reducible to its relations. GRE requires enough analytical independence to speak about a subject's actions, interests, experiences, holdings, or capabilities when those categories are warranted. The point is that such independence is historically and institutionally achieved to varying degrees. A property owner can act independently with respect to an asset because institutions stabilize ownership claims. A worker can negotiate because labor law, organizational rules, scarce skills, collective representation, or outside options provide a position from which negotiation is possible. A household can plan because some flows of income, care, residence, and obligation persist through time. Subjecthood therefore contains a relation between relative individuation and continuing dependence.

This approach also prevents agency from being treated as a single scalar quantity. A subject may possess substantial agency in one relation and little in another. A highly skilled employee may exercise considerable control over technical decisions while possessing limited bargaining power over employment conditions. A small firm may choose its product design while remaining strongly constrained by a dominant platform or creditor. A government agency may have formal authority but limited informational or implementation capacity. GRE therefore asks which dimensions of

agency are operative, through which relations, and at which scale.

Relational situatedness further allows preferences and objectives to be historically formed without assuming that they are infinitely malleable. Education, advertising, professional communities, organizational cultures, social norms, technologies, and repeated interactions can affect what subjects attend to, expect, desire, or regard as feasible. A research programme can study these processes without denying that subjects also exhibit persistence, reflection, resistance, and internally organized commitments. GRE's analytical interest lies in the conditions through which orientation is formed and revised, a problem developed more directly in the following section on the orientation of generation.

The relationally situated subject therefore supplies an intermediate analytical position. It is more structured than an undifferentiated relational field because it permits attribution of action, capacity, burden, and value to relatively stabilized participants. It is more historically open than a permanently given agent because its boundaries, capacities, orientations, and recognized positions can themselves become objects of inquiry. This duality is central to GRE's treatment of subjecthood.

3.8.2 Subjecthood and Institutional Recognition

Economic subjecthood depends partly on recognition. Institutions specify who can open an account, hold property, enter a contract, receive a payment, owe a tax, register a company, claim a benefit, represent an organization, access a market, or be counted within an administrative category. Recognition converts a potential participant into a legible participant for a particular institutional process. The resulting subject position can carry rights, obligations, expectations, records, and pathways for future action.

Recognition is distributed across institutions rather than concentrated in a single act. Legal systems recognize persons, organizations, property titles, and contractual capacities. Firms recognize employees, managers, vendors, customers, and authorized representatives. Financial institutions recognize account holders, borrowers, guarantors, and beneficial owners through their own procedures. Platforms recognize users, creators, advertisers, sellers, developers, and automated processes through technical accounts and permissions. Public programmes recognize beneficiaries through eligibility categories. Statistical systems recognize populations through classifications that subsequently shape policy and resource allocation.

These forms of recognition need not coincide. A participant can be economically active while remaining weakly represented in administrative data. A person can be recognized by one institution and excluded by another. An organization can exist juridically while possessing limited practical capacity to act. A platform account can exercise extensive economic functions while the relevant legal obligations remain assigned to a human or organizational principal. GRE therefore treats recognition as relation-specific. It asks who or what recognizes the subject, for which purpose, under which criteria, and with which consequences.

Institutional recognition can also generate capacities. Registration can permit access to banking, procurement, insurance, or legal enforcement. A professional credential can authorize entry into a labor market. A credit history can create or restrict

borrowing possibilities. A platform reputation can affect visibility and transaction opportunities. Recognition is therefore more than descriptive classification. Under some conditions it becomes a productive resource whose possession changes future possibilities.

The converse process is economically consequential as well. Misrecognition, weak recognition, or exclusion from relevant categories can constrain participation even when material capacity exists. A skill that lacks accepted certification may command less value. Informal work can remain economically important while receiving limited legal protection or statistical visibility. Care activities can sustain productive systems while remaining weakly represented in monetary accounts. GRE can analyze these situations by separating material contribution, institutional recognition, representational visibility, and normative valuation rather than treating them as a single dimension.

Recognition also creates subject positions that may reshape conduct. A person classified as debtor, beneficiary, employee, high-risk customer, eligible applicant, or verified creator encounters a different opportunity structure and may respond to the expectations associated with that position. The category becomes economically generative when it affects access, incentives, treatment by others, or self-understanding. The same mechanism applies to organizations. Classification as a regulated institution, nonprofit entity, startup, contractor, or systemically significant actor can alter available strategies and obligations.

GRE therefore treats institutional recognition as one mechanism through which economic subjecthood becomes stabilized. It remains distinct from ultimate personhood or moral status. Institutional categories can be revised, contested, strategically used, or shown to be inadequate. Their analytical importance lies in the fact that economies operate through such acts of recognition, and those acts participate in generating the subjects that economic analysis subsequently encounters.

3.8.3 Subjecthood and Relational Persistence

Recognition at one moment is insufficient for many economic processes. Credit, employment, ownership, reputation, insurance, investment, planning, responsibility, and cooperation depend on some capacity to identify a subject across time. GRE therefore treats relational persistence as another condition of economic subjecthood. Persistence means that a configuration can remain sufficiently identifiable across a sequence of interactions for expectations, records, obligations, capacities, and value to accumulate around it.

Persistence does not require immutability. A corporation can change employees, owners, strategies, and assets while remaining recognizable as the same juridical organization for relevant purposes. A household can change membership while retaining continuing obligations and resources. A person can change occupation, preferences, health, wealth, and social position while maintaining biographical and institutional continuity. An artificial system can be updated or retrained while an operational identity, account, mandate, or deployment context persists. Subjecthood therefore depends on criteria of continuity that vary by domain.

Different institutions stabilize continuity through different devices. Names, iden-

tifiers, contracts, registries, records, credentials, accounts, signatures, organizational charts, audit trails, reputational histories, and technical logs can all support persistence. These devices allow past interactions to influence present treatment. They make possible credit histories, employment records, accumulated reputation, continuing ownership, delegated authority, and accountability. In this sense, memory is partly institutionalized in economic relations.

Persistence has generative consequences because accumulated history changes future opportunities. Trust can deepen through repeated cooperation. Debt can compound. Reputation can open or close markets. Skills can accumulate through practice. Organizational routines can increase coordination capacity. A history of exclusion can constrain later access even when formal rules change. Economic subjecthood therefore has a temporal dimension: the subject is often a carrier of selectively preserved history.

The preservation is always partial. Institutions decide which past events remain legible and which disappear. Credit systems preserve some payment histories while ignoring many contextual circumstances. Employment records preserve formal roles while omitting informal contribution. Platform metrics preserve selected traces of participation. Historical records may be unequally available across groups and organizations. GRE therefore treats persistence as an epistemic and institutional construction as well as a temporal fact. The subject that appears stable to an analyst may be stabilized by selective recording.

Relational persistence can also fail. Organizations dissolve, identities become contested, records disappear, contractual relations end, platforms remove accounts, or political and technological transformations invalidate previous classifications. Such failures can release subjects from prior constraints, erase accumulated value, disrupt responsibility, or create opportunities for reconstitution. Subject dissolution is therefore part of the economic analysis of subjecthood rather than a mere exception to stable identity.

This temporal view enables GRE to analyze subject formation without assuming a permanent core that economic relations simply reveal. A subject can become more or less coherent, legible, capable, autonomous, or constrained through time. The relevant question is which mechanisms sustain continuity, what they preserve, what they suppress, and how persistence alters the subject's future generative possibilities.

3.8.4 Human and Artificial Economic Subjects

The increasing delegation of economically consequential tasks to artificial systems makes the category of economic subject more complex. Software already performs functions such as ranking, pricing, matching, forecasting, bidding, recommending, filtering, scheduling, allocating attention, and executing transactions under specified conditions. More capable artificial systems can also participate in extended sequences of planning, communication, and decision support. GRE requires a vocabulary that can analyze such participation without presuming that functional capability settles questions of consciousness, personhood, moral standing, or legal status.

A useful distinction is between *human subjecthood* and *artificial operational subjecthood*. Human economic subjects are embodied, vulnerable, temporally finite par-

ticipants whose economic lives are connected to experience, welfare, social membership, care, rights, and material dependence. Artificial operational subjects can occupy functionally stabilized positions in economic processes when systems are authorized, configured, or institutionally treated as loci through which actions are selected and executed. Their economic relevance can be substantial even when ultimate responsibility, ownership, or legal personality remains assigned elsewhere.

Operational subjecthood can arise through delegation. An organization may authorize a software system to execute trades within limits, set prices, route logistics, select advertisements, or communicate with customers. The system then becomes a proximate locus of economically consequential action. The relevant GRE questions concern the relations that enable this delegated position: who defines the objective, who supplies data, who controls deployment, who bears losses, who can override the system, how actions are attributed, and how generated value returns to the surrounding organization.

This approach avoids a binary choice between treating artificial systems as mere passive tools and treating them as equivalents of human persons. The appropriate analytical status can vary with the inquiry. For a study of market microstructure, an automated trading agent may be a meaningful economic subject because its decisions affect prices and counterparties. For a study of moral injury, welfare, or distributive justice, the same system may be better analyzed as infrastructure or delegated mechanism while the human and organizational subjects bearing consequences remain central. Subject classification is therefore question-relative.

Artificial systems can also become components of hybrid subjects. A professional using advanced decision support may acquire capacities unavailable to either the human or the system considered independently. A firm can reorganize around automated coordination. A scientific team can distribute cognitive work across researchers, instruments, databases, and models. A platform can combine algorithms, human moderators, sellers, and users into an operational configuration. GRE can treat such configurations as composite subjects when the composite exhibits sufficient persistence, coordination, and causal relevance for the local question.

The distribution of agency within hybrid configurations is a separate problem from identifying the composite. Delegation can obscure responsibility when an outcome is attributed to “the algorithm” despite organizational choices concerning data, objectives, thresholds, deployment, monitoring, and recourse. Conversely, attributing every artificial action directly to one human decision-maker can ignore emergent behavior, organizational fragmentation, and the practical autonomy created by scale and speed. GRE therefore encourages mechanism-specific attribution across the relations that produce the action.

The coexistence of human and artificial economic subjects also changes the ecology of capability. Artificial systems can amplify the productive and cognitive capacity of some human or organizational subjects more than others. Access to compute, proprietary data, infrastructure, legal expertise, capital, and distribution can determine who benefits from artificial capability. The economic significance of artificial subjecthood consequently lies not only in what a system can do, but in how its capability is situated within ownership, institutional recognition, delegation, and return structures.

3.8.5 Heterogeneous Subjects

GRE treats heterogeneity among economic subjects as a constitutive feature of inquiry rather than a residual deviation from a representative agent. Subjects can differ in material needs, bodily vulnerability, temporal horizon, information, attention, cognitive style, social recognition, bargaining position, legal status, technological access, organizational scale, ecological dependence, and forms of value they regard as significant. These differences shape both immediate economic behavior and the generative consequences of economic relations.

Heterogeneity matters even when subjects receive formally identical resources. A monetary transfer can have different effects depending on debt, housing security, health, care obligations, local prices, social networks, or access to complementary services. The same information can be useful to one subject and unusable to another because complementary knowledge or infrastructure differs. The same employment opportunity can expand freedom for one person and intensify constraint for another because mobility, care responsibilities, or legal status differ. GRE therefore asks how an intervention interacts with subject-specific and relation-specific conditions.

Heterogeneity also concerns value. Subjects can evaluate the same outcome through different normative, cultural, professional, ecological, or experiential frameworks. A land-use change may appear as increased asset value to one actor, loss of livelihood to another, ecological degradation to a third, and disruption of cultural continuity to a fourth. Economic analysis can sometimes translate these differences into a common measure for a specific decision. GRE does not assume in advance that every relevant value admits such conversion without remainder.

Subjects also differ in their capacity to make their valuations institutionally consequential. Some can purchase expertise, influence standards, control platforms, set contractual terms, or withdraw resources. Others possess weak bargaining power or limited representational access. Heterogeneity therefore interacts with asymmetry. A plural economy does not merely contain different preferences; it contains differently empowered subjects whose ability to stabilize their preferred classifications, metrics, and conversion rules can vary substantially.

Artificial and organizational subjects add further dimensions of heterogeneity. A corporation can persist for durations and command resources unavailable to an individual. An automated system can process information at a speed and scale that differs from human cognition. A public institution can exercise authority through rules rather than exchange. A household coordinates care and consumption through relations that are only partially contractual. Treating these subjects as analytically identical would conceal the mechanisms through which they act.

GRE's response is methodological pluralism at the level of subject modeling. Some questions can use utility functions, representative agents, or homogeneous populations. Others require types, distributions, networks, institutional categories, narratives, or qualitative reconstruction. The choice should follow the mechanism and scale of interest. Heterogeneity becomes analytically important when differences among subjects alter generation, propagation, conversion, bargaining, recognition, or exposure to risk.

This perspective also protects against interpreting difference as deficiency. A sub-

ject whose capacities do not match the requirements of a particular market or institution may still possess substantial capabilities that the institution does not recognize or reward. Economic subjecthood is therefore partly relational to the evaluative and infrastructural environment. The same person or organization can appear highly capable in one configuration and weakly capable in another. GRE analyzes that relational fit rather than converting every difference into a single hierarchy of subject quality.

3.8.6 Capability Asymmetry and Ontological Distinction

Economic subjects can differ enormously in capability. A multinational firm and an individual consumer do not command comparable resources. A state and a household occupy different institutional positions. A specialized artificial system can outperform a human participant on a bounded computational task while lacking many features that organize human economic life. GRE therefore separates capability comparison from ontological classification and from normative status.

Capability is multidimensional. It can concern computation, memory, prediction, physical action, social coordination, capital access, legal authority, mobility, learning, creativity, endurance, attention, bargaining, or the capacity to absorb loss. A subject can be strong on one dimension and weak on another. Aggregate labels such as “more capable” therefore require explicit specification of the relevant capability domain and the task or environment in which it is measured.

The distinction becomes especially important in human–artificial comparison. Superior performance by an artificial system on prediction, optimization, search, coding, or information processing demonstrates a capability difference in the specified domain. It does not by itself establish equivalence in embodiment, vulnerability, experience, social membership, moral standing, legal personality, or other ontological and normative dimensions. Conversely, inferior productive performance by a human subject does not imply diminished moral status or a weaker claim to social participation. Productive capability and normative worth belong to different analytical registers.

GRE therefore resists deriving subject status directly from productivity. Economies routinely assign value to capacities that are historically contingent: strength in one technological regime, literacy in another, credentialed expertise in another, computational skill in another. Technological change can rapidly alter which capacities command market value. If recognition or participation were tied directly to currently scarce productive capabilities, changes in technology could destabilize subject status in ethically and politically consequential ways. GRE treats that possibility as an object of economic analysis rather than as a normative conclusion supplied by productivity itself.

Capability asymmetry also generates power when it affects the terms under which others can participate. A platform with superior information and scale can shape market access. A creditor with greater liquidity can impose conditions on a constrained borrower. An organization equipped with advanced artificial systems can negotiate, monitor, or produce at a level unavailable to smaller actors. The relevant issue is the conversion of capability difference into durable relational advantage. Not

every asymmetry becomes power, and the mechanism of conversion requires specification.

Institutional design can amplify or moderate capability asymmetry. Standards, interoperability, public infrastructure, collective bargaining, competition rules, education, access to compute, liability arrangements, and rights of appeal can change how capability differences affect participation. GRE's interest lies in the resulting generative structure: which subjects gain new capacities, which become dependent, which forms of value are captured, and whether the asymmetry reproduces itself through control over the conditions of future generation.

The separation among capability, ontology, and normativity thus performs several analytical functions. It permits precise comparison where comparison is meaningful. It prevents performance metrics from silently becoming theories of personhood. It allows economic analysis to study artificial subjects without assuming human equivalence. It also preserves a space in which questions of justice, rights, dignity, or welfare can be evaluated through appropriate normative arguments rather than inferred from market productivity.

3.8.7 Subjective Participation beyond Productive Necessity

Technological development raises a further question for the constitution of the economic subject: how is participation organized when a subject's contribution is no longer required for a particular productive task? Automation has long displaced and transformed tasks, while new technologies have also created new occupations, complementary roles, and forms of demand. GRE does not assume a predetermined endpoint of this process. It identifies a structural problem that becomes more visible as productive capability can be supplied by machines or highly concentrated organizations: economic participation and social subjecthood may become less tightly coupled to productive necessity.

Historically, many economic institutions connect income, recognition, schedule, social interaction, insurance, status, training, and future opportunity to employment or productive contribution. When a task disappears, the loss can therefore extend beyond wages. A subject can lose routines, networks, bargaining position, identity, institutional recognition, and pathways for capability development. Analyses that record only the change in output or income can miss this wider transformation of subject position.

GRE uses the idea of *subjective participation* to name participation through which a person or collective can remain an active locus of choice, recognition, relation, contribution, and value formation within economic life. Productive work can be one important form of such participation, but the category is broader. Care, learning, civic contribution, cultural production, scientific inquiry, community activity, consumption, stewardship, and relational maintenance can all organize economically consequential participation even when their market valuation is limited or indirect.

The economic question is therefore partly institutional. If productive necessity declines for some subjects, which mechanisms connect them to resources, capabilities, recognition, and opportunities for meaningful participation? Several institutional arrangements are conceivable, and GRE need not select among them at the level of

disciplinary constitution. The research programme can instead examine how different arrangements affect autonomy, dependence, value generation, social recognition, bargaining power, capability development, and the distribution of future possibilities.

This problem also applies within organizations. An employee whose routine tasks are automated can become more capable when artificial tools release time for judgment, learning, care, design, or coordination. The same technological change can instead narrow the employee's role to monitoring a system controlled elsewhere. The distinction depends on ownership, training, discretion, workflow design, evaluation, and bargaining relations. Automation therefore transforms subjecthood through the surrounding institutional field rather than through task substitution alone.

Artificial systems intensify the question because they can participate in economic processes without requiring the same conditions for welfare, livelihood, social membership, or embodied reproduction as human subjects. A production system organized solely around output can therefore allocate increasingly large shares of economically consequential activity to artificial or organizational subjects while human participation becomes administratively residual. Whether and how institutions respond is a normative and political question; the economic analysis concerns the relations through which such a configuration affects value, demand, bargaining, recognition, capability, and social reproduction.

GRE thus separates the right to analyze productive contribution from the broader question of subject participation. It does not assume that economic inclusion must be earned through scarcity of labor, nor does it presume a specific institutional alternative. It asks how systems generate or foreclose forms of participation when technological and organizational change modifies the economic necessity of particular human capacities. The answer will depend on the orientation of generation, the subject of the following section.

3.8.8 Subject Formation as an Economic Process

The preceding subsections imply a final constitutional claim: subject formation is itself an economic process. Economic relations do more than coordinate already formed subjects. They participate in producing the capacities, identities, expectations, dependencies, temporal horizons, and recognized positions through which subjects subsequently act. GRE therefore includes subject formation within its field of inquiry whenever economic mechanisms materially contribute to that formation.

Labor markets provide a clear illustration. Education and credentialing prepare subjects for occupational categories; hiring procedures classify them; employment develops some skills while allowing others to decay; organizational hierarchies distribute authority; compensation affects outside options; performance metrics orient attention; career ladders shape expectations about the future. The resulting worker is neither created wholly by the labor market nor independent of it. Subject formation occurs through the interaction of economic, educational, familial, legal, cultural, technological, and biological processes.

Credit relations can similarly generate debtor subject positions. Access to credit expands purchasing or investment capacity while repayment schedules reorganize fu-

ture income. Credit histories affect later access. Default categories alter institutional treatment. Financial literacy, risk tolerance, and expectations can change through repeated borrowing. The economic subject that returns to a credit market is therefore historically modified by previous participation.

Platforms generate other subject forms through accounts, metrics, rankings, recommendation systems, monetization rules, and categories of permissible participation. A person can become a seller, creator, driver, host, advertiser, moderator, or rated customer through platform-specific infrastructures. These positions can create capabilities and income while also subjecting participants to new dependencies, forms of visibility, and evaluative systems. Artificial systems can likewise acquire operational subject positions through permissions, interfaces, memory, delegated objectives, and persistent identifiers.

Property institutions contribute to subject formation by stabilizing relations of control, responsibility, inheritance, exclusion, and expectation. Welfare institutions constitute beneficiary categories. Tax systems recognize households, firms, dependents, and taxable events. Corporate law stabilizes organizations that can persist beyond individual members. Monetary institutions constitute account holders and counterparties. Economic subjecthood therefore emerges repeatedly through institutional architectures that define who can do what, with which resources, under which records and obligations.

Subject formation also has recursive effects. Once a subject position is stabilized, subjects can act to preserve, reinterpret, contest, or transform the relations that formed them. Workers organize; firms lobby; consumers coordinate; professional groups set standards; communities create institutions; platform participants develop practices that alter platform design. Subject formation is therefore compatible with reflexivity. Generated subjects can become generators of subsequent institutional change.

This recursive structure connects subject analysis to GRE's broader concern with transformation of generative conditions. An economic system can generate subjects whose capacities and orientations reinforce the system. It can also generate subjects capable of questioning, modifying, or leaving it. Educational investment can create workers suited to an existing industrial structure while also producing knowledge that enables new industries. Financial systems can stabilize prevailing ownership while funding innovations that disrupt incumbent firms. Organizational routines can reproduce hierarchy while creating expertise that later supports institutional reform. The direction of subject formation is therefore neither mechanically reproductive nor inherently emancipatory.

For empirical work, treating subject formation as an economic process requires evidence appropriate to the mechanism. Administrative records can reveal changing classifications and access. Longitudinal data can track capability or income trajectories. Organizational records can show role transformation. Interviews and ethnography can recover changes in interpretation, identity, and perceived possibility. Experiments can identify bounded responses to institutional arrangements. Computational methods can trace large-scale patterns of classification or interaction. GRE does not privilege one method; it requires the method to match the dimension of subject formation being claimed.

The economic subject can now be located within the constitutional architecture of Chapter 3. GRE treats subjects as relatively stabilized participants whose capacities, recognition, persistence, and orientations are relationally conditioned and historically transformable. Human, organizational, and artificial subjects can all enter economic analysis while remaining ontologically and normatively distinct. Capability asymmetry can shape power without determining moral status. Participation can remain economically important even when particular productive contributions lose scarcity. Subject formation itself can be generated through economic relations and can recursively transform those relations in return.

This account also identifies the next constitutional problem. If economic relations help generate subjects, capacities, attention, and future possibilities, the direction of that generation cannot be treated as analytically empty. Economic systems select, reward, amplify, suppress, and stabilize different possibilities. Section 76 therefore turns from the constitution of subjects to the orientation of generation: the processes through which attention, curiosity, aesthetic judgment, epistemic priorities, institutional selection, and heterogeneous value structures influence what becomes economically generative.

3.9 GRE and the Orientation of Generation

Generative Relational Economics treats economic generation as more than the production of additional outputs from given inputs. Economic relations can enlarge, redirect, stabilize, or close future possibilities; they can generate capacities, questions, representations, institutions, expectations, forms of value, and modes of participation. Once generation is understood in this wider sense, a further analytical problem becomes unavoidable: generative processes are oriented. Among many possible objects of attention, questions, investments, designs, interpretations, and institutional trajectories, some become salient and others remain peripheral. The role of this section is to make that directional dimension explicit within the constitution of GRE. Its objective is to identify several mechanisms through which orientation is formed and economically consequential without reducing orientation to a single preference ordering or normative criterion. The discussion proceeds through attention and salience, curiosity and question formation, aesthetic judgment, epistemic orientation, institutional selection, and heterogeneous value structures before locating orientation itself as an economic and political problem. The method remains constitutive rather than exhaustive: these mechanisms identify admissible objects of GRE inquiry and can be combined differently across empirical domains.

Orientation occupies a position between possibility and realized generation. A field can contain several technically feasible innovations, several plausible interpretations of evidence, several ways of organizing care, several institutional reforms, or several investments capable of producing future value. Generativity alone does not determine which possibility receives resources, recognition, attention, or continued development. Selection occurs through subjects, organizations, infrastructures, norms, evaluative conventions, histories, and unequal capacities to make one possibility visible or actionable. GRE therefore asks not only what a relation can generate, but how its generative direction becomes selected, reinforced, contested, or revised.

This problem is distinct from saying that every economic process possesses a conscious purpose. Orientation can arise without centralized intention. Search rankings alter attention; funding rules privilege some questions; professional conventions stabilize standards of relevance; prices redirect investment; built environments make some actions easier than others; inherited categories determine what can be recorded; and repeated interaction can make one trajectory increasingly probable. Orientation can therefore be intentional, institutional, distributed, emergent, or mixed. What matters for GRE is the mechanism through which a space of possibilities becomes unevenly weighted and how that weighting changes subsequent generation.

3.9.1 Direction within Generative Processes

Generation becomes analytically directional whenever several possible continuations are available and the realized process favors some over others. A research group can investigate several questions but allocates effort to a subset. A firm can deploy capital across several technologies but selects particular projects. A city can support several mobility arrangements but builds infrastructure that makes some trajectories easier to reproduce. A household can convert additional income into consumption, education, savings, care, mobility, or debt reduction. In each case, resources enter a relational configuration whose later consequences depend partly on how possibilities are selected.

Direction should be distinguished from destination. A destination specifies an endpoint toward which activity is explicitly organized. Direction can be weaker and more distributed. It can consist in a persistent bias toward particular questions, objects, timescales, values, or forms of recognition even when no actor has specified a final state. An institution that rewards measurable short-term outputs may orient inquiry toward easily countable achievements without formally prohibiting long-horizon research. A credit system can orient firms toward revenue models compatible with repayment schedules without prescribing a specific product. A platform can orient cultural production through visibility metrics even when creators retain formal freedom over content. GRE is interested in these directional effects because they alter the future distribution of generative opportunity.

Orientation should also be distinguished from deterministic selection. A strong directional field can coexist with novelty, resistance, and contingency. Subjects can reinterpret incentives, institutions can be repurposed, and unexpected relations can open alternatives. The analytical claim is therefore probabilistic and structural: some configurations make particular generative pathways easier to enter, sustain, fund, legitimate, or recognize than others. The strength of orientation is an empirical question that can vary across scales and historical periods.

The concept also permits several levels of analysis. At the level of a subject, orientation can concern attention, aspiration, perceived possibility, or evaluative judgment. At the organizational level, it can concern strategy, metrics, hiring, budgeting, and project selection. At the institutional level, it can concern law, professional standards, eligibility rules, and classification systems. At the infrastructural level, it can concern access, interoperability, search, transportation, or computation. At the cultural level,

it can concern what appears admirable, credible, urgent, or worth pursuing. These levels can reinforce or conflict with one another.

Direction becomes especially consequential when orientation feeds back into the conditions of future choice. A selected research programme develops specialized instruments and expertise, making adjacent questions easier to investigate. An industry cluster attracts suppliers and workers, increasing the relative feasibility of further investment in the same domain. A classification adopted for administrative convenience can accumulate datasets organized around its categories, making alternative classifications harder to operationalize. What begins as selection among possibilities can therefore become a transformation of the possibility structure itself.

GRE treats this recursive effect as one reason to study orientation separately from immediate allocation. Allocation determines where resources initially go. Orientation concerns the relational processes that make some uses, interpretations, and continuations more likely to become generative. Their interaction can produce path dependence without requiring that the path was planned in advance. Orientation is thus a bridge between local selection and historical transformation.

3.9.2 Attention and Salience

Attention is a scarce and selective condition of economic participation. Subjects, organizations, and institutions encounter more signals, opportunities, demands, and possible actions than they can process with equal intensity. What enters attention can therefore influence what becomes available for evaluation and generation. GRE treats attention not simply as an internal cognitive resource but as relationally organized through environments, interfaces, institutions, social expectations, and distributions of visibility.

Salience is one mechanism through which this organization occurs. An object can become salient because it is perceptually striking, institutionally emphasized, repeatedly measured, socially endorsed, economically rewarded, emotionally charged, or strategically amplified. Salience need not indicate importance in any independent normative or causal sense. A highly visible indicator can dominate decision making while a less visible condition exerts larger long-term effects. Conversely, a previously neglected relation can become salient when a crisis, measurement innovation, public controversy, or new interpretive framework makes it perceptible as an economic problem.

The economic consequences of salience are therefore twofold. First, salience affects allocation of attention in the present. A firm monitors some indicators more closely than others; an investor notices some opportunities; a public agency prioritizes some risks; a consumer sees some products; a researcher encounters some literatures. Second, repeated attention can alter the object itself. Metrics invite optimization, visibility attracts resources, and recognized problems acquire organizations, professions, and infrastructures devoted to them. Attention can consequently become generative rather than merely observational.

Digital mediation intensifies this issue because ranking, recommendation, notification, and search systems actively order visibility. Their orientation effects may arise from commercial objectives, relevance models, engagement metrics, modera-

tion rules, personalization, or technical constraints. The resulting distribution of attention can affect demand, reputation, cultural production, political communication, and the formation of economic subjects. GRE need not assume that a platform fully controls these outcomes. It can instead ask which mechanisms structure exposure, how users respond, and how visibility feeds back into production and value.

Attention also interacts with inequality. Subjects differ in their capacity to command attention and in their ability to protect their own attention from external capture. Advertising budgets, institutional prestige, network centrality, media access, and control over interfaces can increase one actor's capacity to make objects salient to others. At the same time, workers, consumers, citizens, and researchers can face environments saturated with demands on attention. The distribution of attention therefore has both productive and power dimensions.

A GRE analysis should avoid equating attention with endorsement. A subject may attend to an object because it is threatening, unavoidable, controversial, or institutionally mandatory. Nor should measured engagement be treated as a complete representation of attention. Observable clicks, purchases, dwell time, or citations are partial indicators conditioned by the platform or institution through which they are recorded. The relation between salience, attention, interpretation, and later action requires empirical specification.

Attention becomes a problem of orientation when it changes which possibilities can enter generative processes. What remains persistently unseen may receive neither investment nor institutional articulation. What becomes hyper-salient can attract disproportionate resources and narrow alternative exploration. GRE therefore studies the production and distribution of salience as part of the economic organization of possibility.

3.9.3 Curiosity and Question Formation

Curiosity introduces a different form of orientation. Attention identifies what enters a field of concern; curiosity can transform an encountered difference, anomaly, absence, or possibility into an object of inquiry. This transformation matters economically because new questions can redirect research, entrepreneurial activity, public investment, education, and institutional experimentation before the value of an answer is known.

Question formation is generative in a stronger sense than information acquisition. A subject seeking a known datum operates within a pre-specified problem. A newly formulated question can reorganize the problem-space itself by distinguishing previously conflated phenomena, proposing a new comparison, or making an unrecognized relation investigable. The economic consequences can be substantial. Scientific questions create research programmes; engineering questions motivate design trajectories; policy questions define measurable problems; entrepreneurial questions organize searches for unmet needs or new combinations.

Curiosity should not be romanticized as an unconstrained internal virtue. Opportunities for curiosity are institutionally distributed. Time, income security, educational access, research infrastructure, mentorship, mobility, archival access, computational resources, and tolerance for failure all affect who can pursue uncertain questions. A

person may possess strong curiosity while lacking the relational conditions required to sustain inquiry. Conversely, organizations can create protected spaces in which exploratory questions become economically viable despite uncertain short-term returns.

Question formation is also socially mediated. A discipline defines which questions appear legitimate, mature, trivial, or impossible. A market communicates demand signals that make some problems commercially visible. Public institutions define categories of need. Communities preserve practical knowledge that can make different questions salient from those generated in professional research settings. Interdisciplinary contact can expose assumptions that remain invisible within a single field. Curiosity therefore emerges within histories of classification, authority, and encounter.

The economic orientation of curiosity becomes visible in the distribution of exploratory resources. Research grants, venture finance, procurement programmes, universities, laboratories, foundations, public challenges, and organizational slack all influence which uncertain inquiries can be sustained long enough to generate results. These mechanisms differ from ordinary exchange because expected value may be difficult to estimate ex ante. Selection often relies on judgments concerning plausibility, novelty, promise, social relevance, or strategic fit rather than on known outputs.

GRE can therefore analyze curiosity as a relational capacity with downstream economic effects. It can ask how an environment makes questions possible, how inquiry becomes sustained, how failed questions still generate capabilities or networks, and how exploratory activity alters the future set of feasible projects. It can also examine exclusion: whose questions receive recognition, which experiences become researchable problems, and which uncertainties remain institutionally invisible.

This perspective does not imply that more curiosity is always better. Unbounded exploration can consume resources, produce distraction, or impose risks on others. Some domains require reliability, maintenance, and disciplined exploitation of established knowledge. GRE's task is not to assign curiosity an intrinsic positive value, but to make visible the conditions under which question formation becomes economically generative and the trade-offs through which exploratory orientation is governed.

3.9.4 Aesthetic Judgment

Economic generation often proceeds under incomplete evidence. Researchers choose among conjectures before proof is available. Designers compare forms before market response is known. Investors assess emerging projects with limited histories. Engineers select architectures before every downstream consequence can be calculated. Public institutions imagine futures for which no complete dataset exists. In such settings, judgment frequently includes an aesthetic dimension: a sense that a problem, pattern, design, explanation, or possibility is elegant, coherent, beautiful, compelling, fertile, proportionate, or otherwise worthy of continued attention.

GRE treats aesthetic judgment as a possible orientation mechanism rather than as a universal or infallible faculty. The term refers here to evaluative responses that help rank possibilities when propositional evidence does not fully determine selec-

tion. Such judgments can concern mathematical elegance, conceptual simplicity, visual form, narrative coherence, spatial atmosphere, craftsmanship, symbolic resonance, or the perceived fertility of a question. Their content varies across practices and communities.

Aesthetic judgment can become economically consequential because it directs scarce exploratory resources. Scientists choose which problems feel deep or promising. Architects and planners create environments that shape movement and encounter. Consumers attach value to form and atmosphere. Organizations cultivate identities through design. Investors may respond to narrative and presentation alongside formal projections. Cultural industries depend directly on aesthetic differentiation. In each case, aesthetic orientation participates in the generation of value without being reducible to price.

The relational character of aesthetic judgment is important. Judgments are neither simply arbitrary private tastes nor automatically universal properties of objects. They are formed through histories of training, exposure, comparison, convention, embodiment, and social interaction. What appears elegant to a mathematician, trustworthy to a patient, refined to a consumer, or harmonious to a community can depend on learned repertoires and material environments. Institutions can therefore cultivate, standardize, or marginalize aesthetic criteria.

This relationality creates both generative possibility and power. Shared aesthetic repertoires can coordinate collaboration and make complex quality judgments possible without complete formalization. They can also become exclusionary when dominant groups define legitimate taste, professional style, or intellectual beauty. A funding committee's sense of what constitutes an "interesting" question, for example, may reproduce disciplinary histories that favor some objects and methods. Aesthetic judgment can thus influence resource allocation even when it is not formally acknowledged.

GRE should keep aesthetic judgment distinct from truth, welfare, and justice. An elegant theory can be empirically wrong. A beautiful design can be inaccessible or harmful. A compelling narrative can conceal exploitation. A technically awkward solution can nevertheless generate substantial social value. The analytical significance of aesthetic judgment lies in its role in orientation under uncertainty, not in a presumption that aesthetic approval validates the selected object.

Aesthetic orientation also interacts with serendipity. Encounters that were not sought for instrumental reasons can become generative when a subject experiences them as salient, intriguing, beautiful, strange, or worth pursuing. The generative consequence depends on both encounter and judgment. An environment rich in variation does not guarantee innovation; subjects and institutions must still recognize some differences as invitations to inquiry or creation. This suggests an economic problem of field design: how can environments sustain heterogeneous encounters and exploratory judgment without attempting to pre-engineer the exact novelty that should emerge?

Within GRE, aesthetic judgment therefore belongs to the analysis of orientation because it can influence which possibilities receive further attention, articulation, resources, and institutional support. Its mechanisms require contextual investigation,

and its normative status remains open to separate evaluation.

3.9.5 Epistemic Orientation

Economic generation is also directed by epistemic orientation: the standards, classifications, methods, evidential expectations, and interpretive habits through which subjects and institutions decide what can be known, what counts as relevant evidence, and which uncertainties deserve investigation. Epistemic orientation does not merely affect description after economic processes occur. It can shape which processes become actionable and therefore which futures are generated.

Measurement provides a direct example. Once an organization adopts a metric, activity can reorganize around what the metric makes visible. Data collection creates categories, time series, benchmarks, and comparison groups. These representations can improve coordination and accountability, but they also privilege some dimensions over others. A phenomenon that cannot be recorded within the existing schema can remain difficult to govern even when participants experience it as important. Epistemic orientation therefore influences institutional capacity through the design of observability.

Methods likewise orient inquiry. Randomized experiments, econometric identification, ethnography, archival reconstruction, simulation, network analysis, participatory research, and legal interpretation provide access to different dimensions of a problem. Their strengths are domain-specific. When one method becomes institutionally dominant, questions that fit its evidential architecture can become easier to legitimate and fund. GRE's methodological pluralism is partly a response to this orientation effect: the research problem should guide method selection rather than allowing an inherited method to define the only admissible problem.

Classification is another generative mechanism. Administrative categories determine eligibility, statistics, taxation, regulation, and rights. Market classifications affect comparability and exchange. Scientific classifications shape research populations. Professional categories define expertise. Once stabilized, classifications can influence behavior and identity, making the represented distinctions increasingly consequential. Epistemic orientation therefore links representation to ontology without collapsing the two: categories can help generate social effects even though the category remains analytically distinct from the object it represents.

Epistemic orientation has a temporal dimension. Institutions inherit archives, standards, vocabularies, and datasets from earlier periods. These resources make some historical comparisons possible while leaving other experiences poorly recorded. New questions are therefore conditioned by the epistemic infrastructure accumulated in the past. At the same time, present recording decisions shape what future investigators will be able to reconstruct. The organization of knowledge becomes part of intertemporal economic capacity.

Disagreement over epistemic orientation can be productive. Competing models, disciplinary perspectives, and interpretive frameworks can reveal different aspects of a system. GRE does not require premature convergence on a single representation. It asks whether the plurality of representations is explicit, whether their assumptions and domains of validity are understood, and whether institutions preserve the capac-

ity to revise their epistemic orientation when anomalies or changing conditions make existing categories inadequate.

This emphasis also limits the role of formal precision. A precisely estimated quantity can answer a poorly oriented question, while a qualitative observation can reveal a relation that has not yet been formalized. GRE values formal and computational methods where they perform genuine analytical work, but epistemic orientation precedes technique in the sense that the researcher must first decide what distinctions, scales, and forms of evidence are relevant to the inquiry.

3.9.6 Institutional Selection of What Is Generated

Orientation becomes institutional when durable rules, organizations, infrastructures, and evaluative procedures repeatedly privilege some generative pathways over others. Institutions do not need to specify the content of future outcomes in order to shape them. By controlling eligibility, resources, recognition, standards, timing, and access, they can alter which possibilities survive long enough to become self-sustaining.

Funding systems provide an obvious case. Research grants, venture investment, bank credit, public procurement, philanthropy, and internal organizational budgets each use different selection criteria. Those criteria can favor measurable returns, strategic importance, novelty, reliability, social need, collateral, prior reputation, or compatibility with existing infrastructure. A funding architecture therefore orients generation before the downstream value of a project is known. Its effects accumulate when successful projects create expertise, reputation, and networks that improve their access to future resources.

Legal and regulatory institutions also orient generation. Intellectual-property rules affect incentives and diffusion. Liability rules influence experimentation. Licensing can protect safety while raising entry barriers. Competition policy changes the conditions under which scale can consolidate. Data governance shapes access to informational resources. Labor and social-protection institutions influence the risks subjects can bear when changing occupations or starting new projects. In each case, legal structure changes the feasible and attractive trajectories available to economic actors.

Educational institutions orient generation by shaping capabilities, vocabularies, disciplinary boundaries, and aspirations. Curriculum determines which problems become familiar. Credentials affect access to professions and organizations. Mentorship can make previously invisible pathways imaginable. Evaluation systems influence whether students optimize for standardized performance, exploration, collaboration, or independent inquiry. Education therefore participates in economic generation long before its effects appear as wages or productivity.

Markets themselves are institutional selection environments. Prices, demand, competition, and profitability orient resources toward some activities and away from others. GRE retains this insight while asking how market selection interacts with other orientation mechanisms. Markets depend on property rules, infrastructures, classifications, information, financing, and distributions of purchasing power. A profitable opportunity can reflect genuine social demand, concentrated wealth, regulatory de-

sign, network effects, or externalized costs. Market orientation is therefore economically powerful without being normatively self-interpreting.

Platforms and algorithmic systems add another layer by combining infrastructure, ranking, rule enforcement, and data collection. Their selection mechanisms can shape which sellers are visible, which workers receive tasks, which content gains distribution, and which behaviors become economically rewarded. Because participants often adapt to these selection systems, the platform's orientation can become recursive: metrics influence behavior, behavior supplies new data, and new data update the mechanism that structures visibility or access.

Institutional orientation also creates lock-in and complementarity. Once organizations invest in a technology, standard, profession, or accounting category, adjacent investments may become more valuable. Alternative pathways then face higher switching costs even if they are technically feasible. The resulting persistence can be efficient when coordination benefits are large, but it can also preserve arrangements whose original justification has weakened. GRE therefore asks how institutional selection creates future dependency and what forms of optionality remain available.

The analytical objective is not to identify a single institution responsible for orientation. Selection is often distributed across finance, law, culture, infrastructure, expertise, and public authority. A GRE inquiry traces how these mechanisms combine and where control over selection becomes concentrated, contested, or open to revision.

3.9.7 Plural Orientations under Heterogeneous Values

Economic systems contain subjects and communities whose orientations differ. They may disagree about desirable outcomes, relevant time horizons, legitimate evidence, acceptable risk, ecological obligations, cultural continuity, forms of recognition, or the value of particular capabilities. GRE treats this heterogeneity as a constitutive feature of orientation rather than assuming that all relevant directions can be represented by one shared scalar objective.

Plural orientation creates coordination problems. A project that expands aggregate income can weaken a local form of life. A conservation policy can protect ecological conditions while constraining livelihoods unless transition mechanisms are provided. A technological system can increase convenience for users while intensifying surveillance or labor precarity. A research programme can generate broadly useful knowledge while concentrating intellectual property. These tensions cannot always be resolved by discovering a hidden common metric.

Value conversion can help decision making when the conversion rule is explicit and appropriate. Monetary valuation, cost-effectiveness, multi-criteria analysis, voting, deliberation, legal balancing, and negotiated compromise are among the mechanisms institutions use to compare heterogeneous claims. GRE does not reject such conversions. It asks what is gained and lost through them, whose valuations enter the procedure, and whether the conversion becomes mistaken for an ontological equivalence among the values involved.

Plural orientation also means that generativity itself can be evaluated differently.

One group may value rapid innovation; another may value reliability and continuity. One institution may prioritize employment; another ecological regeneration; another strategic autonomy; another freedom of inquiry. A relation can therefore be highly generative according to one orientation while appearing destructive according to another. The disagreement concerns both produced outcomes and the standards through which generation is interpreted.

Institutions can respond to plural orientation through several architectures. They can aggregate preferences into a single decision, allocate separate domains of authority, preserve local autonomy, establish rights that constrain aggregation, create deliberative procedures, or maintain experimental diversity across jurisdictions and organizations. Each architecture has generative consequences. Centralization can coordinate large-scale investment but narrow local variation. Decentralization can preserve experimentation but weaken collective capacity. Rights can protect vulnerable subjects while limiting some forms of optimization. GRE treats these trade-offs as empirical and normative objects rather than deriving a universal institutional design.

The distribution of voice matters because heterogeneous values do not enter decision processes with equal force. Wealth, legal status, expertise, organizational capacity, time, language, and control over infrastructure can affect which orientations become institutionally consequential. A formally plural process can therefore reproduce asymmetry if some actors possess much greater ability to define agendas, supply evidence, or sustain participation. Analysis of orientation must consequently include the conditions of representation and participation.

Plurality also has an epistemic benefit. Different orientations can reveal consequences that a dominant framework misses. Workers, users, local communities, engineers, ecologists, regulators, and investors can perceive different dimensions of the same system. Maintaining structured disagreement can therefore increase the system's capacity to detect emerging harms or opportunities. Diversity of orientation is not automatically valuable, but under some conditions it functions as a distributed sensing and exploration mechanism.

For GRE, the constitutional implication is that economic orientation should remain representationally plural unless a specific analytical or decision context justifies aggregation. Heterogeneous values are not noise to be removed before economic reasoning begins. They are part of the relational field through which generation is directed and evaluated.

3.9.8 Orientation as an Economic and Political Problem

Orientation becomes an economic problem because it influences the allocation and generation of scarce capacities across time. Attention, research effort, capital, infrastructure, education, organizational commitment, and institutional legitimacy cannot be devoted equally to every possibility. Selection therefore shapes which capabilities accumulate, which industries form, which questions receive answers, which risks become visible, and which subjects gain access to future opportunities. Orientation is economically consequential even when no market transaction directly prices it.

It becomes a political problem when the authority to orient generation is unevenly

distributed or collectively contested. Governments set research priorities and infrastructure plans. Firms select technologies and business models. Platforms organize visibility. Financial institutions influence investment trajectories. Professional bodies define standards. Universities establish curricula and disciplines. Communities defend or transform local practices. Individuals exercise agency within these fields but do not enter them with equal resources. Orientation is therefore partly a question of who can shape the conditions under which future possibilities become more or less available.

This form of power is upstream from many observable outcomes. Control over a final allocation matters, but control over the categories, infrastructures, questions, and selection procedures through which future allocations will be made can have longer-lived effects. A subject that determines what can be measured, funded, connected, certified, or searched can influence generation without dictating every downstream action. GRE can analyze this as power over generative conditions while still requiring concrete mechanisms rather than inferring power from asymmetry alone.

The political character of orientation also appears in conflicts over temporality. Short electoral cycles, quarterly reporting, long infrastructure lifetimes, ecological regeneration, intergenerational obligations, and scientific research operate on different temporal horizons. Institutions that privilege one horizon can redirect generation away from possibilities whose value emerges later. The question is not simply whether actors discount the future, but how organizational and institutional arrangements determine whose future, which risks, and which forms of value remain actionable in the present.

A generative orientation can also produce foreclosure. Investment in one infrastructure can make alternatives expensive. A dominant technical standard can exclude incompatible innovations. A classification can make some identities administratively invisible. A business model can generate dependency that reduces exit options. Foreclosure is therefore the counterpart of orientation: selecting and reinforcing one trajectory changes the feasibility of others. GRE evaluates orientation partly by tracing these changes in future option sets rather than only immediate outputs.

This does not imply that preserving every option is desirable. Coordination, commitment, specialization, and institution building often require closing alternatives. A society cannot maintain every infrastructure standard simultaneously, and an organization cannot pursue every project. The analytical question concerns the terms under which closure occurs, its reversibility, who bears the resulting constraints, and whether institutions retain capacities for revision when conditions change.

Orientation also connects economic analysis to governance. A governance system can attempt to specify desired outcomes directly, or it can shape fields in which desirable forms of generation are more likely to emerge. The latter approach may involve public infrastructure, open standards, rights, research capacity, plural participation, safety constraints, or mechanisms for feedback and revision. Such field-oriented governance does not eliminate political choice; it relocates part of that choice to the design of enabling and constraining conditions.

The constitutional position of GRE is therefore neither that generation should be maximized nor that orientation should be centralized. GRE makes orientation visible

as an object of economic inquiry. It asks how attention, curiosity, aesthetic judgment, epistemic practices, institutions, and heterogeneous values combine to direct generative processes; how orientation distributes future capacities and risks; how power enters selection; and how orientations themselves change through history.

This completes the present chapter's account of one major dimension of GRE's problem-space. Economic generation is mediated by subjects, but subjects themselves are formed through relations; generation is directional, but direction arises through multiple cognitive, institutional, symbolic, and political mechanisms. The next constitutional task is methodological. The following section therefore distinguishes the principal modes through which GRE can describe, explain, reconstruct, compare, interpret, formalize, evaluate, and intervene in the economic processes identified here.

3.10 Modes of GRE Inquiry

Generative Relational Economics requires methodological breadth because its objects are heterogeneous and its questions concern several different kinds of claim. A study may need to describe a relational configuration, explain how it is reproduced, reconstruct how it emerged historically, compare it with alternative configurations, interpret the meanings through which subjects act, identify causal effects, formalize a mechanism, simulate possible trajectories, evaluate consequences normatively, or design an intervention. These tasks are related, but they are not interchangeable. The role of this section is to distinguish the principal modes through which GRE can conduct inquiry while preserving their mutual compatibility. Its objective is methodological clarification rather than the prescription of a single research design. The discussion proceeds from descriptive and explanatory inquiry through historical, comparative, interpretive, causal, formal, computational, normative, and intervention-oriented modes. Across them, the governing principle is that each mode must make explicit what kind of claim it is entitled to support, which evidence or representation bears that claim, and where its warrant ends.

The distinction among modes concerns the epistemic work being performed rather than a rigid classification of disciplines or techniques. An interview can contribute to descriptive, interpretive, historical, causal, or normative inquiry depending on how it is used. A regression can support description, comparison, or causal inference under different designs. Archival material can reconstruct a historical sequence while also revealing institutional meanings and mechanisms. A simulation can clarify the consequences of specified assumptions without establishing that the modeled mechanism exists empirically. GRE therefore classifies inquiry by the relation between question, evidence, representation, and warranted conclusion rather than by the surface form of the method alone.

The modes also differ from the objects and scales identified earlier in this chapter. The same object can be approached through several modes. A platform can be described as an organization and infrastructure, interpreted through the classifications embedded in its interface, studied causally through changes in ranking rules, reconstructed historically through its institutional development, represented formally as a

multilayer network, evaluated normatively through the distribution of generated capacities and harms, and examined interventionally through alternative governance designs. Methodological plurality becomes useful precisely because the object does not determine a unique mode of inquiry.

GRE does not require every project to use every mode. A narrowly designed causal study can be valuable if its boundaries are clear. A historical reconstruction can illuminate the emergence of a generative structure without formalization. An interpretive study can reveal categories that would otherwise be mismeasured. A formal model can clarify possible mechanisms before adequate data exist. The methodological demand is therefore fit rather than comprehensiveness: the mode or combination of modes should match the question and should remain corrigible by evidence or arguments arising from other modes when their domains overlap.

3.10.1 Descriptive Inquiry

Descriptive inquiry establishes what is present, how it is distributed, how it is related, and how it changes over a specified observational domain. In GRE, description can concern entities, subjects, relations, resources, capacities, forms of value, constraints, institutional rules, symbolic representations, trajectories, or fields. Its importance is easily underestimated because description is sometimes treated as a preliminary stage before "real" explanation. Yet a relational research programme depends heavily on careful description: a mistaken boundary, omitted relation, inappropriate unit, or unstable category can distort every later explanatory or normative claim.

A GRE description is therefore more than an inventory of isolated attributes. It can map relational incidence: who is connected to whom, through which mechanism, under what terms, and with what asymmetries. It can characterize distributions of access, exposure, recognition, risk, or capability. It can identify temporal patterns such as persistence, turnover, accumulation, or decay. It can distinguish administrative recipients from affected subjects and can trace where value, constraints, or opportunities appear outside the nominal boundary of a programme or transaction. Description thereby makes the relational field empirically available before deeper attribution is attempted.

The construction of descriptive categories requires explicit judgment. Terms such as worker, household, platform, community, firm, beneficiary, asset, skill, trust, or harm are not self-interpreting. Their operationalization can depend on legal definitions, institutional records, self-identification, measurement conventions, or analytical reconstruction. GRE therefore treats descriptive categories as representations whose adequacy must be justified relative to the question and scale. A category can be useful without being ontologically final, and a stable administrative classification can remain inadequate for a relational question if it suppresses relevant interactions or affected subjects.

Description also has a temporal dimension. Cross-sectional description captures a configuration at a moment or interval, while longitudinal description tracks changes in states, relations, or distributions. The latter becomes especially important when generation concerns future capacities. A programme that appears distributively modest at one date may substantially change later educational, technological, organiza-

tional, or relational possibilities. Conversely, an apparent short-term gain may dissipate or convert into dependence. Descriptive inquiry can reveal these trajectories without yet claiming a mechanism for them.

Rich description can combine quantitative and qualitative evidence. Administrative records may establish scale and distribution; interviews may reveal unrecorded relations; ethnographic observation may show how formal rules are enacted; network data may identify patterns of connectivity; documents may clarify institutional categories; spatial data may reveal infrastructural concentration. GRE has no reason to privilege one evidence type in advance. The relevant standard is whether the descriptive representation captures the features required by the question while making omissions and uncertainty visible.

Descriptive adequacy also depends on boundaries. A study of a firm's wage policy can stop at employees, extend to households, include subcontractors, or incorporate local labor markets and public services. Each boundary produces a different descriptive object. GRE does not assume that the widest boundary is always best; wider boundaries increase complexity and can reduce tractability. The researcher instead states why a boundary is appropriate and tests whether excluded relations materially alter the description.

The output of descriptive inquiry is therefore a warranted account of configuration rather than a claim about why the configuration exists. It establishes patterns that explanatory, historical, causal, interpretive, or normative inquiry may subsequently address. In GRE, this mode is foundational because relational and generative claims become meaningful only after the relevant configurations, transitions, and affected subjects have been specified with sufficient empirical discipline.

3.10.2 Explanatory Inquiry

Explanatory inquiry asks how and why an observed configuration, transition, or regularity occurs. GRE gives particular attention to mechanisms through which relations produce, reproduce, transform, amplify, or constrain later possibilities. Explanation can therefore address immediate effects, recursive feedback, institutional reproduction, conversion among forms of value, subject formation, cross-scale propagation, or changes in the conditions under which subsequent generation occurs.

Explanation requires more than naming a correlation or attaching a familiar concept to an outcome. To say that an outcome results from power, incentives, norms, networks, institutions, culture, or path dependence is incomplete unless the operative process is specified sufficiently to connect conditions to consequences. A GRE explanation should identify the relevant actors or configurations, the relations through which effects travel, the enabling and constraining conditions, the temporal sequence where it matters, and the observations that would distinguish the proposed mechanism from plausible alternatives.

Mechanistic explanation can operate at different levels. A change in organizational behavior may be explained through individual incentives, professional norms, governance rules, technological affordances, inter-organizational dependence, or combinations among them. These explanations need not compete if they address different parts of the process. GRE is particularly interested in explanations that connect

levels without treating one as automatically fundamental. A legal rule can alter organizational incentives; organizational practices can reshape individual capabilities; repeated individual actions can stabilize a convention; a convention can later become codified. The explanatory task is to show how these relations connect rather than to reduce them to a single privileged scale.

Generative explanation extends the temporal horizon beyond the immediate outcome. A scholarship programme may explain increased enrollment through reduced cost, but GRE may also ask how participation generates networks, expectations, credentials, institutional capacities, or new constraints that alter later educational and labor-market trajectories. This does not mean every explanation must trace indefinitely downstream. It means that when later capacities are central to the research question, the explanatory account should not stop at the first measurable output merely because it is administratively convenient.

Explanatory inquiry can draw on several other modes. Historical evidence can reveal how a mechanism became possible. Interpretive evidence can show how subjects understand and respond to classifications. Causal designs can estimate whether an intervention changes an outcome. Formal models can clarify whether a proposed mechanism is internally coherent. Comparative cases can test whether the explanation travels across configurations. Computational models can explore implications that are difficult to derive analytically. Explanation is therefore often integrative, but the contributions of these components should remain distinguishable.

The standard of explanatory sufficiency depends on the claim. A local explanation of a policy effect requires less than a theory of institutional transformation. Claims about altered generative conditions require evidence that the later opportunity structure, rule environment, capacities, or relations changed in a way relevant to subsequent processes. Claims about transformation of the effective rule of change require still stronger evidence that the mechanism governing later transitions itself changed. GRE therefore scales explanatory ambition to evidential support.

Explanatory inquiry is central to GRE because the framework is concerned with more than relational association. It seeks to understand how relations become consequential through identifiable processes. At the same time, explanation remains compatible with ontological suspension: a useful mechanism model can explain an empirical pattern without establishing that its analytical categories constitute the ultimate ontology of the economic system.

3.10.3 Historical Inquiry

Historical inquiry reconstructs how economic configurations, categories, subjects, institutions, and generative conditions emerge and transform through time. Its role in GRE is constitutive rather than supplementary. If entities and relations can be historically generated, then their present form cannot always be understood by treating them as fixed inputs to analysis. Historical inquiry asks how the objects that later appear stable became available, how alternative possibilities were closed or retained, and how prior trajectories condition present generative capacity.

A historical GRE study can begin with an institution, technology, classification, market, profession, infrastructure, or relation and reconstruct the sequences through

which it acquired its current form. The relevant history may include legislation, organizational decisions, conflict, technical development, demographic change, cultural interpretation, investment, crises, accidents, or encounters with other systems. The aim is not to produce chronology for its own sake. The analytical objective is to identify transformations that changed what later actors could perceive, do, coordinate, own, exchange, contest, or generate.

Historical inquiry is especially important for categories that appear natural after stabilization. The distinction between employee and contractor, the legal form of a corporation, a standardized credential, a property right, a data category, a currency regime, or a professional jurisdiction can become embedded in administrative systems and everyday expectations. Once stabilized, these categories structure evidence and action. Historical reconstruction can reveal their contingency, the relations that produced them, and the alternatives that were once viable. Such reconstruction supports ontological suspension by showing that analytical objects may have histories of constitution.

Temporal ordering can also bear explanatory weight. The same set of conditions can produce different outcomes when encountered in different sequences. Early infrastructure can create increasing returns; a legal designation can precede and enable market formation; a crisis can accelerate an institution that had previously remained marginal; a technical standard can become difficult to displace after complementary investments accumulate. Historical inquiry can therefore identify path-dependent mechanisms while avoiding the loose use of "history matters" as an explanation.

GRE also treats methods and evaluative categories as historical. What counts as reliable evidence, recognized value, legitimate participation, acceptable risk, or relevant harm can change. A historical study may therefore examine not only the object of evaluation but the evolution of the evaluative and epistemic apparatus itself. This becomes particularly important when contemporary assessment applies categories that did not exist, had different meanings, or excluded relevant subjects in earlier periods.

Historical evidence is heterogeneous. Archives, legal documents, organizational records, correspondence, material artifacts, statistical series, oral histories, media, technical standards, and retrospective testimony can each illuminate different aspects of a process. Their survival is itself selective. GRE therefore treats the archive as part of the historical relational field: who could record, whose records were preserved, which categories were administratively legible, and which forms of experience remained unrecorded can shape what later researchers are able to reconstruct.

Historical inquiry does not imply that every present problem requires a complete genealogy. The relevant temporal horizon depends on the process. Some mechanisms can be understood through recent organizational history; others depend on decades of institutional accumulation or longer histories of law, infrastructure, or social classification. The methodological requirement is to extend the historical frame far enough that the object and its operative conditions are not mistakenly treated as timeless when their formation is relevant to the explanation.

3.10.4 Comparative Inquiry

Comparative inquiry examines similarities and differences across cases, configurations, periods, scales, or institutional arrangements. In GRE, comparison is valuable because relational and generative mechanisms are often conditional. A relation that generates capability in one institutional environment may generate dependence in another; a governance arrangement that supports participation at one scale may produce exclusion at another; the same technology can reorganize value differently under different property, labor, or regulatory structures.

Comparison can therefore reveal which features are specific to a configuration and which travel across contexts. Cases may be organizations, regions, legal systems, historical episodes, technologies, communities, markets, or interventions. A comparison can hold some features relatively stable while examining variation in others, or it can compare broader configurations whose differences are themselves analytically meaningful. GRE does not require all comparisons to approximate experiments. Configurational comparison can be valuable when the research question concerns how combinations of relations produce different generative trajectories.

The major methodological problem is commensurability. Cases become comparable only through selected dimensions, and the choice of dimensions can obscure differences in meaning or institutional constitution. "Employment," "household income," "community participation," or "innovation" may be measured similarly across jurisdictions while referring to materially different social arrangements. Comparative inquiry must therefore justify both the common dimension and the retained differences. Translation among categories can be part of the research rather than a preliminary technical step.

Comparison across time presents a related problem. A variable can retain its label while the institutional relations that constitute it change. Longitudinal comparisons of occupations, assets, industries, educational attainment, or household forms may therefore require attention to changing definitions and social significance. GRE treats historical comparability as an empirical and interpretive achievement, not an automatic consequence of having a numerical series.

Comparative inquiry is also useful for mechanism assessment. If a proposed explanation depends on a particular relation, cases in which that relation differs can help evaluate the claim. A platform governance mechanism can be compared across ownership models; a welfare intervention across administrative designs; a cooperative across legal environments; a knowledge commons across licensing regimes. The objective is not necessarily to identify a single universally best arrangement. Comparison can instead map how different relational configurations generate different distributions of capacity, value, risk, or closure.

Negative and deviant cases can be especially informative. A case in which an expected self-reinforcing process fails may reveal a missing enabling condition. A community that resists a dominant institutional trajectory can disclose alternative relations that preserve options. A technological diffusion that remains limited despite strong incentives may reveal interpretive, infrastructural, or legal constraints. GRE can use such cases to refine mechanisms rather than treating them as noise around an average effect.

Comparative inquiry thus provides a disciplined way to study plurality. It can test portability without assuming invariance, and it can illuminate alternative economic arrangements without reducing them to a single ranking dimension. Its contribution is strongest when the basis of comparison, the boundaries of each case, and the limits of generalization are stated explicitly.

3.10.5 Interpretive Inquiry

Interpretive inquiry examines the meanings, classifications, narratives, symbols, expectations, and practical understandings through which economic subjects perceive and act within relational configurations. GRE requires this mode because many economic objects are symbolically mediated. Prices, contracts, credentials, reputations, categories, metrics, risk scores, organizational roles, and legal statuses acquire consequences partly through shared or contested interpretations.

Interpretation enters economic processes in several ways. Subjects respond to what they believe a rule requires, what they expect others to do, what a category signifies, or what an action communicates. An institutional classification can alter behavior because it changes eligibility or sanctions, but also because subjects understand themselves and others through it. A market signal can influence investment because actors interpret its informational content. A policy can fail because its official category does not correspond to the categories through which affected communities organize practice. Meaning is therefore neither an ornamental layer nor a universal substitute for material explanation. It is one mechanism through which relations become actionable.

Interpretive inquiry can focus on language, documents, interviews, practices, rituals, interfaces, images, classifications, or institutional procedures. The researcher asks how a representation is produced, which distinctions it makes salient, how subjects use or contest it, and what practical consequences follow. Interpretive evidence can reveal why formally identical incentives generate different responses, why some risks remain unrecognized, or why an institutional reform changes subject positions even when resource distributions move little.

GRE distinguishes the meaning attributed by subjects from the analyst's representation. Researchers can misdescribe a relation if they impose categories that erase locally consequential distinctions. Conversely, subjects' interpretations do not exhaust causal explanation. An institution can have effects that participants neither intend nor perceive. Interpretive inquiry therefore contributes one layer of evidence within a plural methodology: it reconstructs situated meaning while remaining open to material, institutional, statistical, and historical evidence about effects beyond conscious understanding.

Symbolic mediation becomes particularly important under conditions of representational abundance. Rankings, dashboards, automated classifications, recommendation systems, financial models, and AI-generated representations can shape what becomes visible and credible. Interpretive inquiry can examine how these representations acquire authority and how subjects orient action around them. It can also ask how categories designed for one purpose migrate into other domains and begin to organize allocation, recognition, or exclusion.

Interpretive disagreement is itself an economic phenomenon. Different actors may attach incompatible meanings to the same resource, relation, technology, or institutional change. A redevelopment project can signify investment to one group and displacement to another; data sharing can signify innovation, surveillance, or public infrastructure depending on the relation. GRE does not require these meanings to be collapsed into a single utility metric before analysis begins. Their coexistence can shape conflict, coalition, legitimacy, and future generative possibilities.

Interpretive inquiry thus expands what counts as economically relevant evidence while remaining disciplined by context and consequence. Its aim is not to replace causal or material analysis with discourse, but to identify when meaning and representation form part of the mechanism through which economic relations are generated, sustained, or transformed.

3.10.6 Causal Inquiry

Causal inquiry asks whether and through what conditions a change in one factor contributes to a change in another. GRE requires causal discipline because relational language can otherwise encourage unwarranted attribution. The presence of a relation, asymmetry, institution, or field does not by itself establish that it caused an observed outcome. Causal inquiry therefore provides tools for distinguishing association, sequence, mechanism, and intervention-relevant effect.

Causal questions can be narrow or generative. A narrow question may ask whether a transfer increases school attendance. A broader question may ask whether the transfer changes household bargaining, peer networks, expectations, credential accumulation, or later labor-market options. These questions operate on different outcomes and time horizons, and they may require different designs. GRE's contribution is not to replace established causal inference but to broaden the set of causally relevant downstream and relational outcomes when theory gives reason to expect them.

Counterfactual reasoning remains central. To claim that an intervention caused an outcome requires some account of what would have occurred under a relevant alternative. Randomization, natural experiments, quasi-experimental designs, matching, synthetic controls, longitudinal models, process tracing, comparative case analysis, and mechanistic evidence can support counterfactual claims under different assumptions. GRE is methodologically plural about these tools but not indifferent to identification. The choice of design must match the causal claim.

Relational settings create additional challenges. Interference can violate assumptions that one unit's treatment does not affect another. Network spillovers can make the administrative recipient a poor unit for causal analysis. Institutional reforms can change the categories through which outcomes are measured. Feedback can make causes and effects mutually reinforcing across time. Selection into relationships can confound observed associations. GRE therefore treats relational structure as part of causal design rather than as a reason to abandon causal inference.

Causal attribution can also be distributed. A harmful outcome may depend on a sequence of financing rules, organizational incentives, technical standards, local decisions, and infrastructural constraints. No single element is sufficient on its own, yet

the configuration can reliably generate the outcome. GRE can analyze such conjunctural causation while distinguishing it from claims that every contributing condition bears equal explanatory or normative weight.

Generative causal inquiry may ask whether an intervention changes later capacities to produce further effects. This creates nested causal questions. A training programme can directly change skill, which changes network access, which changes employment opportunities, which changes household investment. The causal chain can branch and feed back. Researchers need not estimate every link simultaneously, but they should distinguish measured effects from hypothesized downstream mechanisms and avoid presenting an observed endpoint as evidence for the entire generative story.

Causal inquiry therefore disciplines GRE's ambition. It permits strong claims where design and evidence support them and encourages restraint where mechanisms remain plausible but unverified. Relational complexity expands the causal questions worth asking; it does not lower the evidential burden for answering them.

3.10.7 Formal Inquiry

Formal inquiry constructs explicit representations of economic structures or processes in mathematical, logical, graphical, or computationally specified form. Its role in GRE is clarification. Formalization can make assumptions visible, expose inconsistencies, distinguish mechanisms that natural language leaves conflated, derive consequences, and reveal which empirical observations would discriminate among alternative accounts.

The appropriate formalism depends on the problem. Dynamical systems can represent trajectories, stability, and regime change. Networks and hypergraphs can represent relational topology and higher-order interaction. Multilayer structures can distinguish relation types. Optimization and game-theoretic models can clarify strategic constraints and incentive compatibility. Probabilistic models can represent uncertainty and conditional dependence. Field-like representations can describe distributed conditions when locality or spatial organization matters. Logical or categorical formalisms can clarify compositional structure. GRE does not designate one of these as its universal mathematics.

Formal inquiry begins by specifying what the symbols represent. A node may stand for a person, organization, legal entity, document, or technical component; an edge may encode communication, ownership, exchange, dependency, recognition, or another relation. A state variable can summarize a capacity, stock, classification, or measured condition. The model becomes meaningful only through the mapping between formal object and empirical interpretation. Two models with identical mathematics can therefore represent substantively different economic mechanisms.

Formalization also requires ontological restraint. A network representation does not prove that the economy is fundamentally a network, and a state-space model does not establish that the selected variables constitute a complete economic state. The formal representation is an analytical instrument whose adequacy depends on the question, assumptions, and empirical correspondence. GRE's ontological suspension is compatible with strong formal work precisely because it separates representational

usefulness from metaphysical commitment.

One important use of formal inquiry is to distinguish levels of transformation. A model can represent change in state under fixed rules, changes in parameters, changes in topology, or transformations in the effective rule itself. These are different formal problems. GRE's concern with changing generative conditions becomes clearer when the model states which elements are permitted to vary and which remain fixed. A formalism that endogenizes network ties while fixing node identities captures one form of relational change but leaves other forms outside the model.

Formal inquiry can also produce impossibility or boundary results. Under specified assumptions, certain combinations of objectives may be incompatible; some allocation rules may generate unavoidable trade-offs; some dynamics may be unstable; some information may be insufficient for identification. Such results can be valuable even when the assumptions are idealized because they clarify where a proposed intervention requires additional structure or information.

The evidential status of a formal result must nevertheless remain explicit. A theorem establishes a consequence of assumptions. A numerical model shows behavior of a specified representation. Neither alone establishes that the assumptions hold empirically. Formal inquiry becomes empirically explanatory when the mapping, assumptions, and relevant predictions or mechanisms are supported by evidence. GRE therefore treats formalization as one rigorous mode among several, especially powerful when combined with descriptive, historical, causal, or interpretive work.

3.10.8 Computational Inquiry

Computational inquiry uses algorithmic procedures to analyze data, simulate specified systems, explore high-dimensional models, search large possibility spaces, or construct representations that would be difficult to handle analytically. It overlaps with formal inquiry but is not identical to it. A formal model can be studied without computation, while computational analysis can involve empirical pattern detection whose theoretical structure remains comparatively weak. GRE distinguishes these uses so that computational power is not mistaken for explanatory completeness.

Simulation is one major application. Agent-based models can explore how heterogeneous local rules generate aggregate patterns; network simulations can study diffusion, contagion, coordination, or rewiring; dynamical models can examine sensitivity and regime change; Monte Carlo methods can characterize uncertainty; optimization algorithms can explore feasible designs under constraints. Simulation is particularly useful when feedback, heterogeneity, or combinatorial complexity makes closed-form analysis difficult.

The epistemic status of simulation remains conditional. A simulated trajectory is evidence about the behavior of the model under specified assumptions. It becomes evidence about a target economic system only through an additional argument that the model represents relevant features adequately. Calibration, validation, sensitivity analysis, out-of-sample comparison, qualitative mechanism matching, and robustness checks can strengthen this bridge. The visual plausibility of a simulated pattern is insufficient on its own.

Computational inquiry also includes data-intensive empirical methods. Machine learning can classify, predict, embed, cluster, or detect patterns in large datasets. Natural-language processing can analyze documents and discourse. Network algorithms can identify structural positions or communities. Spatial computation can reveal geographical concentration and accessibility. These methods can extend observational capacity, but the resulting representations inherit the categories, sampling processes, missingness, labels, and objectives of the data-generating system.

For GRE, computational representation can itself become an object of inquiry. A credit score, recommendation model, allocation algorithm, or generative AI system does not merely describe an economic field; once used operationally, it can alter access, visibility, bargaining power, subject classification, and future data. The computational model can therefore enter the generative relation it represents. Researchers may need to study both model performance and the feedback through which deployment changes the target system.

Computation can further support exploratory work under ontological uncertainty. Researchers can test several network boundaries, alternative state representations, or competing mechanisms and examine which are robust to changes in specification. Such exploration is valuable if it is reported transparently and distinguished from confirmatory inference. Computational flexibility increases the importance of documenting choices because many plausible pipelines can yield different apparent structures.

GRE therefore welcomes computational inquiry without treating computation as a substitute for theory, meaning, causality, or normative judgment. Its contribution lies in extending what can be represented and explored while maintaining explicit links among algorithm, data, modeled object, and warranted conclusion.

3.10.9 Normative Inquiry

Normative inquiry evaluates economic arrangements, relations, processes, or interventions according to articulated standards of value, justice, participation, capability, harm, responsibility, freedom, sustainability, or other justified criteria. GRE requires this mode because generativity is not intrinsically beneficial. A relation can generate wealth and dependency, knowledge and exclusion, capability and ecological damage, trust and vulnerability, innovation and concentration. Description of generation therefore cannot settle whether the generated configuration is desirable.

Normative inquiry begins by making the evaluative standard visible. A study may evaluate distribution, procedure, recognition, participation, capability, rights, ecological integrity, intergenerational effects, or the preservation of future options. These standards can converge in some cases and conflict in others. GRE does not resolve such conflict by assuming that all values can be converted into a common metric. Monetary valuation, utility, capability, rights, and relational goods can each illuminate different dimensions while leaving remainders that resist equivalence.

The distinction between generated value and generated harm is central. An intervention that expands productive capacity can simultaneously concentrate decision authority. Infrastructure can increase mobility while displacing communities. A platform can create new forms of participation while producing surveillance or depen-

dency. Normative inquiry therefore follows the distribution and conversion of effects across subjects, scales, and time rather than assigning the entire process a single positive or negative label from one immediate outcome.

Participation matters both instrumentally and intrinsically. Subjects affected by an intervention may hold knowledge unavailable to designers, making participation epistemically valuable. Participation can also constitute recognition and agency rather than merely improve technical outcomes. Yet participation itself varies in form and power. Consultation, veto authority, co-design, ownership, and self-governance are not equivalent. GRE can therefore examine the relational structure of participation rather than treating its nominal presence as sufficient.

Normative inquiry also addresses capability and future generativity. An arrangement can be evaluated partly by how it changes subjects' capacities to act, learn, cooperate, exit, contest, or generate further value. This future-oriented criterion does not imply that more capability is always better or that every option must be preserved. Some capabilities are harmful, and institutional commitments often require selective closure. The normative problem concerns which capacities are expanded or foreclosed, for whom, under what justification, and with what possibilities for revision.

Evaluation must remain historically and contextually responsive. Normative concepts can have general aspirations while their application depends on institutions, technologies, ecological conditions, and available alternatives. Standards themselves can also be criticized and revised through new knowledge or previously excluded perspectives. GRE therefore treats normative inquiry as reasoned and contestable rather than as a final scoring procedure appended after positive analysis.

The mode remains analytically distinct from empirical explanation even when the two interact. Evidence can show who is harmed, which capacities change, or how participation is distributed. It cannot by itself determine how conflicting claims should be weighted. Conversely, normative arguments that ignore empirical mechanisms can recommend interventions that reproduce the very harms they seek to address. GRE joins the modes through mutual constraint while preserving the distinction between what occurs and how it ought to be evaluated.

3.10.10 Intervention-Oriented Inquiry

Intervention-oriented inquiry asks how knowledge can inform deliberate attempts to alter a relational configuration, its generative conditions, or the processes through which future outcomes are produced. It is distinct from normative inquiry because deciding that a condition is undesirable does not establish how it can be changed. It is also distinct from causal inquiry because estimating the effect of one intervention does not by itself provide a complete strategy for governance under changing conditions.

A GRE intervention begins with diagnosis. The researcher or practitioner identifies the relevant relations, subjects, constraints, capacities, value flows, representations, and scales. The intervention target may be an allocation, a rule, an infrastructure, a relation among organizations, an information environment, a participation mechanism, or a field condition that makes certain actions easier or harder. This breadth allows GRE to consider interventions that modify generative conditions rather than

only redistribute final outputs.

Intervention design then requires an explicit theory of change. Which relation is expected to change? Through what mechanism? Which subjects can respond? Which enabling conditions are required? What downstream pathways are anticipated? Which unintended effects are plausible? At what time horizon should evaluation occur? These questions prevent "relational intervention" from becoming a vague label for any complex policy.

Field-oriented intervention is one important possibility. Instead of specifying a single terminal outcome, governance can alter conditions under which desirable forms of generation become more feasible. Open standards can lower barriers to entry; public infrastructure can expand capability; rights can protect participation; information systems can make harms visible; funding structures can diversify inquiry; modular regulation can preserve reversibility. Such approaches remain interventions with distributive and political consequences even when they do not centrally prescribe final behavior.

Intervention-oriented inquiry also requires feedback. Economic systems respond to policy, and subjects can adapt strategically or creatively. An initially effective rule can become ineffective after behavior changes. A subsidy can create dependence; a measurement target can be gamed; a new right can generate institutional innovation; an infrastructure can enable uses that designers did not anticipate. GRE therefore treats monitoring and revision as part of intervention rather than as post hoc maintenance.

Reversibility and repair deserve explicit attention. Some interventions are easy to modify, while others create sunk costs, legal entitlements, ecological damage, technical lock-in, or institutional dependencies. An intervention that transforms generative conditions can make later reversal difficult even if the original allocation was modest. Design can therefore consider exit, rollback, sunset, compensation, remediation, and mechanisms for affected subjects to challenge or revise the arrangement.

Intervention-oriented inquiry is necessarily ethical and political. Choosing what to change, whose capacities to expand, which risks to accept, and which alternatives to close involves normative judgment and distributions of authority. Technical sophistication cannot remove these questions. What GRE can contribute is a disciplined account of how proposed interventions enter relational fields, how their effects propagate beyond immediate recipients, how they alter future capacities and constraints, and how governance can remain responsive to evidence and contestation.

The ten modes distinguished in this section are therefore complementary ways of making GRE's research programme operational. Descriptive inquiry establishes configurations; explanatory inquiry identifies mechanisms; historical inquiry reconstructs formation; comparative inquiry tests variation and plurality; interpretive inquiry recovers meaning and symbolic mediation; causal inquiry disciplines attribution; formal inquiry clarifies explicit structures; computational inquiry extends representation and exploration; normative inquiry evaluates consequences and arrangements; and intervention-oriented inquiry connects analysis to deliberate change. Their combination is problem-dependent rather than fixed.

Methodological plurality, however, requires epistemic discipline. Combining

modes does not automatically produce stronger knowledge if their assumptions, evidential statuses, and inferential limits remain implicit. The next constitutional task is therefore to state the commitments that govern how GRE moves among these modes: ontological suspension, partial observation, distinction between relation and representation, explicit boundary and scale selection, mechanism-sensitive attribution, historical dependence, methodological pluralism, revisability, and epistemic humility.

3.11 Epistemic Commitments of GRE

The methodological plurality established in the preceding section creates a further constitutional requirement. If Generative Relational Economics permits descriptive, historical, interpretive, causal, formal, computational, normative, and intervention-oriented inquiry, it also requires standards governing how claims move across those modes and how uncertainty is represented. Methodological plurality without epistemic discipline can produce a collection of incompatible assertions whose evidential status remains unclear. The role of this section is therefore to state the principal epistemic commitments that constrain GRE inquiry across methods and domains. Its objective is neither to supply a complete philosophy of science nor to impose a single theory of knowledge. It instead specifies a working discipline for research conducted under relational complexity, historical change, partial observability, heterogeneous forms of evidence, and revisable analytical categories.

The commitments are organized around nine requirements: ontological suspension, acknowledgment of partial observation, separation of relation from representation, explicit boundary and scale selection, mechanism before unwarranted attribution, historical and contextual dependence, methodological pluralism, revisability of analytical categories, and epistemic humility. They are mutually reinforcing. Ontological suspension restrains the conversion of useful models into premature metaphysical claims. Partial observation prevents the observed record from being equated with the whole relational configuration. Distinguishing relation from representation keeps measurements, categories, graphs, narratives, and models analytically separate from the processes they represent. Explicit boundary and scale selection makes exclusions visible. Mechanism disciplines attribution. Historical dependence limits the portability of claims across contexts and periods. Methodological pluralism allows different forms of evidence to correct one another. Revisability makes the analytical vocabulary responsive to changing objects and evidence. Epistemic humility calibrates the strength of conclusions to the scope of their warrant.

These commitments do not require a researcher to remain permanently agnostic about every substantive question. GRE can make strong empirical or theoretical claims when evidence, design, and argument justify them. The commitments instead determine what must be shown before such strength is warranted. A causal estimate obtained from a credible design can support a bounded causal claim. A historically reconstructed mechanism can support an explanation when the documentary and comparative record is sufficiently strong. A formal theorem can establish consequences within a defined model. A normative argument can defend criteria un-

der stated premises. Epistemic restraint does not weaken inquiry; it clarifies where the force of a conclusion comes from and which transformations of the claim would exceed the evidence that supports it.

The same discipline is particularly important because GRE studies processes that may alter the categories through which they are observed. A platform can reorganize what counts as work, a legal reform can alter the recognized economic subject, an accounting standard can change what becomes economically visible, an artificial system can redistribute capacities among human and organizational actors, and a governance intervention can transform the relations that later measurements attempt to describe. In such settings, the research object and the research representation can co-evolve. GRE therefore requires epistemic commitments that are compatible with historical transformation rather than assuming a permanently fixed ontology, vocabulary, or observation regime.

3.11.1 Ontological Suspension

Ontological suspension is the first epistemic commitment because GRE deliberately works with heterogeneous representations of economic reality. An inquiry may describe persons, organizations, institutions, flows, relations, fields, trajectories, networks, states, constraints, events, capacities, or symbolic objects. Each representation can disclose features that another suppresses. GRE therefore withholds claims about the ultimate ontological status of these objects unless the local inquiry requires such a claim and adequate argument is available.

Ontological suspension does not imply that nothing exists independently of description, nor does it reduce inquiry to arbitrary perspectivism. It is a methodological restraint concerning the relation between analytical usefulness and metaphysical conclusion. Treating a firm as an entity can be economically useful because the firm has relatively stable legal, organizational, accounting, and decision-making properties. Treating the same firm as a nexus of contracts, a field of authority, a network of relations, a bundle of productive capacities, or a historical process can also be useful for other questions. The availability of several productive representations does not by itself decide which description identifies the firm's final or most fundamental mode of being.

This suspension is especially important when scientific formalisms are transferred into economic analysis. A state space can organize possible configurations without proving that the economy literally consists of points in a pre-given mathematical space. A network model can represent relations without proving that node and edge ontology is fundamental. A field representation can model distributed conditions without establishing a physical field ontology for social life. An agent-based model can operationalize actors without settling the philosophical status of agency. GRE treats such formalisms as analytical constructions whose adequacy depends on the question, assumptions, empirical correspondence, and explanatory gain.

The commitment also protects inquiry against premature reduction. Economic value need not be reduced to price because price is measurable. Institutional recognition need not be reduced to individual preference because choice data are available. Collective capacities need not be reduced to the sum of personal attributes when orga-

nizational relations contribute to what can be done. Conversely, relational language does not license the reduction of entities to relations in every context. Relational constitution and relative entityhood can coexist at different scales and for different purposes.

Ontological suspension therefore supports a layered practice of commitment. GRE can commit locally to an operational ontology for a study: it may define firms, households, algorithms, jurisdictions, or communities as analytical units and proceed rigorously within that specification. The suspension concerns the elevation of that local choice into a universal claim. A representation is adequate when it supports warranted inquiry into the relevant mechanism or phenomenon; it becomes ontologically overextended when its convenience is treated as proof that excluded dimensions are unreal or insignificant.

This commitment also preserves the possibility of theoretical correction. New evidence can reveal that an apparently stable entity is internally heterogeneous, that a presumed relation is mediated by an unobserved institution, or that a category formerly treated as natural is historically contingent. GRE should permit the analytical ontology to change with the inquiry rather than defend the initial representation merely because it was useful at an earlier stage. Ontological suspension is thus not indecision. It is a discipline of keeping the strength of ontological claims proportionate to the work they actually perform.

3.11.2 Partial Observation

GRE assumes that economic observation is structurally partial. Researchers encounter traces, measurements, classifications, documents, transactions, interviews, images, records, behavioral outputs, and other manifestations of processes rather than an exhaustive presentation of the processes themselves. This partiality is not a temporary defect that disappears once sufficiently large datasets are obtained. Even abundant observation remains conditioned by what can be recorded, which categories are used, which events become legible, which populations are included, and which temporal or relational scales are accessible.

Partial observation has several forms. Some variables are simply unobserved. Others are observed through proxies whose validity depends on context. Some relations leave weak administrative traces. Informal activity may be systematically missing from official records. Household labor can remain economically consequential while being absent from market transactions. Platform data can be highly granular while revealing little about off-platform constraints. Historical archives can preserve institutional voices more consistently than marginalized ones. A sensor system can continuously observe behavior while remaining unable to identify meaning or motive. The volume of evidence therefore does not determine its completeness.

The relational character of GRE makes this issue especially consequential. Observing an individual without observing relevant relations can produce a misleading description of capacity, constraint, or choice. A worker's income does not fully disclose bargaining power, household obligations, visa dependence, care responsibilities, access to infrastructure, or exposure to algorithmic evaluation. A firm's balance sheet can omit the public infrastructures, ecological dependencies, cultural resources, or

community relations that condition production. A policy's administrative beneficiary list can omit subjects affected through prices, labor markets, household relations, ecological effects, or institutional precedents.

Partial observation also has a temporal dimension. Data may capture a process after important generative events have already occurred. Current inequality can reflect earlier institutional selections that are no longer directly visible. An observed preference can be the result of prior adaptation, exclusion, learning, or habituation. A stable relation may have emerged from a sequence of contingencies that cross-sectional evidence cannot recover. GRE therefore distinguishes observing a current configuration from knowing the history that generated it.

The commitment to partial observation changes how evidence is reported. Missingness, measurement error, selection, proxy construction, archival survival, model dependence, and unobserved mediation should be treated as substantive features of the epistemic situation rather than technical footnotes. A study need not solve every limitation, but it should identify those that materially affect interpretation. When evidence supports only a restricted claim, the claim should remain restricted.

Partiality also motivates triangulation without turning triangulation into automatic confirmation. Different evidence sources can compensate for different blind spots. Administrative data may establish distributional patterns; interviews can identify mechanisms or meanings absent from records; archival sources can reconstruct institutional change; ethnography can reveal enactment; experiments can isolate effects under constrained conditions; computational traces can show large-scale patterns. Agreement among these sources can strengthen confidence, while disagreement can reveal that they are observing different layers of the process.

GRE therefore treats observability as part of the economic and institutional environment. What becomes observable can itself be shaped by law, technology, organizational incentives, classification systems, and power. Some actors can make their activities legible while others remain invisible; some institutions can require reporting; some platforms can monopolize data; some harms appear only after measurement categories are created. Observation is consequently both an epistemic relation and, in many settings, an object of economic analysis.

3.11.3 Distinction between Relation and Representation

GRE distinguishes the relations under study from the representations through which those relations become analytically accessible. A representation can be a variable, category, graph, matrix, equation, narrative, map, model, legal classification, accounting entry, database schema, or visual diagram. Each representation selects and organizes features of a target domain. None should be treated as identical to the relation merely because it is useful for describing it.

This distinction is fundamental to relational inquiry because representations can create an appearance of precision that exceeds their empirical warrant. A network edge can encode communication, ownership, authority, trust, exchange, co-membership, or inferred association. Two edges of identical graphical form can represent substantively different relations. A weight attached to an edge may record frequency, monetary value, probability, distance, or a model-derived score. The

mathematical object is therefore interpretable only through the measurement and theoretical decisions that produced it.

The same issue appears in categorical and institutional representations. A legal category can stabilize a relation for governance without exhausting its social meaning. An accounting classification can make a form of value visible while excluding others. A survey category can facilitate comparison while compressing heterogeneous experiences. An algorithmic score can summarize observed correlates while becoming institutionally consequential through decisions made on its basis. Representation can therefore both describe relations and participate in their transformation.

GRE consequently requires researchers to specify the mapping between representation and target. If "trust" is represented by repeated cooperation, the inferential gap should be stated. If "power" is represented by network centrality, the mechanism connecting centrality to power must be argued rather than assumed. If a latent variable is used to summarize capability, the construction and interpretation of that variable should remain visible. If text embeddings represent semantic similarity, similarity in the model space should not automatically be equated with shared meaning among subjects.

This distinction also protects formal analysis from reification. A model can derive properties of a representation with complete mathematical rigor while leaving open whether the represented mechanism is empirically operative. Computational sophistication cannot bridge that gap by itself. A simulation result is a consequence of a model and its parameterization. It becomes evidence about an empirical target only through validation, calibration, comparison, and argument connecting the representation to observed processes.

Representations can nevertheless become economically real in a second sense: actors may respond to them. Credit scores, rankings, performance indicators, ratings, risk categories, forecasts, and accounting metrics can alter behavior and resource allocation. The fact that a representation becomes causally consequential does not erase the distinction between representation and relation; it creates an additional relation in which the representation enters the system it describes. GRE should then study both its descriptive adequacy and its performative effects.

Maintaining this distinction enables stronger rather than weaker modeling. It allows researchers to use abstraction aggressively while keeping track of what has been abstracted. A representation can be deliberately narrow if the local question is narrow. The epistemic requirement is transparency concerning what the representation contains, what it excludes, how it was constructed, and which claims can legitimately be inferred from it.

3.11.4 Explicit Boundary and Scale Selection

Every GRE inquiry selects a boundary and scale. The selection determines which entities, relations, periods, jurisdictions, infrastructures, ecological conditions, and forms of value enter the analysis. Because GRE often studies effects that propagate beyond administrative recipients or immediate transactions, boundary selection is an epistemic decision with direct consequences for what can be observed and explained.

A boundary is never justified merely by being available in the data. Firm-level data encourage a firm boundary; household surveys encourage a household boundary; national statistics encourage a national boundary. These sources can be appropriate, but the research question may require a different relational domain. A wage change can affect households, local demand, public revenue, migration, or subcontracting. A technological intervention can change organizational workflows, professional identities, educational demand, and infrastructural dependence. An ecological extraction can produce effects beyond the jurisdiction in which economic value is recorded. The boundary should therefore be selected in relation to the mechanism under investigation.

Scale selection poses a related problem. The individual, organization, community, institution, ecosystem, and transnational system are not simply nested containers with fixed causal priority. A process that appears exogenous at one scale can become endogenous at another. An organizational rule can constrain an individual while being generated by industry regulation, professional norms, or platform infrastructure. A national policy can appear autonomous until cross-border capital, legal regimes, or supply chains are included. GRE requires the researcher to state which scale is analytically primary and which cross-scale effects are being omitted or modeled.

Explicit selection does not require maximal expansion. The widest possible system boundary is rarely the most useful. Expanding a model can reduce identification, tractability, interpretability, or evidential quality. A bounded inquiry can be superior when the excluded relations are unlikely to alter the conclusion materially. GRE therefore favors justified boundaries rather than maximal boundaries. The researcher should explain why the chosen domain is sufficient for the claim and identify plausible pathways through which excluded relations could matter.

Temporal boundaries require equal attention. A programme evaluated after six months may appear successful while longer-term dependency, capability formation, institutional learning, or ecological cost remains unobserved. Conversely, a long historical window can obscure short-run mechanisms by aggregating distinct institutional regimes. The relevant temporal scale depends on the generation process being studied. Some effects are immediate; others emerge through accumulation, threshold crossing, learning, reproduction, or delayed conversion.

Boundary and scale choices can themselves be politically consequential. Administrative categories define who counts as a beneficiary, employee, resident, household member, owner, victim, or stakeholder. Jurisdictional boundaries determine which costs enter public accounting. Corporate boundaries can externalize labor or ecological relations into subcontracting and supply chains. GRE therefore examines not only the researcher's boundary but also the boundaries through which economic actors and institutions organize responsibility and visibility.

The epistemic commitment is straightforward: boundary and scale should be stated, defended, and revisable. Where conclusions are sensitive to alternative boundaries, that sensitivity is part of the result. A claim that survives reasonable changes in scale has different epistemic status from one that depends on a narrow administrative frame. GRE treats this sensitivity as informative rather than embarrassing because it reveals where economic descriptions are relationally contingent.

3.11.5 Mechanism before Unwarranted Attribution

GRE is interested in generation, propagation, conversion, subject formation, power, orientation, and structural transformation. These concepts can become excessively expansive if they are used to attribute every downstream difference to an initial relation. The fifth epistemic commitment therefore requires mechanism before unwarranted attribution. A relational association or temporal sequence becomes a generative claim only when the study provides a defensible account of how the earlier configuration contributed to the later one.

Mechanism can take different forms. It may involve incentives, authority, learning, information, legal recognition, technological affordances, resource transfer, network diffusion, social interpretation, institutional reproduction, ecological feedback, or strategic adaptation. The relevant mechanism can be probabilistic rather than deterministic and can operate jointly with other causes. GRE does not require a single universal mechanism of generation. It requires the mechanism invoked in a particular explanation to be specified sufficiently that evidence could distinguish it from plausible alternatives.

This standard is especially important for relational language. A relation between two actors does not automatically explain an outcome merely because the actors are connected. Network position, for example, can matter through access to information, bargaining leverage, reputational visibility, control of brokerage, exposure to contagion, or institutional authority. Different mechanisms can produce similar network patterns. A claim about the economic significance of structure therefore requires more than descriptive topology.

The same discipline applies to power. Persistent asymmetry is relevant to power, but asymmetry alone does not establish the mechanism through which one actor constrains another's options, shapes rules, controls resources, determines classifications, or alters future generative conditions. GRE should identify how asymmetry becomes actionable. Ownership rights, legal authority, infrastructure dependence, agenda control, data access, financial leverage, or control over recognition may provide such mechanisms. Where the pathway remains uncertain, the claim should be framed as a hypothesis rather than a conclusion.

Mechanism also disciplines claims about value conversion. If educational participation is said to generate social capital, which interactions produce continuing relations? If trust is said to generate economic cooperation, what institutional or experiential processes stabilize expectations? If cultural recognition is said to improve economic capability, through which access, motivation, legitimacy, or network pathways does the conversion occur? Naming the initial and final categories is insufficient; the transformation between them is the object that requires explanation.

This commitment does not imply that every GRE study must identify a complete micro-mechanism. Some phenomena are best explained at organizational, institutional, or ecological scales. A legal rule can have a causal effect without being reduced to individual psychology. A market design can alter incentives without reconstructing every subjective deliberation. Mechanistic adequacy is scale-relative. The requirement is that the explanatory link be more specific than a retrospective association and that the proposed pathway fit the level at which the claim is made.

Mechanism before attribution also protects normative analysis. Harm should not be assigned to a particular actor or intervention merely because the harm occurred within a broader relational system. Responsibility can be distributed, mediated, historically inherited, or structurally reproduced. Normative attribution may therefore require a separate analysis of control, foreseeability, benefit, capacity, institutional role, and available alternatives. GRE's relational orientation expands the field of possible responsibility while simultaneously requiring greater care in attributing it.

3.11.6 Historical and Contextual Dependence

GRE treats economic categories, mechanisms, and regularities as potentially dependent on historical and institutional context. This commitment follows from the earlier chapters' emphasis on changing productive relations, subject forms, technologies, norms, legal categories, and value structures. A relation that operates in one institutional environment may change meaning or effect in another. Historical and contextual dependence therefore constrains generalization without eliminating the possibility of general knowledge.

Context dependence can enter through mechanisms. Credit can expand productive capacity in one institutional setting and reinforce dependence in another. Informal networks can provide resilience where formal systems are weak while reproducing exclusion where membership is restrictive. Algorithmic evaluation can reduce some forms of discretion while creating new informational asymmetries and dependencies. A cooperative structure can enable collective control under supportive legal and financial conditions yet remain marginal under a regime that withholds access to capital or procurement. The nominal form of a relation therefore does not uniquely determine its generative effects.

Historical dependence also affects categories. The economic meaning of "worker," "firm," "household," "property," "skill," "platform," or "currency" is shaped by institutional arrangements that change over time. A category can retain its name while the relations that constitute it transform. GRE should therefore avoid treating administrative continuity as proof of substantive continuity. Historical reconstruction can be necessary even when contemporary data appear precise.

The commitment does not require every proposition to be historically unique. Recurrent mechanisms can be identified across cases, and comparative analysis can reveal robust patterns. The epistemic task is to specify the domain of portability. A mechanism may generalize across institutional settings under identifiable conditions; a formal model may describe a family of processes; a causal effect may transport when relevant effect modifiers are sufficiently similar. GRE therefore distinguishes universalizing language from conditional generalization.

Context dependence also concerns meaning. Economic actors interpret rules, resources, risks, and opportunities through historically situated symbolic and normative frameworks. The same monetary transfer can signify compensation, obligation, charity, recognition, debt, or entitlement in different settings, with different relational consequences. Interpretive evidence can therefore be necessary when the mechanism depends on how actors understand the relation.

The historical commitment extends to the researcher's categories and methods.

Measures calibrated in one period can lose validity as institutions change. A proxy for employment stability can fail when contractual forms transform. A model of media attention can become obsolete after a platform redesign. A measure of technological capability can change meaning as complementary infrastructures diffuse. GRE should treat measurement regimes as historically situated rather than assume that a stable variable label guarantees stable construct validity.

This commitment encourages temporal comparison and repeated evaluation. A finding can be valid for the period studied and later require revision because the object changed. Such revision does not necessarily invalidate the earlier research; it can reveal the historical conditions under which the earlier claim held. GRE therefore regards the temporal domain of a claim as part of its specification.

3.11.7 Methodological Pluralism

Methodological pluralism is an epistemic commitment because no single method has privileged access to every aspect of a generative relational process. Quantitative estimation, qualitative interpretation, historical reconstruction, formal modeling, computational simulation, comparative analysis, experiments, ethnography, archival work, network analysis, and participatory methods each make some features more visible and others less so. GRE therefore treats methods as differentiated instruments of inquiry whose adequacy depends on the claim being made.

Pluralism differs from methodological eclecticism without standards. The presence of several methods does not strengthen a study automatically. Each method must contribute an identifiable epistemic function. A qualitative study can identify mechanisms and meanings that guide quantitative measurement. A quantitative design can estimate the distribution or magnitude of an effect suggested by qualitative evidence. Historical analysis can reveal institutional transitions that make a cross-sectional association intelligible. Formal modeling can clarify whether a proposed mechanism is internally coherent. Simulation can explore trajectories under specified assumptions. Their combination is valuable when the outputs constrain or inform one another.

Pluralism also means that methodological disagreement can be productive. If administrative data indicate improved employment while interviews reveal increased insecurity, the discrepancy may reflect different populations, time horizons, definitions, or dimensions of the outcome. GRE should investigate the divergence rather than force immediate convergence. Different methods can reveal multiple aspects of a heterogeneous value structure or relational configuration.

No hierarchy follows automatically from formal precision. Mathematical and computational methods can make assumptions explicit, derive implications, and handle complexity that prose alone cannot. Their precision concerns the representation once specified. Empirical relevance still depends on the quality of the mapping between model and target. Conversely, qualitative richness does not eliminate the need for disciplined inference. Interpretive accounts require transparent evidence, plausible alternatives, and attention to scope. Historical narratives require source criticism. Normative arguments require defensible premises. Methodological pluralism therefore expands the repertoire of rigor rather than relaxing it.

The commitment also preserves compatibility with established economics. GRE does not require replacing econometrics, experiments, equilibrium analysis, mechanism design, industrial organization, public economics, labor economics, or other established approaches when they answer the relevant question well. A GRE inquiry can incorporate these methods and add relational or generative analysis where it materially changes explanation. Pluralism includes the possibility that the best answer to a bounded question is supplied by an existing method without specifically GRE additions.

Pluralism has institutional implications for research design. Data infrastructures, publication norms, disciplinary training, and funding systems often privilege some evidence types over others. A research programme that studies heterogeneous relational processes must resist converting institutional convenience into epistemic hierarchy. This does not mean every project must be interdisciplinary. It means that exclusions among methods should be justified by the question rather than inherited uncritically from disciplinary boundaries.

The strongest form of methodological pluralism in GRE is mutual corrigibility. Formal models can expose ambiguity in conceptual claims. Historical evidence can show that apparently universal categories are contingent. Qualitative evidence can reveal omitted mechanisms. Causal designs can challenge compelling narratives. Computational models can test whether proposed local rules produce the claimed system-level pattern. Normative analysis can reveal that an empirically efficient intervention depends on contested evaluative premises. Methods become part of a common research programme when they can correct one another without being forced into a single epistemology.

3.11.8 Revisability of Analytical Categories

GRE treats its analytical categories as revisable. Relation, subject, value, capacity, institution, field, constraint, trajectory, generativity, and power are working concepts whose definitions should become more precise through research. The commitment to revisability follows from ontological suspension and historical dependence: if the objects of inquiry can change and if different representations disclose different aspects of them, then the vocabulary of the research programme cannot be permanently fixed at its founding stage.

Revisability does not imply conceptual looseness. A study should define its categories precisely enough to support inference. The revision occurs when evidence, theoretical contradiction, cross-case comparison, or improved formalization shows that the existing category fails. The relevant distinction is between local precision and global finality. GRE can use a precise operational definition while remaining open to revising that definition in later research.

Category revision can take several forms. A category can be subdivided when previously hidden heterogeneity becomes important. Several categories can be combined when distinctions prove analytically unproductive. Boundaries can change when new relations become visible. A category can move from exogenous condition to endogenous object of inquiry. A variable treated as an attribute can be reconceptualized as relationally generated. A representation can be abandoned if it systemat-

ically misclassifies the phenomenon.

Economic subjecthood provides one example. A research programme built exclusively around human individuals would be strained by organizations, automated systems, collective entities, or hybrid arrangements that make economically consequential selections. Expanding the category of operational economic subject can improve analysis, but that revision need not erase distinctions concerning consciousness, personhood, legal standing, or moral status. Revisability allows the category to change while preserving distinctions that remain normatively or empirically necessary.

Value provides another example. Price can remain a central economic representation of value without exhausting the relevant evaluative or relational phenomena. Research can discover forms of value whose realization depends on access, recognition, participation, ecological capacity, institutional continuity, or future capability. Revising the analytical vocabulary to capture these forms does not require treating them as commensurable or collapsing them into a single metric.

Revisability also applies to GRE itself. Concepts introduced in this book are provisional elements of a research programme rather than protected doctrine. Later empirical work may show that some distinctions are unproductive, that other concepts are missing, or that the framework overstates the usefulness of generative analysis in particular domains. A research programme becomes cumulative not by preserving every founding category but by creating procedures through which categories can be criticized, compared, refined, and replaced.

This commitment places a burden on documentation. When categories change across studies or over time, researchers should record how definitions differ and why. Conceptual drift can otherwise appear as empirical change. GRE therefore favors transparent conceptual provenance: the history of a category's operationalization is part of the knowledge needed to compare results.

3.11.9 Epistemic Humility

Epistemic humility is the concluding commitment because it governs the relation among all the preceding ones. It requires the strength, scope, and precision of a claim to remain proportionate to the evidence and argument that support it. Humility does not require weak conclusions where strong conclusions are justified. It requires researchers to distinguish what has been observed from what has been inferred, what has been modeled from what has been validated, what is locally supported from what is generalized, and what is normatively defended from what is empirically established.

In relational economic inquiry, overstatement can arise easily because the studied systems are interconnected. Once a downstream effect is observed, it is tempting to narrate a complete chain of generation. Once a network pattern appears, it is tempting to attribute power or influence. Once a simulation reproduces a stylized fact, it is tempting to treat the mechanism as confirmed. Once an intervention succeeds locally, it is tempting to generalize it across contexts. Epistemic humility interrupts these moves by requiring an explicit account of the inferential bridge.

Humility also concerns uncertainty that cannot be reduced to a probability es-

timate. Researchers can face model uncertainty, category uncertainty, boundary uncertainty, interpretive disagreement, historical incompleteness, unknown unknowns, or normative pluralism. Quantification is valuable when a defensible probability model exists, but not every epistemic limitation is probabilistic. GRE therefore permits qualitative statements of uncertainty where numerical precision would be misleading.

The commitment is especially important for intervention. Application-dominant praxis often requires action before knowledge is complete. Epistemic humility does not imply inaction under uncertainty. It changes how intervention is designed: assumptions are made explicit, monitoring is built in, reversible steps are preferred where feasible, affected subjects retain opportunities for contestation, and the intervention is treated as a source of new evidence rather than the execution of a final truth. Learning and governance become coupled.

Humility also requires attention to the distribution of epistemic authority. Researchers, administrators, firms, communities, workers, users, and affected populations can possess different forms of knowledge. Expertise can be real without being total. Local experience can identify mechanisms invisible to aggregate data while remaining limited in scope. Institutional actors can possess operational information while having incentives to frame it selectively. GRE therefore treats disagreement among knowledge holders as an object for analysis rather than assuming that one standpoint has automatic priority across all questions.

This commitment extends to artificial and computational systems. Large models, automated inference, and high-dimensional data can increase the scale and speed of analysis, but they do not eliminate uncertainty concerning data generation, representation, causal identification, normative criteria, or institutional effects. Computational confidence can be numerically precise while remaining epistemically narrow. GRE should therefore distinguish predictive performance from explanatory adequacy, statistical calibration from normative legitimacy, and representational capacity from knowledge of the target process.

Epistemic humility finally concerns the research programme's own historical position. GRE is being constituted under particular contemporary conditions: changing productive relations, computational abundance, new forms of artificial capability, ecological constraints, institutional complexity, and increasing visibility of relational and generative processes. These conditions make the programme plausible and potentially useful; they do not guarantee its enduring adequacy. Future economic forms may require different concepts. Existing theories may explain domains where GRE adds little. Evidence may contradict central hypotheses. The programme should be organized so that such correction is possible without treating revision as failure.

Taken together, the commitments of this section define a disciplined epistemic posture for Generative Relational Economics. GRE can make strong claims, employ sophisticated formalisms, combine diverse evidence, and participate in intervention, but it should do so while suspending unnecessary ontological conclusions, acknowledging partial observation, separating relations from their representations, making boundaries and scales explicit, demanding mechanisms for attribution, locating claims historically, preserving methodological pluralism, revising categories when required, and calibrating confidence to warrant. These commitments prepare the

transition from inquiry to praxis. The following section turns to how GRE moves from explanation and evaluation toward relational diagnosis, generative diagnosis, and intervention under conditions where knowledge remains necessarily incomplete.

3.12 Praxis in Generative Relational Economics

The preceding sections established the objects, scales, questions, analytical perspective, modes of inquiry, and epistemic commitments of Generative Relational Economics. Those elements define how GRE can study economic relations, but a research programme concerned with generative conditions also requires an account of how inquiry can enter practice. The role of this section is to specify a preliminary praxis architecture for GRE: a disciplined way of moving from explanation toward intervention while preserving the epistemic restraints developed above. Its objective is not to provide a universal policy cycle or a general theory of governance. It identifies a recurrent sequence of practical operations through which relational and generative knowledge can inform action under conditions of incomplete knowledge, heterogeneous values, changing environments, and effects that propagate beyond the administratively designated recipient.

GRE praxis begins from a distinction between understanding a system and acting within it. Explanation can identify mechanisms, constraints, distributions, histories, and relational structures, yet intervention changes the very configuration that explanation describes. An intervention can redistribute resources, alter expectations, create or dissolve relations, redefine institutional categories, shift bargaining positions, generate new dependencies, reorganize attention, and modify later capacities for action. Praxis therefore cannot be represented as the simple application of a finished model to a passive target. It is an entry into an evolving relational domain in which the intervention, the affected subjects, the environment, and the relevant knowledge can all change through their interaction.

For that reason, the praxis architecture developed here is iterative. It moves through relational diagnosis, generative diagnosis, identification of constraints and enabling conditions, intervention design, allocation understood as relational intervention, tracing of downstream effects, feedback and revision, adaptive governance, and, where required, withdrawal, reversal, or repair. These operations can overlap, recur, or be entered from different points. They are not a mandatory sequence imposed on every practical problem. Their function is to prevent a narrow intervention logic in which resources are allocated, an immediate output is measured, and wider changes are treated as externalities unless they happen to fit the original administrative frame.

The praxis perspective also preserves the distinction between research-dominant and application-dominant activity. Research-dominant praxis principally seeks improved understanding, even when research design itself changes the studied field. Application-dominant praxis principally seeks to alter an economic or institutional situation under practical constraints. The difference concerns orientation rather than an absolute separation between knowledge and action. Research can generate interventions, and interventions can generate knowledge. GRE therefore treats

praxis as a domain in which explanation, evaluation, experimentation, governance, and learning become coupled while remaining analytically distinguishable.

A further constraint is normative. Generativity is not itself a sufficient criterion of success. An intervention can generate economic activity while deepening dependence, produce capabilities for one group while foreclosing possibilities for another, increase circulation while accelerating extraction, or create institutional stability by suppressing exit and contestation. Section 3.12 therefore develops the architecture of intervention without resolving the normative standards by which generated consequences should be judged. Those standards are taken up in the following section. Here the central concern is more basic: how GRE can intervene without treating either the target of intervention or the intervention's own consequences as fixed in advance.

3.12.1 From Explanation to Intervention

The movement from explanation to intervention is a change in epistemic and practical burden. Explanatory inquiry asks what relations, mechanisms, histories, and conditions contributed to an observed pattern. Intervention asks what may happen if some part of that configuration is deliberately altered. The second question contains the first but adds counterfactual, organizational, ethical, and temporal demands. A mechanism that explains a past outcome may not remain invariant after actors learn about the intervention, institutions adapt, or the distribution of resources changes. GRE therefore resists the assumption that an explanatory model can be converted directly into a policy instrument without re-examining the relations through which the intervention will operate.

A practical intervention enters a field already structured by prior relations. Subsidizing a household, financing a firm, redesigning a public service, opening access to data, changing a legal entitlement, or introducing an artificial system does more than modify one variable. It can alter who interacts with whom, which claims become enforceable, which actions become feasible, whose knowledge becomes authoritative, and which future trajectories become easier to sustain. The intervention should therefore be represented not only by its administrative action but also by the relational changes through which its consequences may be mediated.

This perspective changes the meaning of implementation. Implementation is often treated as the stage in which a previously selected intervention is executed with fidelity. GRE instead treats implementation as an epistemically productive period in which assumptions about relations, mechanisms, and capacities encounter an evolving empirical configuration. Deviations from the original design can indicate administrative failure, but they can also reveal that the initial model omitted relevant actors, constraints, interpretations, or feedback mechanisms. Praxis requires distinguishing avoidable execution error from informative evidence that the intervention theory requires revision.

The transition from explanation to intervention also introduces strategic interaction. Subjects can anticipate policy, resist classification, exploit new opportunities, reorganize coalitions, change reporting behavior, or redirect resources. Organizations can internalize an intervention into routines that differ from its stated purpose. Plat-

forms can redesign interfaces in response to regulation. Beneficiaries can combine an allocation with household, community, or informal resources in ways that produce unanticipated effects. These responses are part of the relational system rather than noise surrounding an otherwise fixed treatment.

GRE therefore favors interventions whose theory of change states at least four elements. First, it identifies the relevant relations through which the intervention is expected to operate. Second, it specifies the generative claim: what capacities, structures, opportunities, constraints, or forms of value are expected to emerge or transform. Third, it states the anticipated temporal and scalar pathways through which effects may propagate. Fourth, it identifies observations that would count against the intervention theory. The resulting design remains provisional, but its provisionality is disciplined rather than vague.

Intervention under uncertainty does not imply paralysis. Many economic and governance problems require action before the relational system is fully known. The practical question is how to make action compatible with learning. GRE therefore gives special weight to staged implementation, monitoring, contestability, modularity, reversible components, and explicit review points where feasible. These features do not eliminate uncertainty. They reduce the cost of discovering that the intervention has altered the field in ways the initial explanation did not anticipate.

3.12.2 Relational Diagnosis

Relational diagnosis identifies the configuration within which the practical problem is constituted. Its purpose is not to produce an exhaustive map of all social relations. It asks which relations are materially relevant to the problem, how they are organized, which boundaries have been selected, and where the apparent administrative object depends on actors or conditions outside that boundary. Diagnosis therefore precedes intervention design because the same nominal problem can require different action when its relational constitution differs.

A relational diagnosis begins by identifying the subjects, organizations, institutions, infrastructures, symbolic systems, and ecological conditions that participate in the relevant economic situation. It then asks how access, authority, recognition, information, resources, obligations, and opportunities are distributed among them. The resulting map may be qualitative, quantitative, historical, network-based, institutional, or mixed. Its adequacy depends on whether it reveals relations that are necessary to understand the practical problem rather than on whether it maximizes representational complexity.

Consider a programme intended to improve employment access. An administrative diagnosis might begin with unemployed individuals and available jobs. A relational diagnosis can reveal additional mechanisms: transportation, childcare, credential recognition, social networks, disability access, hiring intermediaries, platform ranking, visa status, household obligations, employer risk practices, or regional housing costs. These are not automatically the correct variables in every case. Their relevance depends on whether they mediate the conversion of an employment opportunity into an actual capability to obtain and sustain work.

Relational diagnosis also identifies asymmetry. The relevant question is not only

who possesses more resources, but which actors can define categories, set terms of exchange, control infrastructures, impose switching costs, delay decisions, externalize risk, or withdraw without comparable loss. Two actors may exchange voluntarily while facing highly unequal exit conditions. A platform and a small supplier may both be organizations, yet their capacity to redesign the interaction can differ drastically. Diagnosing these asymmetries matters because an intervention that treats formally similar actors as substantively equivalent can reproduce the mechanism that generated the problem.

The diagnosis should also be historical. Present relations can depend on prior institutional settlements, accumulated debts, inherited infrastructures, past exclusions, or sequences of investment that make current alternatives unequally costly. A cross-sectional map can show who is connected to whom while missing why the relation has its present form or why some apparently available alternatives are practically inaccessible. Historical reconstruction helps distinguish a relation that is contingent and readily modifiable from one stabilized by layered commitments and path-dependent investments.

The output of relational diagnosis is therefore a bounded working representation of the practical field. It should make its exclusions visible. No map captures every relation, and an attempt to include everything can make intervention impossible. GRE instead requires an explicit statement of which relations are treated as inside the diagnostic boundary, which are treated as environmental conditions, and which remain uncertain. The map is revisable as intervention reveals previously hidden dependencies.

3.12.3 Generative Diagnosis

Relational diagnosis identifies the configuration; generative diagnosis asks what that configuration tends to produce. The distinction matters because the same relational structure can be significant for different reasons depending on the processes it sustains. A credit relation can generate productive capacity, dependency, reputational effects, data, bargaining power, future borrowing opportunities, or combinations of these. A school can distribute instruction while also generating networks, credentials, expectations, classifications, and future access. A platform can facilitate exchange while generating information asymmetries, behavioral dependence, market visibility, or new organizational capabilities.

Generative diagnosis therefore focuses on transformations rather than only states. It asks what changes because a relation persists, intensifies, weakens, or is removed. The relevant outcomes can include resources, capacities, identities, institutional routines, legal positions, expectations, symbolic categories, ecological conditions, or the ability to enter later relations. This focus is particularly important when immediate outputs are poor proxies for longer-horizon consequences. A grant may be fully disbursed while failing to produce the organizational capacity it was intended to support. A training programme may improve measured skills while weakening participation because the credential is not institutionally recognized. A subsidy may increase adoption while entrenching dependence on a proprietary infrastructure.

The generative diagnosis should distinguish several pathways. Some effects arise

directly from the intervention target. Others are mediated through relations with third parties. Some emerge from feedback: an initial change alters behavior, which changes the environment faced by later participants. Some effects accumulate only after repeated interactions. Others occur through symbolic or classificatory change, where being recognized as eligible, risky, employable, innovative, or compliant modifies later treatment by institutions.

Generative diagnosis also asks what is reproduced. A relational configuration may produce no dramatic new outcome while continually regenerating a distribution of advantage, vulnerability, or access. Stable inequality can be generative in this sense because institutions repeatedly convert initial asymmetries into later opportunities. Conversely, a relation can sustain capabilities that would deteriorate if the relation disappeared. Maintenance, reproduction, and repair are therefore forms of generation when they preserve conditions that require continuing relational work.

A further question concerns foreclosure. Generation can expand possibilities for some actors while reducing the future option set for others or for the same actors at a later time. Infrastructure investment can enable activity while creating technological lock-in. Debt can finance capacity while narrowing future discretion. Standardization can reduce coordination costs while suppressing alternative forms of practice. Generative diagnosis therefore traces both enabling and constraining transformations without assuming that generation is uniformly expansive.

The practical output of generative diagnosis is a set of plausible mechanism pathways linking the relational configuration to changes that matter for the intervention. These pathways can be compared, tested, revised, or ranked by evidential support. GRE does not require every pathway to be fully identified before action. It requires the intervention to state what it expects to generate and why, so that later observations can update rather than merely decorate the original theory.

3.12.4 Identification of Constraints and Enabling Conditions

Diagnosis becomes actionable when it identifies conditions that limit or enable transformation. GRE uses constraint in a broad but disciplined sense: a constraint changes the set, cost, probability, or viability of available transformations without necessarily making an action logically impossible. Enabling conditions operate in the opposite direction by making some transformations more feasible, durable, or accessible. The same condition can constrain one pathway while enabling another.

Constraints can be material, institutional, relational, informational, temporal, symbolic, ecological, or cognitive. A lack of capital is a material constraint, but the ability to use capital may depend on licenses, trusted partners, language access, data, infrastructure, or the timing of payments. A legal entitlement can exist while remaining practically inaccessible because procedural complexity, documentation requirements, or fear of institutional contact limits its use. An organization can possess technical capacity while lacking the authority to deploy it. A community can possess knowledge while lacking channels through which institutions recognize that knowledge as actionable.

The distinction between constraint and symptom is central. Low participation can be treated as a behavioral problem and addressed through incentives, yet the under-

lying constraint may be timing, distrust, inaccessible procedures, reputational risk, or exclusion from the networks through which information circulates. Raising an incentive can improve participation while leaving the deeper constraint unchanged, or it can worsen inequality if only already advantaged actors can respond. Constraint identification therefore asks which conditions actually regulate the transformation pathway relevant to the intervention.

Enabling conditions deserve equal analytical attention. Praxis often becomes overly problem-centered and maps only deficits. Existing trust relations, local organizations, informal knowledge, public infrastructure, legal protections, professional norms, ecological capacities, and mutual-aid practices can already support generation. An intervention that ignores these conditions can displace them with a formal system that appears more legible while being less generatively capable. GRE therefore asks which existing relations should be preserved, strengthened, connected, or left undisturbed.

Constraints and enabling conditions are also scale-relative. A national regulation can constrain an organization while enabling fairer competition across a sector. A household norm can constrain an individual's labor-market participation while enabling care provision that sustains other members. A standardized protocol can constrain local discretion while enabling interoperability. Praxis requires representing these tensions rather than declaring a condition simply enabling or constraining in the abstract.

The identification process should therefore produce intervention points rather than a flat inventory. Some constraints are proximal and modifiable; others are structural conditions that cannot be changed within the intervention horizon. Some enabling conditions can be activated with modest resources; others require institutional reform. Distinguishing these categories helps prevent designs that target visible but weakly generative variables while leaving the mechanisms of exclusion or capacity formation intact.

3.12.5 Intervention Design

Intervention design translates diagnosis into a provisional configuration of actions, resources, institutions, and learning procedures. GRE does not require a distinctive policy instrument. Taxes, transfers, public investment, regulation, organizational redesign, information provision, infrastructure, standards, cooperative arrangements, educational programmes, platform rules, procurement, or combinations of these can all be compatible with GRE. What distinguishes the praxis perspective is how the intervention is specified: in relation to mechanisms, downstream generation, scale, feedback, and revisability.

A GRE intervention should first identify its operative target. The target can be a resource constraint, a relation, a conversion mechanism, an institutional rule, a boundary, a feedback loop, an information structure, or an enabling condition. Target clarity matters because interventions with the same administrative recipient can act through different mechanisms. A cash transfer and a childcare service may both support household economic participation, but they alter different constraints and relational structures. Their effects should not be inferred from the shared identity of

the recipient.

Second, intervention design should distinguish the intended immediate change from the intended generative effect. Providing equipment is an immediate allocation. Developing a durable productive capacity may be the generative objective. Changing a regulation is an immediate institutional act. Increasing entry, reducing dependency, or enabling new organizational forms may be the intended downstream effect. This distinction makes it possible to observe successful implementation together with failed generation, or imperfect implementation together with unexpected generative benefits.

Third, design should state relevant temporal horizons. Some interventions seek rapid stabilization; others seek capacity formation whose effects appear slowly. A short evaluation window can misclassify a long-horizon intervention as ineffective or reward interventions that produce immediate outputs by drawing down future resources. GRE therefore encourages explicit differentiation among immediate, intermediate, and longer-horizon effects without assuming that longer is always better.

Fourth, intervention design should anticipate heterogeneity. Subjects differ in resources, vulnerabilities, interpretation, institutional status, and ability to convert an allocation into later capacity. Uniform provision can therefore generate unequal outcomes. The design question is not necessarily to individualize every intervention, which can become administratively costly or intrusive. It is to identify forms of heterogeneity that are mechanism-relevant and to determine whether adaptive, tiered, or plural pathways are needed.

Fifth, design should include learning architecture. Monitoring variables, qualitative feedback, review intervals, stop conditions, and procedures for incorporating affected participants should be established before implementation where possible. This prevents evaluation from becoming an after-the-fact search for favorable indicators. It also recognizes that some of the most important effects may be discovered only after the intervention enters the field.

Intervention design in GRE is therefore closer to constructing a revisable relational hypothesis than to selecting a fixed treatment. The design states what is being changed, through which relations, toward which generative effects, under which assumptions, across which scales and time horizons, and with what procedures for detecting error. The resulting intervention can still be administratively simple. Analytical sophistication does not require operational complexity when the mechanism is clear.

3.12.6 Allocation as Relational Intervention

Allocation is a central economic operation, but GRE treats allocation as the beginning of a relational process rather than its endpoint. Money, time, attention, infrastructure, rights, data access, institutional recognition, expertise, or productive assets enter existing relations when allocated. Their consequences depend on conversion conditions, obligations, expectations, complementary resources, and the position of the recipient within wider structures.

This perspective changes the unit of practical analysis. A transfer to an individ-

ual may affect a household, landlord, creditor, employer, local market, or platform through expenditure, bargaining, debt repayment, mobility, or information. Funding an organization can change its internal authority, external partnerships, reputational standing, and future ability to attract resources. Granting data access can create research capacity while redistributing informational advantage. Allocation therefore changes relations even when the formal instrument is directed to a discrete recipient.

Relational allocation does not mean that every allocation must be socially conditioned or collectively administered. Direct individual transfers can be valuable precisely because they reduce dependence on gatekeepers. The analytical point is that the intervention should ask what relations the allocation enters or transforms. An unconditional transfer can weaken a coercive relation by increasing exit capacity. A conditional transfer can create a new monitoring relation. A loan can expand productive capacity while strengthening a creditor's claims. The relational effects depend on design and context rather than on the category of instrument alone.

Allocation also has temporal structure. Resources can be consumed, invested, circulated, pooled, converted, or used to maintain existing capacities. Timing can determine which pathway becomes viable. A delayed payment can destroy a fragile organization even if the total allocation is adequate. A predictable stream can generate planning capacity beyond its nominal monetary value. A one-time grant can enable experimentation but fail to sustain maintenance. GRE therefore treats schedule, predictability, reversibility, and duration as properties of the allocation relation.

The recipient itself may be generated through allocation. Programmes define eligibility categories, create beneficiary identities, establish reporting obligations, and sometimes produce organizations capable of receiving funds. Public procurement can constitute firms as qualified suppliers. Credit scoring can define economically consequential categories of risk. Allocation systems therefore participate in the production of subjects and classifications, not merely in the distribution of pre-existing resources among them.

For praxis, the implication is that allocation should be evaluated through both direct transfer and relational transformation. The relevant questions include what capacity the resource creates, what dependencies accompany it, what complementary conditions are required, which actors gain authority, how value is recirculated or extracted, and what happens when the allocation stops. These questions extend ordinary allocation analysis rather than replacing it.

3.12.7 Tracing Downstream Effects

Once an intervention enters a relational field, praxis requires tracing effects beyond its immediate output. Downstream tracing follows the propagation, conversion, recirculation, dissipation, extraction, and stabilization of changes generated by the intervention. The purpose is not to attribute every later event to the intervention. It is to identify plausible pathways through which initially local changes become economically consequential elsewhere or later.

Downstream effects can be direct, mediated, recursive, or displaced. A subsidy can increase demand directly, alter supplier investment through expectation, change local prices through market response, and affect future policy through political inter-

pretation. A new infrastructure can reduce transport costs, reorganize land values, change settlement patterns, and later alter fiscal capacity. A platform rule can affect user behavior, which changes the data used by the platform, which then changes ranking or recommendation, producing a recursive effect.

Tracing requires temporal discipline. Early indicators can differ from later effects because actors adapt and complementary investments emerge. Some harms are delayed. Some benefits require repeated interaction before they become visible. GRE therefore distinguishes outcome timing from causal distance. An effect that occurs quickly can still be relationally distant if it is mediated through several actors, while a delayed effect can arise from a simple accumulation mechanism.

Tracing also requires counterfactual restraint. Observing a later change in a connected actor does not prove that the intervention generated it. Evidence can come from experimental or quasi-experimental designs, process tracing, comparative cases, administrative sequences, qualitative testimony, network change, simulation, or combinations of these. The method should match the claim. The broader the asserted downstream attribution, the greater the burden of distinguishing intervention effects from concurrent change.

Some downstream effects concern value conversion rather than magnitude. An allocation can be converted into political influence, social recognition, technical capacity, ecological pressure, or future access. These forms may not be commensurable with the original resource. Tracing therefore cannot always be reduced to adding monetary benefits and costs. GRE can use monetary valuation where appropriate while preserving additional dimensions when conversion into a scalar measure would erase mechanism-relevant differences.

The practical function of downstream tracing is to maintain contact between intervention and evolving reality. It provides evidence for revision, identifies beneficiaries or harmed parties omitted from the original frame, and detects when an intervention's generative pathway has changed. It also prevents a programme from declaring success solely because the administratively proximate output was delivered as planned.

3.12.8 Feedback and Revision

Feedback converts intervention into learning when observations are allowed to alter the intervention theory and design. GRE distinguishes feedback from mere monitoring. Monitoring records whether specified indicators change. Feedback becomes analytically consequential when those observations can revise assumptions about relations, mechanisms, boundaries, timing, subject heterogeneity, or normative effects.

A useful feedback architecture separates implementation evidence from generative evidence. Implementation evidence asks whether the intervention occurred as intended: funds reached recipients, infrastructure was built, a rule was applied, or a service became available. Generative evidence asks whether the intended transformations followed and what additional transformations occurred. Maintaining this distinction prevents implementation fidelity from being mistaken for substantive success.

Revision can occur at several levels. Parameters can be adjusted while the intervention theory remains intact. Delivery can change because conversion conditions differ across groups. The relational target can change when a hidden intermediary becomes visible. The generative objective itself can be revised when the original aim proves infeasible, harmful, or normatively contested. In more substantial cases, the intervention can reveal that the original problem representation was wrong and requires reconstruction.

Feedback should include affected subjects where their experience provides access to mechanisms or harms not visible in aggregate indicators. Participation is not automatically epistemically superior; local actors can disagree, possess partial information, or face incentives that shape reporting. Their knowledge nevertheless belongs to the evidential field. A feedback system that listens only to administrative data can systematically miss changes in trust, dignity, informal burden, strategic adaptation, or hidden exclusion.

Revision also requires institutional capacity. An organization can collect excellent evidence yet be unable to change because budgets, legal mandates, procurement contracts, professional incentives, or political commitments lock the intervention into its original form. GRE therefore treats the ability to revise as part of intervention design. Review authority, modular contracts, contingency funds, sunset clauses, and explicit decision rules can create practical room for learning, where appropriate.

Feedback is thus not a final stage after implementation. It is a continuing relation between action and evidence. Praxis becomes adaptive when the intervention is organized so that new information can change subsequent action without abandoning accountability or making goals infinitely movable.

3.12.9 Adaptive Governance

Adaptive governance is the institutionalization of revision under changing conditions. It becomes relevant when the intervention affects a system whose relations, actors, or environment evolve on a time scale comparable to the governance process. In such settings, a one-time optimal design can become obsolete even if it was well justified when adopted. GRE therefore treats governance as an ongoing arrangement for observing, deciding, revising, coordinating, and contesting changes in a relational field.

Adaptation does not mean continuous discretionary change. Constant revision can destroy predictability, undermine investment, and make rights dependent on administrative mood. Stable rules can themselves be enabling conditions. Adaptive governance therefore requires deciding which elements should remain stable and which should be revisable. Constitutional protections, procedural rights, or long-horizon commitments may provide a stable frame within which parameters, implementation mechanisms, or experimental components can change.

The architecture of adaptation should match the distribution of knowledge and consequence. Centralized revision can coordinate across regions and prevent local capture, while decentralized adaptation can respond to context and reveal heterogeneous mechanisms. Multi-level governance can combine these functions when authority, information, and accountability are allocated explicitly. GRE does not presume decentralization to be intrinsically more relational or generative. The relevant

question is which governance structure can perceive and respond to the mechanisms that matter while preserving legitimate constraints on power.

Adaptive governance also involves threshold decisions. Some observed variation is noise; some indicates a changing mechanism. Revising too quickly can chase temporary fluctuations, while revising too slowly can entrench harm. Governance therefore needs criteria for escalation, experimentation, suspension, and review. These criteria can be quantitative, qualitative, procedural, or mixed depending on the domain.

Learning across cases is another component. Local adaptation can generate knowledge that becomes useful elsewhere, but portability requires comparison of mechanisms and boundary conditions. A successful intervention in one institutional environment may fail where trust, infrastructure, legal authority, or subject composition differs. Adaptive governance therefore builds cumulative knowledge by documenting not only whether an intervention worked, but under which relational conditions and through which pathway.

At its strongest, adaptive governance alters its own learning capacities. Monitoring systems improve, categories are revised, participation channels change, and institutional memory accumulates. Governance thereby becomes a generative process whose output includes future ability to govern. This recursive feature is central to GRE praxis: the intervention should be evaluated partly by whether it leaves the system more capable of perceiving, contesting, and responding to later problems.

3.12.10 Withdrawal, Reversal, and Repair

A praxis architecture is incomplete if it specifies how to begin and revise interventions but not how to stop them. Withdrawal, reversal, and repair are distinct practical operations. Withdrawal ends or reduces an intervention. Reversal seeks to restore a prior condition or undo a change where feasible. Repair addresses harms, dependencies, damaged relations, or lost capacities that persist after withdrawal. GRE treats these operations as part of intervention design rather than exceptional responses to obvious failure.

Withdrawal can be required for several reasons. An intervention may fail to generate its intended effect, produce unacceptable harm, become obsolete as conditions change, or create costs that exceed its continuing value. It can also succeed so thoroughly that the intervention is no longer required. A temporary guarantee, emergency subsidy, or transitional institution should not become permanent merely because its removal was never designed.

Stopping an intervention can itself be generatively consequential. Organizations may have invested around a subsidy, households may depend on a service, communities may have reorganized around infrastructure, or markets may have adapted to a regulatory regime. Abrupt withdrawal can therefore destroy capacities that the intervention helped create. Exit design should consider notice, transition periods, transfer of responsibilities, preservation of useful infrastructure, and the distribution of adjustment costs.

Reversal is more demanding because relational change is often path dependent.

Restoring a prior rule does not necessarily restore the prior system. Actors have learned, investments have shifted, expectations have changed, and some capacities may have disappeared. A policy reversal can therefore create a third configuration rather than return to the first. GRE treats reversibility as a graded property: some components can be reversed mechanically, others only approximately, and some transformations are effectively irreversible within the relevant horizon.

Repair addresses the residual consequences of intervention. It can involve compensation, restoration of access, institutional reform, rebuilding trust, data deletion or correction, ecological remediation, debt restructuring, reinstatement of rights, or support for capacities weakened by the intervention. Repair is not equivalent to monetary compensation because the harmed object may be relational, institutional, ecological, symbolic, or temporal. A payment can acknowledge loss while leaving the mechanism that produced the loss intact.

The possibility of repair also changes how interventions should be designed. Systems that preserve audit trails, appeals, modularity, data provenance, and institutional responsibility are easier to correct. Interventions that diffuse responsibility across opaque chains can make harm difficult to attribute and repair. GRE therefore treats repairability as a practical design consideration alongside effectiveness and adaptability.

Withdrawal, reversal, and repair complete the preliminary praxis cycle developed in this section. GRE moves from explanation toward intervention by diagnosing the relational field, identifying what the field generates, locating constraints and enabling conditions, designing a provisional intervention, treating allocation as a relational act, tracing downstream effects, learning through feedback, adapting governance, and retaining the capacity to stop or repair what has been created. The sequence remains heuristic rather than universal. Its purpose is to organize intervention under incomplete knowledge without reducing practice to either static optimization or unconstrained experimentation.

This praxis architecture also clarifies why evaluation cannot be postponed to a single terminal outcome. Each stage creates questions about value, harm, participation, capability, dependency, future possibility, and domination. An intervention may be operationally adaptive while normatively unacceptable, or normatively attractive in intention while generatively destructive in practice. The following section therefore turns from the architecture of action to the standards by which generated consequences can be evaluated under plural and sometimes incommensurable values.

3.13 Evaluation and Normative Orientation

Generative Relational Economics requires a normative vocabulary because the processes it studies can enlarge possibility, redistribute capacity, stabilize cooperation, create dependency, intensify domination, or foreclose alternative futures. The role of this section is to specify the evaluative dimensions through which such consequences can be examined without converting generativity itself into a moral criterion. Its objective is to distinguish descriptive claims about what an economic relation generates

from normative judgments about whether the generated configuration should be sustained, revised, constrained, or repaired. The discussion proceeds through ten connected dimensions: the normative status of generativity; generated value and harm; participation; capability; relational quality; future possibility; dependency and domination; generative foreclosure; plural and incommensurable values; and the division of labor between GRE and GREthic. The method is constitutive and normative. It does not attempt to derive one complete moral theory from GRE. It identifies evaluative objects and inferential disciplines that allow GRE to remain normatively explicit while preserving plurality among competing theories of justice and ethical judgment.

The need for this distinction follows directly from the analytical architecture developed above. A relation can be highly generative in the descriptive sense because it produces new organizations, knowledge, technologies, markets, habits, classifications, capabilities, and forms of value. The same relation can distribute those consequences asymmetrically, externalize harms, narrow exit options, or reorganize the field so that some future possibilities become inaccessible. An intervention can therefore succeed according to one generative objective while producing losses elsewhere in the relational domain. GRE evaluation must trace both kinds of consequence rather than allowing the presence of generation to function as evidence of desirability.

Normative evaluation also requires attention to temporal depth. Immediate welfare gains can be accompanied by long-run dependency. Short-term loss can sometimes create later capability. A stable relation can protect vulnerable participants while also becoming difficult to contest. An institution can increase aggregate opportunity while decreasing the range of trajectories available to a particular group. GRE therefore treats present outcome, relational position, future capacity, and transformation of possibility as analytically separable evaluative objects. Their relative importance cannot be fixed once for every inquiry.

Evaluation is also complicated by heterogeneous value. Economic decisions can affect income, security, care, recognition, ecological integrity, autonomy, knowledge, belonging, trust, aesthetic experience, institutional legitimacy, and many other forms of value whose relations are only partially commensurable. Monetary valuation can be useful within a defined problem while leaving significant evaluative remainders. GRE consequently distinguishes commensuration as an analytical or institutional operation from the stronger claim that the values being compared possess a common natural metric.

The resulting normative stance is neither value-neutrality nor normative closure. GRE accepts that economic inquiry frequently contains evaluative choices in the selection of outcomes, boundaries, scales, and affected subjects. It therefore seeks to make those choices explicit and contestable. At the same time, GRE does not treat its own analytical categories as sufficient to decide every ethical conflict. Participation, capability, relational quality, future possibility, dependency, domination, and foreclosure provide a multidimensional evaluative field. Normative judgment still requires specification of who is affected, which values are at stake, how conflicts among values are handled, and which ethical or political principles justify intervention.

This distinction creates an interface with GREthic. GRE supplies economic analysis of generative structures, distributions, dependencies, conversion pathways, and changes in future possibility. GREthic addresses the broader ethical problem of how

such findings should enter judgment, justification, institutional design, and the evolution of normative criteria. Their relation is therefore collaborative without being identical. The present section establishes that interface while keeping GRE's disciplinary center within economics.

3.13.1 Normative Status of Generativity

Generativity describes a capacity of a relation, process, institution, or configuration to produce further states, capacities, relations, values, or possibilities. That descriptive property has no fixed normative sign. Productive networks, monopolistic infrastructures, extractive regimes, scientific communities, predatory markets, mutual-aid institutions, and systems of surveillance can all generate durable consequences. The fact that a configuration generates more than its immediate output identifies an important economic property; it does not establish that the resulting trajectory should be preferred.

This distinction is foundational because GRE gives generativity an unusually prominent analytical role. Without an explicit normative separation, the vocabulary of generation could encourage a subtle bias toward expansion, novelty, proliferation, or self-reproduction. Economic history supplies many cases in which highly generative arrangements produced wealth together with coercion, ecological depletion, exclusion, or durable hierarchy. A relation can reproduce itself efficiently because the costs of exit are high. An institution can generate rapid innovation because risks are shifted toward actors with weak bargaining power. A platform can generate dense interaction while concentrating control over the infrastructure through which that interaction occurs. Descriptive generativity therefore requires an additional evaluative step.

The relevant question is not whether generation occurs, but what is generated, for whom, through which relations, under which constraints, and with what effects on later possibility. These questions prevent GRE from treating generativity as a scalar objective that can be maximized independently of content. More generation can be desirable in one dimension and damaging in another. A research system can generate knowledge while degrading working conditions. A credit system can generate entrepreneurial capacity while expanding vulnerability to debt. A welfare programme can generate security while also creating administrative classifications that constrain mobility. Evaluation therefore concerns the structure and distribution of generation.

Normative analysis must also distinguish generativity from regeneration. A system can generate novelty while eroding the material or social conditions required for continuation. Another system can maintain those conditions without producing substantial novelty. A third can restore damaged capacities while limiting some current activities. These trajectories involve different evaluative questions. GRE therefore avoids equating novelty, persistence, resilience, growth, and regeneration with one another. Each describes a different relation between current activity and future conditions.

A similar distinction applies to self-reinforcement. Some beneficial institutions require positive feedback to remain viable. Some harmful institutions also acquire self-reproducing capacities. The presence of a stable attractor-like pattern, increasing

returns, or institutional persistence does not imply normative legitimacy. Evaluation must examine whether the mechanisms of reproduction preserve contestability, participation, and the possibility of revision or whether they make domination and exclusion increasingly difficult to reverse.

The normative status of generativity is consequently conditional and relational. GRE can identify generative mechanisms and compare their consequences without assigning a universal value to generation itself. Normative evaluation begins when the analysis asks how generated consequences affect subjects, relations, capacities, values, dependencies, and future possibility. The remaining subsections specify those dimensions in greater detail.

3.13.2 Generated Value and Generated Harm

Generated value and generated harm are parallel analytical objects. Both can emerge downstream from an economic relation, both can propagate beyond the administrative recipient, and both can change form as they circulate. The evaluative task is therefore broader than measuring the immediate benefit and subtracting a directly observed cost. GRE asks how value and harm are produced, distributed, converted, accumulated, displaced, and transmitted across scales and time.

Generated value can include income, capability, knowledge, security, trust, coordination, infrastructure, recognition, institutional capacity, ecological restoration, or access to future opportunities. Some forms of value are directly appropriable by a subject; others exist only through a relation or shared condition. A public standard, a trusted institution, a functioning ecosystem, or a community of practice can generate benefits whose value cannot be represented adequately as the possession of one individual. GRE therefore evaluates value at the level at which it is generated and realized.

Generated harm has equally varied forms. An intervention can increase surveillance, dependency, stigma, ecological burden, exclusion, precarity, misinformation, or concentration of bargaining power even when the designated recipient receives a material benefit. Harm can also be displaced. A low consumer price can be sustained through labor conditions elsewhere in the supply chain. Local ecological improvement can depend on transferring waste or extraction to another region. An automated system can reduce transaction costs while increasing the exposure of a minority of users to unreviewable classification errors. Evaluation must therefore examine relational incidence rather than only administrative incidence.

Value and harm can coexist within the same generative pathway. Education can expand capability while imposing debt. Infrastructure can improve access while displacing residents. Intellectual-property protection can support some forms of investment while constraining downstream experimentation. Social protection can reduce insecurity while creating reporting burdens or intrusive eligibility regimes. Such configurations should not be forced into a premature net-value judgment when the affected values are heterogeneous and differently distributed.

Temporal ordering further complicates evaluation. Harm can be immediate while value is delayed, or the reverse. Some effects are reversible; others create durable path dependence. A temporary subsidy may generate a lasting market or a lasting de-

pendency. A short-lived exclusion can alter educational or professional trajectories for decades. GRE therefore records persistence and reversibility as part of the evaluative description rather than treating all consequences as contemporaneous flows.

This framework also makes attribution important. A downstream harm may be associated with an intervention without being generated by the mechanism under study. Conversely, a benefit may be credited to an intervention even though it depends mainly on pre-existing relations or complementary institutions. Normative evaluation should therefore inherit the epistemic discipline of Section 3.11: claims about generated value and harm require a stated mechanism, boundary, scale, and degree of evidential confidence.

3.13.3 Participation

Participation concerns the capacity of affected subjects to enter, influence, contest, benefit from, and withdraw from the relations through which economic life is organized. It is an evaluative object because economic systems do more than distribute resources. They distribute positions from which subjects can speak, act, create, coordinate, challenge classifications, and contribute to future generation. A configuration can therefore increase material output while narrowing meaningful participation.

Participation has several dimensions. Access concerns whether a subject can enter a relevant institution, market, infrastructure, profession, community, or decision process. Voice concerns whether the subject can make claims that receive institutional attention. Influence concerns whether participation can alter decisions rather than merely register preference. Recognition concerns whether the subject is legible within the categories through which resources and rights are allocated. Contestability concerns whether classifications, decisions, or rules can be challenged. Exit concerns whether participation remains voluntary in a meaningful sense or is sustained by dependence and prohibitive switching costs.

These dimensions need not move together. A platform can provide wide access while retaining centralized control over ranking and rule change. A formal consultation process can permit voice while leaving participants with little influence. A labor market can allow nominal exit from an employer while economic insecurity makes exit practically costly. A public service can grant rights in principle while administrative categories render some users difficult to recognize. GRE therefore avoids reducing participation to formal inclusion.

Participation also has a generative dimension. Being able to participate can develop knowledge, confidence, social ties, institutional literacy, bargaining capacity, and new forms of collective organization. Exclusion can have the opposite effect by reducing opportunities to acquire the capacities later required for participation. Present access can therefore shape future access. Evaluation should examine whether an arrangement generates broader capacities for participation or produces cumulative disadvantages that narrow future entry.

The economic significance of participation becomes especially visible under conditions of technological abundance. If productive tasks can increasingly be performed by artificial or highly automated systems, a framework that ties economic participation exclusively to productive necessity can leave human subjects with reduced ac-

cess to income, institutions, social recognition, or meaningful collective activity. GRE does not presume a particular technological outcome, but it treats the institutional organization of participation as a distinct problem from the allocation of productive tasks.

Participation should not be romanticized. More participation can impose time costs, reproduce inequalities in voice, or shift responsibility onto subjects with limited resources. Some technical decisions require specialized knowledge; some participants may prefer delegation. The normative question therefore concerns the quality and consequences of participation, including who bears its burdens, what forms of representation are available, and whether nonparticipation is compatible with protection from arbitrary decisions.

3.13.4 Capability

Capability concerns the effective ability of subjects to pursue relevant actions and ways of living within their actual relational and institutional conditions. For GRE, capability is an especially important evaluative object because economic relations can generate or destroy the conditions through which resources become usable. An allocation that appears equal at the level of resources can produce unequal capability when subjects face different conversion conditions.

Capability therefore extends evaluation beyond possession. Access to money, information, technology, or legal rights matters only partly through the quantity received. Its practical significance depends on health, time, knowledge, infrastructure, social recognition, legal status, language, care obligations, physical accessibility, institutional trust, and many other conversion conditions. GRE can analyze these conditions as part of the relational field through which a resource becomes an effective opportunity.

Capabilities can also be cumulative. Education can increase the ability to learn further skills. Secure housing can improve the ability to sustain employment or study. Access to digital infrastructure can expand the capacity to participate in markets, administration, and knowledge production. Conversely, repeated exclusion can reduce the capacities needed to take advantage of later opportunities. Evaluation should therefore trace capability trajectories rather than treating capability as a static stock.

The generative perspective adds a second question: who controls the conditions under which capability can be exercised? A subject may possess technical competence while depending on a platform, license, visa, credential, payment network, data infrastructure, or institutional recognition. Capability is then relationally enabled. If access to the enabling condition can be withdrawn unilaterally, the subject's practical freedom may be more fragile than a simple skill inventory suggests.

Capability evaluation must also preserve normative pluralism. GRE does not need to specify one universal list of valuable capabilities in order to treat capability formation as economically significant. Different inquiries can justify different evaluative sets depending on the affected population, institutional context, and normative framework. The important discipline is to state which capabilities are being evaluated, why they matter, and how their measurement relates to the actual opportunities of subjects.

The distinction between capability and performance is equally important. A subject can possess a genuine opportunity without exercising it. Economic evaluation should not automatically infer deprivation from nonuse or success from observed functioning. Choices can reflect preference, but they can also reflect adaptation to constraint, uncertainty, social expectation, or limited information. GRE therefore treats capability as an evaluative lens that requires contextual interpretation rather than direct inference from observed behavior alone.

3.13.5 Relational Quality

Relational quality concerns the properties of the relations through which economic activity is organized. It directs evaluation toward features that can disappear when analysis looks only at individual outcomes. Two arrangements can deliver similar material distributions while differing substantially in reciprocity, transparency, recognition, reliability, contestability, vulnerability to arbitrary power, or the burdens required to sustain cooperation.

Relational quality is deliberately a plural category. A high-quality relation in one context can emphasize trust and continuity; another can require independence and easy exit; a third can require procedural transparency or protection from discrimination. GRE therefore does not assume that one relational form is universally superior. It asks which properties are normatively relevant to the local relation and how those properties affect both current experience and later generative possibility.

Trust provides one example. Trust can reduce transaction costs, support cooperation, and enable forms of joint action that formal contracting cannot fully specify. Yet trust can also create vulnerability when one party controls information or enforcement. Dense trust within a group can coexist with exclusion of outsiders. Evaluation therefore concerns the conditions under which trust is generated, whether reliance is reciprocated, and what protections exist when trust is breached.

Recognition provides another example. Economic relations can treat subjects as interchangeable units or as participants whose claims and histories matter. Recognition can affect bargaining, access, dignity, willingness to cooperate, and institutional legitimacy. At the same time, institutional recognition often depends on categories that simplify complex identities. A recognition regime can include some subjects by making others invisible. Relational quality therefore includes the revisability of the categories through which recognition is granted.

Contestability is especially important in relations involving asymmetry. A subject may accept unequal expertise, authority, or capability when decisions remain reviewable and reasons can be challenged. The same asymmetry can become more problematic when rules are opaque, appeals are impossible, or dependence makes disagreement costly. GRE therefore treats relational quality as connected to the governance of asymmetry rather than to equality in every dimension.

Relational quality also has generative consequences. Relations characterized by reliability and fair contestation can support investment, experimentation, and long-term cooperation. Relations characterized by arbitrary sanction or unstable recognition can encourage defensive behavior, information withholding, and short planning horizons. Evaluation should consequently examine both the intrinsic and generative

significance of relational quality without assuming that its value can be reduced to later efficiency gains.

3.13.6 Future Possibility

Future possibility concerns the range and quality of trajectories that remain realistically available after an economic relation or intervention has taken effect. It is central to GRE because present arrangements continually reshape the conditions of later action. Evaluation therefore extends beyond current welfare to ask whether subjects and institutions retain meaningful capacity to revise, learn, exit, recombine resources, or pursue alternative forms of life and organization.

Future possibility differs from abstract logical possibility. An option can exist formally while remaining practically inaccessible because of cost, law, infrastructure, knowledge, social position, or path dependence. GRE is concerned with feasible and relationally supported possibility. The relevant question is whether subjects possess the conditions required to convert an apparent option into a credible trajectory.

Economic development can expand future possibility by generating infrastructure, education, savings, institutional competence, public knowledge, and trusted coordination. It can also narrow possibility through debt lock-in, ecological depletion, monopoly, rigid standards, irreversible investment, or loss of local capability. The same intervention can expand options for one group while constraining another. Evaluation must therefore be distributional and multiscale.

Optionality also interacts with commitment. Some valuable projects require long-term coordination, sunk investment, and stable expectations. Preserving every option can prevent the formation of institutions whose value depends on continuity. GRE therefore does not treat maximal reversibility as a universal goal. It asks whether commitments are justified, whether affected subjects understand the resulting constraints, whether revision remains possible under changing conditions, and whether the burdens of irreversibility are distributed fairly.

The temporal horizon of evaluation matters. A policy that preserves short-run choice can undermine long-run ecological or fiscal possibility. A restrictive rule can reduce present options while protecting conditions needed for future generations. GRE therefore requires explicit time horizons and rejects the assumption that present preference alone exhausts normative relevance. Intergenerational effects become part of economic evaluation when current activity alters the capability and action space available later.

Future possibility also provides a bridge between economic and political evaluation. Control over infrastructure, standards, data, property, legal categories, or knowledge systems can determine which later projects become feasible. Power can therefore operate by structuring possibility before any specific decision is made. Evaluation of future possibility helps identify such upstream effects and prepares the analysis of power in the following section.

3.13.7 Dependency and Domination

Dependency is a pervasive feature of economic life. Individuals depend on households, organizations, infrastructures, ecological systems, legal institutions, markets, and other persons. Firms depend on suppliers, finance, standards, workers, customers, and public order. Dependency therefore cannot serve as a simple indicator of injustice. The evaluative problem concerns the structure of dependence: how essential the relation is, whether alternatives exist, how burdens and benefits are distributed, and whether one party can exercise discretionary power over another's conditions of action.

Some dependencies are reciprocal and mutually enabling. Specialization creates interdependence because actors can achieve more through coordinated reliance than through autarky. Care relations can involve deep dependence while also generating security, capability, and belonging. Public infrastructure creates dependence on collective institutions that may be normatively desirable. GRE therefore distinguishes dependency from domination rather than treating self-sufficiency as the default ideal.

Domination becomes relevant when dependency is combined with power that is difficult to contest, exit, or subject to accountable rules. A worker can depend on an employer, a seller on a platform, a tenant on a landlord, or a state on a creditor. Whether the relation becomes dominating depends on the available alternatives, procedural protections, transparency, collective organization, legal constraints, and the ability to challenge arbitrary decisions. The analysis therefore concerns relational structure rather than the mere presence of unequal capability.

Generative mechanisms can deepen dependency over time. A platform can become more indispensable as participants invest in platform-specific reputation or data. A lender can acquire increasing influence when refinancing becomes necessary. A technology ecosystem can create switching costs through proprietary standards and complementary investments. Such processes transform an initially optional relation into one that shapes the subject's future possibilities. GRE evaluates the trajectory of dependency, not only its initial contractual form.

Dependency can also be hidden by administrative boundaries. An organization may appear autonomous while relying on unpaid care, public infrastructure, ecological services, or precarious subcontracting. A wealthy region can reduce local dependence by externalizing extraction elsewhere. Evaluation should therefore trace dependency across scales and identify whose capacities sustain the apparent independence of others.

The normative task is consequently to distinguish enabling interdependence from dependency that concentrates arbitrary power or systematically transfers risk. This distinction is contextual and requires attention to alternatives, voice, exit, reciprocity, and governance. GRE can map these conditions economically while leaving broader ethical judgment open to explicit normative argument.

3.13.8 Generative Foreclosure

Generative foreclosure occurs when a present economic relation, intervention, or institutional arrangement reduces the capacity to generate relevant future alternatives. Foreclosure is stronger than an ordinary opportunity cost. Every choice excludes some alternatives because resources and time are finite. Generative foreclosure concerns changes to the conditions of future generation themselves: the loss of capabilities, relations, infrastructures, ecological conditions, institutional pluralism, or epistemic resources required to create or recognize later options.

A technological standard can produce generative foreclosure when complementary investment makes alternative architectures prohibitively costly. Concentrated ownership of research infrastructure can narrow which questions can be investigated. Educational exclusion can reduce not only present opportunity but also the later capacity to formulate and pursue new projects. Ecological degradation can remove future productive and cultural possibilities that current actors cannot fully specify. In each case, the loss concerns the generative field rather than one foregone transaction.

Foreclosure can be intentional or emergent. A dominant actor may deliberately raise barriers to entry. An institution may unintentionally create lock-in through cumulative coordination. A society may deplete a resource without any actor intending to eliminate later possibilities. Normative evaluation therefore cannot rely only on motive. It must examine the mechanisms through which possibility is narrowed and the distribution of the resulting loss.

The concept also requires restraint. Stable institutions necessarily reduce some degrees of freedom by creating rules, commitments, standards, and expectations. Such constraint can itself enable generation by lowering uncertainty and coordinating investment. GRE therefore distinguishes productive structuring from foreclosure by asking whether the constraint preserves meaningful routes for learning, contestation, recombination, and revision relative to the values at stake.

Irreversibility is an important but incomplete indicator. Some irreversible changes are desirable; some reversible systems can still reproduce severe domination. The evaluative question concerns which future capabilities and relations are lost, who bears the loss, whether the loss was foreseeable, whether affected subjects had meaningful participation, and whether compensating generative capacities are created elsewhere. Foreclosure is thus a relational and normative concept rather than a synonym for permanence.

Generative foreclosure gives GRE a way to evaluate economic processes whose most important harms are difficult to observe in present output measures. The absence of a future innovation, institution, community, ecological state, or life trajectory cannot be measured in the same way as an existing commodity. Evaluation therefore requires counterfactual and historical reasoning, explicit uncertainty, and humility concerning possibilities that current categories may fail to represent.

3.13.9 Plural and Incommensurable Values

GRE assumes that economic evaluation can involve several forms of value whose relations are partial, contested, or context-dependent. Income, security, autonomy, care, recognition, ecological integrity, knowledge, cultural continuity, trust, and future possibility can matter simultaneously without reducing naturally to one metric. The presence of plural value therefore creates a problem of judgment rather than a technical defect awaiting universal conversion.

Commensuration can still be useful. Budgets require numerical comparison; cost-effectiveness analysis can clarify trade-offs within a defined objective; markets generate prices that coordinate many transactions; legal and administrative systems require thresholds and categories. GRE treats these operations as institutionally situated forms of comparison. The existence of a price or index demonstrates that a conversion rule has been established for a purpose. It does not prove that every ethically relevant dimension has been captured.

Partial comparability is often sufficient for action. One option can dominate another across several relevant dimensions without requiring a common cardinal scale. Thresholds can exclude arrangements that violate minimum conditions of safety, participation, or rights. Deliberative procedures can address remaining conflicts. Scenario analysis can reveal how rankings change under different value weightings. GRE therefore does not infer decision paralysis from incommensurability.

Plural value also changes the interpretation of conversion. An institution can transform cultural recognition into market demand, social trust into credit access, educational status into employment opportunity, or ecological resources into monetary revenue. Such conversions can create value while also degrading or crowding out the source relation. Evaluation should therefore examine who controls conversion interfaces, which values become legible after conversion, and which remainders disappear from institutional accounting.

Conflicts among values can also be distributional. A policy may maximize aggregate income while concentrating ecological harm in one community. A conservation programme may protect biodiversity while limiting livelihoods or customary access. An automated service may improve average efficiency while weakening procedural recognition for individuals who require exceptions. These conflicts cannot be resolved by naming all values equally important. Normative judgment must specify priority rules, procedural safeguards, compensation, thresholds, or other principles appropriate to the case.

GRE's contribution is to keep the value architecture visible. It can trace where values are generated, converted, captured, dissipated, or rendered institutionally invisible. It can identify the relations through which one value form gains priority over another. It can also expose where apparent commensurability depends on a contested institutional convention. The choice among competing normative resolutions remains an explicit ethical and political task.

3.13.10 Relation between GRE and GREthic

The normative dimensions developed in this section create a direct interface between GRE and GREthic. Their division of labor should remain explicit. GRE is an economic research programme concerned with relational constitution, generation, allocation, value transformation, capability, power, dependency, and changes in future possibility. GREthic addresses the broader ethical problem of how relational and generative consequences should be interpreted, justified, contested, and governed when several values, subjects, and temporal horizons are involved.

This division does not make GRE normatively empty. Economic research already contains evaluative choices in the definition of welfare, harm, efficiency, opportunity, risk, and admissible intervention. GRE adds explicit dimensions such as participation, relational quality, future possibility, dependency, domination, and foreclosure. These dimensions belong legitimately within economic evaluation because they describe economically generated conditions. The ethical question becomes more demanding when the inquiry asks how competing dimensions should be weighted, which constraints should function as side conditions, whose claims have priority, or what constitutes a just relation.

GREthic can therefore operate as a neighboring normative domain rather than as a final module appended after economic analysis. Ethical judgment can alter the research boundary, the choice of evaluative dimensions, the treatment of uncertainty, the design of participation, and the interpretation of evidence. Conversely, economic analysis can revise ethical judgment by revealing hidden dependencies, indirect harms, conversion mechanisms, or long-run consequences that were absent from the initial normative description. The relation between GRE and GREthic is consequently iterative.

A generative ethical perspective also faces the problem of changing criteria. Institutions learn, social meanings evolve, new subjects become visible, and technologies create forms of action that earlier normative vocabularies did not anticipate. Ethical evaluation therefore cannot assume that a fixed list of criteria will remain sufficient under every historical condition. GREthic must be capable of examining how normative categories themselves emerge, stabilize, exclude, and require revision. This does not imply that every value is historically arbitrary. It means that the institutional expression and interpretation of values require continuing critical examination.

The interface is especially important for application-dominant praxis. An intervention can be technically effective and economically generative while raising unresolved questions of justice. In such cases GRE can provide the relational diagnosis, trace the effects, identify capability changes, map dependency, and evaluate future possibility. GREthic can help articulate the normative standards governing participation, acceptable asymmetry, protection from domination, treatment of irreversible harm, and procedures for revising the intervention when values conflict.

The distinction also protects disciplinary restraint. GRE need not become a complete moral philosophy in order to analyze normatively significant economic processes. GREthic need not replace economic explanation with ethical vocabulary. Their productive relation depends on maintaining both the empirical and normative burdens of argument. Ethical claims require justification; economic claims require

evidence and mechanism; interventions require both.

The normative architecture established in Section 3.13 therefore completes an important part of Chapter 3's constitution of GRE. Generativity becomes an object of evaluation rather than a criterion of goodness. Generated value and harm, participation, capability, relational quality, future possibility, dependency, domination, foreclosure, and plural values provide a multidimensional field for judgment. The following section turns to one of the most consequential mechanisms through which these dimensions become unequally distributed: power and asymmetry within the GRE problem-space.

3.14 Power and Asymmetry within the GRE Problem-Space

Generative Relational Economics requires an explicit account of power because economic relations rarely begin from symmetric positions, and the consequences of those asymmetries can accumulate through the very processes that GRE studies. The role of this section is to identify the principal forms of asymmetry that can become economically consequential and to clarify the conditions under which asymmetry is converted into power. Its objective is to avoid two opposite reductions: treating every difference between subjects as domination, and treating power as a property possessed independently of the relations through which it becomes effective. The discussion proceeds through resource, capability, knowledge, institutional, vulnerability, and exit asymmetries; the conversion of asymmetry into power; the limits of capability equalization and counter-power; and relational governance under persistent asymmetry. The method is constitutive and analytical. It establishes a vocabulary for later empirical, normative, and governance work without presuming that one scalar measure can represent every relevant form of power.

The starting point is a distinction between *asymmetry* and *power*. An asymmetry exists when subjects occupy different positions with respect to resources, capacities, information, institutional authority, vulnerability, or alternatives. Power arises when such differences become usable, durable, or institutionally supported means of shaping another subject's feasible actions, access to resources, interpretive environment, exposure to risk, or future conditions of generation. A highly capable subject can therefore remain weak in a particular relation when its capabilities are irrelevant to the terms of interaction. Conversely, a subject with modest resources can exercise substantial power when it controls a scarce interface, legal authorization, standard, platform, bottleneck, or exit option on which others depend.

Power is consequently relational, domain-specific, and temporally structured. The same pair of subjects can be asymmetric in opposite directions across different domains. A worker can possess knowledge essential to production while remaining institutionally subordinate in wage negotiation. A state can regulate a corporation domestically while depending on that corporation for infrastructure, tax revenue, or technological expertise. A user can choose among digital services while having little capacity to alter the standards through which data are collected and converted into commercial value. The relevant question for GRE is therefore not simply who has more, but how a difference is connected to a mechanism through which one subject

can affect another subject's present options or future generative conditions.

This emphasis also distinguishes power from immediate coercion. Power can operate through direct commands, but it can also operate by shaping defaults, eligibility criteria, technical standards, access routes, classifications, expectations, and the cost of refusal. It can be episodic or structurally persistent. It can be consciously exercised or reproduced through institutions whose participants do not individually intend the resulting asymmetry. GRE therefore treats power as a family of relational mechanisms that affect the generation and distribution of possibility. Normative evaluation enters when those mechanisms are assessed in terms of domination, justice, harm, participation, capability, or foreclosure, but descriptive power analysis must first identify how the relation works.

3.14.1 Resource Asymmetry

Resource asymmetry concerns unequal access to economically consequential stocks or flows such as money, land, infrastructure, energy, data, equipment, labor time, organizational slack, credit, logistics, or legally protected assets. It is among the most visible forms of economic difference because many resources are already measured through accounting, ownership, or administrative systems. Yet possession alone does not determine relational power. What matters is the role that a resource plays within a specific relational configuration.

A resource becomes power-relevant when control over it changes another subject's feasible set or bargaining position. The owner of a scarce input can influence downstream producers when substitutes are limited and switching is costly. A lender can impose conditions when borrowers face liquidity constraints and alternative finance is unavailable. A landlord's control over housing can become consequential when residence is tied to employment, schooling, legal status, or local social networks. A platform's control over computational infrastructure can matter when users, firms, or public institutions depend on that infrastructure for participation in other economic processes. The same nominal resource can therefore carry very different power consequences depending on substitutability, timing, dependence, and institutional context.

Resource asymmetry also has a generative dimension. Resources can be consumed, but they can also be converted into capacities for producing later resources. Capital can finance research, data collection, legal representation, lobbying, recruitment, or acquisition. Infrastructure can make future coordination cheaper. Land ownership can generate collateral. A large user base can generate additional data and network effects. Resource inequality can therefore reproduce or amplify itself when existing holdings enable access to mechanisms that generate further advantage.

GRE analysis should distinguish this recursive possibility from simple accumulation. A subject can possess more resources without gaining additional structural leverage if the relevant relation remains competitive and alternatives remain accessible. Conversely, a relatively small resource difference can become decisive when it controls a bottleneck or threshold. The analytical task is thus to identify the conversion mechanism: which resource matters, to which relation, over what time horizon, through which institutional or technical structure, and with what downstream effects

on future capacity.

This distinction also matters for policy. Redistribution of money can reduce one resource asymmetry while leaving infrastructural, legal, informational, or organizational asymmetries intact. Access subsidies can improve current consumption without altering control over the mechanisms that generate future options. Resource equalization is therefore one possible intervention among several. GRE asks whether the relevant inequality lies in holdings, access, conversion capacity, rule-making position, or the structure through which resources become generative.

3.14.2 Capability Asymmetry

Capability asymmetry concerns differences in what subjects are able to do within a defined economic relation. Capabilities may include technical competence, organizational coordination, computational capacity, mobility, learning, bargaining skill, physical endurance, social connectivity, legal competence, linguistic access, or the ability to mobilize resources under time pressure. Capability differs from resource possession because two subjects with formally similar resources can have very different capacities to convert them into effective action.

This distinction is central in contemporary economies where productive capability can differ sharply across persons, organizations, and artificial systems. A large model can process information at scales unavailable to an individual worker. A multinational firm can coordinate legal, financial, and logistical operations across jurisdictions that a small supplier cannot match. An experienced organization can exploit a regulatory opportunity that a newly formed association does not yet understand. These differences can affect bargaining positions, speed, error tolerance, and the range of feasible strategies.

Capability asymmetry becomes power-relevant when it changes the terms under which other subjects must participate. Superior prediction can support price discrimination. Superior legal capacity can make contractual complexity costly for weaker parties to contest. Superior computational capacity can enable rapid experimentation over markets, attention, or product design. Superior logistical coordination can make a supplier difficult to replace. In each case the capability matters because it is connected to a relation through which the more capable subject can shape conditions faced by others.

At the same time, capability differences do not by themselves establish domination, moral superiority, or ontological hierarchy. Specialized capabilities are common in cooperative systems. A surgeon and patient, pilot and passenger, engineer and user, or teacher and student occupy asymmetric capability relations that can be socially valuable when authority, accountability, consent, and institutional safeguards are appropriately organized. The relevant GRE question is whether capability asymmetry becomes a mechanism for unilateral control, extraction, dependency, or foreclosure, or whether it is embedded in reciprocal and revisable arrangements that distribute benefits and protect affected subjects.

Capability asymmetry also changes historically. Training, tools, institutional access, automation, collective organization, and technical infrastructure can expand or reduce particular capabilities. The introduction of artificial intelligence makes this es-

pecially visible because capability gaps can change quickly and unevenly across tasks. A useful GRE analysis therefore tracks the trajectory of capability differences rather than treating them as fixed attributes. It asks who gains new capabilities, who loses the economic relevance of existing ones, what new dependencies arise, and which institutions govern the conversion of capability differences into economic authority.

3.14.3 Knowledge Asymmetry

Knowledge asymmetry concerns unequal access to information, interpretive resources, expertise, explanatory models, evidence, or the capacity to recognize the significance of available information. It extends beyond the familiar problem of one party knowing more facts than another. Economic power can also arise from asymmetries in classification, prediction, interpretation, and the ability to determine which descriptions become institutionally actionable.

A seller may know more about product quality than a buyer. A financial institution may know more about pricing models and contractual risk than a client. A platform may observe aggregate behavioral patterns invisible to individual users. A government agency may hold administrative records unavailable to the public. A technical community may control specialized vocabularies required to contest a decision. These are distinct knowledge relations, and their power effects depend on how the knowledge is connected to action.

Knowledge becomes especially consequential when one subject can make decisions on the basis of information that another cannot inspect, verify, or meaningfully interpret. The weaker subject may then depend on assurances, reputation, certification, professional norms, or institutional oversight. Such dependence is not intrinsically pathological; complex economies require extensive reliance on expertise. The power problem emerges when epistemic dependence combines with weak accountability, conflicts of interest, high switching costs, or control over the channels through which claims can be challenged.

Knowledge asymmetry also includes the power to produce or stabilize representations. Economic subjects are frequently acted upon through categories: credit scores, risk classes, performance metrics, eligibility rules, rankings, profiles, diagnoses, forecasts, and algorithmic classifications. The subject who controls the production or interpretation of a category can influence access to employment, credit, insurance, visibility, public benefits, or market participation. In such cases knowledge power does not consist only in possessing hidden information. It also consists in shaping the representational architecture through which institutions perceive other subjects.

GRE therefore distinguishes informational access, interpretive competence, model authority, and representational control. These dimensions can diverge. Data can be publicly available while computational requirements make meaningful analysis inaccessible. A model can be technically transparent while the institutional consequences of its output remain opaque. A subject can understand a classification yet lack any procedure for contesting it. Knowledge governance consequently requires more than disclosure. It may require intelligibility, auditability, contestability, alternative expertise, evidential access, and institutional routes through which interpretations can be revised.

The generative dimension of knowledge asymmetry is equally important. Knowledge can generate later knowledge, and control over data or research infrastructure can compound advantages. Organizations with larger observational fields can train better models, attract more users, and generate still more data. Institutions that define legitimate evidence can also shape which questions receive funding and which phenomena become visible. Knowledge asymmetry can therefore alter the future epistemic field itself, making it a central GRE object rather than merely a background imperfection in exchange.

3.14.4 Institutional Asymmetry

Institutional asymmetry concerns unequal positions within rule-making, authorization, recognition, enforcement, classification, and dispute-resolution structures. It is distinct from resource or capability asymmetry because an institution can grant authority to a subject whose private resources are limited. A regulator, court, standards body, professional association, university, central bank, certification agency, or platform governance unit can exercise substantial influence through the rules it is authorized to establish or interpret.

Institutional position shapes who can define admissible participation, whose claims count, which categories receive legal recognition, and which remedies are available when conflict occurs. Formal authority is one obvious form. Less visible forms include agenda-setting, control over procedure, discretionary interpretation, default-setting, accreditation, and the capacity to delay or accelerate decisions. Timing itself can become power when one party can tolerate delay and another cannot.

Institutional asymmetry is often self-reinforcing because rules influence the resources and capabilities available to participants. Licensing can protect quality and safety while also raising entry barriers. Intellectual-property rules can reward innovation while concentrating control over subsequent use. Procurement standards can improve accountability while favoring organizations with administrative capacity to comply. Corporate governance rules can distribute formal voting rights while leaving agenda formation concentrated. Institutional analysis therefore asks not only what a rule states but how it reorganizes relational possibilities.

GRE treats institutional asymmetry as especially important because institutions mediate conversion among other forms of asymmetry. Wealth can be translated into lobbying, litigation, or organizational access. Expertise can be converted into recognized professional authority. Formal office can provide privileged information. Institutional status can determine whose vulnerability receives protection and whose losses remain externalized. Institutions are thus conversion structures through which resources, capabilities, knowledge, and recognition become power.

This does not imply that institutional asymmetry should be eliminated. Governance itself requires differentiated roles, mandates, and responsibilities. The relevant question is how authority is bounded, justified, monitored, revisable, and connected to affected subjects. An institution can exercise asymmetric authority while remaining constrained by procedure, transparency, appeal, rotation, representation, or substantive rights. GRE therefore analyzes the architecture of authority rather

than treating formal symmetry as the only legitimate institutional form.

3.14.5 Vulnerability Asymmetry

Vulnerability asymmetry concerns differences in exposure to loss and differences in the capacity to absorb, recover from, or adapt to that loss. It introduces a dimension of power that is easy to miss when analysis focuses only on holdings or productive capacities. Two subjects may enter the same formal transaction while facing radically different consequences if the transaction fails.

A worker dependent on one employer can face greater loss from contract termination than the employer faces from replacing one worker. A small supplier can be more vulnerable to delayed payment than a large purchaser is to delayed delivery. A tenant can face relocation costs that exceed the landlord's costs of replacing the tenant. A household with minimal savings can be more affected by a small price shock than a wealthier household is by a larger nominal loss. These differences change bargaining relations even when contractual rights appear formally symmetric.

Vulnerability can arise from biological, social, legal, ecological, financial, or infrastructural conditions. It can also be generated by prior economic relations. Debt can increase sensitivity to income interruption. Loss of public infrastructure can increase dependence on private providers. Concentrated employment can make a region vulnerable to one firm's decisions. Data-driven personalization can expose particular groups to targeted exploitation. Vulnerability is therefore often historically produced rather than merely given.

The conversion of vulnerability into power occurs when another subject can credibly condition access to necessities, impose risks, or shift costs onto those less able to bear them. The stronger party need not intentionally threaten harm. Structural vulnerability can influence behavior because subjects anticipate the consequences of refusal. A worker may accept unfavorable terms because unemployment is costly. A state may offer concessions to a mobile investor because local employment is concentrated. A consumer may accept invasive data practices because essential services have become digitally mediated.

GRE analysis should also distinguish vulnerability from weakness in every domain. A subject can be technologically capable and financially wealthy while highly vulnerable to reputational, legal, ecological, or infrastructural disruption. Conversely, a subject with few resources can be relatively resilient when needs are modest, alternatives are available, and social support is strong. Vulnerability therefore requires explicit specification of the relevant hazard, exposure, recovery capacity, and time horizon.

This perspective has normative implications, but the descriptive analysis comes first. Governance can reduce vulnerability by creating buffers, insurance, redundancy, public options, collective support, or guaranteed access to essentials. Yet such interventions can create new dependencies if they centralize provision without contestability. The GRE question is how vulnerability is generated, distributed, converted into leverage, and transformed by the institutions intended to manage it.

3.14.6 Exit Asymmetry

Exit asymmetry concerns differences in the cost, feasibility, and consequences of leaving a relation. It is one of the clearest mechanisms through which other asymmetries become durable. A relation can appear voluntary at entry while becoming difficult to leave once investments, identities, data, legal obligations, infrastructures, social ties, or specialized capabilities accumulate around it.

Exit costs take many forms. Financial penalties and contractual restrictions are explicit examples. Others include retraining, relocation, loss of reputation, incompatibility of technical systems, loss of accumulated data, social isolation, disruption of care arrangements, immigration consequences, or forfeiture of institution-specific benefits. Exit can also be asymmetric because one party can replace the other more easily. A large platform can lose an individual user with little consequence, while the user may lose access to a network on which professional or social activity depends.

Exit asymmetry matters because it alters the practical meaning of consent. Continued participation can reflect genuine preference, but it can also reflect high switching costs, dependence, fear of retaliation, or lack of viable alternatives. GRE therefore treats observed continuation as evidence that requires interpretation rather than as automatic proof that a relation remains mutually beneficial.

The generative dimension of exit is particularly important. Participation in a relation can produce assets that are specific to that relation: reputation scores, social connections, customized tools, accumulated knowledge, eligibility, or identity. These assets can increase productivity and value while simultaneously making exit more costly. Successful cooperation can therefore deepen dependence even without intentional lock-in. The governance problem is to preserve the benefits of relational investment while preventing accumulated specificity from becoming unilateral leverage.

Exit is also only one response to problematic relations. Voice, contestation, collective bargaining, institutional appeal, and internal reform can be preferable when relationships are valuable and exit would destroy jointly generated capacities. An exclusive focus on exit can therefore privilege subjects already able to move while leaving the most embedded or vulnerable participants unprotected. GRE analyzes exit together with voice, representation, repair, and alternative provision.

Exit asymmetry can be reduced through interoperability, portability, non-retaliation rules, social insurance, public alternatives, transferable credentials, data mobility, and limits on restrictive contracts. Such measures alter the relational field even if few subjects actually leave. The credible possibility of exit can change bargaining power. Exit governance is therefore about the structure of alternatives, not merely the observed frequency of departure.

3.14.7 Conversion of Asymmetry into Power

The preceding forms of asymmetry become analytically significant when they are connected to mechanisms of conversion. GRE treats conversion as the process through which a difference in resources, capability, knowledge, institutional position, vulnerability, or exit becomes effective influence over another subject's options or over the conditions from which future options are generated. This conversion is

neither automatic nor uniform.

Several relational conditions commonly affect conversion. Scarcity matters because control over abundant and substitutable resources usually provides less leverage than control over bottlenecks. Dependence matters because the value of an asymmetry rises when other subjects rely on the advantaged subject for essential functions. Replaceability matters because subjects with many alternatives can resist conditions that dependent subjects must accept. Coordination matters because individually weak subjects can aggregate resources or voice. Institutional recognition matters because formal rules can authorize, limit, or redirect the use of an advantage. Information matters because leverage can depend on subjects understanding their alternatives and the likely consequences of refusal. Time matters because a party that can wait often has bargaining advantages over a party facing urgent costs.

Power conversion can also be recursive. A resource advantage can buy expertise; expertise can influence institutional design; institutional design can protect future resource accumulation. Superior knowledge can improve targeting; improved targeting can increase profit; profit can finance further data collection. Control over infrastructure can generate dependence; dependence can support contractual authority; contractual authority can increase exit costs. Such cycles matter to GRE because they transform temporary differences into persistent relational structures.

The concept of conversion also helps distinguish power from inequality. A wealthy subject can lack power over a regulator empowered to impose binding rules. A technically capable firm can remain dependent on a monopolistic supplier. A state with formal sovereignty can be constrained by financial, technological, or security dependencies. Power maps therefore need not reproduce wealth rankings. GRE analysis should trace conversion pathways rather than infer power from one observable variable.

Power can furthermore operate through the generation of expectations. If subjects anticipate that one party can impose costs, deny access, classify them adversely, or shape future opportunities, they may alter behavior before any explicit exercise occurs. This anticipatory effect can make power difficult to observe through events alone. Stable compliance can coexist with strong asymmetry precisely because overt conflict becomes unnecessary. Empirical inquiry may therefore need to study suppressed alternatives, unrealized options, counterfactual bargaining positions, and institutionalized expectations.

The conversion perspective also clarifies why power is domain-specific. A subject can be powerful in hiring and weak in finance, powerful in data and weak in law, powerful domestically and dependent internationally. GRE should therefore resist the temptation to compress heterogeneous power relations into one universal rank. A multidimensional mapping of asymmetries, conversion mechanisms, and affected generative conditions is often more informative than a single power score.

3.14.8 Limits of Capability Equalization

Capability enhancement is one important response to asymmetry. Education, public infrastructure, assistive technology, access to finance, legal aid, data access, computational tools, collective organization, and social protection can increase the ability

of weaker subjects to participate, contest, adapt, and generate alternatives. Yet capability equalization has limits as a general theory of power reduction.

First, some asymmetries arise from differentiated roles rather than remediable deficits. Regulators and regulated entities, doctors and patients, judges and litigants, infrastructure operators and users, or specialized technical teams and general publics occupy different positions because complex systems distribute functions. Governance must then organize accountability across unequal roles rather than assume that every participant should acquire identical capabilities.

Second, capability enhancement can leave institutional conversion mechanisms untouched. Training workers may improve mobility while employers retain unilateral control over scheduling, surveillance, or termination. Financial literacy can improve decisions while contractual complexity and market concentration remain. Digital skills can expand participation while platforms retain control over standards, visibility, and data. Strengthening the weaker subject can therefore be valuable without fully altering the relation that generates the asymmetry.

Third, capabilities can themselves become positional. If all participants acquire a skill that was previously scarce, the advantage associated with that skill can move elsewhere. Credential inflation provides one familiar pattern: expanding qualifications can increase absolute competence while preserving relative competition for scarce positions. In technological domains, widespread adoption of one tool can raise the baseline expected from all participants and create a new asymmetry around access to more advanced infrastructure.

Fourth, equalization can impose burdens. Requiring vulnerable subjects to become expert negotiators, data analysts, legal specialists, or cybersecurity practitioners shifts responsibility onto those already facing structural disadvantage. Some protections are better provided through institutional design, fiduciary duties, public options, default rules, or limits on permissible extraction than through endless demands for individual capability upgrading.

GRE therefore treats capability equalization as one component of relational governance. The relevant question is which asymmetry should be reduced by expanding capability, which should be bounded through institutional rules, which should be made contestable through collective organization, and which should be accepted as functionally necessary but governed through accountability. The objective is not symmetry for its own sake. It is to prevent capability differences from becoming unjustified control over the conditions of participation and future generation.

3.14.9 Limits of Counter-Power

Counter-power refers to capacities that enable subjects to resist, negotiate, constrain, or redirect an existing concentration of power. Collective bargaining, competition, regulatory oversight, courts, professional associations, consumer organization, public alternatives, investigative journalism, open technical standards, mutual aid, and democratic participation can all function as forms of counter-power in different contexts. GRE treats them as relational interventions rather than as automatic restorations of balance.

Counter-power is often necessary because persistent asymmetry cannot be addressed by individual adaptation alone. Workers can negotiate more effectively through collective organization. Small firms can benefit from shared infrastructure or interoperability mandates. Consumers can rely on regulators or courts when individual monitoring is costly. Communities can build institutions that reduce dependence on a single provider. Such arrangements change the structure through which asymmetry is converted into power.

Yet counter-power has limits. It can become concentrated in its own right. A union, regulator, professional body, platform cooperative, or civic organization can develop internal hierarchies and exclusion mechanisms. Institutions created to represent weaker subjects can become difficult for those subjects to contest. Competition can constrain one monopoly while producing instability or shifting concentration to another layer of the system. Transparency can expose misconduct while advantaging actors with superior capacity to process disclosed information. Counter-power therefore requires its own governance.

Counter-power can also reproduce the ontology of the power it contests. If resistance must use the same metrics, platforms, legal categories, or technical infrastructure established by the dominant actor, alternatives may remain confined within the existing field. A community can gain representation without gaining control over the categories through which its interests are recognized. A new market entrant can challenge price while leaving data extraction practices unchanged. GRE therefore asks whether counter-power changes bargaining within a relation or transforms the generative conditions of the relation itself.

Temporal asymmetry further complicates counter-power. Concentrated actors can sometimes act quickly while collective organizations require deliberation, consent, and coordination. Conversely, public institutions can impose durable constraints that private actors cannot easily evade. The relevant balance is therefore dynamic. Effective governance must consider response speed, persistence, institutional learning, and the capacity of power holders to adapt around controls.

The limit of counter-power does not imply resignation. It indicates that balancing strategies should be evaluated recursively. A mechanism introduced to constrain power should itself be analyzed for new dependencies, exclusions, and conversion pathways. GRE's contribution is to keep that second-order question visible: what does the counter-power generate, whose capacities does it strengthen, which relations does it stabilize, and what new asymmetries emerge from its operation?

3.14.10 Relational Governance under Persistent Asymmetry

Many economic systems will continue to contain substantial asymmetries even under ambitious reforms. Subjects differ in knowledge, scale, specialization, mobility, resources, biological needs, legal mandates, technical capabilities, and exposure to risk. Relational governance therefore cannot depend on the expectation that legitimate order will emerge only after differences have been eliminated. Its task is to organize persistent asymmetry so that necessary differentiation does not become uncontrolled domination or generative foreclosure.

A GRE governance perspective begins by specifying the relevant asymmetries and

their conversion mechanisms. It asks which subjects depend on which others, what alternatives exist, which resources or capabilities function as bottlenecks, who defines the institutional categories of participation, how vulnerability is distributed, and what happens if a subject attempts to exit or contest the relation. This diagnosis identifies where safeguards are likely to matter.

Several governance principles follow from the analysis, although their concrete form remains context-dependent. Authority can be bounded by mandate and review. Essential services can be protected by continuity obligations or public alternatives. Exit can be made more credible through portability and interoperability. Knowledge asymmetry can be addressed through independent expertise, audit, contestation, and evidential access. Vulnerability can be reduced through buffers, insurance, redundancy, and guaranteed minimum capacities. Collective organization can strengthen voice. Rule-making can include affected subjects without presuming that participation alone resolves all asymmetry. Institutions can preserve appeal, revision, and sunset mechanisms so that temporary arrangements do not harden into unchallengeable structures.

Relational governance also requires attention to generative conditions. A policy can constrain abusive behavior in the present while leaving the mechanisms that reproduce future dependence untouched. Conversely, an intervention can redistribute immediate resources while weakening the organizational capacities through which a community previously governed itself. GRE therefore evaluates governance at more than one temporal layer: present protection, future capability, relational quality, structural transformation, and preservation of alternative pathways.

The concept of persistent asymmetry also changes the meaning of fairness. Formal equality of rules can coexist with radically unequal vulnerability or exit costs. Identical disclosure can be useless when interpretive capacities differ. Equal access to a market can mask unequal control over infrastructure. Governance may therefore require differentiated protections or obligations in order to make participation substantively contestable. Such differentiation must itself remain transparent and revisable because protective categories can reify the subjects they are intended to assist.

Power analysis should also remain separate from final normative judgment. A concentrated authority may sometimes be justified by coordination, safety, fiduciary responsibility, or public purpose. A decentralized arrangement can reproduce severe power through infrastructure, convention, or cumulative advantage. GRE therefore does not infer justice from decentralization, symmetry, or participation alone. It supplies a relational map of how influence is generated and sustained; normative evaluation then asks whether those mechanisms are justified under the relevant ethical, legal, and political standards.

This section therefore places power within the GRE problem-space as a dynamic relation among asymmetries, conversion mechanisms, dependencies, institutional structures, and future generative conditions. Resource, capability, knowledge, institutional position, vulnerability, and exit are analytically distinct sources of asymmetry. Their conversion into power depends on scarcity, substitutability, dependence, coordination, authorization, time, and the structure of alternatives. Capability equalization and counter-power can alter these relations, but each has limits and can gen-

erate new asymmetries. Relational governance must consequently remain adaptive, contestable, and attentive to second-order effects.

The analysis also prepares the next constitutive problem. Persistent asymmetry does not occur among identical subjects. Economic relations increasingly connect persons, organizations, states, artificial systems, ecological systems, and other heterogeneous participants whose capacities, temporalities, vulnerabilities, and value structures differ in kind as well as degree. The following section therefore turns from asymmetry within relations to the broader problem of heterogeneity and coexistence.

3.15 Heterogeneity and Coexistence

Generative Relational Economics requires an explicit account of heterogeneity because many economic relations connect subjects, systems, and processes that differ in ways that cannot be reduced to variation along a single scale. The role of this section is to establish coexistence across heterogeneous forms as a constitutive problem of GRE rather than as a residual complication added after a homogeneous model has been constructed. Its objective is to clarify how economic coordination, exchange, dependence, conflict, and joint generation remain possible when participants differ in subject form, intelligence, temporality, vulnerability, value structure, and degree of mutual intelligibility. The discussion proceeds from heterogeneous subjects and forms of intelligence through temporal and vulnerability differences, heterogeneous values, partial mutual intelligibility, economic relation under incomplete commensurability, human–AI relations, more-than-human relations, and boundary cases involving radically different subjects. The method is constitutive and analytical. It identifies conditions under which heterogeneous coexistence can be studied without presuming either complete commonality or complete incomparability.

Heterogeneity matters to GRE for a reason deeper than descriptive diversity. Difference can alter the mechanisms through which relations are formed, interpreted, stabilized, and transformed. Subjects that process information at different speeds can experience the same contract differently. Subjects with different vulnerabilities can bear the same nominal risk unequally. Subjects organized around different value structures can participate in the same economic arrangement while understanding its significance in different terms. Human and artificial systems can cooperate productively while differing sharply in embodiment, temporal horizon, memory, responsibility, and normative status. Economic coexistence therefore often depends on interfaces that enable coordination across difference rather than on the elimination of difference itself.

This perspective also changes the analytical meaning of coordination. Coordination need not imply shared ontology, identical preferences, common measures of value, or full mutual comprehension. It can arise through partial translation, rule-governed interfaces, protocols, conventions, negotiated thresholds, legal forms, institutional guarantees, or stable expectations concerning a limited domain of interaction. Such arrangements can be robust even when deeper interpretations remain divergent. They can also be fragile when the interface suppresses differences that

later become economically consequential. GRE therefore asks both how heterogeneous subjects manage to relate and which differences remain unresolved beneath an apparently successful relation.

Heterogeneity should consequently be distinguished from disorder. A heterogeneous system can possess highly organized relations, and a homogeneous representation can conceal important differences. Likewise, coexistence should be distinguished from harmony. Subjects can coexist through cooperation, competition, dependency, conflict, indifference, mutual constraint, or asymmetric accommodation. The relevant GRE question is not whether heterogeneity produces agreement, but how different forms remain connected, how the relation distributes benefits and burdens, and how the terms of coexistence shape future generative possibilities.

3.15.1 Heterogeneous Subjects

The first dimension of heterogeneity concerns the kinds of subjects that participate in economic relations. Earlier sections treated economic subjecthood as relationally situated, institutionally recognized, temporally persistent, and historically transformable. The present section extends that argument by emphasizing that an economy can contain multiple subject forms at once. Individual persons, households, firms, states, cooperatives, communities, platforms, algorithmic systems, hybrid organizations, and other collective or artificial arrangements can all occupy economically consequential positions while remaining different in constitution and status.

These differences matter because the capacities through which subjects enter relations are not interchangeable. A natural person may possess legal rights, embodied needs, lived vulnerability, memory, social identity, and moral standing that differ categorically from the capacities of a corporation or software system. A corporation can persist across changes in personnel, accumulate assets, sign contracts, and coordinate action across large spatial scales. A public institution can exercise legally authorized powers that private actors lack. An artificial system can process or generate representations at speeds and volumes unavailable to human participants while lacking many forms of embodied participation through which human economic life is organized.

GRE therefore resists the temptation to create one abstract subject model and treat every participant as a parameterized instance of it. A unified formal representation can be useful for a local task, but the analyst must identify which dimensions of subjecthood have been suppressed. Treating a household, a company, and an automated trading system as “agents” can clarify interaction structure while obscuring differences in accountability, embodiment, temporal persistence, legal rights, or the capacity to experience harm. The representational convenience of a common agent label does not establish ontological or normative equivalence.

Heterogeneous subjecthood also means that relations can be constitutive in different ways for different participants. Employment may constitute livelihood and social identity for a worker while functioning as a cost and organizational input for a firm. Credit can appear as a portfolio exposure to a lender and as a condition of continued residence or enterprise survival to a borrower. A platform can treat a user interaction as data-generating activity while the user experiences it as communication,

work, entertainment, or social participation. The same relation can therefore occupy different places in the reproduction of each subject.

This asymmetry of significance is analytically important. Economic relations cannot always be understood by assigning the same type of variable to each side. The relation may link subjects whose persistence conditions are fundamentally different. One participant can exit with limited consequence while another loses access to income, identity, infrastructure, or social connection. GRE analysis should therefore specify what the relation does for each subject, which capacities it supports, which vulnerabilities it exposes, and how these differences affect bargaining, interpretation, and future generation.

Heterogeneous subjects can nevertheless form stable relations. Stability may arise through law, trust, standards, routines, contracts, technical interfaces, conventions, organizational design, or repeated adaptation. The existence of such stability shows that shared subject form is not a prerequisite for economic relation. What matters is whether the relation contains sufficiently compatible interfaces for action, interpretation, and expectation within the domain that must be coordinated.

3.15.2 Heterogeneous Forms of Intelligence

Economic analysis often speaks of information, knowledge, skill, and rationality as though intelligence were a single capacity that subjects possess in greater or lesser amounts. GRE treats intelligence more cautiously. Different subjects can exhibit different forms of problem solving, inference, adaptation, memory, perception, coordination, judgment, and representation. These forms may be partly comparable for a defined task without being reducible to one general economic scale.

Human economic intelligence includes dimensions that are difficult to separate cleanly: practical know-how, embodied familiarity, social interpretation, linguistic competence, moral judgment, imagination, aesthetic discrimination, memory, emotional response, and the capacity to act under incomplete and ambiguous conditions. Collective subjects can display organizational intelligence that no member possesses individually, including routines, distributed expertise, institutional memory, and coordinated response. Computational systems can display high performance in search, optimization, prediction, generation, classification, or symbolic transformation while relying on infrastructures, training processes, objectives, interfaces, and external forms of validation that structure what their outputs mean and how they are used.

Task-specific comparison is therefore often more informative than a universal ranking. One system may outperform another at high-dimensional pattern recognition while performing poorly where contextual interpretation, embodied judgment, accountability, or long-horizon institutional memory is decisive. An expert organization may coordinate a complex regulatory process effectively while responding slowly to unfamiliar technological change. A local community may possess detailed ecological knowledge that is poorly represented in standardized datasets. Heterogeneous intelligence appears as differentiated capability profiles rather than as a single ladder.

This matters economically because different forms of intelligence can become complementary. A relation can generate value precisely because participants perceive

or process different features of a problem. Human–machine systems can combine computational scale with human contextual judgment. Interdisciplinary teams can connect different epistemic traditions. Firms can coordinate specialized units whose local knowledge would be insufficient in isolation. Markets themselves can sometimes coordinate dispersed information without requiring any participant to possess a complete representation of the system.

Complementarity, however, does not eliminate power. The party that controls the interface among forms of intelligence can shape which outputs count, which errors are visible, which judgments are overridden, and which forms of knowledge become economically legible. Standardization can facilitate coordination while devaluing tacit or local knowledge. Automated decision systems can increase processing capacity while concentrating control over model design, data, thresholds, or appeals. The governance of heterogeneous intelligence is therefore partly a problem of interface design and partly a problem of institutional power.

GRE should accordingly distinguish capability difference from epistemic authority. Superior performance in one domain does not automatically justify decision authority in another. Prediction accuracy does not itself settle normative legitimacy. Computational scale does not settle interpretive authority. Human status does not guarantee technical competence. A mature analysis asks which form of intelligence is relevant to which claim, what evidence supports its reliability, how different forms are combined, and who controls the terms of combination.

3.15.3 Heterogeneous Temporalities

Economic subjects also inhabit different temporal structures. Temporal heterogeneity concerns differences in pace, horizon, persistence, delay, memory, reversibility, and the timing through which consequences become visible. These differences can be as consequential as differences in resources or capability because a relation that is sustainable at one temporal scale can be destructive at another.

Individuals often make decisions under lifetimes measured in decades, daily needs measured in hours, and contractual obligations measured in months or years. Firms may evaluate projects through reporting cycles, investment horizons, product lifecycles, or expectations concerning market entry and exit. Public institutions can operate through electoral, budgetary, legal, and infrastructural timescales. Financial systems can react within milliseconds while housing, education, ecological restoration, demographic change, and institutional trust can unfold over decades. Artificial systems can process and update representations rapidly while the social institutions required to evaluate, regulate, or contest their deployment move more slowly.

Temporal heterogeneity creates coordination problems. A rapidly adjusting actor can repeatedly change strategy before a slower institution completes review. Short-term financial incentives can conflict with long-term maintenance or ecological resilience. A policy may generate immediate benefits while degrading capacities that become visible only years later. Conversely, insisting on very long evaluation horizons can leave urgent present vulnerabilities insufficiently addressed. No single time horizon is automatically privileged across all economic questions.

GRE therefore treats temporal alignment as an analytical problem. Contracts, stan-

dards, insurance, reserves, review periods, waiting times, sunset clauses, intergenerational institutions, and adaptive governance can all be understood partly as devices for coordinating subjects whose consequences and capacities unfold at different rates. Such devices do more than schedule action. They distribute whose temporality receives priority. A deadline can privilege the actor able to mobilize quickly. A long approval process can protect against irreversible harm while disadvantaging subjects facing immediate need. A quarterly reporting regime can orient organizations toward measurable near-term outputs at the expense of slower generative effects.

Temporal heterogeneity also complicates attribution. A downstream effect may emerge long after the originating intervention, after intermediate relations have changed and after responsible institutions or personnel have disappeared. Conversely, a long-standing structure can condition present action without appearing in short observational windows. GRE analysis should therefore state the temporal horizon of its claims and examine whether the relevant mechanism operates faster or slower than the data used to identify it.

Coexistence across heterogeneous temporalities requires more than synchronization. Some differences should remain. Ecological regeneration cannot necessarily be accelerated to match financial expectations. Human deliberation may require time that automated processing does not. Institutional due process can be intentionally slower than market reaction. The governance question is therefore which temporal differences should be bridged, which should be protected, and how costs created by temporal mismatch are distributed.

3.15.4 Heterogeneous Vulnerabilities

Subjects differ not only in what they can do but also in what can harm them, how quickly harm occurs, how visible it is, and how readily recovery is possible. Vulnerability heterogeneity concerns these differentiated exposures and recovery conditions. It is especially important because relations that appear symmetric in formal terms can create highly asymmetric consequences when participants have different capacities to absorb loss.

The same monetary loss can be marginal for one subject and existential for another. A temporary service interruption can inconvenience a large organization while eliminating a small firm's only route to customers. Delayed payment can be a minor accounting issue for a well-capitalized buyer and a liquidity crisis for a supplier. Exposure of personal information can create embodied or social risks for an individual that have no equivalent in the experience of an automated system. Environmental degradation can affect communities whose livelihoods depend directly on local ecosystems while remaining abstract in the accounting of distant investors.

Vulnerability is therefore relational and domain-specific. A subject can be highly capable in one domain and vulnerable in another. Large firms can possess extensive resources while depending critically on specific infrastructure or regulatory permissions. States can exercise coercive authority while remaining technologically dependent. Artificial systems can be operationally powerful yet dependent on electricity, hardware, data centers, network access, maintenance, and human authorization. Vulnerability analysis should identify the failure conditions that matter for the par-

ticular relation rather than infer resilience from general size or capacity.

Recovery is as important as exposure. Two subjects exposed to the same disturbance can differ in reserves, insurance, social support, legal recourse, substitutability, repair knowledge, or access to alternative relations. These differences affect bargaining because the subject that can survive delay or failure usually possesses greater strategic freedom. Exit asymmetry, discussed in the previous section, is one expression of this wider vulnerability structure.

GRE also asks how relations generate vulnerability over time. Specialization can increase efficiency while producing dependence on narrow supply chains. Platform participation can expand market access while making future income dependent on ranking systems or account continuity. Debt can finance productive capacity while increasing sensitivity to interest rates or income interruption. An ecological intervention can raise present output while reducing resilience to later shocks. Vulnerability is therefore often produced jointly with value.

Governance under heterogeneous vulnerability should not assume that formally equal treatment produces equivalent protection. Uniform rules can distribute risk unequally when participants have different failure thresholds. At the same time, vulnerability should not be used as a permanent identity that freezes subjects into protected categories. The analytical task is to identify specific exposure, consequence, recovery capacity, and the mechanisms through which the relation modifies them.

3.15.5 Heterogeneous Value Structures

Economic coexistence frequently connects subjects that organize value differently. Value heterogeneity includes differences in what is valued, how value is recognized, which trade-offs are acceptable, what temporal horizon matters, what forms of loss are considered substitutable, and which goods are treated as inappropriate for exchange. GRE therefore treats value structure as plural rather than assuming that all relevant evaluation can be represented through a single utility, price, welfare index, or scalar measure.

Some values are readily expressed through monetary exchange because institutions already provide stable units, markets, contracts, and accounting conventions. Others are represented through rights, duties, thresholds, rankings, narratives, professional norms, ecological indicators, cultural meanings, or qualitative judgments. A community may value continuity of place in ways poorly represented by compensation for relocation. A worker may value autonomy, recognition, security, or meaningful participation alongside income. A public institution may be bound by legality and equal treatment even where another arrangement would reduce cost. Ecological relations can involve irreversibility, species loss, or system resilience that resists straightforward substitution.

Heterogeneous value structures do not imply that coordinated decision is impossible. Institutions routinely make decisions under plural values. They use budgets together with rights constraints, technical standards, minimum thresholds, deliberation, priority rules, side constraints, multicriteria evaluation, and negotiated settlements. These devices are forms of practical ordering rather than proof that all underlying values have become commensurable.

This distinction between ordering and commensurability is central. A decision can select one option without establishing a universal measure that converts every relevant value into a common unit. A legal prohibition can exclude some options before cost comparison begins. A safety threshold can structure a feasible set without pricing every possible injury. Negotiation can produce agreement acceptable to different parties for different reasons. GRE can analyze these arrangements as relational mechanisms for coordinating value heterogeneity.

Value heterogeneity also creates power questions. The institution that chooses the metric can privilege values that fit that metric. Monetary valuation can make some losses legible while rendering others peripheral. Quantitative indicators can improve transparency while narrowing attention to what is measurable. Expert vocabularies can facilitate comparison while excluding affected participants whose reasons are expressed differently. The politics of value therefore includes the design of representation and conversion rules.

GRE evaluation should preserve this plurality where it is substantively real. Scalar measures remain useful where a common measure is justified, but they should not acquire authority merely because they simplify optimization. When values are only partially commensurable, the analysis should record the remaining plurality rather than treating it as noise around a preferred metric.

3.15.6 Partial Mutual Intelligibility

Heterogeneous subjects rarely understand one another completely. Their categories, temporal horizons, sensory access, institutional roles, languages, models, and value structures can differ. Yet complete mutual understanding is not required for economic relation. Partial mutual intelligibility refers to the degree of shared interpretation sufficient for a defined form of coordination while leaving other aspects of the participants' worlds untranslated.

A buyer and seller can agree on quantity, quality, price, and delivery without sharing the same reasons for valuing the transaction. Organizations from different legal cultures can cooperate through contracts and technical standards while retaining different institutional assumptions. Humans can use computational systems whose internal representations they do not fully reconstruct, provided interfaces, validation procedures, and accountability arrangements make the relevant outputs sufficiently interpretable for the task. Scientific and local knowledge systems can sometimes coordinate around observable indicators while interpreting causal significance differently.

Partial intelligibility is therefore often produced by interfaces. A contract translates complex intentions into enforceable obligations. A standard reduces heterogeneous production processes to specified performance criteria. An API enables computational systems built on different internal architectures to exchange defined messages. A price compresses information relevant to exchange while leaving many reasons and consequences outside the transaction. A legal category makes different cases administratively comparable while suppressing detail. These interfaces enable relation precisely by limiting what must be mutually understood.

The reduction involved in an interface can be productive, but it can also generate

misrecognition. When the interface omits a difference that later becomes consequential, coordination can fail. A metric can appear shared while participants interpret it differently. A model output can be operationally accepted without agreement on its epistemic status. A standardized category can group subjects whose vulnerabilities diverge sharply. The existence of a functioning interface therefore does not establish deep mutual understanding.

GRE analysis should ask what must be intelligible for the relation to function and what remains opaque. It should also ask who bears the risk created by opacity. If one party can demand explanation while the other cannot, interpretive asymmetry can become power. If a computational system influences access to credit, employment, or public services, the intelligibility required for legitimate use can be greater than the intelligibility required merely for technical operation.

Partial mutual intelligibility offers a middle position between two unrealistic assumptions: complete transparency and complete incommensurability. Economic life often proceeds through workable but incomplete translations. The quality of coexistence depends on whether these translations are sufficient for the stakes involved, revisable when they fail, and governed in ways that distribute interpretive risk fairly.

3.15.7 Economic Relations without Full Commensurability

Economic relation does not require every relevant object, value, subject, or consequence to be representable on one common scale. Exchange itself can involve commensuration for a limited purpose while broader aspects of the relation remain incommensurable. GRE therefore distinguishes local comparability from full commensurability.

A wage places a monetary value on labor time for the purpose of employment, but it does not establish that income exhausts the value of work, identity, health, autonomy, or social recognition. Insurance can assign compensation schedules to losses without implying that the compensated state is equivalent to the pre-loss state. Environmental markets can price particular emissions or ecosystem services while leaving cultural, ecological, and intergenerational values only partially represented. Cost-benefit analysis can support a decision under specified assumptions without becoming a complete theory of value.

Relations under incomplete commensurability often rely on layered decision rules. Some dimensions are priced. Others are protected through rights or prohibitions. Some are represented through minimum standards, negotiated conditions, or procedural safeguards. Others remain open to qualitative judgment. Such layered arrangements can be analytically messy, but the mess may reflect genuine plurality rather than methodological failure.

GRE can therefore study conversion without assuming equivalence. A value can be converted into another form through an institution even when the conversion is contested or incomplete. Time can be converted into wages; attention into advertising revenue; reputation into credit access; ecological damage into compensation obligations; research prestige into funding opportunity. The existence of a conversion mechanism shows that a relation connects the forms. It does not prove that the forms are intrinsically equivalent.

This distinction helps analyze exploitation and loss. When an institution repeatedly converts one form of value into another under asymmetric terms, the question is not only how much is transferred but which dimensions disappear during conversion. A platform can monetize social interaction while leaving users with limited claims on the resulting economic value. A development project can compensate property loss while failing to restore community networks. A labor contract can pay for output while externalizing health or care burdens. In each case, commensuration can enable exchange while concealing residual effects.

Coexistence under plural values therefore requires institutional creativity. Markets are one mechanism among several. Deliberation, commons governance, public provision, professional standards, rights, mutual aid, licensing, quotas, thresholds, and hybrid arrangements can coordinate heterogeneous values in different ways. GRE does not presume in advance which mechanism is appropriate. It asks how the chosen mechanism makes some values comparable, leaves others outside comparison, distributes authority over conversion, and alters future possibilities.

3.15.8 Human–AI Relations as a Contemporary Case

Human–AI relations provide a contemporary case in which heterogeneity of subject form, intelligence, temporality, vulnerability, and value can appear simultaneously. GRE can analyze these relations without first resolving philosophical questions about machine consciousness or personhood. The immediate economic question is how human and artificial operational subjects become connected through production, decision, communication, ownership, infrastructure, and institutional authority.

The asymmetry is multidimensional. Artificial systems can process or generate large volumes of symbolic material rapidly, replicate outputs at low marginal cost, and operate continuously within suitable infrastructure. Humans retain forms of embodiment, lived vulnerability, social membership, legal standing, moral responsibility, contextual experience, and value formation that are not established by computational performance. Organizations often mediate between the two, determining data access, deployment goals, review procedures, liability, and the distribution of gains.

This heterogeneity creates complementary possibilities. Artificial systems can extend search, translation, drafting, prediction, pattern recognition, or simulation. Human participants can contribute contextual interpretation, problem selection, normative judgment, embodied knowledge, accountability, and decisions concerning what purposes should be pursued. The generative question is how the relation changes the capabilities of both the immediate participants and the surrounding institutions.

It also creates new dependencies. Workers can become dependent on tools they do not control. Organizations can become dependent on model providers, computational infrastructure, or proprietary interfaces. Users can rely on systems whose update cycles alter behavior faster than institutional procedures adapt. Expertise can shift from producing outputs directly to evaluating, directing, integrating, or contesting machine-generated outputs. These changes can redistribute bargaining power even when aggregate productivity rises.

Human–AI coexistence therefore should not be analyzed through replacement

alone. Substitution is one possible relation. Others include complementarity, supervision, delegation, contestation, infrastructural dependence, mutual adaptation, and reorganization of occupational or institutional roles. The relevant GRE object is the evolving relational configuration: who controls the system, who defines objectives, who bears error, who receives generated value, which human capacities are strengthened or weakened, and how future alternatives are shaped.

The case also clarifies partial mutual intelligibility. Humans may use outputs without understanding every internal computational process, while artificial systems operate on representations that do not amount to human understanding in any straightforward sense. Economic coordination can nevertheless occur through interfaces, tests, standards, feedback, and institutional review. The adequacy of that partial intelligibility should depend on stakes. A low-risk drafting aid and a system affecting liberty, livelihood, healthcare, or public authority require different evidential and governance conditions.

GRE therefore treats human–AI relations as an important contemporary domain of heterogeneous coexistence, while maintaining ontological and normative caution. Operational capability does not settle personhood. Performance difference does not settle moral status. Economic usefulness does not settle legitimacy. These questions remain connected but analytically distinct.

3.15.9 More-than-Human and Ecological Relations

Economic systems also coexist with organisms, ecosystems, climatic processes, material cycles, and other more-than-human structures whose dynamics are constitutive of production and life. GRE includes these relations because economic generation depends on ecological and material conditions even when those conditions are poorly represented by conventional economic subjects.

More-than-human analysis requires ontological care. A forest, river, species, or ecosystem need not be treated as a subject in exactly the same sense as a human person or organization for its relational role to be economically consequential. Ecological systems can impose constraints, provide capacities, absorb waste, regenerate resources, transmit disturbances, and respond to interventions through dynamics that exceed the intentions of economic actors. Some legal or cultural traditions may also recognize nonhuman entities through forms of representation or standing. GRE can study these arrangements without requiring one universal theory of nonhuman subjecthood.

Ecological heterogeneity is strongly temporal. Soil formation, forest succession, hydrological cycles, species recovery, and climate processes can unfold at rates that differ from market, budgetary, and political cycles. An economic system can therefore appear productive within a short window while drawing down slower regenerative capacities. Conversely, ecological protection can impose immediate costs while preserving long-horizon generative conditions. The choice of temporal scale becomes part of evaluation rather than a neutral technical setting.

Vulnerability is likewise heterogeneous. An industrial actor may be able to relocate while a local ecosystem cannot. A community may depend on a specific river or coastal system whose loss is not replaceable by monetary compensation. Species and

ecological processes can cross thresholds beyond which recovery becomes difficult or impossible on humanly relevant timescales. These differences complicate models that assume reversible substitution among resources.

Partial intelligibility appears here as well. Human institutions do not fully observe ecological systems. Models, indicators, monitoring networks, local knowledge, and scientific interpretation provide partial representations. Intervention therefore occurs under uncertainty about feedback, thresholds, and delayed effects. GRE's epistemic commitments require the distinction between ecological reality and its representation to remain explicit, especially where uncertainty interacts with potentially irreversible change.

The economic question is how relations with more-than-human systems affect present and future capacities. Extraction, cultivation, conservation, restoration, pollution control, infrastructure, and land-use rules all modify ecological conditions from which later economic possibilities emerge. More-than-human coexistence is thus central to generative analysis because the future economy is partly generated through relations with systems that exceed the boundaries of human institutions.

3.15.10 Boundary Cases of Radically Different Subjects

The most demanding cases for GRE arise when participants differ so substantially that ordinary assumptions of shared preference, common language, reciprocal recognition, or comparable vulnerability become unreliable. These boundary cases may involve relations among human communities with sharply different ontologies, future artificial systems with unfamiliar forms of agency, interspecies relations, intergenerational relations in which one party is not yet present, or institutional interactions with ecological systems that cannot participate in negotiation in conventional terms. The purpose of considering such cases is not to classify every entity as a subject. It is to test which parts of GRE remain usable when mutual similarity is minimal.

The first requirement is to separate relation from reciprocity. A subject or system can be economically affected by another without being able to respond in the same channel. Future generations can bear consequences of present debt, infrastructure, ecological damage, and knowledge preservation without participating in present bargaining. Nonhuman systems can constrain or respond to economic activity without expressing preferences through markets or language. An artificial system can alter human opportunities while its own status as a bearer of interests remains unsettled. Economic relation can therefore exist under asymmetric capacities for representation and response.

The second requirement is representational humility. When one side cannot articulate its interests through the dominant institutional interface, another actor often speaks on its behalf. Guardians, regulators, scientific experts, community representatives, trustees, legal advocates, or technical proxies can perform this role. Representation may be necessary, but it creates a second-order relation in which the representative's categories can shape what becomes visible. GRE analysis should therefore examine not only the represented subject or system but also the institutions that authorize, translate, and contest representation.

The third requirement is to distinguish coordination from assimilation. Radically

different subjects need not become similar in order to coexist. Governance can instead create protected distances, limited interfaces, non-interference rules, thresholds, buffer zones, rights, or protocols that make coexistence possible while preserving difference. In some cases the appropriate relation is closer integration; in others it may be separation or restriction of contact. GRE does not prescribe one universal form of coexistence because the relevant vulnerabilities, values, and generative effects differ.

Boundary cases also expose the limits of commensuration. Where interests or values cannot be credibly translated into one metric, decision may require procedural legitimacy, precaution, rights, representation, plural evaluation, or explicit acknowledgment of unresolved disagreement. A decision can still be made, but the residual disagreement remains part of the record rather than disappearing into a scalar result. This is especially important where the affected party cannot later recover from the imposed decision.

The broader constitutional implication is that GRE should be able to study economies composed of heterogeneous forms without making homogeneity a hidden precondition of analysis. Economic relation can persist through partial intelligibility, bounded interfaces, heterogeneous values, differentiated temporalities, unequal vulnerabilities, and incomplete commensurability. The task is to identify which differences matter to the relation, which interfaces make coordination possible, which conversions obscure residual losses, and how the terms of coexistence alter future generative possibilities.

Heterogeneity therefore belongs inside the GRE problem-space rather than at its margins. It prevents the economic subject from being silently standardized, prevents intelligence from being reduced to one ranking, prevents temporality from being treated as uniform, prevents vulnerability from being inferred from formal equality, and prevents value from being collapsed into a single measure. It also provides a bridge to the next constitutional problem. Once GRE accepts heterogeneous forms as legitimate participants and objects of inquiry, it must state more precisely where its own disciplinary boundaries lie and how it relates to neighboring economic and social-scientific traditions. The following section therefore turns to the boundaries of Generative Relational Economics.

3.16 Boundaries of Generative Relational Economics

Generative Relational Economics is intended to remain intellectually permeable without becoming disciplinarily indeterminate. The role of this section is to specify the principal boundaries through which GRE relates to neighboring economic and social-scientific traditions while preserving a recognizable problem-space of its own. Its objective is neither to rank adjacent approaches nor to absorb them into a single synthesis. Instead, the section clarifies where GRE can borrow concepts, methods, evidence, and explanatory mechanisms; where genuine overlap exists; and where a distinction should be maintained because the neighboring tradition asks a different primary question, uses a different evaluative register, or makes commitments that GRE does not need to adopt. The discussion proceeds through mainstream eco-

nomics, political economy, relational economics, economic sociology, complexity economics, evolutionary economics, capability approaches, ecological and regenerative economics, generative justice, and general Generative Relational Theory. The method is boundary-setting rather than genealogical. Chapter 2 reconstructed intellectual lineages; the present task is to define interfaces for an emerging research programme.

A disciplinary boundary in this sense is not a wall. GRE can use optimization, causal inference, institutional analysis, network models, historical interpretation, capability concepts, ecological accounting, or justice-oriented evaluation whenever those tools are appropriate to the claim under investigation. The boundary concerns the conditions under which such borrowing remains intelligible. A borrowed method does not make a study identical with the field from which that method came, and a shared object does not erase differences in analytical emphasis. Firms, households, technologies, institutions, ecosystems, capabilities, and power can all be studied by several traditions at once while being rendered differently by each.

This openness is necessary because many GRE questions are intrinsically composite. A study of platform labor may require conventional price and labor-market analysis, institutional and legal interpretation, network structure, computational measurement, political-economic analysis of control, and normative evaluation of capability or dependency. A study of agricultural transition may require cost and productivity analysis, ecological constraints, household reproduction, institutional history, technological coevolution, and long-horizon generative effects. GRE contributes when the inquiry asks how relations among these elements generate, distribute, stabilize, transform, or foreclose later capacities and possibilities. It does not require every neighboring perspective to be translated into GRE terminology.

Boundary maintenance therefore serves two purposes. First, it protects GRE from conceptual inflation. If every relational, dynamic, institutional, or justice-oriented economic study were automatically classified as GRE, the programme would lose analytical content. Second, it protects neighboring fields from retrospective appropriation. GRE can inherit and recombine resources while acknowledging that those resources have their own histories, standards, and unresolved debates. The disciplinary identity developed in this chapter depends on dialogue without theoretical identity.

3.16.1 GRE and Mainstream Economics

GRE has no constitutive need to define itself through opposition to mainstream economics. Standard economic analysis contains powerful tools for studying prices, incentives, choice under constraints, equilibrium, strategic interaction, causal effects, welfare consequences, production, and allocation. Where a research problem is adequately specified by those objects, GRE gains little by redescribing the same analysis in relational vocabulary. The boundary is therefore positive: GRE becomes useful when the research question concerns how the relevant preferences, capacities, constraints, institutional positions, relations, or future opportunity sets are themselves generated and transformed through economic processes.

This distinction can be stated through analytical depth rather than disciplinary hierarchy. A conventional model may treat preferences as given over the horizon of

analysis. GRE can accept that local simplification when preference formation is irrelevant to the question. A different study may need to explain how advertising, institutions, peer relations, platform design, education, or repeated participation reshape preferences or salience. In that setting, what was reasonably exogenous in the first model becomes an object of inquiry. The same logic applies to technology, endowments, legal categories, information structures, capabilities, and market boundaries.

Equilibrium analysis provides another example. GRE does not reject equilibrium as a mathematical or empirical concept. A stable or approximately stable configuration can be analytically important. The additional GRE question concerns what relations sustain the configuration, how the stability distributes capacities and vulnerabilities, whether the configuration generates new conditions that alter its own persistence, and what happens when the relevant state space or institutional rules change. Equilibrium can therefore appear within GRE without defining the whole research programme.

The relation is similarly complementary in empirical work. Econometric identification, experimental design, structural estimation, administrative data analysis, and causal inference can provide strong evidence for particular mechanisms or effects. GRE should use such evidence where available and should not substitute relational prose for identification. At the same time, an estimated local causal effect does not automatically reveal downstream institutional transformation, changing subject positions, altered exit conditions, or long-run generative consequences. Those further claims require further evidence.

The boundary can thus be summarized in terms of problem selection. Mainstream economics often provides the strongest available analysis when the relevant agents, constraints, preferences, technologies, and institutional rules can be treated as sufficiently stable. GRE becomes especially relevant when those conditions are part of what must be explained. The relationship is therefore one of selective extension and mutual correction rather than displacement.

3.16.2 GRE and Political Economy

GRE overlaps substantially with political economy because both can treat economic outcomes as inseparable from institutions, power, historical formation, distribution, and collective organization. Questions concerning ownership, labor, state capacity, financial structure, class, technological control, colonial legacies, regulation, and asymmetric dependence are naturally shared terrain. GRE does not need a separate vocabulary when political economy already provides an adequate account of the relevant mechanism.

The principal difference lies in analytical center of gravity. Political economy frequently organizes inquiry around the distribution and exercise of power among classes, states, firms, institutions, or social groups. GRE includes these objects but asks an additional family of questions concerning what those relations generate over time: capacities, subject positions, dependencies, values, institutional pathways, representational structures, ecological conditions, and the possibility of later action. Power remains central, yet GRE does not make every economic relation reducible to power.

This distinction matters because a relation can be generatively important even when domination is weak or absent. Cooperative institutions can generate capabilities and norms. Public infrastructure can create new spaces of participation. Educational systems can alter the subjects capable of entering later markets or political processes. Technological standards can coordinate activity without being explainable primarily through coercion. Political-economic analysis may already address these effects; GRE emphasizes their generative structure as a recurring cross-domain problem.

Conversely, GRE should not dilute political-economic mechanisms by translating them into neutral language of relation. Ownership, coercion, exclusion, dispossession, monopoly, dependency, and state authority possess specific institutional and historical content. When such mechanisms explain an outcome, they should be named directly. Relational vocabulary is not a substitute for analyzing who controls resources, who bears risk, who sets rules, or who can credibly exit.

GRE therefore sits near political economy while preserving a broader generative question. It can investigate how power structures generate future inequalities and institutional lock-in, but it can also study relations of learning, cooperation, care, ecological reproduction, or symbolic orientation whose economic importance is not exhausted by power. The boundary allows GRE to inherit political economy's seriousness about history and asymmetry without treating political-economic conflict as the sole grammar of economic generation.

3.16.3 GRE and Relational Economics

The strongest conceptual overlap may appear between GRE and approaches that explicitly place relations at the center of economic analysis. Relational economics, relational goods, network-based economic analysis, and other relation-sensitive traditions already challenge the assumption that economic value and behavior can always be understood through isolated individuals and possessed objects. GRE shares the view that access, interaction, recognition, coordination, dependency, and participation can be economically constitutive.

The boundary arises from the second term in the name: generative. GRE is interested not only in the existence or quality of relations but also in what relations bring into being, reproduce, transform, or foreclose. A relation can connect already-defined actors, but it can also alter their capabilities, identities, institutional positions, preferences, expectations, and future relations. The analytical question moves from the structure of a relation to the consequences of participating in and reproducing that relation.

This distinction prevents a relation-first approach from becoming static. Two networks can share similar topology while differing in what their ties generate. Two contractual arrangements can appear similar at one moment while producing different long-term capabilities or dependencies. A cooperative relation can initially create shared capacity and later become exclusionary. A market relation can transmit value while also changing the conditions under which future exchange occurs. GRE therefore requires temporal and generative specification beyond identifying relational structure.

At the same time, GRE does not claim that every relation generates deep transformation. Many relations may be transient, weak, or analytically negligible for the research question. The researcher must establish which relations matter, through which mechanisms, and over what horizon. Relation itself is not an explanatory endpoint.

The boundary with relational economics is thus narrow but meaningful. GRE belongs naturally within a wider family of relational economic approaches, while adding a systematic focus on downstream generation, recursive transformation, heterogeneous forms of value, changing subjects, and future possibility. That addition should be treated as a research orientation rather than as a claim that earlier relational work failed to recognize change or emergence.

3.16.4 GRE and Economic Sociology

Economic sociology provides many of the concepts required for GRE to avoid an overly thin account of economic action. Institutions, social networks, conventions, organizations, classifications, trust, status, embeddedness, cultural interpretation, and collective identity can all shape what economic relations are possible and how they are understood. GRE therefore shares a substantial empirical and conceptual domain with economic sociology.

The boundary is not based on a sharp separation between "economic" and "social" facts. GRE rejects such a simple partition. The distinction is better located in the organizing research problem. Economic sociology can ask how markets, firms, money, organizations, or valuation are socially constituted. GRE can use those analyses and then ask how the resulting economic relations transform later capacities, values, constraints, subject positions, and structures of possibility. The two directions can be mutually reinforcing.

GRE also retains an explicitly economic concern with allocation, production, circulation, extraction, capability, scarcity, and the organization of resources. These objects prevent the programme from dissolving into a general sociology of relations. A sociological account of trust may explain why exchange becomes possible; GRE may further analyze how the exchange redistributes capacity, creates dependency, alters future bargaining positions, or changes the institutions that sustain trust. A sociological account of classification may explain category formation; GRE may examine how that classification changes access to credit, work, insurance, mobility, or recognition.

This interface is especially important for symbolic and representational objects. Prices, ratings, credentials, risk scores, categories, and rankings can be both social facts and economic mechanisms. GRE can study their generative effects without claiming that economic sociology is merely a precursor to GRE. The traditions differ in disciplinary history and in the questions they prioritize.

The boundary therefore remains porous. GRE depends on sociological evidence whenever economic relations are constituted by social meaning, institutional recognition, or organizational form. It remains recognizably economic when the inquiry centers on how such relations organize resources, capacities, value, scarcity, exchange, production, and future economic possibility.

3.16.5 GRE and Complexity Economics

Complexity economics and GRE share an interest in heterogeneous agents, nonlinearity, adaptation, path dependence, interaction effects, emergent macro-patterns, and systems that change outside simple equilibrium descriptions. Complexity methods can be especially valuable when aggregate outcomes arise from distributed interactions and when feedback alters the trajectory of the system.

The overlap is methodological as well as conceptual. Agent-based models, network models, simulation, nonlinear dynamics, and computational experiments can all contribute to GRE where the research problem is compatible with their assumptions. These tools allow researchers to study distributed generation, threshold effects, coordination, cascading change, and multiple possible trajectories.

GRE nevertheless remains broader than a complexity methodology. A GRE contribution need not contain a simulation, a network model, or a nonlinear formal system. Historical interpretation, institutional analysis, qualitative research, comparative case studies, legal analysis, causal inference, and participatory inquiry can all be appropriate. Complexity is one representational and explanatory family among several.

A second boundary concerns the representation of emergence. A computational model can demonstrate how a macro-pattern emerges from specified micro-rules. That result is important, but it establishes emergence within the model. GRE must still ask whether the selected agents, rules, state variables, and interactions adequately represent the empirical process. It may also need to explain how the rules themselves were historically generated, interpreted, contested, or transformed.

A third boundary concerns normativity and meaning. Complex adaptive behavior can persist without being desirable. A resilient system can stabilize exclusion, ecological harm, or domination. Actors can interpret the same rule differently, and those interpretations can alter later action. GRE therefore combines complexity-sensitive analysis with explicit attention to historical meaning, institutional authority, heterogeneous value, and normative evaluation.

The relationship is consequently close but non-identical. Complexity economics supplies powerful tools for distributed and nonlinear generation; GRE adds a wider methodological repertoire and makes the generation of rules, subjects, meanings, and evaluative conditions available as research objects where evidence permits.

3.16.6 GRE and Evolutionary Economics

Evolutionary economics offers another close interface because it treats economic systems as historically changing populations of technologies, routines, organizations, practices, and institutions. Innovation, variation, selection, retention, path dependence, learning, and coevolution provide important resources for analyzing processes that cannot be reduced to static optimization.

GRE shares the historical and processual orientation while avoiding an automatic translation of every generative process into evolutionary terms. Generation can occur through variation and selection, but it can also arise through deliberate institutional design, legal reclassification, collective interpretation, negotiated coordination,

education, care, public investment, conflict, or sudden technological recombination. Evolutionary mechanisms are therefore important members of a broader generative repertoire.

The distinction is also useful for normative analysis. Persistence or selection does not demonstrate efficiency, justice, desirability, or superior adaptive value in every relevant sense. Institutions can survive because alternatives are suppressed, switching costs are high, incumbents control infrastructure, or vulnerable groups bear the costs of persistence. GRE therefore treats selection outcomes as explanatory objects that may require separate normative evaluation.

Coevolution provides particularly fertile common ground. Firms and technologies, institutions and practices, infrastructures and habits, or policies and expectations can change in mutually conditioning ways. GRE extends the question when the process changes the kinds of subjects, capacities, value forms, or relations that can exist in the next period. The interest lies not only in reciprocal adaptation but in transformation of the conditions under which later adaptation occurs.

GRE can thus use evolutionary models and concepts whenever variation, selection, retention, innovation, and coevolution explain the empirical process. Its boundary lies in refusing to make those mechanisms exhaustive. The programme remains open to generative processes whose historical logic is interpretive, institutional, juridical, ecological, political, or deliberately designed rather than primarily evolutionary.

3.16.7 GRE and Capability Approaches

Capability approaches and GRE share a concern with what people and other relevant subjects are substantively able to do and to become. This creates a natural interface between the evaluation of resources and the analysis of conversion conditions. Equal resources can produce unequal capabilities when subjects face different institutions, environments, social relations, embodied conditions, or access structures.

GRE adopts this insight without treating capability as its sole evaluative language. Capability is one dimension of generative consequence. Economic relations can generate or erode capabilities, but they can also transform dependency, recognition, institutional participation, relational quality, ecological conditions, symbolic orientation, and the possibility of collective action. Some of these effects can be translated into capability terms; others may be better preserved as distinct analytical objects.

The temporal orientation also differs in emphasis. Capability analysis can evaluate the substantive opportunities available at a given time. GRE places particular attention on how those opportunities were generated, how they are maintained, and how present relations alter the capability-generating conditions of the future. This makes capability formation, reproduction, concentration, and erosion central dynamic questions.

Capability asymmetry further enters the analysis of power. A difference in capability does not automatically create domination, but it can become leverage when one subject controls an infrastructure, knowledge resource, legal permission, computational system, or exit option required by another. GRE therefore connects capability analysis to relational conversion mechanisms without reducing capability to power.

The boundary is normative as well as analytical. GRE can use capability-oriented evaluation without claiming to settle the philosophical questions that capability theories address concerning freedom, human flourishing, lists of central capabilities, or the justification of public priorities. Those debates remain neighboring normative resources. GRE's contribution is to investigate how economic relations generate and distribute the conditions under which capabilities become possible, durable, or foreclosed.

3.16.8 GRE and Ecological and Regenerative Economics

Ecological and regenerative economics provide essential resources for any GRE analysis in which economic generation depends on material, energetic, ecological, or more-than-human conditions. Production cannot be understood solely through monetary circulation when it depletes soils, water, biodiversity, climate stability, or other conditions required for future activity. Conversely, economic relations can sustain and regenerate ecological capacities under some institutional arrangements.

GRE shares the emphasis on stocks, flows, throughput, ecological limits, interdependence, and long-horizon reproduction. It also shares the concern that apparent short-term gain can undermine the conditions of later possibility. Generative foreclosure has a direct ecological meaning when present extraction damages the ecological capacities through which future livelihoods or social systems could otherwise be sustained.

The boundary again concerns scope and normativity. GRE uses "generative" in a broader sense than ecological regeneration. A process can generate institutions, subject positions, knowledge, technological capacities, dependencies, or symbolic values while degrading ecological conditions. Conversely, ecological regeneration can occur within social arrangements that distribute benefits or burdens unjustly. The descriptive fact of regeneration therefore requires separate social and normative evaluation.

GRE also avoids treating circularity, resilience, regeneration, and generativity as synonyms. A circular material flow can preserve an unjust labor relation. A resilient system can stabilize harmful dependence. A regenerative ecological practice can impose burdens on communities whose knowledge or land is appropriated. The relevant analysis must specify what is being regenerated, for whom, through which relations, and with what consequences elsewhere.

The relationship is therefore strongly complementary. Ecological and regenerative economics prevent GRE from treating future possibility as socially generated in isolation from biophysical conditions. GRE contributes a wider account of how ecological and economic processes interact with institutions, power, subjects, value forms, and the distribution of future generative capacity.

3.16.9 GRE and Generative Justice

Generative justice is one of the closest normative neighbors of GRE because it directs attention to the circulation and return of generative value and to the conditions under which communities retain control over the processes that produce value. Earlier in the book, this lineage was treated as an established theoretical resource rather

than as a retrospective expression of GRE. That distinction remains important at the disciplinary boundary.

GRE shares the concern that evaluation should extend beyond the immediate allocation of outputs. A relation can appear distributively acceptable at one moment while extracting the capacities, knowledge, infrastructures, or ecological conditions that enable future generation. Conversely, an arrangement can strengthen future capability by returning value, knowledge, authority, or productive infrastructure to the subjects and communities involved.

The two programmes nevertheless have different scope. Generative justice is explicitly normative. GRE combines descriptive, explanatory, causal, historical, formal, computational, normative, and intervention-oriented modes. A GRE study can analyze how value recirculates or is extracted without concluding that a particular pattern is just. Normative judgment requires additional premises concerning participation, domination, capability, harm, ecological sustainability, procedural legitimacy, plural values, and future possibility.

GRE also uses a wider conception of what may be generated. Material wealth and productive capacity are central, but economic relations can also generate subject positions, representations, institutional authority, dependencies, expectations, knowledge, ecological conditions, and future option structures. Return of value is therefore one important pattern among several possible generative trajectories.

The boundary preserves attribution and conceptual clarity. GRE can learn directly from generative justice while maintaining a broader economic research programme whose normative analysis remains open to several theories of justice and to the neighboring work of GREthic. The overlap is substantive, but theoretical identity would obscure differences in purpose and scope.

3.16.10 GRE and General Generative Relational Theory

The final boundary is internal to the wider research programme. General Generative Relational Theory provides the broader conceptual space in which relations, generation, ontological emergence, epistemic mediation, historical transformation, power, normativity, and praxis can be studied across domains. GRE is the economic instantiation of that wider framework. The distinction is necessary because not every generative-relational problem is an economic problem.

GRE therefore adopts only the amount of general GR required to investigate economic objects. It studies production, allocation, circulation, exchange, extraction, capability, scarcity, institutions, economic subjecthood, value, power, ecological dependence, and the transformation of future economic possibility. General GR may address analogous structures in law, politics, education, science, aesthetics, knowledge, culture, or other domains where the primary research problem is not economic.

This distinction prevents disciplinary expansion by analogy. A relational pattern discovered in economic analysis should not automatically be generalized to every social domain. Conversely, a concept developed in another GR domain may require translation before it becomes economically meaningful. The relevant mechanisms, evidence, units of analysis, institutions, and normative stakes can differ substantially

across domains.

The relation is nevertheless recursive. GRE can contribute concepts and findings back to general GR. Economic studies may reveal new mechanisms of generative foreclosure, recursive power, value conversion, subject formation, or cross-scale transformation that later become useful outside economics. Other GR domains can likewise correct GRE by showing that an apparently economic process depends on legal, political, epistemic, cultural, or ecological structures that GRE alone cannot adequately explain.

General GR should therefore function neither as a doctrinal authority over GRE nor as a collection of metaphysical propositions that economic research is expected to confirm. It is a broader, revisable framework that can coordinate comparison among domains while remaining open to correction from domain-specific work. GRE retains disciplinary responsibility for the quality of its economic evidence and explanation.

The boundaries established across this section give GRE a position that is open without being unlimited. The programme can use mainstream economic models, political-economic accounts of power, relational and sociological analyses, complexity and evolutionary methods, capability concepts, ecological and regenerative analysis, and generative-justice insights. None of these interfaces requires GRE to become identical with the neighboring field. The criterion is whether the borrowed resource helps explain how economic relations generate, reproduce, distribute, transform, or foreclose later capacities and possibilities.

This boundary-setting also prepares the next task of disciplinary constitution. Once GRE's neighboring interfaces have been identified, a further question becomes unavoidable: what would make a particular study count as a contribution to GRE rather than merely a study that uses relational language? The following section therefore turns from external boundaries to internal research standards, specifying the criteria by which a GRE contribution can state its relational problem, generative claim, evidence, boundary conditions, normative commitments, and cumulative contribution with sufficient clarity to be evaluated and revised.

3.17 Criteria for a GRE Research Contribution

The preceding sections have defined the problem-space, analytical objects, scales, modes of inquiry, epistemic commitments, praxis orientation, normative concerns, and disciplinary boundaries of Generative Relational Economics. A research programme, however, also requires internal standards by which particular studies can be recognized, criticized, compared, and accumulated. The role of this section is to state those standards. Its objective is neither to create a rigid checklist nor to police disciplinary membership through terminology. It is to specify the minimum analytical work required for a contribution to make a recognizably GRE claim. The discussion proceeds through ten criteria: specification of the relational problem; explicit scale and boundary conditions; identification of the generative claim; evidence appropriate to that claim; distinction between representation and relational reality; attention to downstream effects; consideration of alternative generative mechanisms; normative transparency; reproducibility and interpretive traceability; and contri-

bution to cumulative knowledge. The method is constitutional and methodological. These criteria are intended to make GRE research more contestable, revisable, and cumulative rather than more doctrinal.

A study need not satisfy every criterion with the same intensity. A conceptual paper may contribute primarily through category formation and theoretical clarification. A historical study may establish a generative mechanism through archival reconstruction. An econometric study may identify a restricted causal relation while leaving wider ontological questions open. A simulation may explore the consequences of a specified generative mechanism without claiming empirical completeness. An intervention study may generate evidence about relational change that could not be obtained through detached observation alone. The relevant standard is proportionality: the claims made should be supported by an appropriate combination of analytical specification, evidence, and methodological transparency.

GRE therefore treats disciplinary contribution as a relation between a problem, a claim, a representation, evidence, and a cumulative research context. Relational vocabulary alone does not establish that relation. A paper that describes a network, invokes emergence, or discusses downstream effects is not thereby a GRE contribution. The GRE character becomes substantive when the research shows how a specified economic relation contributes to the generation, reproduction, transformation, distribution, or foreclosure of later capacities, values, subjects, constraints, structures, or conditions of possibility, and when that claim is made in a form that other researchers can examine and revise.

3.17.1 Specification of the Relational Problem

A GRE contribution begins by specifying the relational problem under investigation. This requirement is stronger than stating that the topic is "relational." The study should identify which subjects, entities, institutions, infrastructures, representations, ecological conditions, or other analytically relevant configurations are connected, what kind of relation is at issue, and why that relation matters to the economic problem being studied.

The relation may involve exchange, production, financing, employment, ownership, access, dependence, coordination, classification, care, information, legal recognition, infrastructure use, platform participation, resource extraction, ecological dependence, or another economically consequential connection. Its empirical form may be contractual, informal, symbolic, technical, organizational, institutional, spatial, ecological, or distributed across several of these forms. GRE does not require a single taxonomy of relations. It requires enough specification for the researcher and reader to know what is being claimed to connect what.

Relational specification should also identify the economically relevant incidence of the relation. The administrative recipient of a resource, policy, payment, model, or intervention may be only one locus within a wider relational field. A subsidy to a firm can affect workers, suppliers, competitors, financial institutions, local communities, infrastructure demand, and future investment. A credit decision can affect households, landlords, employers, insurers, and later access to other services. A platform rule can alter users, complementors, advertisers, content producers, and labor

conditions. The research problem becomes relational when these connections are treated as analytically constitutive rather than as residual externalities added after the main analysis.

The study should further clarify whether the relation is itself the principal object or whether it mediates another object of interest. A paper may examine the formation of a labor relation, the consequences generated through that relation, or the way the relation transforms its own future conditions. These are different research problems. Stating the relation precisely prevents a general language of interdependence from substituting for explanation.

Relational specification does not require exhaustive mapping. Every inquiry selects some relations and leaves others outside the active representation. The contribution lies partly in justifying why the selected relations are sufficient for the local question and in making visible which important relations have been bracketed. A study that names its relational problem clearly can later be extended, challenged, or re-scaled. A study that leaves the relation implicit is harder to evaluate because disagreement about evidence can conceal disagreement about what the object actually is.

3.17.2 Explicit Scale and Boundary Conditions

Every GRE contribution should state the scale and boundary conditions within which its claims are intended to hold. Economic relations change character across temporal, organizational, spatial, institutional, ecological, and analytical scales. An apparent entity at one scale can decompose into heterogeneous relations at another. A mechanism visible in a household, firm, or platform may operate differently at sectoral, juridical, ecological, or transnational scales. Explicit scale selection therefore belongs to the substance of the analysis rather than to a technical appendix.

Boundary conditions specify what is treated as inside the active system of analysis, what is treated as an environment or background condition, and what is excluded. These boundaries can be geographical, institutional, temporal, jurisdictional, organizational, technological, ecological, or representational. They can also be nested. A study of a labor platform may define the platform ecosystem as the primary boundary while treating labor law, payment infrastructure, and macroeconomic conditions as surrounding systems that enter through specified interfaces.

Temporal boundaries require particular care because generative effects can be delayed. An intervention that raises income over six months may reduce a productive or ecological capacity over five years. A technology that expands access in one period can create dependence on proprietary infrastructure later. A relational configuration that appears stable during one institutional regime may dissolve when law, prices, expectations, or political authority change. A GRE contribution should therefore identify the temporal horizon of the claim and, when appropriate, distinguish immediate effects from slower structural or generative transformations.

Explicit boundary conditions also constrain generalization. Evidence from one sector, jurisdiction, historical period, or technological architecture does not automatically establish the same mechanism elsewhere. A GRE study can make a narrow claim and still be theoretically important if it states the conditions under which the

mechanism is expected to operate. Conversely, broad claims require correspondingly broad evidence or a carefully justified theoretical argument.

Scale and boundary transparency creates a path for cumulative research. Later studies can test whether a mechanism persists under different institutional arrangements, whether a relation changes when the scale is expanded, or whether a boundary previously treated as external should become endogenous to the analysis. Boundary choice is therefore both a limitation and a research instrument.

3.17.3 Identification of the Generative Claim

A GRE contribution should identify its generative claim explicitly. The generative claim states what the specified relation is proposed to generate, reproduce, transform, distribute, or foreclose, through which mechanism, and over what temporal horizon. This is the criterion that most clearly distinguishes a GRE contribution from a study that merely uses relational language.

The generated object can take many forms. It may be a capability, resource, institutional position, subject identity, expectation, dependency, value form, knowledge structure, ecological condition, network topology, bargaining position, classification, infrastructure, norm, or future option. It may also be a change in the conditions under which further generation occurs. The generative claim should therefore name the analytical object rather than relying on the generic statement that a relation "creates value" or "produces effects."

The mechanism also matters. A relation may generate later capacity through learning, investment, access, network reinforcement, institutional recognition, technological complementarity, legal stabilization, reputational accumulation, ecological regeneration, coordination, or another process. It may generate foreclosure through extraction, depletion, lock-in, exclusion, deskilling, dependency, displacement, institutional erosion, or destruction of alternatives. Different mechanisms can produce similar observed outcomes, and the same mechanism can have different consequences under different conditions.

Generative claims can vary in strength. A descriptive contribution may show that a relational configuration is systematically associated with later capacity formation. A historical contribution may reconstruct a plausible mechanism across a sequence of institutional changes. A causal contribution may identify the effect of a specified relation on a downstream outcome under defined assumptions. A formal contribution may demonstrate that a mechanism can generate a class of patterns within a model. A simulation may explore the conditions under which a proposed mechanism becomes sufficient or insufficient. These claims should be distinguished rather than compressed into one category of proof.

A strong GRE contribution also clarifies whether the mechanism concerns generation within an existing structure or transformation of the structure itself. Creating additional productive capacity under stable rules differs from changing ownership, classification, institutional authority, or the effective rules by which future capacities are generated. The distinction helps prevent ordinary output expansion from being mislabeled as deep generative transformation.

The purpose of requiring an explicit generative claim is therefore diagnostic as well as disciplinary. It enables readers to ask whether the claimed generated object actually changes, whether the proposed mechanism is observed or inferred, whether alternative mechanisms fit the evidence, and whether the effect persists beyond the immediate horizon. Generativity becomes a researchable proposition rather than an honorific description.

3.17.4 Evidence Appropriate to the Claim

Evidence in GRE should be appropriate to the epistemic form and strength of the claim. No single evidential hierarchy governs every generative question. Historical reconstruction, ethnography, interviews, administrative records, experiments, quasi-experiments, surveys, network data, financial records, ecological measurements, computational traces, legal documents, formal proofs, and simulations can each support different kinds of inference. Methodological pluralism therefore requires disciplined matching between claim and evidence.

A claim about lived dependency may require qualitative or interpretive evidence that cannot be replaced by aggregate transaction data. A claim about population-level incidence may require quantitative evidence that interviews alone cannot establish. A claim about historical institutional transformation may require archival evidence and temporal reconstruction. A causal claim about an intervention may require an identification strategy capable of distinguishing the effect from confounding processes. A formal claim requires internally valid derivation under stated assumptions. A simulation establishes consequences of modeled rules and parameters rather than direct observation of the empirical target.

The evidence should also correspond to the downstream object named in the generative claim. If a paper claims that a financing relation generates capability, it should observe or defensibly proxy the relevant capability rather than infer it solely from the initial allocation of finance. If a platform intervention is claimed to increase autonomy, measures of throughput or usage alone are insufficient unless the relation between those measures and autonomy is theoretically and empirically justified. If an ecological practice is claimed to regenerate future production conditions, evidence should reach beyond current output toward the ecological capacities that support future activity.

Mixed evidence can be especially valuable when the generative mechanism crosses representational levels. Quantitative data may reveal a distributional pattern while interviews clarify how the relation operates. Institutional documents can establish formal authority while observed practice reveals its implementation. Simulation can explore whether a proposed mechanism is sufficient to produce an observed macro-pattern while empirical data constrain the plausible parameter range. Such combinations should be integrated through a stated inferential logic rather than accumulated as decorative methodological diversity.

Evidence appropriateness also includes negative evidence and failed expectations. When a proposed generative mechanism predicts downstream change that does not occur, the absence can narrow the mechanism, reveal a missing condition, or indicate that the representation is wrong. GRE should therefore retain evidential structures

that permit a generative claim to be weakened or rejected. A programme that can only reinterpret every outcome as evidence of hidden generativity would cease to be empirically corrigible.

3.17.5 Distinction between Representation and Relational Reality

A GRE contribution should distinguish the representation used in analysis from the relational reality the representation is intended to illuminate. Networks, graphs, categories, state spaces, fields, equations, indicators, taxonomies, maps, legal classifications, interview codes, and computational models are analytical constructions. They can disclose important structure while also suppressing, aggregating, or transforming aspects of the target.

The distinction is particularly important because relational analysis often makes structure visually or mathematically compelling. A network diagram can make nodes and edges appear ontologically given even when node identities, tie definitions, missing relations, and temporal aggregation are products of the data-generating process. A scalar indicator can make heterogeneous value appear commensurable. A field representation can suggest continuity where the empirical system contains discontinuities or institutionally discrete categories. A model can hold agents or rules fixed even when historical change in those objects is part of the substantive problem.

GRE does not therefore require researchers to distrust representation. Representation is unavoidable and productive. The requirement is reflexive specification. A contribution should explain what the representation makes visible, what it treats as stable, what it aggregates, what it excludes, and how those choices affect the claim. The more strongly the conclusion depends on a representational choice, the more important sensitivity to alternative representations becomes.

This criterion also applies to institutional representations. Legal categories, accounting classifications, platform metrics, credit scores, productivity measures, and administrative identities can become economically operative representations. They are not merely researcher-created descriptions. Their use can shape access, recognition, risk, resource allocation, and subject positions. A GRE study may therefore analyze a representation both as an epistemic device and as an economic mechanism.

Maintaining the distinction between representation and relational reality supports ontological suspension. Researchers can use network, field, dynamical, or computational language without claiming that the empirical economy literally possesses the complete ontology of the formalism. The analytical question is whether the representation is adequate to the local problem and generative claim. Competing representations can remain simultaneously useful when they disclose different aspects of the same economic configuration.

3.17.6 Attention to Downstream Effects

A GRE contribution should examine downstream effects far enough to evaluate the stated generative claim. This requirement does not demand infinite causal tracing. It requires the researcher to look beyond the immediate administrative output when the theoretical claim concerns later capacities, relations, values, constraints, or pos-

sibilities.

Downstream analysis begins by identifying plausible channels of propagation. A transfer to one organization may alter wages, procurement, investment, debt, market entry, local prices, or political influence. A new classification system may affect eligibility, insurance, credit, employment, or legal recognition. An AI system deployed to increase productivity may alter skill formation, supervision, bargaining power, organizational knowledge, and dependency on technical infrastructure. A conservation intervention may change ecological capacity, land access, community authority, and future livelihood options.

GRE should distinguish propagation from attribution. Observing a downstream change after an intervention does not establish that the focal relation generated it. The contribution should specify the pathway through which the effect is expected to travel and identify evidence consistent with that pathway. Where causal identification is unavailable, the claim should remain calibrated accordingly.

Downstream attention should also include distribution. The same relation can generate gains for one subject while shifting risk, depletion, dependency, or opportunity loss to another. Aggregate improvement can therefore coexist with localized generative foreclosure. A GRE contribution should identify who receives immediate outputs, who gains later capacity, who bears costs, and whose future options become more or less available when these differences are material to the research question.

Temporal depth matters as well. Some generated effects decay quickly; others accumulate or become self-reinforcing. A short evaluation horizon can misclassify a process whose main economic significance lies in later lock-in, learning, institutionalization, ecological regeneration, or erosion. Researchers should therefore justify the chosen horizon in relation to the mechanism rather than treating the observation window as analytically neutral.

The downstream criterion ultimately protects the concept of generativity from collapsing into ordinary output measurement. GRE asks what a relation leaves behind in the capacities and conditions from which later economic processes proceed. The appropriate downstream horizon is the one required to make that question empirically meaningful.

3.17.7 Attention to Alternative Generative Mechanisms

A GRE contribution should consider plausible alternative mechanisms capable of generating the observed pattern. This criterion follows directly from epistemic humility and from the fact that similar outcomes can emerge from different relational configurations. Mechanism identification becomes stronger when the researcher explains why the preferred account fits the evidence better than important alternatives.

Alternative mechanisms can operate at the same scale or at different scales. Increased productivity within a firm may result from worker learning, capital deepening, selection of more productive workers, changes in task allocation, demand expansion, or measurement artifacts. Increased community income after an intervention may reflect genuine local capability generation, temporary transfers, migration, price effects, or extraction from another location. Institutional persistence may arise from

legitimacy, coordination benefits, legal coercion, network lock-in, sunk costs, or the absence of viable alternatives.

GRE should also remain attentive to equifinality: different histories can produce similar configurations. The existence of a stable relation does not uniquely reveal how it was generated. Comparative, historical, and process evidence can help distinguish pathways. In formal or computational research, sensitivity analysis can show whether the result depends on a narrow mechanism or emerges across several model structures.

Alternative mechanisms include representational alternatives. An apparent relation can arise because of measurement, classification, selection, aggregation, or omitted variables. A network pattern can change when edge definitions change. A capability indicator can move because the proxy changes while the underlying capability does not. A historical discontinuity can reflect an archival or institutional change in what was recorded. These possibilities do not invalidate the analysis; they specify additional hypotheses that should be considered where material.

The purpose of this criterion is not to require exhaustive refutation of every imaginable mechanism. It is to prevent a favored generative narrative from becoming insulated from competition. A GRE contribution should identify the most consequential alternatives given the domain, evidence, and claim strength, and state what additional evidence could discriminate among them. Competing mechanisms are part of cumulative research rather than threats to disciplinary coherence.

3.17.8 Normative Transparency

A GRE contribution should make its normative premises transparent whenever evaluative language enters the argument. Terms such as improvement, harm, empowerment, exclusion, justice, sustainability, resilience, capability, autonomy, participation, regeneration, and desirable generation carry normative content that should not be smuggled into a descriptive mechanism claim.

Normative transparency begins by distinguishing what the study observes from how it evaluates what is observed. A relation may generate new productive capacity while also increasing domination. A technology may expand access while weakening privacy or exit. A policy may preserve an institution while reducing the possibility of alternative forms of organization. A regenerative ecological intervention may improve biophysical conditions while distributing burdens inequitably. These cases cannot be evaluated solely by establishing that generation occurred.

The relevant evaluative principles should therefore be stated at the level needed for the claim. A study may adopt a capability perspective, a rights-based standard, a distributive criterion, a relational account of domination, a procedural standard, an ecological constraint, a plural-value framework, or another justified normative basis. GRE does not require one universal normative theory at the level of research contribution. It requires researchers to distinguish the empirical and generative analysis from the premises through which consequences are judged.

Normative transparency is equally important when a study refrains from full evaluation. Researchers may state that a mechanism increases a capability, concentrates

control, or changes future options while leaving the overall justice of the arrangement unresolved. Such restraint can be more informative than forcing heterogeneous effects into a single welfare ranking.

Value plurality further requires explicit treatment of commensuration. If a study aggregates several forms of value into one index, score, monetary measure, or optimization objective, it should explain the justification and consequences of that aggregation. Practical commensuration may be necessary for decision-making without establishing that the underlying values are genuinely commensurable. A GRE contribution should preserve this distinction when it matters.

Normative transparency thus protects both positive and normative inquiry. It prevents descriptive evidence from carrying more evaluative force than it can support, while allowing ethical and political judgments to enter economic analysis openly rather than being hidden in model structure, metric selection, or outcome definition.

3.17.9 Reproducibility and Interpretive Traceability

A cumulative research programme requires other researchers to be able to reconstruct how a conclusion was produced. GRE therefore treats reproducibility and interpretive traceability as complementary standards. Their concrete form varies by method, but the underlying requirement is that the pathway from material or data to claim should remain inspectable.

For quantitative and computational work, reproducibility may involve accessible data where ethically and legally possible, documented preprocessing, variable definitions, code, model specifications, parameter choices, random seeds, robustness checks, and version information. Where data cannot be shared, the study should provide enough procedural detail to clarify what another researcher would need to reproduce the analysis under authorized access.

For qualitative, historical, and interpretive research, exact replication may be impossible or conceptually inappropriate. Interpretive traceability becomes the more suitable standard. The researcher should document source selection, coding or interpretive procedures, archival boundaries, translation choices, interview protocols, contextual assumptions, and the evidential basis for major interpretive moves. Readers should be able to distinguish the source material from the interpretation built upon it.

Formal research requires a related form of traceability. Definitions, assumptions, derivations, propositions, and the relation between formal objects and empirical interpretation should be explicit. A proof can be reproducible while its empirical meaning remains ambiguous; both layers therefore need documentation. Simulation requires the same separation between reproducibility of the computational experiment and validity of the modeled representation.

Traceability also applies to boundary and category revision. If a study changes the definition of a subject, relation, value form, or relevant system during analysis, the change should be visible. Such revision can be intellectually productive, especially in relational research where the empirical material may reveal that initial categories are inadequate. The contribution becomes stronger when readers can see why the

revision occurred and how it affected the result.

These standards are not merely procedural ideals. They distribute epistemic authority. A claim whose evidential path can be inspected is easier to contest, reinterpret, update, and reuse. Reproducibility and interpretive traceability therefore support the broader GRE commitments to revisability, methodological pluralism, and re-epistemization across time.

3.17.10 Contribution to Cumulative Knowledge

A GRE contribution should clarify what becomes more knowable because of the study and how that result can enter a cumulative research programme. Novel terminology alone is insufficient. A contribution may refine a concept, establish a new typology, identify a mechanism, map a relational configuration, provide comparative evidence, develop a formal representation, test an intervention, construct a measure, document a boundary condition, falsify an earlier claim, or expose an unresolved contradiction. These are different forms of cumulative advance.

Cumulative contribution requires relation to prior work. A study should indicate which GRE problem, concept, mechanism, or empirical domain it extends, revises, or challenges. Because GRE is an emerging programme, this relation may initially be internal to the book's preliminary constitution or to a small body of subsequent work. The standard should nevertheless be established early: later research should not repeatedly reinvent the same relational vocabulary without specifying what has changed.

Negative and limiting results are especially important. Demonstrating that a proposed generative mechanism fails under certain institutional conditions can advance the programme by specifying its scope. Showing that two indicators previously treated as proxies diverge can improve measurement. Identifying a case in which downstream generation is negligible can prevent overextension of the framework. Revealing that competing representations yield materially different conclusions can redirect theoretical development. Cumulative knowledge includes disciplined contraction as well as expansion.

A contribution should also preserve reusable analytical objects where possible. Clearly defined categories, documented datasets, mechanism diagrams, typologies, validated measures, formal models, intervention protocols, comparative cases, and explicit boundary conditions can support later synthesis. Reusability does not require standardization of every method. It requires enough conceptual and evidential continuity for results to be compared rather than remaining isolated narratives.

Cumulative knowledge in GRE is expected to remain historically revisable. Concepts adequate to one technological or institutional period may become insufficient as economic subjects, relations, infrastructures, and forms of value change. The purpose of accumulation is therefore not to build an immutable doctrinal core. It is to build a record of concepts, mechanisms, evidence, boundary conditions, disagreements, and revisions from which later inquiry can proceed with greater precision.

Taken together, the criteria in this section provide a practical threshold for recognizably GRE research. A contribution should specify the relation under study, state

its scale and boundaries, articulate the generative claim, match evidence to the claim, distinguish representation from relational reality, trace relevant downstream effects, consider plausible alternative mechanisms, disclose normative premises, preserve reproducibility or interpretive traceability, and explain how the result contributes to cumulative knowledge. The criteria remain proportional to the type of inquiry, but they create a common language for criticism across heterogeneous methods.

These standards also shift Chapter 3 from disciplinary constitution toward research development. Once contributions can be evaluated individually, the next question concerns how they can accumulate across projects into a programme that develops concepts, typologies, maps, mechanisms, formal models, simulations, intervention evidence, measures, and revisions over time. The following section therefore turns from the criteria for a single GRE contribution to the architecture of a cumulative GRE research programme.

3.18 Cumulative Research Programme

The preceding section specified the standards by which an individual contribution can be recognized as part of Generative Relational Economics. A research programme, however, requires more than a sequence of individually competent studies. It requires mechanisms through which concepts can be stabilized and revised, cases can become comparable, mechanisms can be accumulated across contexts, formal and computational representations can become reusable, interventions can generate transferable evidence, measures can be improved, and theoretical claims can contract as well as expand. The role of this section is therefore to specify how GRE can develop cumulatively without converting cumulative development into doctrinal closure. Its objective is to identify several forms of accumulation through which a still-emerging research programme can become more precise, more testable, more comparable across domains, and more corrigible over time.

Cumulative development in GRE is expected to be heterogeneous. Historical reconstruction, conceptual clarification, comparative case analysis, mechanism identification, formal modeling, simulation, intervention research, and indicator construction do not accumulate in identical ways. A concept can become more precise without becoming more universal. A mechanism can recur across cases while remaining conditional on institutional context. A formal model can improve analytical discipline without establishing empirical adequacy. An intervention can generate evidence about a relational configuration that cannot be transferred unchanged to another scale. The programme therefore needs forms of accumulation that preserve local differences while still allowing knowledge to travel.

The central commitment is that accumulation should increase the quality of future inquiry rather than merely increase the quantity of publications. A cumulative programme should make later researchers better able to distinguish objects, specify boundaries, formulate mechanisms, compare cases, identify failed expectations, construct representations, and revise earlier claims. Accumulation is therefore closely related to memory: the programme must preserve not only successful formulations but also boundary conditions, null findings, abandoned distinctions, incompatible

representations, and reasons for revision. This historical record is part of the epistemic infrastructure through which GRE can remain generative without repeatedly rediscovering its own problems.

3.18.1 Conceptual Development

Conceptual development provides one of the earliest forms of cumulative work in an emerging research programme. GRE depends on terms such as relation, generativity, capacity, subject, field, orientation, propagation, conversion, foreclosure, and generative condition. These terms can guide inquiry only when their meanings become sufficiently explicit for disagreement, comparison, and revision. Conceptual development therefore concerns the progressive clarification of what a term denotes, what it excludes, how it differs from neighboring terms, which empirical indicators can bear upon it, and under what conditions the concept ceases to be useful.

Such development should proceed through distinction rather than inflation. A concept becomes stronger when researchers can identify nearby phenomena that it should not subsume. Generativity, for example, should not become a general synonym for causation, productivity, innovation, emergence, or social change. Relationality should not become a label attached to any situation containing more than one actor. Orientation should not become equivalent to intention. Power should not become interchangeable with every asymmetry. Conceptual accumulation therefore requires negative space: a concept is partly stabilized by the cases and mechanisms that researchers agree belong elsewhere.

Conceptual development is also historical. A distinction useful in one institutional or technological period may become insufficient when the object changes. The meaning of economic subjecthood may need revision when artificial systems undertake increasingly consequential operational roles. The concept of resource may change when informational, ecological, infrastructural, or symbolic forms become central to production. The concept of value may require further differentiation when heterogeneous value forms interact without stable conversion ratios. GRE should therefore treat conceptual stabilization as provisional achievement rather than final definition.

A cumulative conceptual record should preserve successive formulations and their reasons. Later versions should make visible whether a term was broadened, narrowed, divided, or replaced. This allows conceptual disagreement to become cumulative rather than repetitive. Researchers can then ask whether a difference arises from incompatible definitions, different empirical domains, different scales, or genuinely competing theoretical commitments. Conceptual development becomes part of research infrastructure when it reduces ambiguity while preserving the possibility of revision.

3.18.2 Typology Development

Typologies allow recurrent heterogeneity to be organized without requiring reduction to a single scalar dimension. They are especially important for GRE because many objects of inquiry are structurally plural: economic subjects can differ in kind, relations can differ in direction and persistence, value can take multiple forms, gener-

ative effects can propagate through different channels, and interventions can create benefits and harms through distinct mechanisms. A typology provides a way to preserve these differences while making comparison possible.

Typology development should begin from analytically relevant distinctions rather than from the desire to populate a classificatory table. A useful typology changes what can be observed or compared. Distinguishing resource asymmetry from capability asymmetry, for example, matters because possession and effective capacity can diverge. Distinguishing relational dependence from domination matters because dependence can exist without one subject acquiring durable control over another. Distinguishing propagation, conversion, recirculation, dissipation, and extraction matters because downstream value trajectories differ even when an initial allocation is identical.

Typologies should also remain open to overlap. GRE objects are frequently multidimensional, and a single case can instantiate several types at once. A platform may be simultaneously an organizational actor, a field-structuring infrastructure, a representational system, and a locus of institutional power. A transfer programme can be allocative, capability-enhancing, dependency-producing, and institution-forming at different stages. Typological clarity therefore does not require exclusive membership unless exclusivity is substantively justified.

Cumulative typology development requires empirical confrontation. Categories should be revised when recurrent cases do not fit, when two categories fail to produce meaningful explanatory differences, or when one category hides internally distinct mechanisms. Cross-case work is especially important because a typology derived from one institutional context may mistake a local classification for a general one. Typologies accumulate when their boundary conditions, empirical uses, exceptions, and revisions are recorded rather than when their labels simply proliferate.

3.18.3 Relational Mapping

Relational mapping concerns the systematic representation of economically consequential connections among subjects, institutions, resources, infrastructures, representations, capacities, and environments. The purpose is not to impose a universal network ontology. It is to make relational structure visible enough that claims about mediation, dependence, propagation, power, or generation can be examined rather than assumed.

Different research problems require different maps. A transaction map may trace flows of money or goods. An authority map may represent legal and organizational powers. A capability map may identify which relations enable access to knowledge, infrastructure, care, finance, or mobility. A representation map may show how classifications and metrics connect institutional decisions to subject positions. A temporal map may represent the order through which one relation conditions a later possibility. Ecological or supply-chain analysis may require several of these layers simultaneously.

Cumulative relational mapping depends on comparability without forced standardization. Researchers should document node definitions, relation types, temporal windows, missing-data assumptions, scale choices, and the meaning of direction or

weight where these are used. When mappings from different studies cannot be directly combined, the reasons should be visible. Differences in mapping conventions can then become substantive evidence about how the object itself is differently constituted across contexts.

Relational maps can also accumulate historically. Repeated mapping can show how a configuration changes, which ties persist, which dependencies become concentrated, where new intermediaries emerge, and whether an intervention alters the topology of opportunity or control. Longitudinal mapping is particularly useful for GRE because generative claims often concern changes in the conditions from which later actions become possible. The cumulative product is not a final map of the economy, but a set of documented representations that can be compared, revised, and linked to mechanism claims.

3.18.4 Mechanism Identification

Mechanism identification provides a central bridge between relational description and generative explanation. GRE is concerned not only with whether two conditions are associated, but with how a relation contributes to the production, reproduction, transformation, or foreclosure of later capacities and possibilities. A cumulative programme therefore needs recurrent mechanism families that can be investigated across settings without assuming that the same mechanism operates universally.

Mechanisms may involve resource access, learning, coordination, institutional recognition, bargaining leverage, infrastructural dependence, feedback, expectation formation, classification, imitation, exclusion, risk transfer, ecological regeneration, or many other processes. What makes such a process a useful GRE mechanism is not its novelty of name but its role in connecting a relational configuration to a downstream change. The mechanism should specify intermediate transformations sufficiently clearly that evidence can support, weaken, or reject the claim.

Cumulative mechanism work benefits from decomposition. A broad claim that an intervention ”builds capability” may contain several distinct processes: it may increase material resources, reduce uncertainty, create social recognition, provide technical knowledge, alter institutional eligibility, or change expectations about future access. Disaggregating these processes allows later studies to test whether the same downstream effect arises through different mechanisms or whether similar interventions produce different outcomes because only some mechanism components are present.

Mechanism accumulation should therefore include enabling conditions, inhibiting conditions, competing mechanisms, and failure modes. A mechanism that appears robust in one setting may depend on trust, legal enforceability, technological infrastructure, social norms, or complementary public goods. Recording these conditions turns isolated explanations into a comparative mechanism library. Such a library remains revisable and context-sensitive, but it gives later researchers a stronger starting point than an undifferentiated appeal to relational complexity.

3.18.5 Comparative Case Accumulation

Cases become cumulative when they are documented in ways that permit meaningful comparison. GRE therefore requires comparative case accumulation rather than a collection of richly described but analytically disconnected examples. The purpose of comparison is not necessarily to produce universal laws. It can identify recurring relational configurations, clarify boundary conditions, distinguish mechanisms, reveal alternative pathways, and show how similar interventions generate different outcomes under different institutional or historical conditions.

Comparison can be organized around cases, mechanisms, trajectories, scales, or interventions. Two regions may receive similar infrastructure investments yet generate different capability effects because institutional access differs. Two platforms may use similar algorithms but create different labor dependencies because ownership and exit options differ. Two ecological restoration projects may produce comparable short-term outputs while diverging in long-run regenerative capacity. A comparative design becomes especially informative when the axis of comparison corresponds to a plausible mechanism difference.

Cumulative case repositories should therefore preserve more than outcome variables. They should record relational boundaries, subject categories, institutional context, temporal horizon, intervention history, relevant value forms, and evidential limitations. Standardized metadata can help without forcing all cases into identical theoretical categories. The aim is to make later synthesis possible while retaining the contextual features through which generative mechanisms may differ.

Negative and anomalous cases are particularly valuable. A case in which a predicted mechanism fails can identify a missing enabling condition or expose an overgeneralized concept. A case that produces an unexpected downstream effect can reveal a propagation channel absent from the original theory. A cumulative programme should therefore preserve cases that resist prevailing formulations rather than treating them as noise to be excluded from the archive.

3.18.6 Formal Model Development

Formal models can contribute cumulative value by making assumptions, relations, and implications explicit. In GRE, formalization may represent dynamics, networks, allocation processes, bargaining relations, value conversion, capability change, field-like influence, institutional rules, or recursive transformations of generative conditions. The purpose is analytical discipline rather than formalization for its own sake.

A cumulative formal programme should preserve model lineage. Later models should indicate which assumptions are inherited, relaxed, extended, or replaced. If one model treats subject identities as fixed while another allows subject formation, the difference should be explicit. If one model uses scalar value while another represents plural value dimensions, the comparison should identify what explanatory capacity is gained and what tractability is lost. Formal accumulation then becomes a sequence of interpretable modifications rather than a disconnected set of mathematical constructions.

Model families can also help identify which conclusions depend on which assump-

tions. Robustness across several formal representations strengthens confidence that a result reflects a structural feature rather than an artifact of one specification. Divergence across models can be equally informative when it reveals sensitivity to boundary conditions, topology, time horizon, or behavioral assumptions. GRE should therefore treat model disagreement as a source of theoretical information rather than merely as a problem to be eliminated.

Formal development remains subject to ontological suspension. A model can establish the consequences of stated relations without proving that the empirical economy possesses the model's ontology. Cumulative formal progress therefore requires empirical interpretation and clear links to the concepts or mechanisms represented. Reusable models, documented assumptions, and transparent derivations can become infrastructure for later studies even when empirical validation remains partial.

3.18.7 Simulation and Computational Exploration

Simulation and computational exploration extend formal development when analytic solutions are unavailable, when interaction structures are heterogeneous, or when researchers want to examine the consequences of alternative rules and parameter regimes. GRE can use agent-based models, network simulations, dynamical systems, optimization procedures, synthetic populations, and other computational methods to explore how local relations may generate larger-scale patterns.

Cumulative computational work requires reproducible experimental design. Code, parameter ranges, initialization procedures, random seeds, stopping rules, and output measures should be documented where possible. More importantly, the relation between computational objects and theoretical concepts should remain explicit. A simulated agent may represent a household, firm, algorithm, institution, or abstract decision unit, but that mapping is a modeling choice rather than an ontological fact.

Computational exploration can support cumulative knowledge by identifying candidate mechanisms, sensitivity regions, threshold behavior, path dependence, or unexpected interactions. It can also help discriminate among theories by showing that some verbal mechanism claims are insufficient to generate the observed pattern under plausible assumptions. Such findings remain conditional on the model, but they can direct empirical work toward the variables and relations most likely to matter.

Simulation results should accumulate together with failed parameterizations and negative results where feasible. If a proposed mechanism produces a target pattern only under implausibly narrow conditions, that fact is theoretically relevant. Computational archives can therefore preserve the history of model development, including abandoned specifications, so that later researchers can distinguish genuine theoretical progress from repeated rediscovery of previously rejected configurations.

3.18.8 Intervention Evidence

Interventions provide a distinctive source of evidence because they modify the relational configuration under study. Policy changes, institutional reforms, experimental programmes, platform redesigns, governance mechanisms, public investments, organizational changes, and community initiatives can reveal how relations respond

when constraints or enabling conditions are altered. GRE treats such evidence cautiously because intervention effects can be path-dependent, scale-specific, and entangled with adaptation.

A cumulative intervention programme should document design, implementation, context, immediate outputs, downstream effects, unintended consequences, and later structural changes. Evidence about failure is as important as evidence about success. An intervention that produces an initial benefit but creates long-term dependency contributes different knowledge from an intervention whose effects persist after external support is withdrawn. An intervention that changes institutional recognition without altering material capacity reveals a different mechanism from one that changes both.

Intervention evidence also benefits from variation in intensity, timing, sequence, and institutional setting. Comparative intervention research can identify whether an effect depends on complementary relations, threshold conditions, or prior histories. Where randomized or quasi-experimental identification is possible, it can strengthen causal claims. Where it is not, careful process tracing, comparative design, and longitudinal evidence can still contribute to mechanism understanding if the limits of attribution are explicit.

Cumulative praxis requires preserving correction histories. Researchers should record when an intervention was modified, suspended, reversed, or repaired and why. These histories provide evidence about the adaptability of both the intervention and the governing institutions. They also help later researchers understand which apparent outcomes were produced by the initial design and which emerged through iterative revision.

3.18.9 Measure and Indicator Development

Measures and indicators allow recurrent GRE concepts to become empirically tractable, but measurement should follow conceptual clarification rather than substitute for it. Possible GRE measures may concern relational dependence, capability access, exit conditions, propagation, concentration of generative control, value conversion, institutional recognition, ecological capacity, or forms of generative foreclosure. Each indicator compresses a more complex concept and therefore requires explicit justification.

Cumulative indicator development should include validity, reliability, sensitivity, and domain restrictions. An indicator useful in one institutional setting may fail elsewhere because the same observable carries a different relational meaning. A measure of platform dependence based on revenue concentration may miss infrastructural lock-in. A measure of capability based on resource possession may ignore conversion constraints. A measure of generativity based on output growth may overlook depletion of future enabling conditions. Indicator accumulation therefore depends on comparison with alternative measures and on documented cases where the proxy fails.

Composite indices require particular caution. Combining heterogeneous value dimensions into one score can aid communication or decision-making, but the weighting rule performs substantive evaluative work. GRE should distinguish between an

index created for practical coordination and a claim that the underlying values are intrinsically commensurable. Sensitivity analysis can show how rankings or conclusions change under alternative weighting schemes.

A mature cumulative programme can maintain indicator families rather than seeking one universal GRE metric. Different measures may be appropriate for different objects, scales, and purposes. The cumulative goal is not metric unification but increasing clarity about what each measure captures, what it omits, and how it relates to the generative claim being tested.

3.18.10 Theory Revision

Theory revision completes the cumulative architecture because accumulation without revision would convert GRE into a repository of additions rather than a research programme. Concepts, typologies, mechanisms, models, indicators, and intervention assumptions should all remain revisable when evidence, comparison, formal analysis, or historical transformation shows that earlier formulations are inadequate.

Revision can take several forms. A concept can be narrowed because it was applied too broadly. A typology can be divided because one category contains distinct mechanisms. A mechanism can be reclassified as conditional rather than general. A formal model can replace a fixed parameter with an evolving relation. An indicator can be abandoned because it tracks a proxy rather than the target concept. A normative criterion can be separated from an empirical one when the two were previously conflated. Revision is cumulative when the reason for change is documented and the consequences for earlier findings are made visible.

GRE should also preserve superseded formulations. Historical traceability allows later researchers to understand why a theory changed and whether an earlier version may still be useful in a restricted domain. Erasing theoretical history would make apparent progress difficult to evaluate because researchers could not distinguish genuine correction from terminological replacement.

Theory revision may also be triggered by transformations in the object of inquiry. New technologies, institutional forms, ecological conditions, legal arrangements, or types of economic subject can make previously adequate categories insufficient. A research programme committed to historical dependence should expect some of its own concepts to age. Revisability is therefore not a weakness added to GRE from outside; it follows directly from the claim that economic relations and their generative conditions are historically transformable.

Taken together, the ten forms of accumulation described in this section define a research programme that can grow without equating growth with theoretical expansion. Conceptual clarification can narrow terms. Typologies can remove distinctions that fail empirically. Comparative cases can reveal boundary conditions. Mechanism research can reject attractive explanations. Formal and computational work can expose contradictions. Intervention evidence can show that a promising design generates harmful dependencies. Indicators can be retired. Theory can contract. Cumulative development is therefore the organized capacity to preserve, compare, test, reuse, and revise knowledge across heterogeneous forms of inquiry.

This cumulative architecture also prepares an important disciplinary problem. As GRE develops, researchers will not necessarily converge on one ontology, one preferred method, one formal representation, one account of value, or one definition of generativity. A cumulative programme therefore requires a way to distinguish productive internal plurality from conceptual fragmentation. The following section turns to internal pluralism and competing formulations, asking how divergent approaches can coexist, criticize one another, and become comparable without forcing premature theoretical unification.

3.19 Internal Pluralism and Competing Formulations

The preceding sections have progressively specified the identity, objects, scales, questions, epistemic commitments, praxis, normative interfaces, power problems, contribution standards, and cumulative structure of Generative Relational Economics. A cumulative research programme, however, cannot remain open merely by permitting new topics to be added. It must also preserve the possibility that several incompatible or partially incompatible formulations of the same problem coexist long enough to be compared, criticized, revised, and sometimes rejected. The role of this section is therefore to specify the place of internal pluralism within GRE. Its objective is to distinguish productive plurality from conceptual indeterminacy: GRE can sustain multiple ontologies, methods, formalisms, evidential strategies, value representations, and accounts of generativity without treating every formulation as equally adequate or every disagreement as irreducible.

Internal pluralism follows from the programme's earlier commitments. Ontological suspension limits the authority of any single representational scheme. Methodological pluralism recognizes that different research questions warrant different modes of access. Heterogeneous subjects and values make premature commensuration hazardous. Scale-relative entityhood means that the same economic configuration can be represented differently at different analytical resolutions. The cumulative programme further requires that alternative formulations remain visible so later work can determine which distinctions travel across contexts, which mechanisms recur, and which representations fail. Pluralism is therefore not an exception to GRE's constitution. It is one of the conditions under which the programme can remain corrigible.

Pluralism nevertheless requires discipline. A research programme becomes weak if incompatible claims are retained merely because they use different vocabularies. It also becomes weak if every disagreement is redescribed as a matter of perspective before empirical or conceptual comparison has occurred. GRE should therefore distinguish plurality of representation from incompatibility of prediction, plurality of method from contradiction in evidence, plurality of value from inconsistency in stated normative commitments, and plurality of ontology from unrestricted metaphysical permissiveness. Competing formulations become productive when their objects, boundaries, assumptions, inferential claims, and failure conditions can be made sufficiently explicit for comparison.

3.19.1 Ontological Pluralism

Ontological pluralism in GRE begins from the recognition that economic inquiry can require several kinds of object-description. A firm can be represented as a legal person, an organization, a nexus of contracts, a hierarchy of authority, a network of relations, a bundle of capabilities, an institutionalized process, or a temporally persistent configuration. These descriptions do not necessarily refer to different empirical worlds. They select different features of the same or overlapping configurations for different analytical purposes.

The earlier principle of ontological suspension therefore does not prohibit ontological language. It restricts the movement from analytical usefulness to ultimate metaphysical commitment. GRE can state that a corporation is treated as an economic subject in one analysis, a relational configuration in another, and an institutional field component in a third. Each formulation must explain what distinctions it preserves, what mechanisms it makes visible, and what questions it suppresses. Ontological pluralism is legitimate when alternative object-descriptions improve inquiry without being silently conflated.

This plurality becomes especially important when objects change historically. A category that functions as a relatively stable entity during one period may later require decomposition because its internal relations become explanatory. Conversely, a dense set of relations may become sufficiently stabilized that entity-level treatment is efficient and empirically adequate. GRE therefore permits movement between entity-centered and relational descriptions as the problem changes. The choice is governed by explanatory and evidential adequacy rather than by a requirement that one level possess permanent ontological priority.

Ontological pluralism does not imply that every proposed object deserves equal standing. Some entities may be administratively convenient yet analytically misleading. Some relational categories may be too broad to identify mechanisms. Some field descriptions may erase important discontinuities. Some claims of emergence may simply rename aggregation. Competing ontological formulations should therefore be assessed by the empirical distinctions they sustain, the mechanisms they clarify, the observations they organize, and the errors they make possible to detect.

A plural programme can also contain genuine ontological disagreement. Researchers may disagree about whether a particular social fact should be treated primarily as an emergent property, an institutional rule, a represented category, a distributed relation, or a relatively autonomous object. GRE need not resolve such disagreements through constitutional fiat. It should require the competing formulations to state their consequences. If two ontologies generate indistinguishable descriptions, predictions, or interpretations for the relevant problem, the dispute may remain underdetermined. If they imply different observations, interventions, or normative diagnoses, the disagreement becomes a substantive research question.

3.19.2 Methodological Pluralism

Methodological pluralism concerns the coexistence of different strategies for producing warranted claims. GRE admits historical, interpretive, qualitative, quantitative,

causal, comparative, formal, computational, and intervention-oriented inquiry because its objects can be only partially accessible through any single mode. The justification for plurality is therefore epistemic rather than diplomatic. Different methods disclose different aspects of relational and generative processes.

A historical reconstruction can identify how categories, institutions, or subject positions came to exist. Ethnographic or interpretive work can reveal meanings, tacit practices, and situated understandings that are unavailable in administrative data. Quantitative analysis can estimate distributions, associations, heterogeneity, and temporal regularities at scales difficult to observe directly. Causal designs can test specific intervention or mechanism claims under stated assumptions. Formal models can expose logical consequences and structural possibilities. Computational models can explore high-dimensional, adaptive, or path-dependent systems. None of these capacities automatically contains the others.

Methodological pluralism therefore requires claim-method matching. A computational simulation cannot by itself establish that its mechanism generated an observed historical outcome. A historical narrative cannot by itself estimate the magnitude of a population-level effect. A statistically identified average treatment effect may not explain the meanings through which the treatment was received or the institutional conditions through which it propagated. An interpretive account may clarify subject formation while leaving distributional prevalence unresolved. The value of a method depends on the claim it is used to warrant.

Pluralism also permits methodological competition. Two studies can approach the same generative claim through different designs and produce conflicting evidence. Such conflict should not be resolved automatically by a fixed hierarchy of methods. The programme should examine differences in population, scale, measurement, boundary selection, intervention timing, model specification, and inferential target. Sometimes one method will expose a limitation in another. Sometimes the disagreement will reveal that the original theoretical claim was underspecified.

The strongest form of methodological pluralism is therefore cumulative correction. Methods become mutually informative when they identify each other's blind spots and help refine the target of inquiry. GRE does not require every project to use mixed methods. It requires the programme as a whole to remain open to correction from methods capable of observing dimensions that another approach leaves unresolved.

3.19.3 Formal Pluralism

Formal pluralism extends the same principle to mathematical and computational representation. GRE has inherited resources from dynamical systems, complexity theory, network science, higher-order and multilayer representations, field formalisms, information theory, computation, and simulation. These formalisms organize different kinds of structure. A dynamical system emphasizes state, trajectory, stability, and transformation through time. A network emphasizes patterned relations among identifiable nodes. A higher-order representation can make irreducibly multi-actor interactions explicit. A field representation can describe distributed conditions that vary across a domain. Agent-based or computational models can explore local rules, heterogeneity, and emergent aggregate behavior.

GRE therefore has no constitutional reason to privilege one formal language as the universal representation of economic relations. Formal choice should follow the structure of the research problem. A model of propagation through contractual dependencies may be naturally network-based. A problem concerning distributed accessibility or exposure may be represented more effectively through a field. A question about transition between regimes may require dynamical analysis. A question about heterogeneous adaptive actors may benefit from simulation. Several representations may be needed for the same empirical system.

Formal pluralism also protects the programme from a recurrent category error: mathematical elegance should not be mistaken for ontological authority. Two mathematically distinct representations can sometimes encode the same empirically relevant relation. Conversely, one formalism can fit several empirical situations whose mechanisms differ. Formal equivalence, approximation, simulation, or mapping therefore needs to be distinguished from substantive equivalence of the represented processes.

Competing formalisms should be compared through their assumptions, representational losses, empirical accessibility, computational tractability, and consequences for inference. A more complex formalism is not necessarily better. Additional dimensions, layers, parameters, or interacting fields can increase expressiveness while reducing identifiability. A simpler model can be preferable when its omissions are explicit and its inferential target is narrow. Formal pluralism is productive when representational choice remains accountable to evidence and purpose.

3.19.4 Quantitative and Qualitative Approaches

Quantitative and qualitative approaches often differ in data structure, inferential form, sampling logic, and the kinds of uncertainty they make visible. GRE treats these differences as analytically important rather than as a division between rigorous and non-rigorous inquiry. Quantitative work can establish patterns across large populations, estimate magnitudes, compare distributions, and model temporal or relational structures. Qualitative work can reconstruct meaning, institutional practice, local causal process, category formation, tacit knowledge, and the situated experience through which economic relations become operative.

The distinction is particularly important for generative analysis. A downstream effect can be quantitatively measurable while its mechanism remains poorly understood. Conversely, an interactional mechanism can be richly documented in a small number of cases while its prevalence, distribution, or aggregate contribution remains uncertain. GRE should therefore resist converting one form of evidence into claims warranted only by the other.

Mixed designs can be valuable when the forms of evidence address complementary parts of the same generative claim. A qualitative study can help identify mechanisms, categories, or boundary conditions that later quantitative work tests across cases. Quantitative anomalies can direct qualitative inquiry toward previously invisible heterogeneity. Administrative or network data can identify patterns of propagation, while interviews or archival evidence reveal why particular pathways existed. Such integration should be designed around a shared research problem rather than

around the ceremonial inclusion of multiple methods.

Qualitative and quantitative approaches can also disagree productively about the object itself. A variable that appears stable in a dataset may combine historically different institutional meanings. A locally salient category may have no reliable population-level measure. A statistically robust association may depend on classifications whose social production requires separate analysis. GRE's relational commitments make these disagreements substantive because measurement categories can participate in the relations they represent.

The programme therefore treats quantitative and qualitative approaches as mutually corrective without requiring symmetry in every project. The relevant question is which claims remain unsupported when only one form of evidence is available and whether the resulting limitation materially changes the argument.

3.19.5 Causal and Interpretive Approaches

Causal and interpretive approaches address different but frequently intersecting questions. Causal inquiry asks whether and through what mechanisms a change in one condition contributes to a change in another under specified assumptions. Interpretive inquiry asks how actors, institutions, representations, and practices acquire meaning within a situated historical and relational context. GRE requires both because economic relations can operate through mechanisms whose effectiveness depends on interpretation.

A legal classification, price signal, credential, ranking, or algorithmic recommendation can alter behavior partly because subjects recognize, contest, trust, misunderstand, or strategically use what the representation means. In such cases, interpretation is not merely commentary after causal analysis. It can be part of the causal mechanism. At the same time, the existence of meaning does not establish the magnitude or distribution of its effects. Interpretive adequacy and causal identification remain distinct epistemic achievements.

The same distinction applies to subject formation. Researchers may interpret how a worker, consumer, creditor, beneficiary, or platform participant is institutionally constituted and how that subject position is experienced. A causal study may then examine whether entering that position changes behavior, income, access, or later opportunities. The two analyses can support each other without collapsing into a single method.

Competing causal and interpretive accounts become especially useful when they disagree about where the mechanism lies. A causal model may attribute an effect to incentives, while interpretive evidence suggests that the intervention changed recognition, legitimacy, or perceived obligation. Rather than treating one vocabulary as necessarily deeper, GRE should ask what observable consequences follow from the alternative mechanism accounts and whether both processes operate at different stages or scales.

Causal and interpretive pluralism therefore requires translation without reduction. Researchers should state when an interpretive category enters a causal model, how it is observed, and what is lost in operationalization. Conversely, causal evi-

dence can constrain interpretations by showing that a proposed meaning-making mechanism does not produce the expected distributional or temporal pattern. Productive integration occurs when each approach can expose conditions under which the other's claims fail.

3.19.6 Network and Field Representations

Network and field representations provide a concrete example of formal pluralism because they organize relational structure differently. A network begins from distinguishable nodes and relations among them. It is well suited to questions concerning adjacency, centrality, brokerage, diffusion, dependence, multilayer connectivity, and evolving topology. A field representation describes conditions distributed across a domain and can be useful when influence, accessibility, exposure, salience, or constraint varies continuously or when pairwise ties provide an incomplete description.

These representations can overlap without being interchangeable. A network of financial obligations can identify who depends directly or indirectly on whom. A field representation may instead characterize how liquidity conditions, regulatory exposure, information availability, or market accessibility vary across positions. The network makes discrete relational pathways explicit; the field can make distributed background conditions visible. A system can contain both.

Choice between network and field representation should therefore follow the mechanism. If transmission occurs through identifiable connections, a network may be the natural first representation. If subjects respond to a spatially, institutionally, or symbolically distributed condition, a field can be more informative. Some problems require hybrid representations in which nodes and edges evolve within fields that also respond to network activity.

The competing representations can generate different intuitions about intervention. Network analysis may suggest altering connections, central nodes, or dependency pathways. Field analysis may suggest changing distributed conditions that shape many interactions simultaneously. GRE should not infer that one intervention is superior from the representation alone. The empirical question is which representation captures the mechanisms through which the relevant generative effects actually propagate.

The plurality also reinforces ontological suspension. Network nodes need not be ultimate entities, and fields need not be literal physical fields. Both are representational devices whose adequacy depends on what they permit researchers to observe, explain, predict, or intervene upon.

3.19.7 Scalar and Non-Scalar Value Representations

Value presents a particularly consequential case of internal pluralism. Some economic questions require scalar representation. Prices, costs, quantities, income, expected returns, or index values can support comparison, optimization, aggregation, and accounting. Other forms of value resist stable reduction to one dimension because they involve heterogeneous goods, rights, relationships, capabilities, ecological conditions, meanings, or obligations whose trade-offs are context-dependent or

normatively contested.

GRE therefore permits scalar and non-scalar representations of value. The choice must be justified by the evaluative task. A scalar representation can be useful when a common unit is institutionally established, empirically meaningful, and relevant to the question. It becomes misleading when the numerical scale hides changes in what is being valued, who has authority to define the conversion, or which losses cannot be represented adequately by the chosen unit.

Non-scalar representation can preserve plurality through vectors, partial orderings, categorical distinctions, threshold conditions, lexicographic priorities, narrative evaluation, or explicit statements of incommensurability. Such representations do not eliminate the need for decisions. Institutions frequently must act even when values cannot be reduced to a common metric. The analytical task is to distinguish practical commensuration from demonstrated commensurability and to make visible who establishes the conversion rules.

Competing value representations can lead to different judgments about the same intervention. A project may generate positive monetary returns while degrading ecological resilience, increasing dependency, or reducing future option sets. A multidimensional representation can reveal this divergence. Conversely, retaining every value dimension without prioritization can make decision procedures indeterminate. GRE therefore treats value representation as part of the problem rather than assuming that either scalarization or irreducible plurality is universally preferable.

Comparison among value representations should examine what each includes, excludes, weights, converts, and renders visible. It should also ask how the representation itself affects institutional action. An indicator that becomes a target can reorganize behavior; a price can alter the relation it measures; a ranking can generate new incentives and subject positions. Value representation is therefore both epistemic and potentially generative.

3.19.8 Competing Accounts of Generativity

Generativity is the organizing concept most likely to produce internal theoretical disagreement within GRE. The term can refer to several related but distinct phenomena: production of downstream capacities, emergence of new entities or relations, transformation of subject positions, expansion or contraction of future possibilities, creation of new value forms, alteration of institutional pathways, or modification of the effective rules through which later change occurs. These processes can coexist, but they should not be treated as interchangeable by definition.

One account of generativity may emphasize the creation of capacities. Another may focus on the reproduction and transformation of relational structures. A third may treat generativity primarily as alteration of future possibility spaces. A fourth may emphasize recursive change in the mechanisms that produce subsequent outcomes. GRE should allow these accounts to compete because their differences can clarify what exactly is claimed to be generated.

Competing accounts should state their unit of analysis, temporal horizon, baseline, mechanism, and observable consequences. A claim that a relation generates capa-

bility requires evidence different from a claim that it generates institutional persistence. A claim that an intervention expands future possibility requires a specification of whose possibilities, over what horizon, under which constraints, and relative to which counterfactual or historical baseline. A claim that a rule transforms its own conditions of reproduction requires evidence beyond ordinary downstream effects.

The programme should also permit the possibility that generativity is not a single natural kind. Different domains may contain several mechanisms that share a family resemblance but cannot be reduced to one formal definition. In that case, cumulative research should develop a typology of generative mechanisms rather than force premature unification. Conversely, if apparently different mechanisms can be shown to instantiate a common structure, theory can become more parsimonious.

Internal competition around generativity is therefore desirable when it increases discriminability. A successful formulation should make it easier to determine when a process is merely productive, causal, adaptive, or reproductive and when a stronger generative claim is warranted. The concept becomes weaker when it absorbs every form of change and stronger when competing accounts specify different empirical commitments.

3.19.9 Productive Disagreement

A plural research programme depends on disagreement that can change what researchers subsequently do. Productive disagreement is therefore more demanding than the coexistence of opinions. It requires disagreement to be localized sufficiently that evidence, argument, or comparison can alter the standing of competing claims.

Researchers can disagree about concepts, boundaries, mechanisms, measurements, formal representations, empirical generalization, normative premises, or intervention implications. These forms of disagreement should be distinguished because they require different responses. A definitional disagreement may be resolved through conceptual clarification. A measurement disagreement requires validity evidence. A mechanism disagreement may require process tracing, experiments, comparative cases, or temporal data. A normative disagreement may persist even after empirical questions are settled because the disagreement concerns values or justificatory principles.

Productive disagreement also requires preserving losing formulations long enough to understand why they failed. If a model is rejected because its mechanism does not fit observed timing, that reason should become part of programme memory. If a concept is narrowed because it collapsed several distinct phenomena, the earlier broader usage should remain traceable. If two formulations apply at different scales, the outcome is not necessarily victory of one over the other but clarification of boundary conditions.

Disagreement becomes unproductive when formulations shift whenever evidence challenges them, when different vocabularies hide identical claims, when claims are insulated from possible counterevidence, or when normative and empirical disagreements are repeatedly confused. A plural programme therefore needs conventions for making commitments explicit enough that revision is possible.

The social organization of disagreement also matters. Dominant institutions, disciplines, languages, data infrastructures, or publication norms can determine which formulations are visible enough to be contested. GRE's own commitment to pluralism therefore includes attention to the conditions under which alternative formulations can enter the research programme. Inclusion of alternatives, however, does not suspend standards of evidence or argument. Productive pluralism widens the space of contestation while preserving the possibility of criticism.

3.19.10 Conditions for Theory Comparison

Internal pluralism becomes cumulative only when competing formulations can be compared under explicit conditions. Theory comparison in GRE should therefore begin by determining whether the formulations address the same object, scale, temporal horizon, and inferential target. Apparent disagreement can disappear once researchers recognize that one theory describes short-run adjustment while another describes long-run institutional transformation, or that one concerns individual behavior while another concerns field-level conditions.

Where the targets overlap, comparison should examine at least six dimensions: conceptual clarity, empirical scope, mechanism specification, evidential support, representational cost, and capacity for revision. Conceptual clarity concerns whether the theory distinguishes its principal objects and mechanisms from neighboring concepts. Empirical scope concerns the domains and boundary conditions within which the theory is expected to apply. Mechanism specification concerns what processes connect conditions to outcomes. Evidential support concerns whether available observations discriminate the theory from alternatives. Representational cost concerns the assumptions, data, computation, and abstraction required to use the formulation. Capacity for revision concerns whether failure can lead to identifiable modification rather than indefinite accommodation.

Predictive accuracy can be important but should not become the sole criterion. Some GRE problems concern historical explanation, interpretation, institutional constitution, normative evaluation, or intervention design where prediction is only one dimension of adequacy. Conversely, conceptual richness should not excuse a formulation from empirical consequences when it makes empirical claims. The criteria for comparison should therefore track the kind of contribution being evaluated.

Theories can also be compared by their generative usefulness for further research. A formulation can be valuable because it produces new measurable distinctions, suggests discriminating cases, clarifies a previously vague mechanism, or exposes a class of interventions whose consequences can be studied. Such usefulness does not establish truth, but it can justify continued investigation when direct adjudication remains incomplete.

Some competing formulations may remain partially incommensurable because they begin from different objects, values, or explanatory purposes. GRE should not manufacture a single ranking when the comparison lacks a common criterion. It should instead identify the dimensions on which comparison is possible and preserve the residual disagreement. Partial comparability is preferable to either false unification or premature declaration of complete incommensurability.

The constitutional role of internal pluralism can therefore be stated compactly. GRE should remain open to multiple formulations while requiring each formulation to expose enough of its objects, assumptions, mechanisms, evidence, values, and failure conditions to permit criticism. Pluralism protects the programme from premature closure; theory comparison protects it from indiscriminate accumulation. Together they allow disagreement to become part of cumulative inquiry.

The existence of a plural and revisable research programme also means that several difficult questions remain unresolved even after its disciplinary constitution has been specified. The following section turns from the permitted diversity of formulations to the substantive open problems that future GRE research must address.

3.20 Open Problems

The preceding sections have specified the preliminary identity, objects, scales, modes of inquiry, epistemic commitments, praxis, normative interfaces, contribution standards, cumulative structure, and internal pluralism of Generative Relational Economics. A research programme becomes more credible, however, when its unresolved problems are stated with comparable precision. The role of this section is therefore to identify several problems that remain open after the current constitution of GRE has been articulated. Its objective is neither to close those problems through definition nor to convert uncertainty into a rhetorical virtue. The aim is to distinguish questions for which GRE already has an analytical vocabulary from questions for which the mechanisms, measurements, evidential strategies, or normative criteria remain materially underdeveloped.

The open problems considered here concern identification, attribution, measurement, boundary selection, changing transformation rules, heterogeneous value, justice, symbolic reification, governance under persistent asymmetry, and long-horizon evaluation. These problems are connected, but they should not be collapsed. Better identification of a generative relation does not by itself solve downstream value attribution. A useful indicator of generativity does not establish normative desirability. A formally specified transformation rule does not guarantee that the relevant rule remains stable through the period being studied. A governance mechanism that mitigates one asymmetry can create another. The purpose of separating the problems is therefore to make future progress discriminable.

Open problems also differ in the kind of resolution they permit. Some may yield to better data, identification strategies, historical reconstruction, or formal representation. Others arise because economic relations are reflexive, boundaries are purpose-dependent, values are only partially comparable, and future possibilities cannot be observed before they are realized. GRE should therefore allow for the possibility that some uncertainty can be reduced while other uncertainty remains structural to the object of inquiry. A mature research programme needs both ambitions: to improve what can be known and to specify what remains underdetermined.

3.20.1 Identification of Generative Relations

The first open problem concerns the identification of generative relations. GRE frequently asks whether a relation contributes to the production of later capacities, institutions, subject positions, value forms, or conditions of possibility. Such claims are stronger than statements that two variables covary or that one event precedes another. They also exceed the observation that a relation participates in ordinary causal production. A relation becomes generatively relevant when its operation changes what can subsequently be produced, sustained, accessed, recognized, or transformed. The empirical difficulty lies in demonstrating that stronger claim.

Identification requires a specification of the relation, the object said to be generated, the time horizon over which generation occurs, and the mechanism that connects them. These elements can be difficult to observe simultaneously. Some relations operate through repeated interaction rather than singular events. Some produce latent capacities that become visible only when later conditions activate them. Some operate through institutional recognition or symbolic classification rather than directly observable material transfer. Some are distributed across several actors or infrastructures, making bilateral attribution misleading.

A further difficulty is that generative relations may be constitutive rather than merely productive. A worker's access to a professional network, for example, can affect opportunities while also contributing to the formation of recognized expertise, identity, or standing. A credit relation can transfer purchasing capacity while simultaneously generating dependency, reputational records, or future exclusion. In such cases the relation changes properties of the participating subjects and the environment in which later action occurs. Identification must therefore distinguish immediate output from transformation of later possibility.

Progress on this problem will require multiple forms of evidence. Longitudinal observation can reveal whether capacities persist beyond the originating relation. Comparative cases can test whether similar relational configurations produce similar downstream structures under different contexts. Process tracing can identify intermediate mechanisms. Experiments or quasi-experiments can help isolate particular pathways when intervention is possible. Formal or computational models can clarify what observations would discriminate generative mechanisms from ordinary transmission. Interpretive evidence can be necessary when generation operates through meaning, recognition, or institutional classification.

No single identification strategy is likely to cover the full range of GRE objects. The open task is therefore to develop a disciplined family of identification standards. Such standards should make it possible to distinguish a plausible generative hypothesis from a demonstrated mechanism, and a demonstrated local mechanism from a general claim about generativity across contexts.

3.20.2 Attribution of Downstream Value

A second open problem concerns attribution once value has propagated beyond an initial relation or intervention. Economic processes commonly produce effects through chains of mediation. Training can alter later employment, organizational

practice, peer learning, and household security. Infrastructure can generate uses that were not anticipated by its designers. Knowledge can be recombined by actors distant from its original producer. Institutional reforms can change incentives, expectations, classifications, and later policy capacities. GRE needs ways to analyze such downstream value without converting every remote benefit into a claim of credit for the initial source.

Attribution becomes difficult because downstream effects are usually co-produced. Later value can depend on complementary resources, independent decisions, institutional environments, accumulated knowledge, ecological conditions, and subsequent interventions. A generative relation can be necessary without being sufficient. It can raise the probability of an outcome without determining it. It can create an enabling condition whose significance varies strongly across contexts. A later actor can transform an inherited resource so substantially that simple origin-based attribution becomes conceptually misleading.

The problem therefore has at least three dimensions. Causal attribution asks whether the earlier relation materially contributed to the later outcome. generative attribution asks whether it altered the conditions from which later value could emerge. Distributive attribution asks how recognition, return, responsibility, or claims on value should be allocated among contributors. These dimensions should remain distinct because evidence for causal contribution does not settle the distributive question, and normative entitlement cannot be inferred directly from causal ancestry.

Future GRE work requires methods for tracing contribution without assuming additive decomposition. In some domains, contribution analysis may be approximately scalar. In others, interaction effects, complementarities, threshold behavior, or non-substitutable roles make scalar shares unstable or arbitrary. Network and process representations may help locate pathways without requiring a single attribution percentage. Counterfactual analysis can identify whether a contribution changed the set of feasible trajectories. Historical reconstruction can reveal how later actors transformed inherited conditions.

The objective should therefore be calibrated attribution. GRE should become better at saying that an upstream relation enabled, constrained, amplified, redirected, or conditioned later value while preserving uncertainty about the exact share attributable to that relation. Such calibrated language is important both for explanation and for later questions of return, compensation, responsibility, and justice.

3.20.3 Measurement of Generativity

The measurement of generativity presents a related but distinct problem. The concept is attractive because it directs attention toward effects on later productive and transformative possibilities. Yet the concept can become analytically weak if every beneficial downstream effect is redescribed as generativity. Measurement therefore requires a more discriminating account of what is being measured and at which scale.

Several candidate dimensions are possible. One study may measure new capabilities acquired by participants. Another may measure the diversity of subsequent activities enabled by an intervention. A third may examine persistence of effects after

direct support ends. A fourth may study whether new actors can enter a domain, whether dependence on a central provider declines, or whether local reproduction becomes possible. A fifth may examine changes in the range of feasible future states. These measures capture different aspects of generativity and should not automatically be aggregated.

The temporal horizon also changes the result. An intervention can generate high short-run activity while degrading future ecological or institutional capacity. Another can impose substantial near-term cost while creating durable infrastructure or knowledge. A third can generate options that remain unused for years. Measurement therefore requires explicit time horizons and, where possible, sensitivity to delayed activation and depreciation.

Baseline selection is equally important. Generativity can be expressed relative to a prior state, a plausible counterfactual, an alternative intervention, or a historically available possibility set. These baselines answer different questions. A project can be generative relative to local past conditions while remaining less generative than another feasible arrangement. A technology can expand one actor's possibilities while narrowing those of another. A scalar score that suppresses these distinctions can obscure more than it reveals.

GRE should therefore resist the premature construction of a universal generativity index. The more promising direction is a family of measures tied to explicit objects: capability generation, institutional reproduction, option expansion, relational diversification, knowledge recombination, ecological regeneration, or transformation of future constraints. Some domains may support quantitative indicators; others may require ordinal, categorical, historical, or qualitative evidence.

The open problem is to determine when these heterogeneous measures can be compared and when they should remain separate. Measurement should increase discriminability while preserving the multidimensional character of generation. A measure becomes useful when it makes a claim more testable or comparable, not merely when it assigns a number to a concept.

3.20.4 Relational Boundary Selection

Every relational analysis requires a boundary, yet the boundary can materially determine the result. A firm can be analyzed through internal employment relations, supply chains, financial dependencies, legal institutions, ecological inputs, community effects, or global infrastructures. A household can be treated as a unit or decomposed into members with different resources, vulnerabilities, and bargaining positions. A platform can be bounded by formal ownership or expanded to include complementors, users, data providers, moderators, advertisers, and regulatory institutions. Each choice creates a different relational object.

Boundary selection is therefore more than a technical preprocessing decision. It affects which mechanisms are visible, which costs are externalized, which subjects count as participants, and which downstream effects are attributed to the focal process. A narrow boundary can produce apparent efficiency by excluding displaced burdens. An excessively broad boundary can make explanation indeterminate by treating nearly everything as part of the system.

GRE currently has principles that help discipline boundary choice: explicit scale selection, ontological suspension, claim-relative objecthood, and attention to downstream effects. These principles do not yet provide a general procedure for deciding how far a relational analysis should extend. The appropriate boundary depends on the claim. A study of contractual propagation may require one boundary; a study of ecological regeneration may require another; a study of institutional recognition may require several overlapping boundaries.

One direction for future work is sensitivity analysis across relational boundaries. Researchers can ask whether the principal inference changes when adjacent actors, longer time horizons, or additional infrastructures are included. Another direction is boundary justification through mechanism: include relations that participate materially in the mechanism under investigation and distinguish them from contextual conditions whose role is secondary. A third is normative boundary review, especially where exclusion from the analytical boundary also removes affected populations from evaluation.

The deeper problem is that boundaries can themselves be generated and contested. Legal categories, accounting rules, administrative jurisdictions, platform architectures, and disciplinary conventions determine what appears internal or external. GRE therefore needs methods for studying boundary formation while still selecting workable boundaries for empirical research. This is an inherently reflexive task: the researcher must construct a boundary without mistaking that construction for a natural edge of the economic world.

3.20.5 Dynamics of Changing Transformation Rules

GRE places particular emphasis on situations in which the effective mechanisms of change are themselves transformed. This possibility is analytically important because many models assume that states change under a rule that remains sufficiently stable for the period of analysis. Economic history repeatedly presents harder cases: technologies alter feasible production processes, institutions modify incentives and classifications, learning changes decision procedures, political settlements alter property and authority, and adaptive systems modify the relations through which later adaptation occurs.

The open problem is empirical representation of these changing transformation rules. It is relatively straightforward to estimate changing states under a fixed model. It is harder to determine whether parameter drift is sufficient, whether the structure of interaction has changed, whether new variables have become relevant, or whether the model class itself must be revised. A sudden forecasting failure can indicate structural transformation, measurement change, omitted context, or ordinary stochastic variation. The observation alone does not identify rule change.

Different forms of rule transformation should therefore be distinguished. Parameters can change while the functional structure remains stable. Network topology can evolve while node types remain fixed. Agents can learn and alter local decision rules. Institutions can redefine available actions or recognized categories. New technologies can introduce previously unavailable operations. Symbolic changes can alter how subjects interpret the same formal option. More radical transformation can

make earlier state variables inadequate because the kinds of economically relevant entities have changed.

Future GRE work requires diagnostics for these levels. Change-point methods, time-varying parameter models, adaptive networks, institutional process tracing, computational learning models, and historical comparison can each contribute. None should be treated as a universal representation. The important question is what evidence warrants movement from a claim of state change to a claim of structural change, and from structural change to transformation of the effective rule of change.

This problem also concerns anticipation. If governance relies on models whose rules can change in response to the intervention itself, policy evaluation becomes recursively difficult. Agents can adapt to incentives, classifications, metrics, and regulatory thresholds. Institutions can learn from being measured. Artificial systems can modify decision environments at high speed. GRE therefore needs forms of intervention design that monitor the stability of the assumed transformation rule rather than merely updating parameter estimates within it.

3.20.6 Heterogeneous Value Comparison

GRE's commitment to heterogeneous value creates an unresolved problem of comparison. Economic decisions frequently require choices among outcomes expressed through different value languages: income, time, health, dignity, ecological integrity, autonomy, knowledge, cultural continuity, security, care, or future option value. Practical governance cannot always defer choice until a complete theory of commensurability is available. Yet forcing these values into a single metric can erase the distinctions that motivated plural evaluation in the first place.

The problem is therefore to determine which forms of comparison are legitimate under partial commensurability. Some values may be monetizable for a specific administrative purpose while retaining dimensions not captured by price. Some can be ordered ordinally without meaningful cardinal distances. Some can be compared only within a domain. Some are subject to thresholds or rights that constrain trade-offs. Some are held by different subjects whose evaluative frameworks do not share a common scale.

GRE needs a vocabulary for these cases because generative effects often cross value domains. A policy can increase income while reducing ecological resilience. A technology can increase productivity while weakening autonomy or interpretive control. An institution can expand access for one population while eroding cultural continuity for another. The analytical challenge is to preserve these transformations without treating every trade-off as either fully aggregable or completely incomparable.

Several approaches are available for future development: vector-valued representation, partial ordering, threshold constraints, lexicographic priorities, multi-criteria analysis, deliberative comparison, qualitative matrices, and domain-specific indicators. Each imposes assumptions. The important task is to state those assumptions and to distinguish practical decision procedures from claims about underlying value equivalence.

Comparison also has a political dimension. Institutions that control the conversion interface between value forms can determine which values become legible enough to enter allocation decisions. Measurement systems, accounting rules, markets, legal standards, and algorithmic ranking can all privilege particular value representations. GRE should therefore study value comparison both as an analytical problem and as an object of economic power.

The open problem is not to eliminate heterogeneity. It is to make decision-relevant comparison possible while preserving residual differences that remain normatively or empirically meaningful.

3.20.7 Generativity and Justice

Generativity and justice intersect without being identical. An arrangement can generate substantial new capacity while distributing access, control, risk, or return unjustly. A restrictive intervention can reduce some forms of generation while protecting vulnerable subjects or preserving future ecological conditions. A relation can be locally reciprocal while depending on historical structures that shape who possesses the capacity to participate. GRE therefore needs a more developed account of how generative analysis and theories of justice constrain, inform, and revise one another.

One unresolved issue concerns the object of justice. Evaluation can focus on resources, capabilities, recognition, participation, relations, procedures, generated opportunities, or future conditions of generation. These objects can point in different directions. Equal resource distribution can coexist with unequal conversion capacities. Broad participation can coexist with domination inside the participatory process. Expansion of future possibilities for one group can depend on ecological or social foreclosure for another.

A second issue concerns temporal distribution. Generative interventions often move value across time. Present actors can bear costs that create future capacities, while future actors can inherit both benefits and constraints without having participated in the original decision. Justice therefore requires attention to who pays for generation, who controls the generated capacity, who receives later return, and who inherits the risks of failure or lock-in.

A third issue concerns agency and authorship. When value is co-produced through distributed relations, justice cannot rely only on a simple producer-recipient distinction. Contributors can include maintainers, caregivers, communities, infrastructures, knowledge traditions, ecosystems, and future institutions. Attribution uncertainty makes distributive claims more difficult but does not remove the normative problem.

GREthic provides a neighboring domain for deeper normative theory, while GRE retains responsibility for describing the economic relations through which capacities, dependencies, returns, and foreclosures are produced. The open problem is to build interfaces between these domains without allowing normative vocabulary to substitute for economic mechanism or economic description to settle normative judgment automatically.

Progress will likely require multiple justice criteria rather than a single principle centered on generativity. Generativity can become one object of justice—especially

where institutions systematically capture others' capacity to generate—but justice also constrains which forms of generation are permissible and how risks, participation, recognition, and future possibilities should be distributed.

3.20.8 Symbolic Reification

GRE relies heavily on analytical concepts such as relation, field, subject, capability, generativity, value, constraint, and possibility. These concepts are necessary for inquiry, yet repeated use can create symbolic reification: a representation introduced to organize observation begins to be treated as if it were the stable object itself. This problem is especially significant for a programme that explicitly distinguishes relations from their representations.

Reification can occur through ordinary scholarly language. A network diagram can encourage researchers to treat nodes as naturally bounded entities even when the nodes are administrative constructions. A capability measure can become identified with capability itself. A field representation can be spoken of as if the measured scalar were literally the distributed social condition. A generativity score can transform a multidimensional hypothesis into an apparently objective property. Institutional categories can become research variables and then return to practice with the authority of scientific classification.

The danger increases when representations become operational. Metrics influence funding, rankings, eligibility, regulation, and organizational behavior. Models can therefore participate in generating the reality they purport to describe. Subjects adapt to categories, optimize against indicators, and reorganize behavior around algorithmic classifications. A representation can acquire causal power through institutional uptake without becoming ontologically complete.

GRE needs practices that keep this reflexive relation visible. Researchers can document category construction, preserve alternative representations, test sensitivity to operational definitions, distinguish latent constructs from measured proxies, and monitor how measures alter behavior after institutional adoption. Historical work can show how categories change. Interpretive inquiry can reveal meanings lost in standardized representation. Formal work can state which properties are assumed rather than observed.

The open problem extends beyond avoiding conceptual error. Symbolic reification can become a mechanism of power when institutions control the categories through which subjects are recognized, evaluated, funded, or excluded. The study of representations therefore belongs within the economic analysis of generative conditions. GRE must remain capable of using symbols and models decisively while keeping open the possibility that its own categories become objects of later revision.

3.20.9 Governance under Persistent Asymmetry

Section 81 treated asymmetry as a durable feature of many economic relations and distinguished it from power. The open governance problem begins where complete equalization is unavailable, undesirable, or itself generative of new dependencies. Differences in expertise, capital, institutional authority, computational

capability, ecological exposure, time horizon, or exit capacity can persist even under well-designed institutions. Governance must therefore operate in conditions where symmetry cannot be treated as the endpoint.

One challenge is preventing asymmetry from becoming unreviewable domination. Transparency, contestability, exit, representation, auditing, countervailing institutions, liability, redistribution, and public infrastructure can each constrain conversion of asymmetry into power. Their effectiveness depends on context. Transparency is weak where subjects lack capacity to interpret information. Exit is weak where alternatives are costly or unavailable. Counter-power can create another concentration. Redistribution can reduce resource asymmetry while leaving institutional or epistemic asymmetry intact.

A second challenge concerns dynamic asymmetry. Capabilities change at different speeds. Artificial systems, financial institutions, states, and large platforms can update or coordinate more rapidly than individuals or local communities. Governance mechanisms designed for a slower environment can become ineffective before formal rules change. Persistent asymmetry is therefore partly temporal: the ability to learn, respond, litigate, coordinate, or revise can itself be unequally distributed.

A third challenge concerns productive asymmetry. Some differentiation enables specialization, expertise, delegation, and coordination. Governance that attempts to eliminate every asymmetry can destroy useful capacities or impose high administrative cost. GRE therefore requires criteria for distinguishing asymmetries that are functionally productive from asymmetries that generate dependency, exclusion, capture, or foreclosure. The distinction is empirical and normative rather than definitional.

Future work should compare governance architectures by how they affect conversion mechanisms. Which institutions prevent expertise from becoming unaccountable authority? Which infrastructures reduce dependence without eliminating specialization? Which rights preserve contestability when exit is impossible? Which forms of public or cooperative capacity alter bargaining structure? Which monitoring systems remain revisable when the powerful actors being monitored can adapt strategically?

The open problem is governance that remains effective under durable difference. GRE should study how relations can remain productive and heterogeneous while limiting the recursive accumulation of asymmetry into structures that remove others' capacity to participate, contest, exit, or generate alternatives.

3.20.10 Long-Horizon and Intergenerational Evaluation

The final open problem concerns effects that extend beyond ordinary observational and political horizons. Generative analysis often directs attention toward future capacities, institutional trajectories, ecological conditions, knowledge infrastructures, and path-dependent constraints. These objects can persist for decades or generations. Evaluation therefore faces a fundamental difficulty: the most important consequences may occur after the period in which evidence can be directly collected or the relevant decision-makers remain accountable.

Long-horizon evaluation raises familiar forecasting problems and additional generative-relational problems. Future subjects may possess different preferences, technologies, institutions, vulnerabilities, and value languages. Interventions can change the categories through which later outcomes are evaluated. The relevant counterfactual can also evolve. A policy that appears option-expanding under present technology can become restrictive under a later technological regime, while an apparently conservative intervention can preserve ecological or institutional capacities whose future uses are presently unknown.

Discounting provides one way to compare temporally separated effects, but discount rates encode substantive assumptions and cannot resolve all intergenerational questions. Some future losses concern irreversible ecological damage, destroyed knowledge, institutional lock-in, or loss of option-generating capacity. These may be poorly represented as ordinary delayed consumption effects. GRE therefore needs temporal representations that distinguish delayed value from changes in the capacity to generate future value.

Uncertainty compounds the problem. Forecast distributions may widen with horizon; structural transformation can invalidate the model generating those distributions; unknown future innovations can alter feasible trajectories; and future actors cannot participate directly in present deliberation. Evaluation must therefore combine prediction with robustness, precaution, reversibility, preservation of options, and explicit treatment of model uncertainty. Different domains will justify different combinations.

Intergenerational analysis also requires attention to inheritance. Future subjects inherit infrastructure, institutions, debts, ecological conditions, knowledge, classifications, and unresolved conflicts. These inheritances shape both their opportunities and the costs of changing course. A generative intervention should therefore be evaluated partly by what kinds of revision it leaves possible for those who come later.

This problem may retain irreducible uncertainty. Future possibility spaces cannot be observed in full, and the values through which future actors judge inherited conditions cannot be completely known. GRE should not treat this uncertainty as a reason to ignore long horizons. It should instead make the uncertainty explicit and examine which interventions preserve enough diversity, reversibility, capacity, and institutional corrigibility to support later adaptation and re-evaluation.

The ten problems in this section define a research frontier rather than a list of defects awaiting simple repair. Some require better measurement and identification; some require new formal or empirical methods; some concern interfaces with normative theory; and some arise from reflexivity, historical change, and the openness of future possibility. Progress in one area can also alter another. Better generativity measures can intensify symbolic reification if their institutional use is poorly governed. Broader relational boundaries can improve downstream attribution while increasing uncertainty. Stronger governance of asymmetry can change the mechanisms whose effects were initially being measured.

GRE should therefore preserve open problems as active components of its cumulative research programme. An unresolved question becomes productive when competing formulations, evidence, failed approaches, and revisions remain trace-

able. The next section turns from these substantive open problems to the architecture through which the wider GRE programme can organize their investigation across epistemology, methodology, praxis, formalization, governance, knowledge, artificial intelligence, and domain-specific applications.

3.21 Architecture of the GRE Research Programme

The preceding sections have specified the provisional identity, problem-space, objects, scales, modes of inquiry, epistemic commitments, praxis, normative interfaces, contribution criteria, internal pluralism, and open problems of Generative Relational Economics. The role of the present section is different. It organizes those commitments into a research architecture that can support the remainder of the book and, more importantly, a cumulative programme extending beyond this book. Its objective is to identify the principal domains of work that GRE requires, clarify their relations, and show how movement among them can remain coordinated without collapsing them into one method, one ontology, or one normative theory. The architecture is therefore neither a linear sequence nor a departmental division of labor. It is a set of connected research components whose outputs can constrain, revise, or redirect one another.

The programme can be understood as having several recurrent movements. Epistemological work asks what kinds of relational and generative claims can be warranted. Methodological work develops procedures for observing, reconstructing, comparing, and testing those claims. Praxis links explanation to intervention under incomplete knowledge. Substantive economic work specifies economic objects, allocation processes, value trajectories, temporal organization, power, knowledge, artificial intelligence, and domain-specific mechanisms. Formal work provides representations that can clarify structure or generate implications without acquiring automatic ontological priority. Normative and governance work evaluates how generated capacities, dependencies, harms, and possibilities should be judged and governed. None of these components is sufficient by itself. Their interaction is what gives GRE the possibility of becoming a research programme rather than a vocabulary.

This architecture also gives the later chapters a disciplined relation to Chapter 3. The chapters that follow do not merely expand terms introduced here. They test whether the constitutional claims made in Part I can survive more demanding epistemic, methodological, formal, substantive, and applied development. A concept that proves unusable under empirical inquiry should be revised. A formal representation that cannot preserve relevant historical or interpretive distinctions should be limited. A normative framework that obscures economic mechanisms should not replace explanation. An intervention methodology that generates unanticipated dependency should feed back into the theory of power and praxis. The architecture is therefore recursive: later work is expected to modify the preliminary constitution from which it begins.

3.21.1 Epistemology of Relations

A GRE research programme requires an epistemology capable of supporting claims about relations without assuming that relations are directly given to observation. Economic inquiry usually encounters traces: transactions, documents, prices, classifications, narratives, institutional records, behavioral responses, network data, legal categories, measurements, and model outputs. From such traces, researchers infer relations of dependence, recognition, exchange, authority, mediation, constraint, influence, and generation. The first architectural component therefore concerns the conditions under which these inferences are warranted.

The epistemology of relations must keep at least four layers distinguishable. There is the relation or relational process posited as part of the target situation; there are the observations through which researchers gain partial access to it; there are the categories and representations used to organize those observations; and there are the claims made on the basis of those representations. Confusion among these layers produces many characteristic errors. A network edge can be mistaken for the relation itself. A legal category can be treated as a complete description of social participation. A repeated correlation can be interpreted as a stable generative relation even where the mechanism changes historically. GRE therefore requires explicit accounts of how observations become relational claims.

This epistemic component also has to accommodate different kinds of relational evidence. Some relations are materially instantiated through contracts, infrastructures, ownership, payment, or legal authority. Others are reconstructed from repeated interaction, dependence, interpretation, or institutional practice. Still others concern counterfactual or generative effects that cannot be observed directly because they refer to capacities, alternatives, or future conditions. Evidence sufficient for one kind of relation may be inadequate for another. The programme should therefore resist a single criterion of relational observability.

Epistemology of relations also includes reflexivity. Economic categories can alter the relations they represent. Credit scores change access to credit; rankings alter institutional behavior; classifications determine eligibility; models influence expectations; and public descriptions can reshape coordination. The object of knowledge can therefore respond to the means of knowing. This makes epistemology an economic problem as well as a philosophical one. The programme must study how knowledge practices participate in the relational field whose properties they attempt to establish.

The output of this component is not a final theory of knowledge. It is a set of standards for relational claims: how objects are identified, how boundaries are selected, how observations are linked to relations, how representations are validated, how uncertainty is expressed, and how claims remain open to correction. Those standards provide the epistemic ground on which the methodological components of the programme operate.

3.21.2 Methodology of Relational Inquiry

Relational methodology concerns procedures for studying configurations in which the properties or effects of an object depend materially on its relations with other ob-

jects, institutions, environments, or representations. Its central task is to move analysis beyond isolated-unit description without treating every connection as equally significant. A relational study must identify which relations matter, how they are evidenced, what scale they operate at, and which consequences follow from their organization.

The methodological repertoire is necessarily plural. Historical reconstruction can identify how a relation formed and changed. Comparative inquiry can examine why similar entities occupy different relational positions. Network analysis can represent patterned connectivity. Institutional analysis can identify rules that stabilize or authorize relations. Ethnographic and interpretive work can reconstruct how participants understand obligations, identities, and meanings. Econometric and causal designs can estimate effects generated through specified relational exposures. Qualitative process tracing can examine mechanisms that are difficult to reduce to stable variables. None of these methods is intrinsically more relational merely because of its technique. Relationality enters through the structure of the research question and the specification of the object.

A developed relational methodology should make boundary construction explicit. Researchers need criteria for deciding which actors, institutions, ecological conditions, infrastructures, classifications, and temporal histories belong inside the analysis. Because boundaries are analytical choices with substantive consequences, sensitivity to alternative boundaries should become part of methodological practice where feasible. The same transaction can look efficient within a firm boundary and extractive within a regional labor system; a technological intervention can look productive over one year and capability-destroying over a decade.

Relational inquiry also needs procedures for distinguishing direct from mediated effects. Economic outcomes often travel through chains of institutions, expectations, infrastructures, and social recognition. A transfer to one subject can alter bargaining conditions for another; a platform rule can change incentives through ranking systems; a legal reform can transform behavior through expectations before enforcement occurs. Methodological work must therefore support the reconstruction of mediation rather than stopping at the administrative point of intervention.

The programme should accumulate relational methods through reusable design patterns rather than prescribe one canonical protocol. Useful patterns may concern boundary selection, multi-source evidence, relation typing, temporal reconstruction, counterfactual comparison, cross-scale mapping, or identification of institutional mediation. These patterns become a methodological library that later studies can adapt while preserving transparent assumptions and limits.

3.21.3 Methodology of Generative Relational Inquiry

Generative relational inquiry adds a further question to relational analysis: what later capacities, structures, values, subjects, constraints, or possibilities are produced through a relation, and through what mechanism? This shift changes both the temporal horizon and the object of explanation. The researcher is no longer concerned only with what a relation currently connects or distributes. The inquiry follows how participation in the relation changes the conditions from which subsequent economic

processes can occur.

This methodological component therefore requires explicit generative claims. A study should state what is alleged to be generated, over what period, for which subjects or systems, and through which mediating process. Generation may concern skills, trust, dependency, infrastructure, market access, organizational capacity, knowledge, subject positions, ecological resilience, future options, institutional lock-in, or the capacity to generate further value. These are heterogeneous objects, so no single metric can stand in for generativity across domains.

Generative inquiry also requires attention to counterfactual trajectories. The relevant comparison is frequently not simply between treated and untreated units at one time. It may concern how different relational configurations alter later pathways. This creates methodological difficulty because the treatment can change the variables, categories, or institutional environment through which later outcomes are measured. Longitudinal designs, historical comparison, mechanism-based simulation, qualitative reconstruction, and adaptive experimentation may therefore complement conventional causal identification.

A further methodological problem concerns recursion. Generated capacities can alter the relation that generated them. New knowledge changes bargaining power; institutional learning changes governance; accumulated infrastructure shifts future allocation; successful coordination changes expectations; artificial systems can alter the speed and scale of subsequent production. Generative relational methodology must be capable of tracing such feedback without assuming that the original mechanism remains fixed.

The programme should therefore develop a family of generative research designs rather than one universal method. Their common requirement is disciplined movement from relation to mechanism to generated consequence to altered future condition. Where the chain cannot be established, the study should say so. Where several mechanisms remain plausible, competing explanations should remain visible. This methodological restraint protects generativity from becoming an all-purpose label for any downstream change.

3.21.4 Praxis and Intervention

Praxis connects GRE's explanatory programme to purposive attempts to alter economic relations. The architectural function of praxis is to prevent theory from ending at diagnosis while also preventing intervention from outrunning knowledge. GRE therefore treats intervention as an iterative research and governance process in which action generates new evidence, changes the relational field, and may require revision of both the intervention and the theory that justified it.

A GRE praxis architecture begins with relational and generative diagnosis. The analyst identifies the relevant subjects, institutions, dependencies, constraints, capacities, value trajectories, and asymmetries. Intervention design then specifies which relation or enabling condition is to be changed, what effects are expected, which subjects may bear risks, and what indicators or qualitative observations can reveal downstream consequences. Implementation becomes part of inquiry because it tests assumptions under conditions that may differ from those represented in the initial

model.

Adaptive feedback is therefore central. Interventions should include monitoring capable of detecting effects beyond the intended recipient, changes in dependency, emergent exclusion, shifts in power, unexpected conversions of value, and damage to future options. Revision can concern intensity, targeting, institutional design, representation, or even the original diagnosis. Where harm or failure becomes sufficiently probable, withdrawal, reversal, and repair need to remain available.

Praxis also requires institutional design for learning. Organizations often collect data for accountability but not for theoretical correction. GRE would instead treat intervention records, failed mechanisms, participant interpretations, unexpected effects, and reversal attempts as cumulative research materials. This creates a bridge between application-dominant work and research-dominant work. Interventions become sites in which the adequacy of relational and generative hypotheses can be examined.

The praxis component does not imply that every GRE project must intervene. It specifies the architecture required when explanation is translated into action. Its standards are proportional to stakes and uncertainty. The more irreversible, asymmetric, or long-horizon the intervention, the stronger the need for monitoring, contestability, staged implementation, reversibility, and repair capacity.

3.21.5 Economic Objects and Relational Architecture

Substantive GRE begins by reconstructing the architecture of economic objects. Firms, households, platforms, markets, contracts, currencies, technologies, infrastructures, public agencies, communities, and ecological systems can all function as economic objects, but their economic significance depends on relations that constitute access, authority, dependence, recognition, exchange, coordination, and reproduction. The programme therefore needs systematic accounts of how economic objects are stabilized and connected.

Relational architecture concerns more than mapping connections. It asks which relations are constitutive, which are enabling, which are extractive, which are substitutable, and which create dependence or future capacity. It also examines how objects change when their relational architecture changes. A firm can retain a legal identity while its productive relations, knowledge base, ownership, labor dependence, and technological infrastructure transform substantially. An apparently stable object can therefore contain changing generative conditions.

This component also organizes scale. Economic architecture can be reconstructed within organizations, across supply chains, among institutions, between human and artificial subjects, or across economic and ecological systems. At one scale a platform is an entity; at another it is a field of relations among users, advertisers, workers, algorithms, legal authorities, and infrastructures. GRE should be able to move between these representations without presuming that one scale is ontologically final.

A mature programme would accumulate relational architectures comparatively. Which configurations support distributed capability? Which concentrate dependency? Which are resilient to shocks? Which permit exit and revision? Which

externalize ecological or social costs? Which generate durable learning? Comparative architectural work can provide intermediate theory between highly local case description and universal claims about markets or institutions.

This substantive component prepares several later programme domains. Allocation changes relational architecture; value moves through it; generative spacetime records its historical and temporal organization; formal models represent selected features of it; governance attempts to alter its asymmetries. Economic architecture therefore functions as a central integrative object without becoming the sole object of GRE.

3.21.6 Relational Allocation

Allocation is conventionally concerned with who receives which resources under specified constraints. GRE retains that question but expands the analytical unit. An allocation also enters a relational configuration and can change bargaining positions, dependencies, recognition, coordination capacity, expectations, and future productive possibilities. Relational allocation is the programme component that studies these mediated effects systematically.

The relevant object is therefore not merely the resource transferred. It includes the route, institutional conditions, attached obligations, timing, visibility, substitutability, and relations through which the allocation is received and used. The same monetary amount can produce different consequences depending on whether it arrives as wage, grant, debt, benefit, prize, investment, family transfer, or platform payment. The relational form can influence autonomy, stigma, risk, reciprocity, and future access even when nominal quantity is identical.

Relational allocation also widens incidence analysis. Effects can propagate beyond the administrative recipient through households, markets, organizations, networks, and institutions. A subsidy can change prices, a training programme can alter labor-market competition, a public infrastructure investment can change land values, and access to computation can reshape research capacity. GRE therefore asks which relations mediate the allocation and how those relations redistribute later opportunities or constraints.

The programme should develop both descriptive and intervention-oriented allocation research. Descriptive work can reconstruct relational incidence and downstream transformation. Formal work can model how allocation changes network positions or dynamic constraints. Comparative work can examine alternative institutional forms for delivering similar resources. Normative work can evaluate whether an allocation expands capability while generating dependency elsewhere. Application-dominant praxis can use these findings to redesign allocation mechanisms.

Relational allocation is thus a bridge between conventional economic analysis and the generative programme. It retains scarcity, incentives, incidence, and trade-offs while extending attention to how allocation changes the relational conditions under which later value and capability are generated.

3.21.7 Generative Value

Generative value concerns value that arises through the capacity of a relation, resource, institution, or process to enable further valuable activity. The concept does not replace exchange value, use value, welfare, capability, social value, ecological value, or other established categories. Its programme function is to make the production of future value-generating capacity an explicit economic object.

Generative value may appear through learning, infrastructure, trust, institutional competence, scientific knowledge, ecological restoration, network access, organizational routines, or the creation of new possibilities for participation. Its effects can be delayed, distributed, and difficult to attribute to one original intervention. The same process can generate several forms of value while also producing harm, dependence, or exclusion. The programme therefore requires plural representations rather than assuming that generative value is one scalar quantity.

Research in this component should address propagation and conversion. Value generated in one domain can move into another: knowledge can become productive capability, social recognition can become market access, infrastructure can become bargaining power, ecological conditions can enable future production, and data can become organizational advantage. Conversion can also be blocked or asymmetrical. Subjects may contribute to a generative process without capturing the value that later emerges from it.

This creates questions of return and distribution. Who receives the benefits of generated capacity? Which relations permit value to recirculate to those who sustained its emergence? Which institutional arrangements enable extraction by actors positioned downstream? How should delayed or diffuse contributions be recognized? These questions connect generative value to political economy and justice without making one normative rule part of the definition of value itself.

A cumulative research programme should develop typologies of generative mechanisms, methods for tracing value trajectories, domain-specific indicators, and comparative institutional studies. It should also preserve cases in which apparently generative investments fail to create durable capacity or create capacity that later becomes harmful. Generative value becomes analytically useful only if it remains distinguishable from the general fact that economic processes have consequences.

3.21.8 Generative Spacetime

Generative spacetime provides the programme's architecture for analyzing how economic relations are organized across heterogeneous spatial and temporal conditions. The term does not imply that social reality literally possesses the geometry of physical spacetime. It identifies a research problem: economic processes unfold through histories, delays, path dependencies, spatial distributions, institutional boundaries, and differently paced subsystems whose relations shape what can be generated later.

Time in GRE cannot be reduced to a neutral index. The order of events can matter. Early access to capital can alter later bargaining power; institutional sequencing can determine which reforms become feasible; technical standards can lock in infrastructure; educational investments can affect capabilities years later; ecological

degradation can create long recovery periods. Identical quantities introduced at different moments can therefore have different generative effects.

Spatial organization is similarly relational. Geographic distance interacts with infrastructure, jurisdiction, logistics, language, data access, mobility, and ecological conditions. Digital mediation can reduce some distances while creating new forms of concentration in computation, platforms, standards, or data centers. A generative-spacetime analysis asks how locations become connected or separated through these economic relations rather than treating space as a passive container.

The programme also needs to study heterogeneous temporalities. Humans, firms, financial markets, states, ecosystems, infrastructures, and artificial systems can operate at very different speeds. Their coupling can generate asymmetry. A platform can change an algorithm faster than workers can reorganize; financial capital can exit faster than communities can replace employment; ecological recovery can be slower than investment cycles. Temporal mismatch therefore becomes an economic mechanism rather than merely a descriptive feature.

Generative spacetime should support historical reconstruction, dynamic modeling, spatial analysis, and long-horizon evaluation. Its contribution is to preserve the ordering, location, duration, and temporal coupling of generative processes. It thereby links historical analysis to formal dynamics without reducing one to the other.

3.21.9 Formal Models

Formal modeling provides GRE with tools for making assumptions explicit, deriving implications, comparing mechanisms, and exploring trajectories that are difficult to reason about verbally. The programme can draw on dynamical systems, networks, multilayer structures, agent-based models, optimization, game theory, probabilistic models, field-like representations, simulation, and other mathematical or computational techniques where they are appropriate to the object.

The architectural principle is representational pluralism under ontological restraint. A network model emphasizes connectivity; a dynamical model emphasizes state evolution; a game-theoretic model emphasizes strategic interaction; an agent-based model emphasizes local rules and emergent aggregate patterns; a field representation emphasizes distributed conditions. These models need not be translated into one universal formal language. Their adequacy depends on which features of the economic problem they preserve and which they suppress.

Formal work in GRE should state the status of each construction. Some models are descriptive summaries. Some identify structural possibilities. Some generate comparative statics or trajectories. Some serve as counterfactual laboratories. Some are fitted to empirical data; others are heuristic. A mathematically precise model can remain empirically weak if its variables or mechanisms lack adequate correspondence to the target system. Formal rigor therefore complements rather than substitutes for evidential warrant.

Generativity creates particular formal challenges. The variables, interaction structures, or effective rules may themselves change. Models can represent some forms of adaptation, network rewiring, rule learning, or changing parameters, but the pro-

gramme should distinguish represented transformation from genuinely unforeseen category change. Where the formal state space excludes relevant novelty, model revision may be more appropriate than adding complexity to preserve a fixed representation.

The cumulative aim is a library of transparent formal models tied to clearly stated empirical and conceptual problems. Comparability should depend on assumptions, mechanisms, observables, and failure conditions, not on adherence to one mathematical paradigm. Formal models should remain instruments through which GRE sharpens explanation, tests implications, and explores possibilities.

3.21.10 Justice, Power, and Governance

Power and justice form a programme component because generative economic relations distribute more than current resources. They shape who can participate, who can exit, whose knowledge counts, who bears vulnerability, which alternatives remain feasible, and who captures value generated through collective processes. Governance concerns the institutional organization of these relations under persistent asymmetry and uncertainty.

Power research in GRE studies conversion mechanisms. Resource, capability, knowledge, institutional, vulnerability, and exit asymmetries become economically consequential when they can be converted into durable influence over others' options or future conditions. The programme should identify the institutional arrangements that enable or constrain these conversions. Ownership, standards, law, infrastructure, platform design, intellectual property, credit, public authority, and organizational hierarchy can all mediate conversion.

Justice enters as a neighboring evaluative problem rather than a property automatically inferred from generativity. A highly generative arrangement can still distribute participation unequally, impose dependency, externalize harm, or foreclose alternatives. GRE therefore needs interfaces with distributive, procedural, relational, capability-oriented, ecological, and generative approaches to justice while remaining explicit about which normative principles are being used.

Governance research then asks how institutions can organize relations under conditions in which asymmetry cannot simply be eliminated. Relevant mechanisms include contestability, transparency, rights, public capacity, collective organization, auditing, representation, interoperability, liability, redistribution, and preservation of exit or voice. Each can itself generate new dependencies or concentrations. Governance must therefore be evaluated recursively.

This component connects explanation, normativity, and praxis. Its success should be judged not by whether it yields one constitutional ideal but by whether it improves the ability to diagnose power, compare governance architectures, evaluate their generated consequences, and revise institutions as relational conditions change.

3.21.11 Knowledge and Epistemic Economy

Knowledge is simultaneously an input, output, resource, relation, institution, and source of asymmetry. A GRE research programme therefore requires a substantive

epistemic economy concerned with how knowledge is generated, validated, stored, circulated, priced, restricted, translated, forgotten, and converted into other forms of value or power.

The economic organization of knowledge affects who can generate further knowledge. Access to education, archives, computation, laboratories, data, journals, languages, expert communities, and institutional recognition shapes future epistemic capability. Knowledge production can therefore exhibit cumulative advantage and generative inequality even when individual information goods are non-rival. Ownership, paywalls, classification, secrecy, data governance, and platform control can influence the relational conditions of inquiry.

Epistemic economy also concerns recognition. Some observations become evidence, some questions become fundable, some methods acquire authority, and some speakers become credible. These processes are partly scientific and partly institutional. They can generate epistemic injustice when subjects are systematically excluded from contributing, being understood, or influencing the categories through which their situations are represented. At the same time, standards of evidence remain necessary; inclusion cannot mean suspension of criticism.

Artificial intelligence intensifies these questions by reducing some costs of synthesis, drafting, search, modeling, and content generation while increasing dependence on data, computation, model access, evaluation infrastructure, and epistemic filtering. Abundance of generated text can make provenance, attention, verification, and question formation scarcer. The economic object is therefore not knowledge alone but the relational infrastructure through which epistemic capability is distributed.

The programme should study knowledge capital, epistemic labor, archive power, verification, provenance, scientific institutions, open infrastructure, education, and the generative conditions of inquiry. It should also examine how its own research practices distribute epistemic participation and authority.

3.21.12 Artificial Intelligence and Radical Asymmetry

Artificial intelligence provides a contemporary domain in which several GRE problems become unusually visible at once: heterogeneous subjecthood, rapid capability change, concentration of infrastructure, epistemic abundance, organizational transformation, power conversion, temporal mismatch, and uncertainty about future generative trajectories. The programme should therefore treat AI neither as a peripheral application nor as an all-explanatory paradigm. It is a demanding empirical case for testing GRE's concepts.

The central economic problem is not simply automation or substitution. AI systems can alter the cost and speed of cognition-like tasks, reorganize knowledge work, modify decision processes, enable new forms of coordination, and change who can produce valuable outputs. The consequences depend on ownership, access, interface design, labor relations, education, regulation, data, compute, and organizational capacity. Similar model capabilities can therefore produce different economic structures under different relational architectures.

Radical asymmetry refers to cases in which capability differences become large

enough to transform bargaining, monitoring, production, or institutional response. Such asymmetry can occur among firms, states, workers, consumers, or human and artificial operational subjects. It does not establish moral or ontological equality among those subjects. The research problem concerns how capabilities are converted into economic power and how other subjects retain participation, contestability, learning, and exit under rapidly changing conditions.

AI also complicates the generative horizon. Systems that participate in research, design, education, administration, or cultural production can alter the rate at which new possibilities are generated. They can also narrow possibility through standardization, dependence, concentrated infrastructure, or recursive optimization around existing metrics. Evaluation must therefore attend to both capability expansion and generative foreclosure.

This component should integrate empirical labor economics, industrial organization, innovation studies, political economy, governance, epistemic economy, and technical understanding of AI systems. GRE contributes by coordinating these perspectives around relational and generative mechanisms rather than by replacing their specialized expertise.

3.21.13 Domain-Specific Applications

The final architectural component concerns domain-specific application. A research programme becomes substantive only when its concepts survive contact with cases in which institutions, evidence, values, scales, and mechanisms differ. GRE should therefore be tested across domains rather than developed indefinitely at the level of general vocabulary.

Candidate domains include labor, education, scientific research, health, finance, development, migration, humanitarian systems, urban infrastructure, digital platforms, ecological transition, public administration, innovation, culture, and international economic relations. Each domain brings specialized literatures and methods that GRE must respect. Domain application should begin from the empirical problem and available knowledge, then ask whether relational and generative analysis adds explanatory or practical value.

Applications serve several programme functions. They test concepts against heterogeneous evidence. They expose hidden assumptions imported from one domain into another. They identify mechanisms that may travel across cases and mechanisms that remain local. They provide intervention evidence. They reveal where value categories differ and where normative conflict becomes unavoidable. They can also demonstrate that GRE adds little to an already adequate established analysis, which is itself useful boundary knowledge.

Cross-domain comparison should therefore be careful. Similar labels can conceal different mechanisms. Dependency in finance, caregiving, digital infrastructure, and ecology need not be structurally identical. Generativity in education may concern capabilities and inquiry; in ecological restoration it may concern system resilience and future option spaces; in science it may concern knowledge and question formation. Comparative GRE should look for structural correspondence without presuming equivalence.

Domain-specific work also provides the main route through which the architecture remains corrigible. If concepts repeatedly fail in applied settings, they should be narrowed or abandoned. If new objects or mechanisms recur across domains, the programme can revise its typologies. If governance approaches generate predictable secondary harms, praxis should change. Application is therefore not the terminal stage of the programme. It is one of the principal sources through which the architecture itself evolves.

Taken together, these thirteen components define a preliminary architecture for GRE research. They do not form a pipeline in which epistemology is completed before methodology, methodology before substantive economics, and substantive economics before application. Work can begin in any component and move among several. An empirical anomaly can force epistemic revision; an intervention can reveal a new mechanism; a formal model can expose an ambiguous concept; a domain-specific case can require new governance categories; a normative conflict can reveal that a value representation is too coarse.

The architecture therefore functions as a coordination device. It indicates where a research question sits, which neighboring components are likely to constrain it, what forms of evidence or representation may be required, and how results can return to the wider programme. It also gives the remaining parts of the book a common orientation: ontology and epistemology, research praxis and methodology, application-dominant intervention, substantive economic foundations, power and knowledge, artificial intelligence, domain applications, and the later disciplinary return are connected components of one revisable research programme rather than independent theoretical excursions.

The following section condenses this architecture into a preliminary constitution of GRE. That constitution does not close the field. It states, in compact form, what GRE studies, what it does not need to presume, what it attempts to explain and change, what can count as evidence and contribution, and which questions remain deliberately open to historical and theoretical revision.

3.22 A Preliminary Constitution of GRE

The preceding sections have developed Generative Relational Economics from a provisional disciplinary identity into a structured research programme. They have specified its problem-space, methodological primitives, objects and scales of inquiry, characteristic questions, analytical sequence, account of economic subjecthood, orientation of generation, modes of inquiry, epistemic commitments, praxis, normative interfaces, analysis of power and heterogeneity, disciplinary boundaries, contribution criteria, cumulative programme, internal pluralism, open problems, and wider research architecture. The role of the present section is to condense those commitments into a preliminary constitution. The term *constitution* is used here in a limited methodological sense. It denotes a compact statement of the conditions under which GRE can presently recognize its own objects, claims, evidence, interventions, contributions, and limits. It does not denote a final doctrine, a metaphysical settlement, or a fixed disciplinary code.

The objective of the section is therefore both consolidating and restrictive. Consolidation is needed because a research programme can become diffuse when its concepts expand faster than the criteria governing their use. Restriction is needed because GRE should remain distinguishable from any study that happens to mention relations, emergence, complexity, value, or future possibility. A preliminary constitution states what kinds of questions GRE takes responsibility for, which assumptions it withholds, what forms of explanation it seeks, how intervention enters the programme, what can count as evidence and contribution, and which questions remain deliberately unsettled. The method is synthetic rather than genealogical. No new lineage is introduced here. The section reorganizes the commitments already established in Chapters 1–3 into eight constitutional dimensions: domain, restraint, explanation, praxis, evidence, contribution, openness, and historical revisability.

The constitution is preliminary for a substantive reason. GRE studies processes in which relations, subjects, capacities, value structures, institutions, and conditions of generation can themselves change. A research programme directed toward such objects would contradict its own subject matter if it treated its present categories as permanently settled. Constitutional stability is therefore functional rather than absolute. The programme needs enough continuity for researchers to disagree about the same problems, compare findings, and accumulate knowledge, while retaining enough revisability to alter its categories when empirical, historical, formal, or normative work reveals that they have become inadequate. The constitution presented below should be read in that spirit.

3.22.1 Domain and Objects of Study

GRE studies economic relations insofar as those relations help generate, reproduce, distribute, transform, or foreclose later capacities, constraints, values, subjects, institutions, trajectories, and fields of possibility. This domain statement is intentionally broader than the study of transactions and intentionally narrower than a general theory of social reality. GRE remains economic because its questions concern allocation, production, circulation, valuation, work, capability, institutional organization, economic power, dependence, resources, infrastructures, knowledge, and the conditions through which subjects participate in material and symbolic economies. It becomes generative-relational when those objects are examined through the consequences of their relational organization for what can subsequently exist, act, acquire value, coordinate, persist, or change.

The programme therefore treats the immediate recipient of an allocation or intervention as only one possible locus of effect. A subsidy may alter supplier capacity, household bargaining, regional infrastructure, expectations, or political legitimacy. An educational resource may change knowledge, confidence, social connection, question formation, institutional recognition, or later opportunity. A platform rule may change not only prices or matching efficiency but also visibility, dependence, subject formation, and the viability of alternative organizational forms. GRE asks which of these downstream effects are materially connected to the original relation and through which mechanisms they are generated. The downstream horizon is empirical and selective rather than indefinitely expansive: a GRE analysis is responsible

for tracing consequences where plausible generative pathways and evidential access make them analytically relevant.

The objects admitted to this domain are correspondingly plural. Relatively stabilized entities, subjects, relations, resources, capacities, values, constraints, fields, processes, events, trajectories, institutions, social facts, and symbolic representations can each become objects of GRE inquiry. Their analytical status depends on the local problem. A firm may be treated as an entity in one study, as a field of internal relations in another, as an institutional rule complex in a third, and as a node within a wider production ecology in a fourth. GRE does not require one of these descriptions to exhaust the firm's reality. It requires the researcher to state which object construction is being used, at what scale, for which explanatory purpose, and with what evidential consequences.

The domain also includes heterogeneous subjects. Human persons, households, organizations, public bodies, communities, ecological systems, hybrid arrangements, and artificial operational agents may participate in economically consequential relations under different descriptions and with different normative statuses. Their inclusion within a common analytical field does not establish ontological or moral equivalence. It means only that their interactions can affect allocation, value, capability, dependence, coordination, and future possibility in ways that economic inquiry may need to represent. The constitution therefore permits heterogeneous participation while reserving questions of personhood, consciousness, legal personality, moral status, and ecological standing for the appropriate neighboring domains and normative arguments.

A GRE study is consequently identified less by a proprietary object than by a characteristic relation between object and question. The same labor market, school, AI system, household, ecological project, financial institution, or humanitarian intervention can be studied through many legitimate economic approaches. It becomes a GRE problem when the inquiry asks how relational organization changes the capacities and conditions from which later economic and social possibilities are generated. This criterion preserves disciplinary openness while preventing the label GRE from becoming synonymous with any broad interest in complexity or interdependence.

3.22.2 Constitutive Restraints

GRE proceeds under several restraints that are constitutive rather than merely cautious. The first is ontological suspension. The programme can use entities, relations, processes, fields, networks, trajectories, categories, and generative structures without declaring any one of them the final metaphysical furniture of reality. Analytical usefulness establishes neither ontological priority nor completeness. A network representation may clarify connectivity; a field representation may clarify distributed conditions; a process description may clarify temporal transformation. Their value depends on the problem and the evidence. GRE therefore permits ontological commitment at the level required for a particular inquiry while withholding stronger closure.

The second restraint concerns explanatory universality. GRE does not presume that every economically relevant outcome requires a generative-relational explana-

tion. Standard price theory, causal estimation, accounting, institutional description, optimization, historical narrative, or domain-specific expertise may already explain the relevant problem adequately. The programme earns analytical relevance where relational mediation, downstream generation, changing capabilities, path dependence, heterogeneous value, shifting subjecthood, power conversion, or transformation of future possibility materially improve understanding. The GRE label should therefore be unnecessary when a narrower account is sufficient.

A third restraint concerns generativity itself. Generation is not presumed to be beneficial, innovative, progressive, emancipatory, or just. Relations can generate dependency, exclusion, vulnerability, ecological degradation, epistemic closure, concentrated power, or the destruction of alternative futures. A highly generative system can reproduce harm more effectively than a weakly generative one. Evaluation must therefore remain separable from description. GRE can identify that a relation generates new capacities or reorganizes a field while leaving open whether that transformation should be encouraged, governed, limited, repaired, or reversed.

A fourth restraint concerns representation. Variables, categories, network edges, model states, indicators, simulations, legal classifications, and textual interpretations mediate access to the object; they are not automatically identical with it. GRE therefore distinguishes relational reality from its representation and treats boundary choice, measurement, coding, scale selection, and model specification as substantive parts of inquiry. This restraint is especially important where categories can become performative. Rankings, credit scores, eligibility classifications, productivity metrics, and AI-generated representations may alter the relations they purport to describe. The research instrument can become part of the generative field.

A fifth restraint concerns scalar and historical invariance. GRE does not assume that an object retains the same analytical identity across scale or historical transformation. A configuration that is stable enough to be treated as an entity at one level may decompose into changing relations at another. Categories such as worker, household, capital, platform, intelligence, capability, value, or market can change their institutional content over time. The constitution therefore requires explicit scale, boundary, and historical conditions whenever they materially affect the claim.

These restraints make the programme deliberately non-totalizing. They protect methodological pluralism, disciplinary interfaces, and corrigibility. They also impose costs: GRE must often carry more uncertainty, specify more boundaries, and resist attractive universal formulations. Those costs are accepted because a programme concerned with changing relations and future possibility requires a disciplined distinction between useful analytical commitment and premature closure.

3.22.3 Explanatory Commitments

GRE attempts to explain how economic outcomes and future possibilities arise through relations that mediate allocation, interaction, interpretation, institutional recognition, capability, and value. Its characteristic explanatory move is from a local intervention or observed configuration toward the mechanisms through which effects propagate and reorganize later conditions. This move does not replace causal inference. It expands the range of causal and generative questions that may need

to be asked when the object cannot be understood adequately as an isolated unit responding to fixed incentives or constraints.

A generative explanation should identify more than temporal succession. It should specify a plausible mechanism connecting relational conditions to later changes. The mechanism may involve resource transfer, learning, coordination, reinforcement, institutional authorization, recognition, imitation, network exposure, expectation formation, technological complementarity, legal change, ecological feedback, symbolic classification, or another documented process. Claims of generation should remain proportionate to the degree to which such mechanisms can be evidenced. Where mechanism is uncertain, GRE should state the uncertainty rather than substituting the vocabulary of emergence for explanation.

The programme is especially interested in recursive transformation. Economic processes can change the conditions under which later processes operate. A policy can alter not only behavior but institutional trust; a technology can alter not only productivity but the skills and infrastructures required for participation; a market can alter not only allocation but the kinds of actors able to survive within it; an AI system can alter not only task performance but the organization of expertise, attention, and decision authority. In such cases, the effective rule governing later change may differ from the rule that characterized the earlier system. GRE therefore treats transformation of generative conditions, and where warranted transformation of effective rules, as explanatory objects in their own right.

Explanation also requires attention to propagation, conversion, recirculation, dissipation, and extraction. Generated value can move among subjects and institutions, change form, accumulate, decay, or be captured. Knowledge can become capability; capability can become bargaining power; symbolic recognition can become access; ecological capacity can become economic resilience; public infrastructure can become private rent; care can sustain labor capacity without appearing in market price. GRE does not presume that these conversions are complete or commensurable. It seeks to identify the relations through which they occur and the losses, exclusions, and asymmetries that accompany them.

Power enters this explanatory programme as the conversion of asymmetry into durable influence over others' options, vulnerabilities, representations, exit conditions, or future generative possibilities. Resource asymmetry, capability asymmetry, knowledge asymmetry, institutional authority, vulnerability, and exit conditions can each contribute to power when relational conditions allow them to be converted into leverage. This formulation avoids treating all difference as domination while making the reproduction of asymmetry economically analyzable.

GRE also attempts to explain orientation. Economic systems do not only produce outputs; they distribute attention, visibility, curiosity, legitimacy, funding, search capacity, and institutional recognition. These processes influence which possibilities receive the conditions required for further development. An account of generation is therefore incomplete when it describes capacity while ignoring the mechanisms that direct capacity toward some questions, designs, values, or futures rather than others. Orientation can be intentional, institutional, market-mediated, algorithmic, cultural, or emergent. Its explanation belongs within the economic problem-space when it affects resource allocation and future generative capacity.

The constitutional explanatory commitment can therefore be summarized without reducing it to one model: GRE seeks mechanisms linking relational organization to the emergence, persistence, transformation, distribution, or foreclosure of later economic possibilities. Different studies may instantiate that commitment through historical reconstruction, causal inference, formal modeling, computational exploration, qualitative mechanism tracing, comparative inquiry, or combinations of these modes. The explanatory standard lies in the clarity of the claim and its warrant, not in adherence to one technique.

3.22.4 Praxis and Transformative Orientation

GRE is not constituted only as a descriptive programme. It also includes praxis: the disciplined movement from explanation toward intervention under incomplete knowledge. This practical orientation follows from the object of inquiry. If economic relations shape later capacities, dependencies, values, and possibilities, then allocation and governance decisions participate in the generation of future conditions. The research programme should therefore be capable of informing intervention while remaining explicit about the uncertainty and normative judgment that intervention introduces.

Praxis begins with diagnosis rather than prescription. A relational diagnosis identifies the relevant subjects, institutions, infrastructures, dependencies, boundaries, and scales. A generative diagnosis asks which of those relations reproduce present conditions and which enable or foreclose change. Intervention design then specifies what is being altered: resources, constraints, access, recognition, information, rights, infrastructure, incentives, coordination mechanisms, or other conditions. This sequence prevents the language of generativity from becoming a license for indiscriminate experimentation.

Allocation is treated within this praxis as a relational intervention. The economic significance of allocating money, rights, infrastructure, education, information, or computational capacity depends on the relations into which the allocation enters. Identical resources can produce different effects under different conversion factors, institutional rules, recognition structures, ecological conditions, and power relations. GRE therefore asks how an intervention changes the field through which resources become capabilities and how those new capabilities affect other subjects and future options.

Intervention generates evidence as well as effects. Feedback, implementation failure, unanticipated dependence, unequal uptake, symbolic reinterpretation, ecological response, and strategic adaptation can reveal relations that were poorly represented in the initial model. GRE praxis should therefore preserve mechanisms for revision during and after intervention. Adaptive governance is valuable where it institutionalizes learning without turning affected populations into uncontrolled experiments. The practical requirement is not endless flexibility but explicit conditions under which evidence triggers continuation, modification, scaling, suspension, or termination.

Withdrawal, reversal, and repair form part of this constitutional praxis. Interventions can become harmful, obsolete, captured, or self-reinforcing in ways that diverge

from their original aims. A programme concerned with generative effects must ask whether the conditions produced by an intervention can be undone and what restoration would actually mean after the system has changed. Repealing a rule may fail to recreate the earlier state because capabilities, expectations, infrastructures, relationships, and subject positions have already been transformed. Reversibility is therefore an empirical property, not an administrative assumption.

The transformative orientation of GRE remains normatively open in a specific sense. The programme can analyze which interventions expand participation, capability, resilience, plurality, or future possibility, but it does not derive a complete moral ordering from generativity alone. Normative appraisal can draw on justice theory, ethics, law, democratic processes, domain-specific standards, and the neighboring GREthic programme. Praxis is thus constituted by an obligation to connect explanation with action where useful, paired with an obligation to keep empirical mechanism and normative justification distinguishable.

3.22.5 Evidential Admissibility

GRE adopts evidential pluralism constrained by claim-specific standards. Evidence is admissible when it bears materially on the claim being made and when the path from observation or representation to inference is sufficiently explicit for criticism. The constitution therefore does not privilege one evidential form in advance. Administrative records, prices, transactions, experiments, quasi-experiments, surveys, interviews, ethnography, archives, legal materials, organizational documents, ecological measurements, network data, computational traces, comparative cases, formal implications, simulations, and intervention records can all contribute, but they warrant different kinds and strengths of claims.

Descriptive evidence can establish patterns without identifying mechanisms. Causal designs can estimate specified effects without exhausting interpretation or historical formation. Historical evidence can reconstruct sequence, contingency, and institutional development without producing a universal parameter estimate. Interpretive evidence can establish how categories, meanings, or obligations are understood by participants without by itself identifying every material consequence. Formal models can show what follows from specified assumptions without demonstrating that the target system satisfies those assumptions. Simulations can explore implications, sensitivity, and possible dynamics without becoming observations of the world merely through computational complexity. These distinctions are constitutional because GRE depends on combining modes without conflating their warrants.

Evidence for generative claims requires particular care. A downstream change occurring after an intervention is insufficient by itself to establish generation. Researchers should specify a mechanism, consider alternative pathways, examine temporal ordering, identify relevant mediators, and state the boundary over which the claim is intended to hold. Where direct identification is impossible, triangulation among historical, qualitative, quantitative, formal, or comparative evidence can strengthen the claim while preserving residual uncertainty. The programme accepts graded evidence; it does not require false certainty before relational mechanisms

can be studied.

Counterfactual reasoning is often unavoidable. Claims about capability, foreclosure, resilience, opportunity, or future possibility concern alternatives that may never be fully observed. Evidence can include comparison across cases, natural experiments, historical alternatives, participant knowledge, structural models, simulation, sensitivity analysis, or explicit scenario construction. The relevant standard is transparency about which counterfactual is being invoked and why it is credible enough for the intended claim. Counterfactual richness should not be confused with evidential freedom.

Negative and disconfirming evidence also belongs within GRE. Failed interventions, absent downstream effects, unstable mechanisms, measurement failure, non-transportable cases, and situations in which a simpler established theory outperforms a GRE formulation should be retained as programme knowledge. Such evidence narrows the field's domain and improves theory comparison. A research programme that records only successful generative narratives would systematically exaggerate its own explanatory scope.

Finally, evidence is historically situated. Data availability, categories, archives, measurement systems, institutional visibility, and computational capacity change over time. Some subjects leave extensive traces while others remain under-recorded; some value forms are priced while others are rendered administratively invisible. GRE therefore treats the evidential environment itself as potentially structured by power and institutions. Evidential admissibility includes attention to whose relations can be observed, which histories can be reconstructed, and which absences may reflect the organization of recording rather than the absence of the phenomenon.

3.22.6 Criteria of Contribution

A contribution to GRE is constituted by the structure of its research claim rather than by the presence of GRE terminology. At minimum, a recognizable contribution should specify the relational problem, the relevant scale and boundary, the generative or relational claim being advanced, and the evidence or representation that bears that claim. It should distinguish the modeled or represented relation from the target relation, calibrate its inference to the available warrant, and identify material alternative mechanisms where they are plausible.

A contribution may be conceptual. It can clarify a category, distinguish previously conflated mechanisms, develop a typology, or revise the programme's ontology under suspension. It may be empirical, identifying a generative relation or demonstrating a boundary condition. It may be historical, reconstructing how an economic subject, institution, value form, or generative condition emerged. It may be formal, providing a model that clarifies a mechanism or reveals implications. It may be computational, exploring dynamics inaccessible to analytic derivation. It may be normative, identifying evaluative conflicts or consequences that existing frameworks obscure. It may be practical, producing intervention evidence or governance procedures. No one form is constitutively superior.

GRE contribution also requires downstream discipline. A study need not trace every consequence of an intervention or relation, but it should explain why the chosen

horizon is adequate to the research problem and acknowledge plausible effects excluded by that boundary. Where a claim concerns generativity, the analysis should identify what is being generated, for whom or for what system, through which mechanism, over what time horizon, and under what conditions. The term *generative* should carry analytical content rather than function as a general synonym for productive, innovative, or beneficial.

Normative transparency is another criterion. Researchers should distinguish descriptive claims, explanatory claims, forecasts, evaluations, and recommendations. If a contribution favors participation, capability, equality, resilience, pluralism, ecological integrity, autonomy, or another normative objective, the evaluative premise should be stated rather than embedded invisibly in the language of system improvement. GRE can support normatively engaged research while preserving the difference between evidence about consequences and judgment about their desirability.

Contribution further requires reproducibility or interpretive traceability appropriate to the method. Quantitative and computational work should expose data construction, assumptions, code, parameters, and sensitivity where feasible. Historical and qualitative work should make source selection, interpretive steps, category construction, and evidential tensions sufficiently visible for another researcher to understand how the conclusion was reached. Formal work should state assumptions and domains of applicability. Traceability is the general constitutional requirement; exact replication is one method-specific realization.

The final criterion is cumulative relevance. A GRE contribution should leave the programme better able to inquire afterward. It may supply a reusable concept, map, dataset, mechanism, comparative case, formal model, indicator, intervention record, negative result, or theory revision. Cumulative relevance includes contraction. Demonstrating that a concept is too broad, a mechanism fails outside a narrow domain, an indicator systematically distorts value, or an intervention generates recurrent harm is a positive research contribution because it improves the programme's capacity to avoid error.

3.22.7 Open Constitutional Questions

The preliminary constitution deliberately leaves major questions open. The first concerns identification. Generative relations are often distributed, mediated, and historically formed, making it difficult to determine which relation produced which downstream capacity or constraint. Better causal designs, process tracing, comparison, formalization, and computational methods may improve identification, but some relations remain reflexive or multiply realized. The programme does not assume that every generative effect can eventually be assigned to a single source.

A second open question concerns measurement. Generativity can refer to capability formation, relation formation, value propagation, diversification of future possibilities, resilience, subject formation, institutional transformation, or changes in the effective rules of change. These may require different measures and may resist reduction to one scalar index. Measurement research should therefore explore domain-specific indicators, multidimensional representations, and comparative procedures without presuming a universal generativity metric.

A third concerns value. Economic relations can generate several forms of value simultaneously and can convert value across domains imperfectly. Monetary price, capability, symbolic recognition, ecological capacity, care, knowledge, institutional trust, public infrastructure, and future option value cannot be presumed fully commensurable. GRE requires practical ways to compare and govern heterogeneous values while preserving information about what is lost through commensuration. The relation between such comparisons and normative justification remains open.

A fourth concerns boundaries and scale. Relational systems rarely arrive with uniquely given analytical borders. Expanding a boundary can reveal hidden dependencies while making causal identification harder; narrowing it can improve tractability while externalizing relevant effects. Scale changes can also alter what counts as an entity, mechanism, or outcome. GRE therefore needs stronger procedures for boundary sensitivity, multiscale inference, and the comparison of explanations constructed at different resolutions.

A fifth concerns changing transformation rules. When institutions, technologies, categories, expectations, or subject capacities evolve, the model adequate to an earlier period may cease to describe the later system. Some of this can be handled through time-varying or adaptive models; some may require changes in variables and model classes themselves. Distinguishing parameter change from structural change, and structural change from the emergence of new relevant categories, remains a central theoretical and empirical problem.

A sixth concerns justice and governance under persistent asymmetry. Economic relations often depend on differences in capability, information, authority, vulnerability, and exit. Equalization can be desirable in some dimensions while infeasible or counterproductive in others. Counter-power can reduce domination while creating new gatekeepers. Governance must therefore organize asymmetry while preserving participation, contestability, learning, and repair. The programme leaves open which institutional forms achieve those aims under different material and cultural conditions.

A seventh concerns heterogeneous subjects and artificial intelligence. Operational agency, legal personality, moral status, consciousness, accountability, and economic capability can diverge. AI systems can become economically consequential without resolving philosophical questions about machine subjecthood. GRE needs analytical conventions that allow such systems to be studied as participants or mediators where appropriate while preventing capability measures from silently determining ontological or normative status.

An eighth concerns long horizons. Generative effects can unfold across careers, institutions, ecosystems, and generations. Evidence weakens as horizons extend, while path dependence and rule change make extrapolation increasingly uncertain. Yet short-horizon evaluation can systematically favor interventions that consume the conditions of future possibility. Developing responsible long-horizon analysis without manufacturing spurious precision remains one of GRE's most important open problems.

These questions are constitutional because their unresolved status shapes how the programme should behave. Openness does not imply that anything is permitted. It

means that GRE should preserve competing formulations, record uncertainty, compare methods, and allow evidence from later chapters and future research to revise the present constitution. A preliminary constitution identifies the space of legitimate disagreement as much as it identifies present commitments.

3.22.8 Historical Revisability of the Programme

GRE is constituted as a historically situated research programme. Its emergence is connected to changes described in Chapter 1: expanded relational production, globalization, digital mediation, artificial intelligence, ecological constraint, changing scarcity, capability asymmetry, new scientific and computational capacities, and altered conditions of evidence and governance. These conditions make certain relational and generative questions more visible and more tractable. They do not make GRE historically inevitable, universally necessary, or permanently adequate.

Historical situatedness has two implications. First, GRE concepts should be expected to change as the economy changes. Categories useful for contemporary platform economies, AI-mediated production, or ecological transition may require revision under future institutional and technological arrangements. New forms of subjecthood, coordination, property, value, or infrastructure may emerge. Existing distinctions may lose relevance. A theory of historically changing economic reality should preserve the capacity to revise the categories through which it recognizes that reality.

Second, standards of inquiry can also evolve. New measurement technologies, archives, computational methods, legal institutions, participatory procedures, and epistemic practices can change what relations are observable and what interventions are ethically or practically possible. Methods and evaluative procedures therefore possess histories of their own. GRE should record those histories and remain capable of re-evaluating earlier findings when the epistemic resources available to later inquiry change. Revisability applies to methods and standards as well as to substantive theory.

Revision should nevertheless remain disciplined by programme memory. The replacement of one concept by another should preserve the reasons for the change; abandoned indicators, failed models, negative cases, and superseded mechanisms should remain accessible where possible. Otherwise a field can mistake forgetting for innovation. Cumulative knowledge requires both inheritance and correction. A historically revisable constitution therefore needs archives of its own revisions.

The present constitution can be revised through several routes. Empirical anomalies can show that a proposed relation does not operate as expected. Comparative work can reveal that a mechanism is culturally or institutionally specific. Formal work can expose inconsistency or hidden assumptions. Intervention can reveal unanticipated dependence or harm. Normative inquiry can show that an apparently desirable generative process rests on unjust relations. Historical analysis can demonstrate that a category treated as natural is institutionally recent. Domain applications can reveal objects that the existing typology cannot adequately represent. Each route provides a legitimate basis for constitutional amendment when the evidence is strong enough.

Revisability also protects GRE from disciplinary self-insulation. The programme should remain in dialogue with mainstream economics, political economy, economic sociology, complexity and evolutionary economics, capability approaches, ecological economics, legal and institutional analysis, philosophy, computer science, and other relevant fields. GRE has no constitutional entitlement to retain a concept merely because it originated within the programme. Where neighboring theories explain a problem better, GRE should borrow, narrow its own claim, or withdraw it. The integrity of the programme depends more on its capacity for correction than on the preservation of a proprietary vocabulary.

A preliminary constitution therefore combines continuity with amendability. GRE presently studies economic relations through their role in generating, distributing, transforming, and foreclosing later capacities and possibilities. It proceeds under ontological suspension, evidential pluralism, boundary and scale transparency, methodological pluralism, normative separability, and explicit attention to power, heterogeneity, historical dependence, and recursive change. It seeks explanations that identify mechanisms, praxis that remains revisable under feedback, contributions that are traceable and cumulative, and a programme architecture capable of learning from failure as well as success. These commitments are strong enough to coordinate inquiry while remaining open to revision.

Chapter 3 thereby completes the preliminary constitution of Generative Relational Economics and closes Part I. Chapter 1 reconstructed the historical conditions under which the programme becomes intelligible; Chapter 2 reconstructed the intellectual lineages that make its conceptual vocabulary possible; Chapter 3 has stated the provisional research programme that follows from those conditions and inheritances. Part II now turns from constitution to deeper theoretical development. Chapter 4 examines the ontological view of Generative Relational Theory, beginning with the degree and form of ontological commitment that relational and generative inquiry requires. The constitution established here should therefore be treated neither as an endpoint nor as a summary detached from what follows. It is the provisional compact against which the later ontology, epistemology, methodology, formalization, political economy, governance, and applications of the book can be tested and revised.

Chapter 4

The Ontological View of Generative Relational Theory

Chapter 4 begins Part II by making explicit the ontological view that underlies Generative Relational Theory (GR) and, through it, Generative Relational Economics (GRE). Part I established the historical conditions under which GRE becomes salient, reconstructed the intellectual lineages from which it draws, and formulated its preliminary disciplinary constitution. Those tasks repeatedly relied on distinctions among objects, relations, processes, representations, subjects, values, institutions, and emergent forms of reality. The present chapter develops the ontological architecture required to use those distinctions with greater precision. Its purpose is neither to establish a final metaphysics nor to reduce heterogeneous domains to a single relational vocabulary. It is to clarify what kinds of reality GR and GRE can speak about, under what commitments, and with what degree of ontological restraint.

The central architecture developed in this chapter distinguishes three registers: *ontological reality*, *relational reality*, and *manifestational reality*. The distinction is analytical rather than a division of the world into three independent substances or three successive stages. Ontological reality concerns the question of what obtains or occurs at the level of reality whose ultimate constitution may remain partly or wholly outside the commitments required by a particular inquiry. Relational reality concerns objects that emerge within generative-relational systems and acquire sufficient persistence and stability over some region or interval of spacetime to exercise causal efficacy within those systems. Manifestational reality concerns the conditions under which something becomes available in a mode of appearance, experience, articulation, measurement, classification, symbolization, or other manifestation. These registers identify different questions concerning reality and thereby allow existence, relational efficacy, manifestation, knowledge, and representation to remain analytically distinguishable.

Relational reality occupies a particularly important position in GR. An object can become relationally real without the framework first establishing that it possesses an independent or fundamental ontological existence. Money, legal status, institutional authority, socially sustained identities, forms of trust, experienced continuity of self, and objects embedded in religious or cultural relations may acquire persistence, stability, and causal efficacy through the systems in which they emerge. Their relational

reality concerns how they are generated and sustained within those systems and how, once stabilized, they participate in the generation of subsequent relations. This claim leaves their ultimate ontological status open where stronger commitment is unnecessary. Relational reality is therefore neither weakened reality nor a synonym for collective belief. It names a distinct analytical status grounded in generative emergence, persistence, stability, and causal participation.

Relational reality also need not await perception. A relational-generative structure may already persist and exercise causal efficacy before a subject becomes aware of it, before it acquires perceptual salience, or before a symbolic vocabulary has been developed through which it can be articulated. This feature becomes important for later GR inquiries into contingency, aesthetic judgment, subjectivity, historical emergence, and the formation of meaning. A contingent configuration, for example, may possess a relational and historical structure before its contingency becomes manifest to a subject and before an aesthetic judgment concerning it occurs. Manifestation can therefore disclose something whose relevant generative conditions precede the event of disclosure. Neither conscious recognition nor symbolization is a general precondition for relational reality.

The distinction between relational and manifestational reality nevertheless does not establish a one-directional sequence. Manifestations can themselves enter generative-relational systems. Once an appearance, judgment, classification, measurement, declaration, image, symbol, institutional record, or other manifestation becomes operative within a system, it may alter expectations, practices, classifications, capacities, constraints, and subsequent relations. Manifestation may thereby contribute to the stabilization, transformation, or dissolution of relational realities. A declaration of trust can alter the relation through which trust continues to develop; a monetary inscription can participate in reproducing monetary relations; a legal classification can reorganize the institutional relations to which it refers; and a manifested self-description can affect later recognition, conduct, and self-formation. Manifestational reality therefore participates in generation rather than occupying only an observational surface outside it.

For this reason, the three registers are better understood through a graph of heterogeneous relations than through a chain of successive layers. Ontological conditions may participate in the emergence of relational structures. Relational structures may condition what can become manifest. Manifestations may reorganize relational structures and, through historically accumulated effects, alter the conditions encountered by later processes. Relations between the registers can be recursive, many-to-many, temporally extended, and partly non-invertible. No universal sequence from ontology to relation to manifestation is presupposed. Particular trajectories may exhibit such an ordering locally, but the architecture itself permits feedback, mediation, historical transformation, and multiple paths among the registers.

A limited heuristic analogy can be drawn with the three-register architecture associated with Lacanian thought. Ontological reality can recall some of the problems posed through the Real, relational reality some functions associated with the Imaginary, and manifestational reality some aspects of the Symbolic. The correspondence is deliberately incomplete. GR's ontological reality is not equivalent to the Lacanian Real; relational reality extends beyond image and identification; and manifestational

reality includes perceptual, affective, bodily, material, institutional, statistical, and technological manifestations that cannot be reduced to symbolic inscription. The useful analogy lies principally in refusing a linear hierarchy among registers and in attending to their mutual mediation. The relation among the registers matters more here than any attempted one-to-one identification among their names.

A further consequence concerns comparison. The fact that two objects satisfy the conditions for relational reality does not establish that their generative structures are commensurable. They may occupy a common metric space, different metric spaces connected through an explicitly constructed mapping, non-metric spaces admitting another form of structural comparison, or relational domains for which no warranted common comparison structure has yet been established. Shared reality-status therefore does not imply shared structure. A perceptual object generated under conditions ordinarily described as hallucinatory and a perceptual object associated with an independently physical object may both become relationally real within relevant systems while differing substantially in their generative organization. The ontological, relational, and manifestational questions concerning them remain distinguishable, and comparison between their structures requires additional justification.

This point becomes consequential when the chapter turns to manifestation mappings and their possible non-invertibility. Similar manifestations may arise from different relational configurations, while similar relational configurations may yield different manifestations under changing bodily, historical, institutional, cultural, technological, or symbolic conditions. Reverse inference from manifestation to relational structure therefore requires explicit epistemic assumptions. Manifestational similarity alone provides insufficient grounds for relational identity, just as relational comparability does not by itself establish ontological identity. These distinctions provide part of the ontological basis for the epistemological problems developed in Chapter 5.

The chapter proceeds by stages. Section 90 states the ontological position of GR and develops the principle of methodological restraint. The subsequent sections introduce the three registers of reality and clarify ontological suspension before returning to change, structure, constraint, and difference as minimal primitives through which stable configurations can be analyzed. The chapter then develops relational reality and manifestational reality in greater detail, examines the generative emergence of manifestation, and studies the mappings through which relational configurations become manifest. Later sections address non-invertibility, symbolization, recursive relations among manifestation and subsequent relational formation, subjecthood, value, meaning, social facts, institutions, process, events, and becoming. Category-theoretic and scale-relative views are introduced where they offer useful formal or structural clarification, while their ontological interpretation remains deliberately limited. The final movement historicizes ontological categories, clarifies the methodological status of relational-generative analysis, considers compatibility with alternative ontological commitments, and states the boundaries of the chapter's claims.

The resulting ontology is intentionally open. GR requires enough ontological articulation to distinguish kinds of reality, analyze their relations, and prevent epistemic or representational categories from silently replacing the realities under study. It

does not require those distinctions to culminate in a closed metaphysical system. The three-register architecture instead provides a disciplined space within which heterogeneous realities can emerge, persist, act, manifest, mediate one another, and transform historically while questions of ultimate ontology remain open where the inquiry does not require their resolution. This ontological view prepares the transition from the reality of generative-relational systems to the epistemic problem of how such realities can be known through necessarily situated manifestations, traces, representations, and interventions.

4.1 Ontological Position

This section establishes the ontological position from which the remainder of Chapter 4 proceeds. Its role is preparatory: before GR distinguishes ontological, relational, and manifestational reality, it must clarify what kind of ontological commitment an open generative-relational research programme actually requires. The argument proceeds in five steps. It first specifies the function of an ontological position in GR, then examines why economic analysis cannot avoid ontological commitments simply by leaving them implicit. It next distinguishes commitments made for a local explanatory task from stronger claims about the ultimate constitution of reality. The final two subsections formulate methodological restraint and explain how GR can make substantive ontological commitments without converting those commitments into a closed metaphysical system. The mode of argument is conceptual and methodological. The aim is to establish conditions for disciplined inquiry rather than to settle the ultimate furniture of reality.

4.1.1 Ontological Position in Generative-Relational Inquiry

Every inquiry presupposes some account of what kinds of objects, processes, relations, differences, events, or structures can enter explanation. A study of prices presupposes that prices can be identified with sufficient stability for the purposes of the analysis. A study of institutions presupposes that institutions can persist through changes in personnel and individual acts. A study of subjects presupposes some basis on which actions, memories, capacities, or recognitions can be attributed to a subject over an analytically relevant interval. A study of causal effects presupposes that differences in the world can be related to subsequent differences under stated conditions. These presuppositions need not constitute a complete metaphysics, yet they carry ontological content because they determine what the inquiry treats as sufficiently real, persistent, and efficacious to bear explanatory weight. (Quine 1948; Fraassen 1980)

GR makes this background explicit because its principal objects are often emergent, historically variable, multiply realized, reflexive, or only partially accessible through observation. The framework studies how objects and capacities arise through generative relations, how stabilized forms participate in later generation, how manifestations mediate subsequent relations, and how the relevant units of analysis can change with scale and history. Such questions become confused when the status of an analytical object is left unspecified. A relation represented in a model, a relation inferred

from evidence, a relation stabilized in a social system, and a relation posited as part of ultimate reality are different claims even when the same word is used for each of them.

Definition 4.1 (Ontological position)**.** An *ontological position* is the explicit set of commitments through which an inquiry specifies what kinds of entities, relations, processes, differences, structures, or events it treats as real enough to enter explanation, together with the scope and strength assigned to those commitments.

Definition 4.1 treats an ontological position as more than a list of objects. Scope and strength matter equally. A claim that money is real for the analysis of exchange, obligation, accounting, and institutional action differs from a claim that money is a fundamental constituent of reality. A claim that a relational configuration has causal efficacy within a particular generative-relational system differs from a claim that relation is the ultimate substance from which all reality is composed. A claim that a self persists with enough stability to organize action differs from a claim that the self possesses an invariant metaphysical essence. GR therefore requires an ontological vocabulary capable of supporting local explanatory commitments while preserving distinctions among different strengths of claim.

This position also separates ontology from immediate observability. Some structures relevant to explanation may be indirectly inferred, historically reconstructed, experimentally perturbed, or manifested only through partial traces. Their ontological status cannot be reduced to whether a subject currently perceives them. Conversely, something may be vividly perceived or symbolically articulated while its underlying ontological status remains unsettled. Chapter 4 will later formalize this distinction through the three registers of reality. At this stage, the important point is methodological: a theory of reality must distinguish the conditions under which something becomes available to inquiry from the conditions under which it becomes causally or structurally relevant to the system being studied.

GR consequently adopts an ontological position because generative explanation needs objects that can persist, interact, constrain, enable, transform, and become historically consequential. At the same time, the framework resists extending each local explanatory success into a general metaphysical conclusion. This combination provides the starting orientation for the chapter: explicit commitment where explanation requires it, explicit suspension where the evidence and analytical task do not warrant further closure.

4.1.2 Ontology and Economic Analysis

Economic analysis makes ontological selections whenever it decides what counts as an economic object, a relevant relation, a unit of action, a form of value, a resource, an institution, a constraint, or a consequence. These selections can remain implicit because many categories are inherited from established practice. Households, firms, states, markets, prices, contracts, preferences, assets, skills, debts, and technologies can appear sufficiently familiar that their status as analytical constructions receives little attention. Yet each category compresses a field of heterogeneous relations into an object that can be compared, measured, modeled, regulated, or acted upon. (Giere 2004)

The ontological significance becomes clearer when categories change. A platform can function simultaneously as a firm, infrastructure, market organizer, data environment, contractual authority, and technological mediator. An artificial system can participate in production, recommendation, bargaining, classification, and coordination while questions of agency, subjecthood, legal personality, and responsibility remain separately unsettled. Knowledge can appear as a private asset, a shared capacity, an institutional memory, a public resource, or a relation embodied in practices and networks. Care can be treated as labor, relation, capability formation, social reproduction, or a mixture whose relevant ontology varies with the research question. Such cases reveal that economic analysis does not merely observe a world already partitioned into self-identifying economic units. It also selects and stabilizes objects for inquiry.

GRE requires particular care because its central questions concern generation across time. An economic relation can alter the capacities of subjects, the availability of future actions, the structure of institutions, the distribution of recognition, the meaning of categories, and the conditions under which later value can be generated. The object relevant at the beginning of a process may therefore differ from the object relevant at its end. A training relation can alter the capabilities through which a worker later participates in production. A credit relation can change both material capacity and future bargaining conditions. An institutional classification can reorganize eligibility and thereby reshape the population to which the classification is subsequently applied. The ontology of the analysis must accommodate objects that are partly constituted through the histories in which they participate.

This historical mutability does not imply that economic objects are analytically arbitrary. An object can be historically generated and still become stable enough to constrain action, coordinate expectations, carry obligations, or produce measurable consequences. The relevant question is therefore not whether an object is timeless, but how its stability is generated, over what interval it persists, through which relations it is reproduced, and what causal difference its presence makes. This is one reason relational reality becomes important later in the chapter: many economically consequential objects derive their practical reality from sustained generative relations without requiring an immediate claim about their ultimate metaphysical status.

Economic representations also participate in the realities they describe. Prices, rankings, credit scores, accounting categories, legal forms, forecasts, and classifications can become inputs into later action. Once institutionalized, a representation may influence resource allocation, access, expectations, strategy, or identity. The economic analyst therefore encounters a reflexive environment in which manifestational and representational forms can become causal components of subsequent relational organization. This feature gives ontology a practical significance. Treating a category as merely descriptive can obscure the process through which its use contributes to reproducing or transforming the object under analysis.

Claim 4.2 (Ontological relevance of economic categories)**.** *An economic category acquires ontological relevance for GRE when its stabilization, transformation, or disappearance makes a causal or structural difference to the generative-relational processes under study.*

Claim 4.2 does not require every economic category to possess the same mode of

reality. A legal corporation, a price, a bodily capacity, an ecosystem, a debt, and an expectation can enter economic explanation through different generative histories and different forms of persistence. Their inclusion in one inquiry does not imply that they share a common substance or a common metric. It establishes only that the analysis has reasons to treat them as causally or structurally relevant within its stated domain.

This pluralism is especially important for GRE because heterogeneous objects can interact without becoming ontologically homogeneous. A legal rule can affect material production; an aesthetic judgment can redirect research attention; a symbolic classification can change access to finance; a bodily limitation can alter bargaining relations; an imagined future can influence present investment. The causal field of economic action therefore crosses domains that may require different descriptive vocabularies. A useful ontology must permit interaction across heterogeneous forms of reality while resisting the inference that interaction proves reducibility to one underlying analytical language.

4.1.3 Locality and Scope of Ontological Commitment

Ontological commitment in GR is local to an explanatory task unless a stronger scope is independently established. Locality here refers to the domain within which a commitment is warranted: a generative-relational system, a historical interval, an analytical scale, a class of mechanisms, or a specified research problem. This principle allows GR to say that an object is real enough to explain a process without requiring the same statement to settle its status across every possible domain of inquiry.

Definition 4.3 (Ontological commitment)**.** An *ontological commitment* is a commitment to treat some object, relation, process, difference, structure, or event as possessing sufficient reality, within a specified domain and for a specified explanatory purpose, that claims about its persistence, efficacy, interaction, or transformation can bear argumentative weight.

Definition 4.3 makes ontological commitment purpose-sensitive without making it arbitrary. The commitment remains answerable to evidence, coherence, explanatory performance, and the consequences of intervention. Its purpose specifies the burden of proof. An analysis of currency circulation may require a robust account of money as an institutionally and relationally stabilized object while remaining neutral about whether monetary value possesses any reality outside such systems. An analysis of subjective continuity may require a stable operational subject over a given interval while leaving open deeper claims about the metaphysics of selfhood. An analysis of religiously organized economic life may need to treat a deity as a relationally real object within the relevant system if the deity organizes obligations, trust, sacrifice, authority, or allocation; that analytical commitment does not itself adjudicate theological claims concerning independent divine existence.

Locality also matters for scale. An object stable at one scale may dissolve into changing components at another. A firm can be treated as a persistent organization in an industry-level analysis while appearing as a changing field of contracts, routines, persons, technologies, and authority relations in an organizational study. A market can function as an analytical object at one scale while a microstructural anal-

ysis resolves it into order books, protocols, matching rules, information flows, and strategic interactions. Neither description automatically invalidates the other. Their adequacy depends on the generative processes each inquiry seeks to explain.

Temporal scope produces a similar effect. Persistence is always persistence over some interval. An institution can be highly stable relative to daily transactions and historically transient relative to centuries. A subject's identity can remain sufficiently continuous for contractual responsibility while changing substantially over a life course. A convention may stabilize coordination for a generation and later disappear. GR therefore avoids treating stability as timeless identity. Stability is a relation between a pattern and an analytical timescale, together with the mechanisms that reproduce the pattern across change.

Proposition 4.4 (Local sufficiency of ontological commitment)**.** *For a generative-relational explanation, the ontological commitment required to support the explanation need extend only as far as the persistence, efficacy, and relations necessary for that explanation, unless additional evidence or argument justifies a stronger claim.*

Proposition 4.4 provides a rule of economy for ontological reasoning. If an account of institutional trust depends on a stabilized relation that changes later action, the inquiry can study that relation without deciding whether trust is reducible to neural states, symbolic structures, expectations, embodied dispositions, or some combination of them at an ultimate level. If a model of knowledge production depends on a research community, shared standards, archives, and infrastructures, those objects can be treated as real components of the explanatory domain without requiring a final ontology of collective entities. Stronger commitments remain possible, but they carry additional argumentative burdens.

Local commitment also protects against a common error in interdisciplinary work. A concept transferred from one domain can be useful without carrying its entire source ontology with it. Field language, network language, dynamical systems, category theory, information, geometry, or computation may disclose structure in an economic problem. Their successful use does not automatically establish that the economic world is fundamentally a field, network, dynamical system, category, informational object, geometric manifold, or computation. The imported representation earns authority over the relations it successfully captures; claims beyond that scope require separate support.

The locality principle prepares the distinction developed in the next sections. Ontological reality, relational reality, and manifestational reality will allow GR to specify different forms of claim without forcing them into a single hierarchy. The present section establishes the prior discipline: the scope of an ontological commitment should remain visible, and movement from a local claim to a stronger claim should be argued rather than assumed.

4.1.4 Methodological Restraint in Ontological Claims

Methodological restraint governs the transition from analytical success to ontological assertion. GR uses strong conceptual resources because generative systems can be difficult to describe with ordinary entity-centered language. Relations can have higher-order structure; constraints can alter the space of possible action; historical

trajectories can produce attractors or path dependence; categories can change the behavior of classified subjects; and manifestations can feed back into the systems from which they emerge. Each of these phenomena may invite formal representations. The quality of a representation, however, does not by itself determine the ultimate ontology of the represented system.

The distinction can be stated through three questions. The first asks whether a representation is useful: does it organize observations, distinguish mechanisms, support inference, or enable intervention? The second asks whether the represented structure is real within the domain: does the structure persist, constrain, enable, or causally alter the system in ways that survive changes in description? The third asks whether the representation identifies the ultimate constitution of what exists. These questions can receive different answers. A network model can be useful even when edges are constructed from imperfect proxies. A relational structure can be causally real even when several mathematical representations capture it equally well. An empirically successful representation can remain silent about ultimate ontology.

Remark 4.5 (Representation and ontological inference)*.* The empirical or explanatory success of a representation can support claims about structures captured by that representation while leaving stronger claims about the ultimate constitution of reality underdetermined.

Remark 4.5 is particularly important for a framework that draws from several formal traditions. A graph can reveal patterns of connectivity, a dynamical system can reveal stability and transition, a field representation can express spatially or relationally distributed influence, and a category-theoretic formulation can clarify mappings among structures. These representations may overlap without being mutually reducible. GR therefore treats formal plurality as evidence that the relation between representation and ontology itself requires analysis.

Methodological restraint also applies to ordinary language. Terms such as "subject," "institution," "value," "power," "relation," and "field" can acquire an apparent solidity through repetition. A concept introduced as an analytical convenience may gradually be spoken of as though its boundaries were discovered rather than constructed. Conversely, a familiar category can appear natural even when its persistence depends on legal, technological, cultural, and historical conditions. Ontological discipline requires the manuscript to mark when a term refers to a stipulated analytical unit, an empirically inferred structure, a relationally stabilized object, a manifestation, or a stronger ontological claim.

Caution 4.6 (Ontological inflation)*.* Ontological inflation occurs when an analytical distinction, representation, measurement, or successful local explanation is extended into a stronger claim about reality without an additional argument adequate to that stronger scope.

Caution 4.6 applies in both formal and qualitative inquiry. Quantification can inflate a proxy into a property; interpretive analysis can inflate a recurrent meaning into a universal structure; historical reconstruction can inflate a contingent lineage into necessity; a relational model can inflate explanatory dependence into a claim that only relations exist. Restraint does not weaken inquiry. It preserves the distinction between what the evidence establishes and what remains open.

The same discipline applies to causal language. GR often studies objects that acquire causal efficacy through relational stabilization. Causal efficacy here means that the presence, persistence, transformation, or disappearance of the object makes a difference to subsequent states or possibilities under relevant conditions. It does not require that the object be fundamental in a reductionist hierarchy. Nor does it imply that causality can always be assigned to a single isolated object. In generative-relational systems, causal contribution may be distributed across configurations, histories, interfaces, and feedback processes. The ontological commitment should match the causal claim being made.

Methodological restraint therefore has a positive function. It makes room for strong local explanation, plural representation, and cross-disciplinary borrowing while protecting the framework from premature metaphysical closure. This discipline will become especially important when relational reality is defined later in the chapter. The fact that an object is relationally real will establish a substantive claim about its emergence, persistence, stability, and causal efficacy within a system. It will not by itself settle whether that object is ontologically fundamental, reducible to another level, or comparable with every other relationally real object.

4.1.5 Ontological Commitment without Closure

GR's ontological position can now be stated more precisely. The framework is committed to the reality of change, difference, constraint, structure, persistence, and causal efficacy wherever these are required and warranted by the inquiry. It is committed to treating generative relations as analytically consequential when transformations in relations alter what objects, capacities, manifestations, or possibilities can emerge. It is also committed to the possibility that some emergent objects become sufficiently stable to act back upon the systems through which they arose. These commitments provide the minimum ontological depth necessary for generative-relational explanation.

The framework simultaneously leaves several stronger questions open. GR does not need to determine whether relations are more fundamental than relata in every domain. It does not need to identify one privileged formal language in which all reality must be represented. It does not need to decide whether every socially consequential object is reducible to physical processes, whether every physical process is best understood relationally, or whether one universal metric can compare heterogeneous forms of reality. These questions can be addressed where a particular inquiry requires them, but the book does not make their settlement a prerequisite for economic analysis.

This openness is compatible with substantive disagreement. Two researchers can share a GRE analysis of the relational generation of money while holding different metaphysical views about social ontology. Two researchers can agree that a self-model becomes relationally stable and causally consequential while disagreeing about consciousness or personal identity. Two researchers can study how a religious object organizes economic action while differing on its ontological status outside the relational domain under investigation. The research programme remains coherent because its shared commitments concern the generative-relational structures re-

quired for the explanation, while stronger metaphysical claims can remain explicit points of divergence.

The position can therefore be summarized through a principle of graded commitment. Claims should become ontologically stronger only when the research question, evidence, and argument require and support the additional strength. Observation may justify a claim about manifestation. Recurrent and causally consequential organization may justify a claim about relational reality. A further claim about ontological reality requires its own warrant. Movement among these registers cannot be inferred merely from vocabulary or intuitive resemblance. Section 91 develops these distinctions directly.

Proposition 4.7 (Open ontological commitment)**.** *GR permits substantive commitments concerning the reality, persistence, efficacy, and transformation of objects within generative-relational systems while keeping stronger metaphysical questions open whenever those questions are not required for the explanatory task.*

Proposition 4.7 expresses the balance sought throughout this chapter. An ontology too thin to distinguish reality from representation would leave GRE unable to explain how emergent objects become causally consequential. An ontology that converts every useful analytical form into an ultimate metaphysical claim would make the programme unnecessarily brittle and would collapse heterogeneous domains into premature unity. Open ontological commitment occupies the intermediate position: reality claims are made where generative explanation requires them, their scope is stated, and further closure remains an additional task rather than an automatic consequence.

This position also preserves historical revisability. The objects recognized by an inquiry can change as institutions, technologies, categories, and relations change. New forms of economic subjecthood may emerge; old classifications may disappear; new infrastructures may create objects that earlier vocabularies could not represent adequately; improved methods may separate structures previously treated as one or reveal continuities previously missed. An ontological position adequate to generative inquiry therefore includes the possibility that its own categories will require revision. Revisability concerns the framework's descriptions and commitments, while the reality under study may exceed any one historical vocabulary used to describe it.

Section 90 thus establishes the ontological discipline for what follows. GR will make reality claims strong enough to support explanation, causal analysis, and historical inquiry. It will distinguish the scope of those claims, preserve the difference between representation and represented structure, and resist the extension of local success into unsupported metaphysical closure. With this position established, Section 91 turns to the chapter's central architecture: ontological reality, relational reality, and manifestational reality as three distinct but mutually mediating registers.

4.2 The Three Levels of Reality

This section introduces the three-register architecture through which GR distinguishes ontological reality, relational reality, and manifestational reality. The inherited outline uses the word *levels*, but the three are not ordered strata in which

one sits above or below another. They are better understood as registers that answer different questions about reality and that can mediate one another through historically situated generative relations. The distinction is necessary because GR repeatedly encounters objects that are causally effective without requiring a settled claim about their ultimate ontology, as well as manifestations that disclose, transform, or even help stabilize the realities to which they relate. Treating these cases within a single undifferentiated category of "reality" would obscure differences among what obtains, what becomes stably effective in a relational system, and what becomes manifest under particular conditions.

The architecture developed here is deliberately minimal. It does not claim that every philosophical problem can be assigned uniquely to one register, nor that each object possesses only one form of reality. The same object may be considered differently according to the question being asked. Money can be examined through the material and institutional conditions that participate in its existence, through the stabilized relational reality by which it organizes exchange and obligation, and through the perceptual, symbolic, legal, or computational forms in which it becomes manifest. A sense of self can likewise be approached through bodily and ontological questions, through the relational processes that stabilize continuity and identity, and through the forms in which selfhood becomes experienced, narrated, classified, or represented. The registers therefore separate analytical questions without requiring the realities under study to be separable in practice. (Whitehead 1929)

4.2.1 Ontological Reality

The first register concerns reality in its ontological status. GR needs this register because an inquiry can refer to what obtains or occurs without claiming that it has already captured the ultimate constitution of what obtains or occurs. The distinction is particularly important when perception, symbolic representation, institutional classification, or model construction provides only partial access to the processes under investigation. Ontological reality marks the fact that the reality of an event, structure, difference, or process cannot be reduced simply to the manner in which it has become available to a particular observer or system of representation. (Husserl 2012; Merleau-Ponty 2012)

Definition 4.8 (Ontological reality)**.** *Ontological reality* denotes what obtains, occurs, or possesses efficacy insofar as its reality is not constituted merely by its being perceived, manifested, represented, measured, classified, or known within a particular epistemic situation. GR may refer to this register while leaving the ultimate constitution of what is ontologically real under ontological suspension.

Definition 4.8 is intentionally compatible with different metaphysical positions. It does not identify ontological reality with matter, physical substance, mind, relation, process, information, or another privileged category. Nor does it define ontological reality as whatever is permanently inaccessible. Some ontologically relevant structures may be directly observable under suitable conditions; others may be reconstructed from traces, inferred through intervention, or remain only partially accessible. The defining distinction concerns the status of the claim rather than the accessibility of the object: ontological reality is not exhausted by a particular manifestation

or representation of it.

This register therefore gives GR a place to formulate questions that exceed what has presently become manifest. A physical process may continue whether or not it is observed. Historical conditions may constrain later possibilities even when no contemporary subject explicitly recognizes those constraints. Differences in biological, ecological, technological, or material organization may participate in generative processes before they acquire a social classification. In each case, an inquiry may have reasons to refer to a reality whose full ontology remains unsettled while resisting the stronger reduction of that reality to what is presently available in experience or representation.

The ontological register also protects GR from an opposite reduction. The fact that a relational or manifestational phenomenon is historically generated does not by itself imply that all aspects of the phenomenon are exhausted by the history through which it has been interpreted. An ontological question may remain open even after a rich account of relational emergence has been developed. This openness is especially important when different ontological interpretations remain compatible with the same relational evidence. The framework can then preserve the difference rather than forcing premature metaphysical closure.

Ontological reality is thus a register of commitment and restraint at once. GR can acknowledge that inquiry addresses realities rather than only descriptions while limiting its claims to what the research problem and evidence support. Section 92 develops this discipline through ontological suspension. For present purposes, the first register provides the background against which relational reality can be distinguished from both ultimate ontological identity and manifest appearance.

4.2.2 Relational Reality

Relational reality is the central technical category through which GR recognizes objects that become real within generative-relational systems. The category was developed to avoid a recurrent false choice. Many consequential objects are difficult to treat as fundamental or independently existing substances, yet treating them as merely fictional, subjective, or representational fails to explain their persistence and causal effects. Money, institutional authority, debt, trust, socially sustained identities, religious objects, and the experienced continuity of a self can organize action and reshape subsequent relations even when their ultimate ontological status is left unsettled. GR therefore requires a criterion of reality grounded in emergence and efficacy within a relational system.

Definition 4.9 (Relational reality)**.** *Relational reality* denotes an object that emerges within a generative-relational system and, over some region or interval of spacetime, persists with sufficient stability to exert causal efficacy upon that system. Its relational reality consists in its generated and sustained participation in subsequent relations rather than in a prior requirement that it possess an independently established ontological identity.

The word *object* in Definition 4.9 is deliberately broad. It can refer to a stabilized relation, configuration, pattern, institution, capacity, identity, process, or other analytically individuated object when the relevant conditions are satisfied. The defini-

tion is not meant to reify every transient correlation or every label introduced by an observer. Emergence alone is insufficient. A relationally real object must acquire persistence or recurrent stability over an analytically relevant spacetime domain, and its presence must make a causal difference within the generative-relational system in which it has emerged. Sections 93 and 94 will develop these conditions more carefully.

The criterion permits GR to treat money as relationally real without requiring a metaphysical substance called money. Monetary reality is sustained through legal recognition, accounting practices, expectations, exchange relations, institutional infrastructures, material and digital inscriptions, and histories of coordinated action. Once sufficiently stabilized, money affects access to goods, contractual possibilities, investment, labor, debt, expectations, and later relations. Its reality within such systems is therefore not adequately characterized by saying that participants merely believe in it. The belief, inscription, institution, and practice form parts of the generative relations through which the monetary object acquires persistence and causal efficacy.

The same logic can apply to a god within a religiously organized generative-relational system without requiring GR to settle the theological question of divine ontological existence. A divine object may become relationally real insofar as it is stably generated through ritual, memory, doctrine, architecture, collective practice, personal experience, authority, and other relations, and insofar as it causally reorganizes conduct, obligation, temporal practice, resource allocation, affect, identity, or institutional life. The relational claim neither establishes nor denies an independent divine ontology. It concerns the reality generated within the relational system and the causal work that this reality performs there.

A similar distinction applies to the experienced continuity of "I." A relatively stable sense of self can emerge through bodily continuity, memory, recognition by others, language, institutional identity, habit, affect, and narrative. Once stabilized, this self-object can organize intention, responsibility, expectation, action, and interpretation. Its relational reality can therefore be studied without requiring GR first to decide whether a metaphysically invariant self exists. The example is especially useful because it shows that relational reality is not confined to conventionally external social objects. A reality can be intimate and subjectively consequential while still being relationally generated and historically sustained.

Relational reality also does not require prior perception. A generative-relational structure can persist and act before any subject recognizes it, before it receives a name, and before it is stabilized in symbolic form. This feature is important for the GR treatment of contingency and aesthetic judgment. The structure through which a contingent conjunction becomes possible can already be historically and relationally real before its contingency becomes salient to a subject. An eventual experience of surprise, beauty, significance, or curiosity is then a manifestation within a structure whose relevant generative conditions did not begin with the experience itself. The relational reality of those conditions is therefore conceptually prior to their recognition, even though later recognition can feed back into the system and change what follows.

Claim 4.10 (Manifestation is not required for relational reality)**.** *An object can sat-*

isfy the conditions of relational reality before it is perceived, consciously recognized, linguistically articulated, symbolized, or otherwise manifested to a particular subject.

Claim 4.10 prevents relational reality from collapsing into phenomenology, discourse, or representation. It also leaves room for a stronger recursive thesis developed later in the chapter: although manifestation is not a general precondition for relational reality, manifestations can become relations within the system and can therefore participate in generating, stabilizing, transforming, or dissolving relational realities. The absence of necessary priority in one direction is precisely why the three-register architecture must be understood as a graph rather than a chain.

4.2.3 Manifestational Reality

The third register concerns the reality of manifestation. Something can become present to a subject, instrument, institution, classificatory system, archive, legal process, market interface, or other relational configuration without the manifestation exhausting either the relational structure from which it emerged or the ontological reality to which it may refer. GR therefore treats manifestation as a positive object of analysis rather than as a transparent window through which an already complete reality is simply observed.

Definition 4.11 (Manifestational reality)**.** *Manifestational reality* denotes reality insofar as something becomes available, differentiated, experienceable, perceptible, recordable, articulable, measurable, classifiable, symbolizable, or otherwise present within a particular relational and historical configuration. A manifestation is conditioned by the relations through which this availability occurs, and its reality does not by itself establish the complete ontological or relational structure of what is manifested.

Manifestation is broader than symbolization. A pain can become manifest affectively and bodily before it is named. A pattern can become manifest statistically through an instrument or dataset without being available to unaided perception. An institutional boundary can become manifest through differential access or treatment before its rules are explicitly articulated. A landscape can become manifest aesthetically through a mode of attention that is partly perceptual and affective. A market condition can become manifest through price movements, queues, shortages, or changes in conduct. Symbolic representation is an especially powerful mode of manifestation because language, categories, diagrams, records, and numbers can stabilize and circulate what has become available, but symbolic inscription does not exhaust the manifestational register.

Manifestational reality should also be distinguished from the referential truth of a manifestation. A vivid perceptual flower generated under pathological or altered perceptual conditions can possess manifestational reality: the flower appears, organizes attention, and may provoke action or affect. An ordinary perceptual flower associated with a physically existing plant can likewise possess manifestational reality. The fact that both are manifestations does not establish that their ontological sources or generative structures are identical. Conversely, a difference in ontological interpretation does not make one of the manifestational events analytically nonexistent. GR can therefore investigate the reality and consequences of a manifestation while

keeping separate the further question of what produced it and what ontological status should be assigned to its apparent object.

This distinction becomes important whenever manifestation itself has effects. A classification printed on a document can alter eligibility. A diagnosis can reorganize self-understanding and institutional treatment. A price displayed on a market interface can change subsequent bids. A public declaration of trust can reshape expectations between participants. A representation of a social category can influence how people act toward those classified by it. In such cases, the manifestation is not merely evidence about an antecedent relational reality. Once incorporated into subsequent interactions, it becomes part of the generative environment.

Claim 4.12 (Manifestational mediation)**.** *A manifestation can enter a generative-relational system as an operative relation or object and thereby participate in the generation, stabilization, transformation, or dissolution of subsequent relational realities.*

Claim 4.12 does not imply that every manifestation substantially changes the system in which it occurs. Its significance is structural: the architecture permits such mediation and therefore cannot treat manifestation as only the terminal output of a prior process. The causal importance of any particular manifestation remains an empirical and historical question. Section 100 will later examine recursive relations among reality, manifestation, and representation in greater detail.

Manifestational reality also has a historical dimension. What can become manifest, to whom, through which medium, and with what resolution depends on available sensory capacities, concepts, institutions, instruments, archives, languages, technical infrastructures, norms, and practices of attention. A relation that was difficult to manifest under one historical configuration can become readily measurable or publicly articulable under another. Conversely, changes in classification or institutional practice can render previously salient realities less visible. Manifestation therefore belongs to history rather than constituting a timeless interface between mind and world.

4.2.4 Distinctions among the Three Registers

The three definitions establish different criteria and therefore resist several common reductions. Ontological reality concerns the status of what obtains or occurs without reducing that status to a particular manifestation. Relational reality concerns stable and causally efficacious emergence within a generative-relational system. Manifestational reality concerns becoming available under a particular configuration of relations and mediation. These registers can overlap in concrete cases, but overlap does not erase the difference among the questions they pose.

A relationally real object does not thereby acquire a settled independent ontology. The social efficacy of money, a legal person, a deity, an institutional role, or a stabilized self does not require GRE to decide that the relevant object exists as a fundamental substance. The relational claim can remain both strong and limited: the object has emerged, persists, and causally matters within the system. Conversely, an ontologically real process does not automatically possess relational reality relative to every generative-relational system. Something may exist yet remain causally disconnected

from the system under study, or it may fail to become sufficiently stabilized within that system to constitute the relational object relevant to the inquiry.

Relational reality likewise does not require manifestation, as Claim 4.10 states. Historical constraints, latent institutional structures, unrecognized patterns of dependence, or the generative conditions of a contingent encounter may operate before they are consciously noticed or symbolically articulated. Manifestation is therefore neither the origin nor the universal criterion of relational reality. At the same time, once a manifestation enters subsequent relations, Claim 4.12 allows it to become one of the conditions through which later relational realities are generated. The distinction between the registers thus supports directional asymmetry in particular cases without imposing a permanent hierarchy among them.

Manifestational reality also does not guarantee that the apparent object possesses the ontological status attributed to it by a subject. A manifestation can be vivid, stable, socially consequential, and repeatedly recorded while the ontological interpretation of its source remains uncertain or contested. Nor does manifestational similarity establish relational identity. Two similar experiences, measurements, classifications, or observable patterns may arise from different generative structures. The inverse problem is equally important: similar relational structures can manifest differently under different bodily, institutional, cultural, technical, or historical conditions. Later sections will develop these many-to-one and one-to-many possibilities more formally.

The distinctions also prevent a further assumption: shared relational reality does not entail comparability. Two objects can each satisfy the criteria of relational reality while lacking a justified common metric, ordering, coordinate system, or structure-preserving comparison. They may inhabit different metric spaces, non-metric relational spaces, or domains for which no warranted mapping has yet been constructed. A hallucinated flower and an ordinarily perceived physical flower provide a simple illustration. Both can be relationally consequential within the systems in which they arise, yet their generative structures need not be treated as instances of the same measurable object merely because the word “flower” is used for both manifestations. Establishing a comparison relation is an additional analytical achievement, not an automatic consequence of assigning the same reality-status.

Claim 4.13 (Non-necessary comparability of relational realities)**.** *The fact that two objects possess relational reality does not by itself establish a common metric, ordering, equivalence relation, structural map, or other justified basis of comparison between them.*

Claim 4.13 has methodological consequences throughout GRE. Comparative analysis must specify what is being compared, through which relation, and under what invariances or losses of information. Isomorphism, homomorphism, simulation, statistical resemblance, functional equivalence, and analogical comparison answer different questions and require different assumptions. Where no warranted comparison structure exists, preserving incomparability can be more rigorous than imposing a common measure for analytical convenience. This point becomes especially important when GRE studies heterogeneous values, forms of life, subjectivities, institutions, and modes of manifestation.

The distinctions among registers should therefore be read as safeguards against premature reduction. Ontological uncertainty need not erase relational reality. Relational efficacy need not establish ultimate ontology. Manifestational vividness need not disclose either register completely. Lack of manifestation need not imply lack of relational structure. Shared reality-status need not imply shared geometry. Each of these distinctions preserves a question that would otherwise disappear if "reality" were treated as a single undifferentiated category.

4.2.5 Relations across the Three Registers

The three-register architecture becomes most distinctive when the relations among the registers are considered. A tempting interpretation would treat them as a sequence: an ontological reality first exists, relational structures subsequently form around it, and a final manifestation presents the result to a subject. Such a trajectory may describe some local cases, but GR does not adopt it as the general architecture. The three registers form a graph of heterogeneous and historically variable relations. Different paths can connect them, and what becomes an effect along one path can become a condition along another.

Ontological conditions can participate in the emergence of relational realities. Material resources, bodily capacities, ecological processes, technical infrastructures, spatial arrangements, and other ontologically relevant conditions can constrain or enable the relations through which an object stabilizes. Yet the resulting relational object need not be reducible to those conditions. A monetary system, for example, requires material and technical supports but acquires causal properties through legal, institutional, symbolic, and practical relations that cannot be read directly from the physical medium of a banknote or database entry.

Relational realities can condition manifestation. What becomes salient, nameable, measurable, experientially coherent, institutionally visible, or symbolically available depends partly on the relations already organizing subjects, instruments, categories, institutions, and environments. A relation of trust can change what conduct is interpreted as reassuring or suspicious. An institutional category can determine which differences enter administrative records. A scientific instrument and its associated practices can make a pattern manifest that unaided perception could not distinguish. The manifestation therefore emerges within a relational field rather than arriving from outside it.

The reverse mediation is equally important. Once a manifestation occurs, it can alter the relational field. A statement, image, classification, measurement, judgment, or public performance can be remembered, circulated, institutionalized, contested, or incorporated into later expectations. Through these processes, manifestation can contribute to new persistence and causal efficacy. A relation may thus help generate a manifestation, while the manifestation becomes one of the relations through which a later relational reality is stabilized. Historical time matters because the system encountered after manifestation need not be the system that preceded it.

This recursive possibility is particularly significant for aesthetic judgment and contingency. The relational-generative-historical structure through which a contingent encounter becomes possible can exist before the encounter is apprehended as con-

tingent. When contingency later becomes manifest through surprise, attention, aesthetic judgment, or conceptual recognition, the manifestation can redirect inquiry, memory, valuation, preservation, or future practice. The recognition therefore neither creates the entire preceding structure nor merely reflects it. It enters the history of that structure and can change what the system subsequently generates.

The architecture has a limited heuristic affinity with Lacan's three registers of the Imaginary, the Symbolic, and the Real. Lacanian register theory itself changed substantially over time, and later formulations emphasize mutual dependence among the registers rather than treating them as a simple developmental sequence (Johnston 2026). GR does not adopt Lacan's definitions or identify its registers one-to-one with his. Ontological reality is not the Lacanian Real; relational reality extends well beyond the Imaginary; and manifestational reality includes forms of appearance and mediation that are not reducible to the Symbolic. The useful analogy lies at the architectural level: a plurality of registers can be mutually conditioning, and the relations among them can be more informative than an attempt to place them in a single hierarchy.

Remark 4.14 (Graph rather than chain)*.* Ontological, relational, and manifestational reality should be treated as registers connected by heterogeneous relations rather than as stages in a universal sequence. Their connections may be recursive, many-to-many, historically changing, and only partially invertible. A path observed in one case does not establish the direction or form of mediation in another.

The graph conception also leaves room for missing edges. A research programme need not assume that every ontological condition is relationally relevant to the system under study, that every relational reality becomes manifest, or that every manifestation permits reliable inference toward its generative conditions. Some relations may be weak, historically absent, technically inaccessible, or analytically unjustified. Treating the architecture as a graph therefore does not mean multiplying connections without discipline. It means that connections are objects of inquiry whose existence, direction, stability, and explanatory importance must be established rather than presumed.

The three registers can now support the rest of the chapter. Section 92 clarifies the methodological status of ontological suspension. Section 93 identifies the primitive vocabulary through which emergence and stabilization can be analyzed. Sections 94 and 95 then return separately to relational and manifestational reality, allowing persistence, stability, causal efficacy, forms of manifestation, and participation in subsequent relations to receive fuller treatment. The later analysis of manifestation mappings, non-invertibility, symbolization, and recursive mediation builds on the architecture established here. The purpose of the present section is therefore not to close the ontology of GR but to preserve three analytically distinct questions and to make their interrelation available for disciplined investigation.

4.3 Ontological Suspension

This section develops *ontological suspension* as a methodological discipline within GR. The preceding sections established that generative-relational inquiry requires ex-

plicit ontological commitments while also distinguishing ontological, relational, and manifestational reality. Ontological suspension specifies how those commitments can remain proportionate to the explanatory task. Its role is neither to weaken reality claims nor to replace ontology with epistemic uncertainty. Rather, it allows inquiry to affirm what has been sufficiently established at one register while withholding stronger claims whose resolution is unnecessary, unavailable, or not yet warranted. The section proceeds by distinguishing suspension from denial and agnosticism, then treats suspension as a disciplined practice, examines its use under ontological disagreement, and concludes by clarifying how suspended questions can remain analytically usable without being prematurely settled. (Fraassen 1980; Quine 1948)

4.3.1 Suspension and Denial

Ontological suspension begins with a distinction between declining to affirm a stronger ontological claim and denying that claim. The distinction is elementary but consequential. An inquiry may have sufficient grounds to establish that an object is relationally real while lacking grounds to determine whether that object possesses an independent ontological status. In such a case, GR does not infer nonexistence from the absence of a stronger commitment. It leaves the stronger question open and continues the analysis at the register for which evidence and explanatory need are available.

Consider money. GRE can study money as a relationally real object because monetary forms can emerge through institutional, legal, material, symbolic, and practical relations; persist with sufficient stability; and causally affect allocation, obligation, expectation, production, and future relations. None of these claims requires GRE to settle whether "money" corresponds to an independently existing ontological kind beyond the relations through which monetary reality is sustained. Suspension therefore preserves the reality relevant to the inquiry while withholding a metaphysical conclusion that the analysis does not need.

The same distinction applies to less conventional objects. A deity can possess relational reality within a religious community when the relevant object is historically sustained, structures expectations and conduct, enters institutional practices, organizes temporal and spatial routines, and causally affects subsequent relations. GR can analyze this relational reality without determining whether the deity also possesses ontological reality independent of those relations. Suspension in this case does not entail atheistic denial, theological affirmation, or the reduction of religious experience to error. It identifies the precise ontological question that the inquiry is not presently resolving.

A similar structure can arise in the analysis of selfhood. The experienced continuity of an "I" may be relationally stabilized through embodiment, memory, recognition, language, institutional identity, habit, and historical continuity. This stabilized self can organize action and therefore possess causal efficacy within the system. The corresponding relational claim does not require GR to affirm or deny an invariant metaphysical self. The inquiry can proceed by studying the generative conditions, persistence, transformations, and consequences of selfhood while suspending stronger ontological commitments about what the self ultimately is.

Definition 4.15 (Ontological suspension)**.** *Ontological suspension* is the disciplined withholding of commitment concerning an ontological claim whose resolution is not presently warranted or required for the explanatory task, while preserving and using those weaker or differently scoped reality claims that the inquiry can support.

Definition 4.15 contains two positive components. First, suspension is directed toward a specified claim rather than toward reality in general. Second, suspension preserves other warranted commitments. It is therefore compatible with strong claims at another register. An inquiry may suspend the ontological status of money while affirming its relational reality; suspend the ultimate nature of consciousness while studying manifestational and relational structures of subjectivity; or suspend the metaphysical status of a social category while examining its institutional stability and causal effects.

This claim-specific character prevents ontological suspension from becoming an indiscriminate refusal to decide anything. GR does not treat uncertainty as an intellectual virtue in itself. Where evidence, argument, or explanatory necessity supports a stronger commitment, suspension can be narrowed or lifted. Where a claim has been sufficiently falsified within the relevant domain, denial may be justified. Suspension therefore occupies a distinct methodological position between unwarranted affirmation and unwarranted negation.

The distinction is particularly important for generative inquiry because the objects of interest may cross registers. A manifestational event can have effects even when the ontological status of what appears remains unsettled. An illusory flower perceived under altered physiological conditions can become relationally consequential through attention, movement, fear, memory, communication, or later interpretation. A physically present flower can likewise become relationally consequential through perception and subsequent action. The fact that both can possess relational reality does not erase differences in their ontological conditions. Suspension allows the inquiry to preserve those differences without requiring an immediate final comparison between them.

Claim 4.16 (Suspension does not imply unreality)**.** *Suspending the ontological status of an object does not entail that the object is unreal at other registers. Relational and manifestational reality remain independently assessable under their own conditions.*

Claim 4.16 is foundational for the remainder of the chapter. It prevents a recurrent collapse in which only ontologically fundamental objects are treated as real, while institutionally, psychologically, culturally, or symbolically mediated objects are relegated to a secondary status. GRE instead asks which reality claim is being made, under which conditions, and with what explanatory consequences.

4.3.2 Suspension and Agnosticism

Ontological suspension also differs from general agnosticism. Agnosticism ordinarily describes a position of non-knowledge or unresolved belief concerning a question. Suspension, as used here, is more local, functional, and methodologically organized. A researcher may personally hold a metaphysical view while suspending it within a particular analysis because the view is not required to establish the argument. Conversely, a researcher may remain personally undecided while the inquiry

itself reaches a sufficiently strong local ontological conclusion. GR therefore treats suspension as a property of an analytical procedure rather than as a report of the researcher's private belief state.

This difference matters because a research programme must coordinate inquiry across people who may hold incompatible metaphysical commitments. If every empirical or theoretical analysis required prior agreement concerning the ultimate ontology of persons, institutions, meanings, values, information, or social facts, large portions of inquiry would become hostage to disputes operating at a different level. Ontological suspension creates a disciplined space in which researchers can identify the stronger question, state that it remains open for the purposes of the analysis, and continue working with commitments that are both sufficient and jointly assessable.

Suspension is also compatible with differentiated confidence. The framework need not divide claims into only affirmed, denied, or suspended categories. A claim can be weakly supported, strongly supported, locally adequate, historically contingent, scale-dependent, or open to revision. Suspension concerns the point beyond which the inquiry refrains from extending its commitments. In this sense, it functions as a boundary on inference. The boundary may move as new evidence, conceptual distinctions, or explanatory requirements emerge.

For example, suppose an analysis establishes that a particular institutional category has persistent effects on eligibility, behavior, and resource distribution. The category can be treated as relationally real within the institutional system. Whether that category tracks a natural kind, a socially constructed kind, a historically contingent administrative device, or some combination may remain unresolved. The inquiry can suspend this further ontological classification while retaining the causal and institutional findings. If later research demonstrates that the distinction among these possibilities is itself necessary to explain the observed dynamics, the suspended question becomes active and must be investigated.

This temporality is important. Suspension is not a permanent exile of difficult questions. It is a way of sequencing inquiry so that questions are addressed when their resolution becomes relevant and when the available methods can bear on them. A suspended claim may later become central; a previously central ontological dispute may later become irrelevant to a more local explanatory task. GR therefore understands suspension as revisable and historically situated.

Remark 4.17 (Suspension is inquiry-relative)*.* The same ontological proposition may be suspended in one inquiry and actively investigated in another. Suspension attaches to the relation between a claim and an explanatory task, not permanently to the object itself.

This inquiry-relative character also prevents the framework from treating ontological suspension as a universal solution. Some questions cannot be responsibly deferred. A study of legal responsibility may require a more explicit account of agency than a study of transaction frequency. A study of machine subjecthood may require ontological distinctions that can be suspended in a narrow analysis of machine-mediated market behavior. A study of hallucination may require distinctions between perceptual generation and external physical objects that are unnecessary in an analysis limited to the subsequent behavioral effects of the experi-

ence. The appropriate degree of suspension therefore depends on what explanatory burden the analysis places on its objects.

A further difference from agnosticism concerns positive use. Agnosticism can leave a proposition untouched. Suspension often permits the object associated with that proposition to remain analytically active under another description. One can suspend whether a deity possesses independent ontological reality while analyzing the relational reality of divine authority; suspend whether the self is ontologically fundamental while analyzing self-continuity; suspend whether value exists independently of valuation while studying value as a historically stabilized relational formation. The suspended question remains visible, but inquiry does not need to stop at it.

4.3.3 Suspension as Methodological Discipline

Ontological suspension becomes useful only when it is practiced with discipline. An unspecified statement that "ontology is suspended" can conceal ambiguity just as easily as an unspecified ontological assertion can. GR therefore requires suspension to identify the claim being withheld, the commitments being retained, the reason for suspension, and the conditions under which the question would need to be reopened.

A minimal procedure can be stated in four steps. First, the inquiry identifies the ontological proposition whose stronger resolution is at issue. Second, it states the reality claims that remain necessary for the analysis. Third, it explains why the stronger proposition is not presently required or not sufficiently warranted. Fourth, it tracks whether later stages of the inquiry silently depend on the suspended proposition. These steps make suspension auditable rather than rhetorical.

Definition 4.18 (Disciplined suspension)**.** A suspension is *disciplined* when the inquiry specifies the suspended claim, preserves the commitments required for explanation, states the reason for withholding further commitment, and prevents later inference from covertly presupposing what has been suspended.

The final condition is especially important. An analysis might claim to suspend whether a category is natural or socially constituted, then later interpret its persistence as evidence of naturalness. It might suspend whether an artificial system possesses subjecthood, then assign responsibility to it in a way that presupposes a particular theory of agency. It might suspend whether a market category reflects intrinsic value, then treat observed price as if it directly disclosed such value. These moves would not constitute ontological suspension. They would amount to concealed reintroduction of the stronger claim.

Disciplined suspension therefore requires attention to language. Terms such as "entity," "agent," "subject," "value," "information," "institution," "identity," and "cause" can carry stronger ontological implications than an analysis intends. GR does not require abandoning ordinary terminology, but it does require sensitivity to when a convenient analytical label begins doing metaphysical work. Local definitions, explicit qualifications, and distinctions among registers can prevent such slippage.

Suspension also has a scalar dimension. An object may be treated as sufficiently

real and stable at one scale while its internal constitution remains suspended. A firm can be analyzed as an organizational actor in a market model even though its internal relations are heterogeneous and contested. A person can be treated as a subject of a legal relation while a theory of personal identity remains open. A currency can be treated as a stable monetary unit for one period while its institutional production, material carriers, and symbolic representations are separately investigated. The relevant question is whether the chosen level of objecthood supports the explanatory task without obscuring transformations that matter to the result.

The same logic applies temporally. A relational object may be stable enough for analysis over one interval and unstable over another. Ontological suspension can prevent the local stability of an object from being mistaken for timeless identity. This is especially important in GRE because many objects of economic analysis are historically generated. Firms change legal form, markets change infrastructure, currencies change institutional backing, identities change classificatory regimes, and technologies alter the relations through which objects acquire causal efficacy. Suspension preserves the distinction between "stable enough here" and "fundamentally invariant."

Methodological discipline further requires that suspension remain compatible with causal explanation. GR does not use suspension to avoid specifying mechanisms. If an object is treated as relationally real because it exerts causal efficacy, the analysis must still investigate the relations through which that efficacy arises. Saying that the object's ultimate ontology is suspended does not permit causal vagueness. On the contrary, the weaker metaphysical commitment increases the importance of showing how persistence, stability, and causal participation are generated within the relevant system.

Claim 4.19 (Suspension and explanatory burden)**.** *Ontological suspension reduces unnecessary metaphysical commitment but does not reduce the explanatory burden associated with relational or manifestational claims. The mechanisms, conditions, and scope supporting those claims remain open to investigation.*

Claim 4.19 prevents suspension from functioning as a refuge from difficult analysis. If GRE claims that trust, money, authority, or identity is relationally real, it must still account for how that reality is generated and maintained. Suspension concerns what need not be claimed beyond that analysis, not what need not be explained within it.

4.3.4 Suspension under Ontological Disagreement

Ontological disagreement is common in the domains GRE studies. Social ontology, philosophy of mind, philosophy of science, religious ontology, theories of value, institutional theory, and theories of agency all contain persistent disagreements concerning what kinds of things exist and what makes them real. Generative-relational inquiry requires a way to work across such disagreement without pretending that the disagreements have disappeared.

Ontological suspension provides one such mechanism. When competing ontologies generate the same commitments required for a local analysis, the inquiry can bracket their stronger divergence and examine the shared relational or manifestational structure. For example, researchers may disagree over whether institutions

possess a reality irreducible to individual action. If both accounts nevertheless recognize a stabilized pattern of rules, expectations, roles, and sanctions that causally affects behavior, a GRE analysis can investigate that relational configuration while leaving the deeper disagreement unresolved for the purposes of that task.

This strategy does not imply that ontological disagreement is always irrelevant. Competing ontologies may produce different explanations, identify different objects, or recommend different methods. A strongly individualist ontology and a strongly structural ontology may disagree not only about metaphysical grounding but also about where causal efficacy should be located. In such cases, suspension of the disagreement would remove precisely what the research needs to test. GR therefore distinguishes *non-operative disagreement*, which can be suspended for a particular task, from *operative disagreement*, which changes the explanatory consequences and must remain visible within the analysis.

Definition 4.20 (Operative ontological disagreement)**.** An ontological disagreement is *operative* for an inquiry when competing ontological commitments alter the identification of relevant objects, mechanisms, causal relations, evidence, or explanatory consequences within that inquiry.

Definition 4.20 gives suspension a limit. If an ontological difference changes what the model predicts, what evidence counts, what mechanism is possible, or what intervention follows, the difference cannot be treated as merely philosophical background. Conversely, when competing metaphysical accounts leave the local explanation unchanged, insisting on prior resolution can add controversy without adding explanatory power.

This distinction also supports pluralism within GRE. Researchers can develop different ontological interpretations of the same generative-relational phenomenon while remaining part of a common research programme, provided the differences are explicitly stated and their consequences can be compared. Ontological suspension therefore does not require theoretical homogeneity. It can create a shared analytical surface on which competing deeper accounts become comparable where comparison is possible.

The possibility of comparison, however, must itself be established. Section 91 emphasized that two relational realities need not inhabit a common metric or even a common comparison space. The same caution applies to ontological theories. Two accounts may use incompatible primitive vocabularies or organize reality at different scales. Suspension can permit local cooperation without forcing artificial commensurability. When translation is possible, the mapping should be stated; when it is partial, the loss should be acknowledged; when no justified mapping exists, the disagreement may remain structurally unresolved.

This point is important for cross-cultural and interdisciplinary inquiry. A phenomenon can be embedded in distinct conceptual, religious, scientific, legal, or experiential ontologies whose categories do not align cleanly. GRE should not assume that one vocabulary can always translate another without remainder. Ontological suspension can preserve analytical openness while allowing researchers to study the relational consequences of each framework within its own domain. The aim is not to declare all ontologies equivalent but to avoid manufacturing equivalence before the

conditions of comparison have been established.

Under disagreement, suspension also has an ethical dimension. Prematurely declaring one ontology to be the sole legitimate description can erase forms of experience or institutional reality that remain causally consequential for the people and systems under study. At the same time, treating every ontological claim as equally warranted would abandon standards of evidence and argument. GR therefore seeks a middle position: stronger ontological judgments remain possible, but they are made only when the inquiry requires them and when the grounds for doing so are explicit.

4.3.5 Suspension and Analytical Usability

The practical value of ontological suspension lies in the fact that analytically useful objects need not wait for metaphysical closure. Economic and social inquiry routinely operates with objects whose ultimate status is contested but whose effects are sufficiently stable to investigate. GRE systematizes this practice by distinguishing analytical usability from final ontological settlement.

An object is analytically usable when it can be specified with enough stability, relational location, and causal relevance to support the explanatory task. This criterion is intentionally weaker than ontological fundamentality. A market index can be analytically useful without constituting a fundamental natural kind. A legal person can be analytically useful without resolving metaphysical theories of personhood. A social identity can be analytically useful without assuming that the category is natural, timeless, or internally homogeneous. A manifestational form can be analytically useful even when the underlying generative structure remains only partially known.

Claim 4.21 (Analytical usability under suspension)**.** *An object whose stronger ontological status is suspended can remain analytically usable when its relevant boundaries, persistence, relations, and causal consequences are sufficiently specified for the explanatory task.*

This principle helps GR avoid two symmetrical errors. The first is ontological inflation: treating analytical usefulness as proof of fundamental existence. The second is ontological paralysis: refusing to analyze an object until every metaphysical question surrounding it has been settled. The former converts models into ontology too quickly; the latter makes inquiry dependent on conclusions it may never need. Suspension preserves a working space between them.

Analytical usability is nevertheless conditional. The object must remain adequate to the task. If a category's internal heterogeneity begins to change the result, the category must be refined. If a boundary that was previously harmless becomes causally consequential, the boundary must be reconsidered. If a manifestation once treated as a proxy ceases to track the relational structure of interest, the proxy must be revised. Suspension therefore works together with the revisability of analytical objects.

This revisability becomes particularly important in recursive systems. A category used for analysis can enter the system and alter what it describes. A risk classification can change credit access; a diagnostic label can alter self-understanding and institutional treatment; an economic forecast can change expectations and investment;

an aesthetic judgment can redirect attention and preservation; a legal designation can reorganize rights and obligations. Once the analytical or manifestational form becomes generatively active, its status may need to be reconsidered as part of the relational reality under study. Suspension does not isolate the analyst from this recursion. It requires the inquiry to notice when its representations have become causal components of the system.

The same principle applies to contingency. A contingent relational configuration may become stable enough to exert causal efficacy before any subject recognizes it as contingent. Its relational reality can therefore be analyzed prior to conscious manifestation. If the contingency later becomes aesthetically salient, symbolically articulated, or institutionally recorded, those manifestations may feed back into the relations through which the object persists. Ontological suspension allows the analysis to follow this history without forcing the pre-manifestational structure, the manifested object, and the ontological substrate into a single category.

The method can therefore be summarized as selective commitment. GR commits to what the explanatory task can support, suspends what lies beyond that support, and reopens suspended questions when they become operative. This practice preserves the reality of emergent and causally efficacious objects while resisting the conversion of local explanatory success into universal metaphysical closure.

Remark 4.22 (Suspension and the three-register architecture)*.* Ontological suspension is one of the mechanisms that keeps the three registers analytically distinct. It permits a researcher to affirm relational or manifestational reality while leaving a stronger ontological claim unresolved, and it permits later evidence or argument to modify that suspension without retrospectively invalidating the earlier local analysis.

Ontological suspension thus completes the methodological groundwork established by Sections 90–92. Section 90 showed why GR requires explicit ontological commitments without ontological closure. Section 91 distinguished ontological, relational, and manifestational reality and treated their relations as a graph rather than a chain. The present section has specified how inquiry can move among those registers without making every local reality claim carry the burden of a final metaphysics. Section 93 can now turn from the status of ontological claims to the primitive analytical vocabulary through which emergent stability becomes describable: change, structure, constraint, and difference.

4.4 Primitive Structure and Ontological Emergence

Chapter 4 requires a vocabulary capable of describing emergence before the analysis presupposes fully constituted entities, subjects, relations, institutions, or values. Chapter 3 introduced change, structure, constraint, and difference as a minimal primitive structure for GRE. The present section develops their specifically ontological role. Its objective is to show how these four methodological primitives can support descriptions of emergence and relative stability while remaining compatible with ontological suspension. The discussion considers each primitive separately, then examines their interaction and the formation of stable configurations. The method is constitutive and deliberately weak: the primitives provide conditions for describing how

determinate objects can become analytically available without being declared the metaphysically fundamental constituents of reality.

Definition 4.23 (Methodological primitive)**.** A *methodological primitive* is a distinction provisionally treated as analytically available before the framework constructs richer objects from it. Its primitive status concerns the organization of inquiry and does not, by itself, establish metaphysical fundamentality, temporal priority, indivisibility, or universal explanatory sufficiency.

Definition 4.23 preserves the restraint developed in Sections 4.1–4.3. Change, structure, constraint, and difference may themselves admit further decomposition under another theory or at another scale. A physical account may redescribe a social constraint through material processes; a phenomenological account may differentiate forms of experienced difference; a mathematical representation may replace ordinary structural language with a more specific formal object. GR does not require those approaches to converge on one final primitive basis. The quartet functions as a minimal analytical grammar within the present research programme.

The order in which the four primitives are presented should likewise be interpreted analytically rather than chronologically. GR does not posit a first moment of pure change followed by the later arrival of structure, constraint, and difference. Each becomes intelligible through the others. Change is identified through differences across configurations; structure supplies organization within which such differences can be tracked; constraints condition accessible transformations; and differences become consequential through structures that preserve, amplify, suppress, classify, or redirect them. Ontological emergence is therefore approached through their interaction rather than through a linear derivation from one primitive. (P. W. Anderson 1972; Simon 1962; Nicolis and Prigogine 1977)

4.4.1 Change

Change provides the minimal temporal opening required for emergence. An analysis of emergence must permit a later configuration to differ from an earlier one, or a process to produce distinctions that were previously absent at the selected resolution. GR therefore uses change in a broad sense: a transformation in state, organization, relation, capacity, boundary, rule, classification, or possibility. This formulation allows the identity of what changes to remain partly open. The object need not be fully constituted before the transformation begins.

This point matters for ontological analysis because many economic and social objects are encountered only after a period of formation. A firm may acquire legal identity after organizational relations have already developed. A monetary practice may stabilize before a standardized representation is established. A collective identity may become causally consequential while its boundaries remain contested. If inquiry requires the object to possess a fixed identity before change can be described, the formative process is partly hidden by the analytical vocabulary. Treating change as primitive permits the analysis to track transformations through which the object itself becomes more determinate.

Change can occur at several levels. A configuration can move among states while its constitutive organization remains relatively stable. Its structure can also change,

altering the pattern through which later states become possible. Constraints can be modified so that transitions previously difficult or unavailable become accessible, while other transitions become costly or foreclosed. Differences that were once negligible can become consequential when a new institution, technology, category, or practice makes them operative. A still stronger transformation can alter the mechanisms through which subsequent change is generated. GR therefore distinguishes change in a configuration from change in the generative conditions of that configuration.

The primitive also includes maintenance. Relative stability frequently depends on continuing activity. A legal status persists through records, procedures, recognition, enforcement, and institutional reproduction. A currency remains usable through repeated practices of acceptance, accounting, settlement, and regulation. A self-description may remain stable through memory, bodily continuity, social recognition, and narrative reproduction. In these cases, stability at one analytical level coexists with ongoing transformations at another. Change and persistence consequently form compatible features of a generative-relational system.

Change alone does not identify emergence. Many transformations dissipate without producing a persistent configuration. Others alter an existing object without generating a new one at the relevant scale. The ontological significance of change depends on the organization through which transformations become patterned, retained, and capable of affecting later processes. Structure supplies that second dimension.

4.4.2 Structure

Structure refers to patterned organization sufficiently coherent for distinctions, transitions, and dependencies to be tracked. Its use in GR is intentionally plural. A structure may be spatial, temporal, institutional, legal, symbolic, computational, ecological, organizational, or relational. Several descriptions may apply to the same configuration at different scales or for different research purposes. The concept therefore identifies organization without requiring one privileged formal representation.

Ontological emergence requires structure because a transient difference becomes analytically significant only within some organization that allows it to persist, recur, combine with other differences, or modify future transformations. A repeated exchange practice, for example, becomes more than a collection of isolated transactions when expectations, roles, records, conventions, enforcement, and material infrastructures organize later exchanges. The relevant structure may remain incomplete and historically variable while already giving the process a degree of continuity.

Structure should therefore be separated from rigidity. A configuration can preserve recognizable organization while its constituents change. An institution can maintain procedural continuity while officeholders, rules, technologies, and interpretive practices evolve. A network can retain a characteristic pattern while particular ties form and dissolve. A person can preserve an experienced continuity of self while memories, relations, capacities, and bodily conditions change. Structural stability is always relative to a selected resolution and timescale.

This relativity is especially important for the three-register architecture. A struc-

ture identified at the manifestational register may differ from the structure inferred at the relational register. Repeated observations can display a stable statistical pattern without uniquely determining the generative configuration that produces it. Conversely, a relational structure can remain sufficiently stable while its manifestations vary across contexts. Structure is therefore register-sensitive: the analyst should specify what is organized, at which register, over what interval, and under which observational or representational conditions.

Structure also enables the preservation of history. Earlier transformations can leave traces in current organization through institutional rules, material infrastructures, learned dispositions, network positions, accumulated resources, classifications, or path-dependent expectations. The resulting configuration carries a history without requiring every historical event to remain explicitly represented. In GR, emergence is therefore commonly historical: a stable object can condense prior transformations into a structure that shapes what happens next.

Treating structure as primitive does not establish that structure exists independently of process. The methodological role is narrower. GR requires a way to describe organized regularity before deciding whether a particular case is best understood through entities, relations, processes, fields, or another ontology. Structure supplies that analytical capacity while leaving its deeper constitution open.

4.4.3 Constraint

Constraint introduces asymmetry into the space of possible transformations. A configuration becomes generatively consequential when some transitions are enabled, favored, stabilized, delayed, made costly, prohibited, or rendered practically unavailable relative to others. Constraint therefore refers to conditions that shape the accessible trajectories of a system. Such conditions can be material, institutional, legal, informational, symbolic, bodily, ecological, computational, or relational, and their mechanisms need not be identical.

This primitive is central to emergence because persistence requires more than repeated occurrence. A configuration that can be displaced by arbitrarily small perturbations may appear momentarily without becoming stable at the timescale relevant to the inquiry. Constraints can help maintain a configuration by limiting departures, supporting repair, directing feedback, preserving boundaries, or making particular responses more probable. They can also prevent an incipient configuration from stabilizing. Emergence and dissolution are therefore both partly intelligible through changing constraints.

Constraint includes enabling conditions. A legal form can restrict certain actions while making others possible by defining authority, ownership, liability, or procedural competence. A technical standard can narrow acceptable formats while allowing coordination among previously disconnected participants. A language constrains expression through grammar and convention while enabling complex articulation. An infrastructure conditions where and how interaction occurs while expanding the range of activities that can be sustained. GR accordingly treats constraint through its effect on accessible possibilities rather than equating it with direct prohibition or coercion.

Constraints are often positional. The same institutional arrangement can enable one subject while restricting another; the same market structure can generate opportunity for one firm while creating dependency for another; the same symbolic classification can confer recognition in one setting and produce exclusion in another. The relevant question is therefore which transitions are conditioned for which subjects or configurations, through which mechanism, and over what scale. A general statement that a system is "constrained" is insufficient without this local specification.

Constraint can itself be historically generated. A practice repeated over time may produce expectations that later function as constraints. A manifestation can be recorded, classified, and institutionalized in ways that reshape subsequent possibilities. Material investments can harden earlier decisions into infrastructure. A legal category can stabilize a distinction and thereby affect later subject formation. In these cases, the outcome of one generative process becomes part of the constraint structure governing another. The graph-like architecture of Chapter 4 is therefore visible already at the primitive level: products of prior emergence can enter the conditions of later emergence.

No normative valence follows from constraint alone. A constraint may preserve a valuable capacity, stabilize domination, prevent harm, sustain cooperation, reproduce exclusion, or combine several of these effects. Normative evaluation requires additional concepts. At this stage, constraint identifies how the space of possible transformation acquires shape.

4.4.4 Difference

Difference provides the minimal condition for distinction. GR uses the term to indicate non-equivalence that becomes analytically or causally consequential within a configuration. Difference may concern state, position, timing, capacity, relation, classification, intensity, direction, accessibility, or another dimension selected by the inquiry. The concept remains weaker than inequality, opposition, hierarchy, or conflict. Those more specific relations can emerge from differences but should not be built into the primitive itself.

Difference is required for change to be identifiable, yet the two concepts remain distinct. A difference can coexist at one time between positions or components without representing a temporal transition. Change can then be described when a relevant difference appears, disappears, increases, decreases, or is reorganized across configurations. Structure determines which differences can be represented as belonging to a common organization, while constraint affects which differences can persist or alter later trajectories.

The significance of a difference is relational. A variation that has no effect under one configuration may become decisive under another. A minor difference in documentation can become institutionally consequential when a legal procedure uses that distinction to allocate status. A small variation in network position can matter greatly under a process that amplifies preferential access. An unarticulated bodily sensation can become salient after a new interpretive category is learned. A price difference can remain irrelevant where exchange is impossible and become operative once an infrastructure connects the relevant markets. Difference therefore becomes genera-

tive through the structures and constraints in which it participates.

This point also guards against equating manifestation with the production of difference itself. A difference can be relationally operative before it is perceived, named, or symbolized. A historical configuration may already contain an asymmetry or contingency that shapes subsequent possibilities before any subject recognizes it. Later manifestation can render that difference salient and can subsequently transform the relational configuration, but the manifestation is not necessarily the origin of the operative distinction. This possibility is especially important for GR accounts of contingency, aesthetic judgment, subject formation, and historical recognition.

Difference also raises the problem of comparability. Two differences cannot automatically be assigned magnitudes on a common scale. Some domains admit a justified metric; others support only ordering, classification, structural correspondence, or qualitative distinction; still others presently lack a warranted comparison map. The primitive of difference therefore establishes distinguishability without presuming commensurability. This restraint preserves the possibility that heterogeneous relational realities can each be real while remaining structurally incomparable under the currently available analytical framework.

4.4.5 Interaction among the Four Primitives

The four primitives acquire their explanatory force through interaction. GR does not treat change, structure, constraint, and difference as independent components that can simply be assembled after separate analysis. Each conditions how the others become meaningful. Structure permits differences and changes to be tracked; difference allows structures and transformations to be distinguished; constraints shape which transformations remain accessible; and change can modify the structures and constraints through which later differences become consequential.

A minimal generative description therefore asks how these dimensions coorganize over time. An initially small difference can be amplified when a structure channels repeated interaction through it. The resulting pattern can generate constraints that preserve the difference and make later trajectories dependent upon it. Conversely, a structural change can weaken an existing constraint, permitting previously suppressed differences to become operative and producing a new configuration. Feedback can stabilize the resulting organization, while another process may destabilize it. Emergence is located in this evolving organization rather than in any one primitive taken alone.

Claim 4.24 (Mutual constitution of the primitive structure)**.** *Within GR, change, structure, constraint, and difference function as mutually conditioning methodological primitives. Their analytical separability supports explanation, while their interaction supplies the minimal vocabulary through which the formation, persistence, transformation, and dissolution of more determinate configurations can be described.*

Claim 4.24 also clarifies why the quartet should not be converted into a universal causal sequence. A local analysis may identify a historically specific trajectory—for example, an initial difference followed by structural amplification and later institutional constraint—but another process can begin from an inherited constraint, a structural rupture, or continuing change that gradually generates a distinguishable

difference. The explanatory order is empirical and historical. The primitive architecture provides the vocabulary within which that order can be reconstructed.

The interaction is likewise compatible with multiple registers. A manifestational difference can alter a relational constraint when an articulated classification changes institutional treatment. A relational structure can condition which manifestations become likely or intelligible. An ontological condition, where warranted, can restrict both relational formation and manifestation. Later sections will develop these cross-register relations in greater detail. At the present stage, the important point is that primitive interactions can occur within a register and across registers, and the mapping among them need not be one-to-one.

This framework also accommodates observer dependence without reducing reality to observation. The analyst chooses boundaries, timescales, and distinctions through which change, structure, constraint, and difference are represented. Those representational choices can alter what becomes visible in the analysis. The causal efficacy of the configuration, however, does not depend on the analyst having represented it correctly. GR therefore separates the methodological primitives used to construct an account from the stronger claim that reality itself is exhausted by those primitives.

4.4.6 Emergence of Stable Configurations

Ontological emergence, in the restrained sense required here, concerns the formation of a configuration that becomes sufficiently organized and persistent to be treated as a determinate object of inquiry. Such a configuration can arise when changes are retained through structure, consequential differences are reproduced or transformed, and constraints support a degree of continuity across further change. Stability is relative to timescale, boundary, and analytical resolution. It does not require immobility, permanence, equilibrium, or immunity to transformation.

Definition 4.25 (Relatively stable configuration)**.** A *relatively stable configuration* is an organized pattern that preserves sufficient continuity across a specified region or interval of spacetime for its identity, effects, or transformations to be tracked at the resolution relevant to an inquiry. Its stability may depend on continuing generative activity and can coexist with substantial internal change.

Definition 4.25 deliberately stops short of defining relational reality. Relative stability is necessary for many relationally real objects, yet stability alone is insufficient. The following section will require the further question of causal efficacy within the generative-relational system. A recurring pattern that remains observationally stable but exerts no relevant causal effect may be descriptively important without satisfying the full GR criterion for relational reality. Section 4.4 therefore establishes the primitive conditions through which candidate objects become available for the stronger analysis that follows.

Stable configurations can be generated through heterogeneous mechanisms. Repetition can reinforce expectations; feedback can maintain a range of states; institutional rules can preserve boundaries; material infrastructures can retain earlier decisions; memory can transmit prior distinctions; legal recognition can stabilize roles; symbolic classifications can coordinate action; repair processes can restore a configu-

ration after perturbation; and dependencies can make departure increasingly costly. GR does not assume that one mechanism explains every case. The ontological architecture should remain broad enough to distinguish different stabilization processes while still asking how they participate in generation.

The emergence of a configuration also does not guarantee a unique level of description. The same process may stabilize an object at one scale while remaining highly variable at another. A market can display stable aggregate patterns while individual relations change rapidly. A person's self-experience can preserve continuity while bodily and social conditions evolve. An institution can remain legally continuous while its practical operation is reorganized. Multiple relatively stable configurations can therefore overlap, nest, or intersect without being reducible to one common metric or hierarchy.

The historical dimension is decisive. Once a configuration stabilizes, it can become part of the conditions under which later emergence occurs. A relational object generated at one time can constrain later action; a manifestation can be institutionalized and become a component of subsequent relational structure; a difference can be preserved in records and reactivated under a later classification regime. Emergence therefore changes the generative field in which future emergence takes place. The result is a recursive historical process rather than a sequence in which completed objects simply accumulate alongside one another.

Claim 4.26 (Primitive structure and ontological emergence)**.** *Change, structure, constraint, and difference provide GR with a minimal methodological grammar for describing how relatively stable configurations can emerge, persist, transform, and dissolve. The adequacy of this grammar is assessed through explanatory use, while stronger claims concerning the ultimate ontology of the primitives or the configurations generated through them remain subject to the local requirements of inquiry and to ontological suspension.*

Claim 4.26 locates the quartet within the broader ontological position of this chapter. GR commits to enough reality for emergence, persistence, and causal organization to be investigated. It refrains from converting its starting vocabulary into a final metaphysics. This combination prepares the next step. Once a relatively stable configuration has emerged, the analysis can ask whether it also satisfies the stronger conditions of relational reality: emergence within a generative-relational system, persistence or stability over a relevant region or interval of spacetime, and causal efficacy within that system. The following section develops that criterion directly.

4.5 Relational Reality

Section 4.2 introduced relational reality as a technical category of GR: an object is relationally real when it emerges within a generative-relational system, persists with sufficient stability over a relevant region or interval of spacetime, and exerts causal efficacy upon that system. Section 4.4 then supplied the weaker primitive vocabulary through which candidate objects can become describable before the full criterion is satisfied. The present section develops relational reality in its own right. Its objective is to clarify the distinct work performed by emergence, persistence, stability, causal

efficacy, and participation in subsequent relations, while preserving the separation between relational reality and ontological identity. The method is constitutive rather than reductive: the section specifies conditions under which GR is warranted in treating an object as real within a generative-relational system without claiming that those conditions provide a final metaphysics of the object.

The criterion is deliberately stricter than the claim that something is related to something else. Almost any object can be placed within a descriptive network, and almost any event can be associated with surrounding conditions. Relational reality instead concerns an object whose generation and continuation depend upon a relational domain in which it becomes sufficiently determinate to participate causally in what follows. A transient correlation, an observer's arbitrary grouping, or a label that leaves the system unchanged does not become relationally real merely because it can be represented relationally. The category therefore joins an ontological claim of limited scope to an explanatory burden: the analyst must specify the relevant system, the object that has emerged, the domain over which it persists, the sense in which it remains stable, and the causal differences attributable to its presence. (Emirbayer 1997; Berger and Luckmann 1966; Searle 1995)

Claim 4.27 (Relational reality is system-relative rather than merely observer-relative)**.** *A claim of relational reality is indexed to a generative-relational system and an analytically relevant spacetime domain. This relativity does not reduce the object to an observer's description: once the relevant conditions are satisfied, the object can constrain, enable, or redirect processes independently of whether a particular subject recognizes or represents it.*

Claim 4.27 is important because the word *relational* can otherwise be misread as subjective or perspectival. GR uses the term differently. The system relative to which an object is real can include human subjects, institutions, technologies, material infrastructures, ecological processes, symbolic practices, artificial agents, or other relevant components. A subject's recognition may participate in the system, but recognition is neither a universal origin nor a universal criterion of relational reality. This allows GR to treat pre-perceptual and pre-symbolic structures as relationally real when they already satisfy the stronger conditions developed below.

4.5.1 Relational Emergence

Relational emergence concerns the formation of an object through the organization of relations rather than its simple discovery as an already individuated unit. The phrase does not imply that nothing existed before the object emerged. Components, processes, histories, constraints, and differences may already be present. What emerges is a relatively determinate object at the scale and register relevant to the inquiry: a monetary form, an institutional office, a trust relation, a collective identity, an experienced continuity of self, a market convention, or another configuration that was not previously available in the same organized form.

Definition 4.28 (Relational emergence)**.** *Relational emergence* is the formation of an analytically individuable object through a generative configuration of relations such that the object's organization and later effects cannot be specified adequately by treating the participating relata as independent of the relations through which the object

is generated.

This definition makes emergence stronger than aggregation. A pile of tokens and a currency system can contain some of the same material objects while differing radically in relational organization. A set of persons and an institution can contain the same persons while the institution introduces offices, expectations, procedures, permissions, records, sanctions, and histories that modify what those persons can subsequently do. The relationally emergent object is therefore not identified merely by listing its components. Its identity depends on the organization through which components, positions, practices, and constraints become mutually consequential.

Relational emergence can be gradual, punctuated, recurrent, or threshold-like. A trust relation may thicken through repeated interaction without a uniquely identifiable first instant. A legal status may acquire a conventional date of creation even though the relational conditions that make it operative developed earlier. A collective identity may emerge unevenly across subgroups and institutions. A digital asset may be technically instantiated at one moment while its economic relational reality develops only as practices of recognition, exchange, custody, valuation, and regulation stabilize around it. GR therefore avoids requiring a universal temporal signature for emergence.

The same caution applies to boundaries. An emergent object can possess fuzzy or contested edges while still becoming causally consequential. Institutional membership may be disputed; the practical boundary of a market may shift; a social category may be internally heterogeneous; the experienced continuity of self may vary over time. Relational reality requires enough individuation for the object's persistence and causal role to be investigated, but it does not require perfectly sharp boundaries. Boundary specification is part of the inquiry and may itself be historically generated.

Relational emergence also need not begin with manifestation. A configuration can develop through material, institutional, ecological, computational, or social relations before any subject recognizes it as a distinct object. This point is especially significant for contingency. A historically specific conjunction may already organize possibilities and causal pathways before its contingency becomes salient, aesthetically judged, or symbolically articulated. Later manifestation can disclose and transform such a configuration, but the event of recognition need not be the origin of its relational reality.

Conversely, manifestation can participate in emergence. A declaration, classification, measurement, ritual, image, diagnosis, price, legal inscription, or self-description can become one of the relations through which an object is generated. The graph architecture developed in Section 4.2 therefore applies within relational emergence itself: the existence of pre-manifestational emergence in some cases does not imply that manifestation is causally external to emergence in all cases. Later sections examine this mediation more directly.

4.5.2 Persistence

Emergence alone is insufficient for relational reality because many configurations appear briefly and disappear without acquiring an enduring role in the system. Persistence identifies the temporal and spatial continuation required for an emergent object to become more than an evanescent event at the chosen scale. The relevant in-

terval need not be long in absolute terms. What matters is whether the object remains available across enough of the system's evolution to participate in the processes under study.

Definition 4.29 (Persistence)**.** For a specified generative-relational system and analytical domain, *persistence* is the continued or recurrent availability of an emergent object's identity across a region or interval of spacetime despite changes in some of its constituents, states, manifestations, or supporting relations.

Persistence is therefore compatible with transformation. A corporation can persist while employees, shareholders, strategies, assets, technologies, and offices change. A currency can persist while notes are redesigned, payment infrastructures change, exchange rates fluctuate, and particular users enter or leave the system. A sense of self can persist through changes in memory, body, social position, and narrative. Treating persistence as invariance would make relational reality unable to describe precisely the historically evolving objects for which the concept is intended.

The criterion instead requires an account of continuity. Such continuity can be maintained through legal succession, memory, records, repeated practices, network position, material infrastructure, reciprocal expectation, reproduction of rules, or other mechanisms. Different objects can therefore persist through different processes. GR does not require one universal substance that remains unchanged beneath all variation. The continuity relation itself is an object of analysis.

Persistence can also be intermittent. A ritual order may become active only at recurrent times; an institutional emergency power may remain latent between invocations; a social identity may become salient in some contexts and recede in others; a market convention may disappear locally and reappear under recurring conditions. If the organization that allows recurrence remains sufficiently preserved, relational reality can extend across periods in which the object is not continuously manifest. Persistence should therefore be evaluated relative to the object's mode of existence rather than by imposing uninterrupted perceptual presence as a universal standard.

This point again separates relational reality from manifestation. An institution does not cease to be relationally real whenever no one is looking at its records. A trust relation does not vanish between encounters merely because it is not presently expressed. A contingency-producing structure can remain operative before anyone recognizes the contingency it affords. Persistence concerns the continuation of the relational organization and its capacity to participate in later processes, not continuous appearance to a subject.

The spacetime domain of persistence must nevertheless be specified. An object can be relationally real locally without possessing the same reality everywhere or indefinitely. A currency can cease to function beyond a jurisdiction or historical period. A deity can organize one community's practices without possessing the same relational status in another community. A classification can be institutionally decisive in one administrative system and irrelevant in another. Locality does not weaken the reality claim; it identifies the domain within which the claim is warranted.

4.5.3 Stability

Persistence and stability are related but distinct. Persistence asks whether the object continues or recurs across a relevant domain. Stability concerns whether its organization remains sufficiently coherent under ordinary variation and disturbance for the object to retain explanatory identity. A pattern can persist statistically while being too unstable to function as a recognizable causal object, while a highly stable configuration can exist only over a short but analytically decisive interval. GR therefore retains both criteria.

Definition 4.30 (Relational stability)**.** *Relational stability* is the capacity of an emergent object to retain sufficient organizational coherence under a specified range of endogenous variation, environmental change, perturbation, or reproduction for its identity and causal role to remain analytically trackable.

The phrase *sufficient organizational coherence* is intentionally contextual. There is no universal numerical threshold at which an object becomes relationally real. Relevant tolerance depends on the system, timescale, question, and kind of object. A high-frequency market convention may be stable over minutes while a constitutional institution is assessed over decades. A transient coalition can be stable enough to determine a vote even if it dissolves immediately afterward. A psychological self-relation may fluctuate affectively while retaining a recognizable organization across a life period. The threshold should therefore be justified by the explanatory task rather than imported from an unrelated domain.

Stability also does not imply equilibrium. Some relational realities persist precisely through continual adjustment. A market-making practice can remain stable through rapid repricing; an institution can preserve authority through repeated reinterpretation; a language can persist through continuous lexical and grammatical change; a trust relation can remain viable because participants repair disruptions rather than because disruptions never occur. Dynamic maintenance is therefore fully compatible with relational stability.

Nor does stability imply desirability. Durable domination, exclusion, debt dependency, stigmatization, and distrust can all become highly stable relational realities. The criterion is descriptive and ontological within GR's limited sense: it asks whether a configuration has acquired sufficient persistence and coherence to act within the system. Normative evaluation remains a separate task. This separation is essential for GRE because some of the most consequential economic realities are precisely those whose stability reproduces harmful or unjust relations.

Stability can furthermore be self-enhancing. Once an object begins to affect expectations and action, those effects can generate relations that increase the probability of its continued reproduction. Trust can induce cooperation that produces shared experience, thereby strengthening later trust. Distrust can induce defensive behavior that is interpreted as evidence for further distrust. Institutional authority can coordinate compliance that makes authority easier to reproduce. Capital can alter access to future opportunities in ways that facilitate further accumulation. GR treats such feedback as a possible mechanism of stabilization rather than as a universal property of relational reality.

The opposite process is equally important. Manifestations, interventions, shocks,

reinterpretations, or changes in supporting relations can destabilize an object. A currency crisis can weaken expectations that previously sustained monetary coordination. A legal judgment can reorganize an institutional category. A new historical archive can transform a collective identity. An aesthetic or epistemic manifestation can redirect attention toward previously unnoticed contingencies. Stability is therefore historically produced and historically vulnerable.

4.5.4 Causal Efficacy

Causal efficacy supplies the decisive condition that prevents relational reality from collapsing into descriptive persistence. A pattern can persist because the analyst repeatedly groups observations in the same way while making no difference to the system itself. GR requires more. The emergent object must participate in producing, constraining, enabling, redirecting, amplifying, suppressing, or otherwise modifying subsequent processes within the relevant generative-relational system.

Definition 4.31 (Causal efficacy in relational reality)**.** An emergent object possesses *causal efficacy* within a generative-relational system when its presence, organization, or state participates in producing differences in subsequent states, relations, capacities, constraints, possibilities, or transformations of that system under a warranted causal account.

This definition is deliberately plural about causal methodology. Causal efficacy may be supported through intervention, counterfactual analysis, process tracing, mechanistic reconstruction, temporal comparison, natural experiment, simulation, ethnographic evidence, historical reconstruction, or another method appropriate to the object. GR does not require every causal claim to be expressed through one statistical formalism. It does require the analyst to distinguish causal participation from mere co-occurrence or interpretive convenience.

The relevant effect also need not be direct. Money alters behavior partly through prices, accounting, law, expectations, infrastructures, and obligations. Institutional authority can act through role recognition, procedure, sanction, habit, and anticipatory compliance. A god that is relationally real within a religious system can affect conduct through ritual, obligation, architecture, collective memory, moral interpretation, or institutional organization without requiring the relational claim to settle independent theological ontology. The experienced continuity of “I” can organize plans, responsibility, avoidance, memory, and future self-interpretation through several mediating processes. In each case, the causal object is relationally constituted while its efficacy is distributed through other relations.

Causal efficacy can also be latent. A legal right may not be exercised during a given interval while its recognized availability changes bargaining and expectation. A credit line may remain unused while altering the decisions available to a firm. An institutional veto can shape proposals precisely because actors anticipate it and avoid triggering its use. An object’s causal reality therefore cannot always be inferred from visible episodes of activation. Capacities, constraints, and expectations can be causally effective through the possibilities they open or foreclose.

At the same time, attribution must remain disciplined. Because relational objects are constituted through networks of supporting relations, it may be difficult to iso-

late their causal contribution. GR does not solve this problem by declaring every surrounding condition part of the object. The analyst must justify the individuation used in the causal account and remain open to competing decompositions. Different inquiries may locate causal efficacy at different but compatible scales; other decompositions may produce genuinely operative disagreements. Section 4.3 provides the framework for preserving such disagreements without forcing premature ontological closure.

The requirement of causal efficacy also clarifies why perception is unnecessary for relational reality. A structure can affect trajectories before it is recognized. Institutional exclusions can shape access before a person becomes aware of the classification producing them. A historical arrangement can make some encounters more likely than others before anyone interprets the resulting event as contingent. A biological or material condition can alter social relations before it is symbolized. Recognition may later become causally important, but the earlier efficacy is enough to establish that manifestation was not the origin of every relevant effect.

4.5.5 Participation in Subsequent Relations

Within GR, the most characteristic expression of causal efficacy is participation in subsequent relation formation. Relationally real objects do not merely produce isolated outcomes; they can alter who or what can enter into relation, which relations become possible or costly, how existing relations are interpreted, what capacities become available, which differences become salient, and how future objects can emerge. The reality of the object is therefore historical and generative: what has emerged can become part of the conditions of later emergence.

Claim 4.32 (Historical recursion of relational reality)**.** *Once an emergent object becomes relationally real, it can enter the generative conditions of subsequent processes. It may thereby participate in producing relations and objects that were not part of the configuration through which it originally emerged.*

This recursive possibility gives relational reality particular importance for GRE. Money generated through prior legal, political, technological, and social relations can later organize labor relations, investment, debt, consumption, taxation, and institutional development. A firm generated through contracts, assets, labor, law, and organizational routines can become a subject of later relations and can itself create positions, technologies, products, obligations, and externalities. A category produced through administrative practice can redirect resource allocation and thereby alter the population to which the category is later applied. A reputation generated from past interaction can change access to future interaction. Relationally real objects can thus become relata in later systems while retaining histories of how they were generated.

This does not require the later system to reproduce the original generative conditions unchanged. An object can migrate across contexts, acquire new supports, or undergo partial reconstitution. A monetary instrument can move from one technological substrate to another. A religious symbol can enter commercial or political relations that differ from those through which its earlier significance formed. A self-description can be taken up by institutions and returned to the subject through clas-

sification. Relational reality can therefore accumulate layers of mediation over time.

Manifestational mediation is one important mechanism in this recursion. Once a relational reality becomes named, measured, pictured, priced, narrated, classified, or publicly performed, that manifestation can become part of the relations through which the object subsequently persists and acts. A trust relation can be altered by an explicit declaration of trust; a market can be changed by the publication of a price index; a person's institutional identity can be changed by the issuance of a document that records it. The manifestation is not merely a passive window onto a completed relational reality. It can become a causal component of the system.

The same logic applies to aesthetic judgment and contingency. A contingent configuration can already be relationally real before it is recognized. Once the contingency manifests as surprising, beautiful, significant, or worthy of attention, the judgment can redirect inquiry, preservation, imitation, funding, teaching, or collective memory. The manifestation then modifies the relational history of the object. GR can therefore affirm both pre-manifestational relational reality and later manifestational mediation without imposing a universal temporal chain between them.

Participation in subsequent relations also makes relational reality vulnerable to path dependence. Early stabilizations can influence which later relations become easier to form and which alternatives become progressively harder to realize. This does not imply deterministic lock-in. New relations, manifestations, shocks, interventions, and reinterpretations can reopen possibilities. The point is rather that a relationally real object can alter the field of later generation and therefore cannot be treated as an inert output of its own origin.

4.5.6 Relational Reality without Ontological Identity

The preceding conditions establish a mode of reality without settling ultimate ontological identity. An object can be generated, persistent, stable, and causally efficacious within a relational system even when competing metaphysical accounts of that object remain unresolved. This is not a concession that the object is somehow less real. It is a restriction on what kind of reality has been established.

Claim 4.33 (Relational reality does not entail ontological identity)**.** *Establishing relational reality does not, by itself, establish that the relationally real object possesses an independent, fundamental, or uniquely specified ontological identity. Conversely, ontological existence does not by itself establish relational reality within every generative-relational system.*

Money again offers a simple example. Its relational reality can be demonstrated through the coordinated practices, institutions, expectations, inscriptions, and causal consequences that sustain monetary relations without deciding that money constitutes an ontologically fundamental kind. The experienced continuity of self can be relationally real because it persists and reorganizes action without requiring an invariant metaphysical ego. A divine object can be relationally real within a religious system because it organizes practice and causally affects subsequent relations while GR suspends the independent theological ontology of divinity. In each case, the relational claim is substantive even though a stronger ontological claim remains open.

This separation also accommodates objects whose manifestational structures differ radically. Consider a flower appearing under hallucinatory conditions and a flower encountered under ordinary physical conditions. Either can become relationally real if, within the relevant generative-relational system, it acquires sufficient persistence or recurrent stability and causally affects attention, action, memory, affect, communication, or subsequent relations. Their common eligibility for relational reality does not imply that the two objects possess the same ontological status, arise through the same generative structure, or admit a justified common metric. Shared reality-status is therefore weaker than structural equivalence.

Remark 4.34 (Reality-status and comparability). Two objects can both satisfy the criterion of relational reality while lacking a warranted metric, ordering, equivalence relation, structure-preserving mapping, or other common comparison framework. Comparability is an additional analytical achievement rather than a consequence of shared relational reality.

Remark 4.34 protects the framework from a hidden homogenization. Money, grief, trust, institutional authority, divine presence, selfhood, market price, mathematical beauty, and physical objects may all become relationally real under appropriate conditions, while the structures through which they emerge remain heterogeneous. Some can be compared quantitatively, some only through partial mappings, some through qualitative or structural relations, and some may presently lack a justified common comparison domain. GR therefore separates the question of reality from the question of commensurability.

The same principle limits causal comparison. The fact that two objects affect a system does not imply that their effects can be placed on one scalar measure. Their causal pathways may differ in kind, scale, timescale, or register. GRE should therefore resist universal measures of "relational reality" unless a particular research problem establishes a defensible comparison structure. The criterion identifies whether an object has become stably and causally real within a system; it does not assign a universal magnitude of reality.

Relational reality consequently occupies a precise position within the three-register architecture. It is stronger than mere appearance because manifestation is not required for its existence. It is stronger than descriptive recurrence because causal efficacy is required. It is weaker than a final ontological identification because the ultimate metaphysics of the object can remain suspended. It is historically generative because objects that satisfy the criterion can become conditions of subsequent relation formation. And it remains heterogeneous because shared relational reality does not erase differences in structure, ontology, manifestation, or comparability.

Section 4.5 therefore provides the central ontological criterion that later GRE analyses will repeatedly use. The next section turns to manifestational reality, where the question changes from how an object becomes stably and causally real within a generative-relational system to how realities become available in particular modes of appearance, experience, articulation, measurement, classification, and symbolization. The distinction prepares the chapter to analyze manifestation without treating manifestation as either a transparent copy of relational reality or the universal condition of its existence.

4.6 Manifestational Reality

Section 4.5 established relational reality through a demanding criterion: an object must emerge within a generative-relational system, persist with sufficient stability over a relevant spacetime region or interval, and exercise causal efficacy within that system. The present section turns to a different register. Its objective is to clarify what GR means when something becomes *manifest*, to distinguish manifestation from perceptual appearance alone, and to specify how manifestation can be real without being treated as transparent disclosure of either relational structure or ultimate ontology. The section also clarifies an asymmetry that is central to the three-register architecture. Relational reality can precede manifestation, while manifestations, once they occur, can enter generative-relational systems and mediate subsequent relational realities. The method is therefore register-specific: manifestation is analyzed according to the conditions of appearing, availability, differentiation, and mediation that make something manifest, rather than by importing the persistence criterion of relational reality into the manifestational register.

The term *manifestation* is used broadly but not loosely. GR does not restrict manifestation to what a human subject consciously sees, hears, or names. A phenomenon can become manifest through bodily sensation, affective salience, institutional classification, a legal record, a measuring instrument, a statistical pattern, a computational output, a material trace, a linguistic expression, or another medium through which a difference becomes available in a determinate form. Conscious perception is one important mode of manifestation, and symbolic articulation is another, but neither exhausts the category. The concept is intended to capture the general problem of how something becomes available *in a mode of appearance* within a historically and relationally structured situation. (Husserl 2012; Merleau-Ponty 2012; Gibson 1979)

Definition 4.35 (Manifestation)**.** A *manifestation* is an event, state, or process through which a difference becomes sufficiently differentiated and available within a particular manifestational configuration to be encountered, registered, expressed, recorded, measured, classified, symbolized, or otherwise operative in a mode of appearance.

The phrase *manifestational configuration* is important. Something does not manifest in an abstract vacuum. Manifestation occurs through conditions that can include bodily capacities, sensory organization, instruments, media, languages, classificatory systems, institutional procedures, technical infrastructures, cultural expectations, temporal position, spatial scale, and prior relational histories. These conditions do not necessarily create ex nihilo whatever becomes manifest. They participate in determining the form, resolution, salience, and availability through which it appears.

Definition 4.36 (Manifestational reality)**.** *Manifestational reality* denotes the reality of something insofar as it becomes manifest within a specified manifestational configuration. A claim of manifestational reality establishes that a manifestation occurs or is available in a determinate mode; it does not by itself establish the ultimate ontological identity of what manifests, the complete relational structure from which the manifestation emerges, or the persistence and causal efficacy required for relational reality.

Definition 4.36 gives manifestation its own reality-status without turning manifes-

tation into an inferior copy of a supposedly more authentic domain. A pain can be manifestationally real as pain even while its physiological, psychological, or social constitution remains under investigation. A recorded market indicator can be manifestationally real as an institutional and statistical object even when the relation between the indicator and the economic processes it is intended to represent is contested. A flower appearing under hallucinatory conditions can be manifestationally real as an appearance without this settling whether its ontological or relational structure is equivalent to that of a physically encountered flower. Manifestational reality therefore protects the reality of appearance while keeping open the question of what kind of reality the appearance discloses.

Claim 4.37 (Manifestation does not require conscious recognition)**.** *A manifestation can occur through a bodily, technical, institutional, material, statistical, or symbolic configuration without having already become the object of a subject's reflective awareness. Conscious recognition is one possible uptake of manifestation rather than its universal condition.*

A sensor can register a signal before a human observer inspects the record. An institution can classify an event through an automated procedure before any individual deliberates about the classification. A bodily change can become affectively or physiologically manifest before it is linguistically identified. A material trace can remain available for later interpretation even though no subject was present when it was formed. Claim 4.37 should not be read as making manifestation independent of every relation of availability. A purely postulated state that makes no difference in any manifestational configuration has not yet been shown to be manifest. The point is narrower: the configuration through which something manifests need not center a conscious human observer.

4.6.1 Manifestation and Appearance

Appearance is one of the most intuitive forms of manifestation, yet the two concepts should remain distinct. *Appearance* usually emphasizes how something presents itself within perceptual or phenomenological experience. *Manifestation* is broader. It includes appearance but also extends to forms whose availability depends on inscription, instrumentation, classification, computation, institutional procedure, or other mediating arrangements. GR uses the broader term because many economically consequential realities become available through mechanisms that are neither immediately perceptual nor reducible to an individual subject's phenomenal field.

A price displayed on a screen is perceptually available, but its economic manifestation also depends on pricing procedures, data infrastructures, currency conventions, temporal updating, and the institutional setting in which the number is treated as a price. An unemployment rate can become manifest through a published statistical series even though no individual can perceive the aggregate directly. A legal status can become manifest through a registry entry, certificate, database record, or institutional response. An affective orientation can become manifest through bodily sensation, conduct, speech, or repeated patterns of attention. These cases differ in medium, yet each involves a transition from conditions that are not fully available in the same form to a determinate mode in which some difference can be encountered or acted

upon.

Remark 4.38 (Appearance is a mode of manifestation)*.* Perceptual appearance is treated in GR as an important subset of manifestation rather than as its general model. This avoids making conscious perception the template against which institutional, technical, symbolic, statistical, and material manifestations must be understood.

The distinction also matters for the relation between manifestation and representation. Some manifestations are explicitly representational: a graph, map, account balance, legal document, or verbal statement purports to stand for or organize something beyond the inscription itself. Other manifestations can occur before any such representational intention is established. Pain, surprise, bodily tension, a sensor spike, an anomalous pattern, or a change in behavioral regularity can become manifest without first being encoded as a representation of a known object. Representation is therefore one important organization of manifestation, but manifestation is analytically prior to the claim that a manifested form successfully represents what produced it.

This distinction is especially useful for contingency. A generative-relational and historical configuration can already exist before a subject recognizes a contingent relation within it. When contingency later becomes salient, striking, surprising, beautiful, troubling, or otherwise available to judgment, the event enters the manifestational register in a new way. The manifestation does not create the entire relational history that made the encounter possible. Yet the manifestational event can redirect attention and later action. GR can therefore distinguish the prior relational conditions of an encounter, the manifestational event through which contingency becomes available, and the subsequent relations generated after the encounter.

4.6.2 Stability of Manifestation

The stability requirement developed for relational reality should not be transferred mechanically to manifestational reality. A manifestation can be brief. A flash of pain, an unexpected image, a transient reading, a momentary affect, or a singular institutional announcement may be manifestationally real even if it disappears quickly. The occurrence of manifestation and the persistence of manifestation answer different questions.

Claim 4.39 (Manifestational reality does not require persistent stability)**.** *A manifestation can be real as manifestation without satisfying the persistence and stability conditions required for relational reality. Stability is therefore a variable property of manifestation rather than a universal threshold for entry into the manifestational register.*

This claim prevents the three registers from collapsing into one criterion. If every real manifestation had to persist and exercise causal efficacy, manifestational reality would become only a special case of relational reality. GR instead permits an event to be manifestationally real while remaining fleeting, weakly consequential, or difficult to reproduce. The analytic task is then to ask what kind of stability, if any, the manifestation acquires.

Several forms of manifestational stability can be distinguished. A manifestation

may be *temporally stable* when it remains available over an interval; *recurrently stable* when similar manifestations reappear under comparable conditions; *inscriptionally stable* when a record preserves the manifestation; *cross-contextually stable* when related forms appear across different manifestational configurations; or *procedurally stable* when a standardized practice repeatedly produces a comparable output. These forms should not be treated as equivalent. A persistent database entry, a recurring bodily sensation, and a reproducible measurement can all display stability while relying on different mechanisms.

Stability matters because stabilized manifestations can acquire new analytical and causal capacities. A fleeting observation can be remembered, recorded, replicated, standardized, circulated, or incorporated into a classification. Repeated manifestations can make a pattern easier to recognize. Institutionalized manifestations can become reference points for action. A statistical indicator that is repeatedly produced can influence contracts, policy, expectations, and investment. Under such conditions, the manifestation itself may begin to satisfy the criteria of relational reality: it can emerge as a relational object, persist, stabilize, and exert causal efficacy within the system. This transition is possible rather than automatic.

Remark 4.40 (Stabilized manifestation and relational reality). A stabilized manifestation becomes relationally real only when the full relational criterion is warranted. Repetition, inscription, or durability can contribute to that criterion, but none alone establishes causal efficacy or relational emergence.

This distinction is particularly important in economics, where measurements and classifications can become embedded in the domains they describe. A rating, index, price category, credit score, or accounting classification may begin as a manifestational device. Once actors coordinate around it, institutions incorporate it, and future opportunities are conditioned by it, the manifestation can participate in producing a new relational reality. The framework therefore leaves open a historically important pathway from manifestation to stabilization to causal participation without treating that pathway as inevitable.

4.6.3 Context-Dependent Manifestation

Manifestation is context-dependent because what becomes available, and in what form, depends partly on the configuration through which availability is produced. Context here does not mean merely a subjective frame imposed by an observer. It includes the material, technical, institutional, bodily, linguistic, historical, and relational conditions that organize manifestation.

Definition 4.41 (Manifestational configuration)**.** A *manifestational configuration* is the organized set of conditions through which differences can become available in a particular mode of manifestation. It may include subjects, bodies, instruments, media, institutions, categories, languages, technical procedures, spatial and temporal scales, and historically formed expectations.

Changing the configuration can change the manifestation without requiring that the underlying relational or ontological conditions have changed in the same way. A market process can look different at transaction-level, daily, and annual temporal resolutions. The same institutional relation can appear differently in a legal document,

an ethnographic encounter, an administrative database, and a network representation. A bodily condition can manifest through pain for one subject, an imaging signal for a clinician, and a coded category for an insurer. These differences are not necessarily errors. They reflect distinct manifestational configurations that select, amplify, suppress, aggregate, or transform different aspects of what becomes available.

Context-dependence therefore places a burden on analysis. A manifestation should be reported together with the conditions under which it arose when those conditions materially affect interpretation. A number without a measurement procedure, an image without information about the instrument or scale, a classification without its institutional rule, or a statement without the relational situation of utterance can obscure how the manifestation was generated. This requirement becomes especially important when manifestations are used epistemically, because the analyst may otherwise mistake properties of the manifestational configuration for properties of the relational reality under study.

Claim 4.42 (Context-dependence and constraint)**.** *The context-dependence of manifestation does not imply that manifestations are freely constructed by the manifestational configuration. Manifestations can be jointly constrained by the object, the generative-relational history, and the conditions of manifestation even when their form varies across contexts.*

Claim 4.42 protects the framework from a simple opposition between naive realism and unrestricted constructivism. GR allows that a manifestation can be mediated and context-sensitive while still being constrained by realities not reducible to the mediating context. The exact distribution of constraint is an empirical and theoretical question. In some cases instrumentation dominates the form of output; in others the object strongly constrains what can appear; in still others institutional categories shape which differences become visible at all. The framework does not decide these cases in advance.

Historical context adds another dimension. Manifestational configurations themselves evolve. Categories that once lacked institutional existence can later become standardized. New instruments can make previously inaccessible differences measurable. Changes in language can alter what can be articulated. Political and administrative reforms can transform what gets counted, recorded, or ignored. Digital infrastructures can increase the granularity and frequency with which economic conduct becomes manifest. Manifestational reality is therefore historical not only because the objects manifested can change, but also because the conditions of manifestation acquire histories of their own.

4.6.4 Multiple Forms of Manifestation

The manifestational register is plural. A single relational reality can become available through multiple forms, and these forms need not preserve the same dimensions of the underlying relations. GR therefore resists treating any one manifestational mode as universally privileged.

For analytical purposes, several broad forms can be distinguished. *Perceptual manifestations* include sensory appearances and experienced salience. *Affective manifestations* include felt intensities, moods, attractions, aversions, and embodied orien-

tations. *Behavioral manifestations* concern patterns expressed through action or response. *Material manifestations* include traces, spatial arrangements, artifacts, and physical inscriptions. *Institutional manifestations* include statuses, decisions, records, procedures, and classifications. *Symbolic manifestations* include linguistic expressions, images, signs, narratives, diagrams, and formal notations. *Statistical manifestations* make patterns available through aggregation, estimation, or comparison. *Computational manifestations* include model outputs, classifications, embeddings, simulations, scores, and other forms whose availability depends on computational procedures. These categories can overlap, and no exhaustive taxonomy is intended.

The plurality matters because different manifestations can support different kinds of action. A person may experience economic insecurity affectively before it becomes visible in an income statistic. A statistical indicator can reveal an aggregate pattern that is unavailable to individual perception. A legal category can make a relation institutionally actionable even when the lived experience of participants differs from the category's description. A model output can make a latent structure analytically tractable while remaining opaque to ordinary experience. GR treats these as different manifestational achievements rather than as successive approximations to a single canonical appearance.

Claim 4.43 (Manifestational plurality)**.** *The availability of multiple manifestations of an object does not establish that one manifestation is universally primary, nor does variation among manifestations by itself establish contradiction. Their relations depend on the conditions, scales, and dimensions through which each manifestation is generated.*

Manifestational plurality also means that absence in one mode does not establish absence in all modes. A relation that is not consciously perceived may nevertheless be institutionally recorded. A pattern that is statistically weak at one scale may become visible at another. A social expectation that is rarely articulated explicitly may manifest through repeated conduct. Conversely, strong manifestation in one mode does not guarantee corresponding manifestation elsewhere. A publicly salient narrative can be weakly reflected in measured behavior, while a powerful statistical regularity can remain culturally unnoticed.

This plurality prepares a later problem. If relationally different structures can sometimes give rise to similar manifestations, and if similar structures can sometimes generate different manifestations under different conditions, reverse inference from manifestation to relation becomes non-trivial. The present section does not yet formalize that inverse problem; Sections 96–98 will develop the generative relation and its possible non-invertibility. The point required here is simply that manifestation is many-formed and mediated.

4.6.5 Manifestation without Ontological Disclosure

A manifestation can be genuine without disclosing ultimate ontology. This is a direct consequence of the distinction among the three registers. The fact that something appears, is measured, is recorded, or becomes symbolically articulated establishes a manifestational fact. It does not automatically settle what ultimately exists, what type of entity is responsible for the manifestation, or which ontological account is uniquely correct.

Claim 4.44 (Manifestation does not entail ontological disclosure)**.** *A warranted claim that something has manifested does not by itself warrant a unique claim about the ontological identity, fundamental constitution, or complete generative structure of what manifests.*

The point is stronger than the familiar possibility of perceptual error. Even highly reliable manifestations can underdetermine ontology. A reproducible measurement may be compatible with several theoretical interpretations. A stable institutional record may establish how an organization recognizes a status without resolving the broader ontology of that status. A subject's persistent experience of self can be manifestationally robust while competing accounts of selfhood remain open. A religious manifestation can be experientially and socially consequential while theological ontology remains under suspension. The reality of manifestation and the ontology of its source are therefore distinct questions.

The flower example clarifies the distinction. A flower appearing under hallucinatory conditions and a flower encountered under ordinary physical conditions can both possess manifestational reality as appearances. Their manifestational status does not establish that their relational structures are the same, that their ontological statuses are the same, or that they can be compared through a common metric. The manifested forms may even be phenomenologically similar while being generated through substantially different relational configurations. Manifestational reality preserves the reality of what appears without using similarity of appearance as a shortcut to ontological identity.

Ontological suspension is therefore especially useful in the manifestational register. An inquiry can investigate the conditions, stability, variation, and consequences of manifestations while suspending stronger claims that are unnecessary for the problem at hand. This suspension should remain disciplined. If an ontological difference becomes causally operative for the manifestation or for the question being studied, the inquiry can no longer treat that difference as irrelevant. Section 4.3's distinction between operative and non-operative ontological disagreement thus applies directly here.

The same restraint is needed in formal analysis. A manifestational space may be modeled statistically, geometrically, categorically, or computationally without implying that the modeled coordinates constitute the ontology of what manifests. Formal proximity among manifestations does not establish ontological proximity among their sources. A classifier can group observations efficiently while leaving open whether the grouped cases share a common generative structure. Manifestational tractability is analytically useful, but it should not silently become metaphysical identification.

4.6.6 Manifestational Reality and Relational Reality

Relational reality and manifestational reality are distinct registers whose relations can run in more than one direction. The first distinction is temporal and constitutive: an object can become relationally real before it manifests within a particular configuration. The second is generative: once a manifestation occurs, it can enter the relations through which later realities are stabilized, transformed, or dissolved.

These two claims are compatible because the three-register architecture is a graph rather than a chain.

Claim 4.45 (Pre-manifestational relational reality)**.** *Relational reality does not require prior manifestation to a subject, institution, symbolic system, or measuring apparatus. A relationally real object can already persist, remain stable, and exercise causal efficacy before it becomes manifest within a particular manifestational configuration.*

This claim is especially important for GR's account of contingency and aesthetic judgment. The generative-relational and historical conditions that make a contingent configuration possible can already be operative before the contingency is recognized. When the configuration later becomes manifest as surprising, beautiful, meaningful, or worthy of attention, the judgment belongs to the manifestational history of the object rather than to the origin of all its relational reality. The same structure applies to latent institutional tensions, unrecognized dependencies, or ecological relations whose effects are already causal before they become publicly salient.

Claim 4.46 (Manifestational mediation)**.** *Once a manifestation enters a generative-relational system, it can participate in the generation, stabilization, transformation, or dissolution of relational realities by altering expectations, classifications, practices, capacities, constraints, or subsequent relations.*

A declaration of trust can modify the trust relation it manifests. A public price can alter transactions and expectations. A diagnosis can reorganize a person's institutional and interpersonal relations. A legal judgment can transform the relations whose status it articulates. An aesthetic judgment can redirect attention, preservation, teaching, funding, imitation, and collective memory. In these cases manifestation is not merely an epistemic window onto a completed relational object. It becomes one of the relations through which later reality is generated.

Manifestational mediation does not imply that every manifestation becomes relationally real. A fleeting image can disappear without reorganizing later relations. A measurement can remain unused. A symbol can fail to stabilize a practice. Conversely, a manifestation can acquire relational reality when it becomes sufficiently persistent, stable, and causally efficacious within the relevant system. The distinction is therefore maintained at the level of criteria rather than by assigning each object permanently to one register.

This point also clarifies why the registers should not be pictured as layers through which an object passes once. The same object can occupy different positions relative to different systems and times. A relation may be causally operative before it is manifest; later it may become visible through measurement; the measurement can then alter the relation; a new manifestation can follow from the altered relation; and some manifestations can become stabilized relational objects in their own right. Historical recursion replaces a universal sequence.

Remark 4.47 (Graph architecture of manifestation and relation)*.* The distinction between relational and manifestational reality specifies different criteria of reality, not a fixed ordering of stages. Their connections are historically variable and can include disclosure, mediation, feedback, stabilization, transformation, and loss.

Section 4.6 therefore gives manifestational reality a precise but non-reductive role within GR. Manifestation concerns the modes through which differences become

available in determinate configurations. It can be perceptual without being only perceptual, symbolic without being only symbolic, stable without requiring stability, and causally consequential without being defined by causal efficacy. Its reality can be affirmed while its ontology remains suspended. Most importantly, manifestation neither creates all relational reality nor merely reflects it. The next section develops this relation more closely by asking how manifestation itself can emerge through generative-relational processes and how historically formed conditions govern what becomes available to manifestation.

4.7 Manifestation through Generative Relational Emergence

Section 4.6 defined manifestational reality in terms of the conditions under which differences become available in determinate forms. The present section asks a prior generative question: how do those conditions themselves arise, and through what relations does one rather than another manifestation become possible? The objective is to treat manifestation as an emergent event within historically formed generative-relational systems rather than as a transparent encounter between a finished object and an abstract observer. The section develops the manifestation relation, clarifies how manifestations can be relationally generated, examines the historical formation of manifestation rules, and studies institutional and cultural mediation. It concludes by specifying how manifestation mechanisms can themselves become embedded within relational reality. This formulation preserves the distinction between the registers while explaining why their relations are recursive rather than sequential.

A manifestation can often be described retrospectively as though an object simply possessed an appearance that waited to be observed. GR treats this description as analytically incomplete. What becomes available, in what form, with what salience, at what resolution, and to which subject, instrument, institution, or practice depends on a configuration of relations. Some of these relations may be bodily or material; others may be linguistic, technical, institutional, historical, cultural, economic, or political. Their participation does not imply that they freely invent what manifests. It means that manifestation has generative conditions. These conditions can select, amplify, suppress, translate, discretize, classify, stabilize, or otherwise organize differences into forms that become available within a manifestational configuration. (Giddens 1984; Archer 1995; Bourdieu 1977)

Claim 4.48 (Generative condition of manifestation)**.** *A manifestation is generated through a determinate configuration of relations among what can manifest, the conditions through which it becomes available, and the historical structures that organize that availability. Manifestation therefore cannot in general be reduced either to an intrinsic property of an isolated object or to a free construction by an observing subject.*

Claim 4.48 gives the term *generative* a specific role. It directs inquiry toward the conditions under which a manifestation becomes possible and toward the processes that shape its form. The claim is compatible with ontological realism, constructivism in limited domains, process ontology, phenomenological inquiry, and other positions whose stronger metaphysical differences may remain suspended. Its commitment

is methodological and explanatory: manifested form has a history and a relational organization that can, at least in part, be investigated.

4.7.1 The Manifestation Relation

The most economical way to begin is to distinguish a manifestation from the *manifestation relation*. A manifestation is the available event, state, or form specified in Definition 4.35. The manifestation relation concerns the structured relation through which that availability is produced. It includes whatever configuration is relevant to explaining why a difference becomes manifest in one way rather than another.

Definition 4.49 (Manifestation relation)**.** A *manifestation relation* is a contextually specified relation among a potential source of difference, a manifestational configuration, and an available manifested form, such that the relations among these components participate in generating how the difference becomes manifest within the relevant system.

The term *potential source of difference* is deliberately cautious. GR does not assume that every manifestation can be traced to a single antecedent object whose independent ontology is already established. The source can be a relational configuration, an event, a process, a field of variation, an interaction, or another analytically warranted object. In some inquiries, the source may remain partly unknown while its manifestations are well characterized. In others, the source may itself be relationally real but not ontologically identified. Definition 4.49 therefore avoids building a stronger ontology into the concept than the inquiry has earned.

The manifestational configuration likewise need not be centered on a conscious subject. A telescope, laboratory protocol, legal procedure, market platform, archival system, machine-learning classifier, bodily sensory apparatus, ritual practice, or collective discourse can participate in the relation. Human awareness may enter later, or it may be only one component among several. The relation is consequently broader than perception and broader than representation.

A manifestation relation also need not be deterministic. The same relational configuration can permit several manifestations, and similar manifestations can arise under substantially different configurations. Noise, contingency, path dependence, measurement error, strategic behavior, institutional discretion, and historical variation can all contribute to this multiplicity. Section 98 will later examine the consequences for invertibility. At the present stage, the important point is that the manifestation relation can be probabilistic, underdetermined, multivalued, or only partially reconstructable.

Remark 4.50 (Manifestation relation and causal relation)*.* A manifestation relation can contain causal relations without being reducible to a single causal edge. It may include enabling conditions, constraints, classifications, selection procedures, interpretive conventions, technical transformations, histories of training, and other relations whose combined organization produces an available form.

This distinction matters for GRE because many economic manifestations are composites. A market price is not merely caused by a single underlying value. It becomes manifest through bids and offers, market rules, time windows, transaction infrastruc-

tures, currencies, accounting conventions, data publication, and expectations. An unemployment rate manifests through administrative and statistical categories that distinguish employment, unemployment, labor-force participation, and reference periods. A credit score manifests through variables, models, institutional objectives, data histories, and technical procedures. In each case, what becomes visible to later actors is generated through a manifestation relation whose components can themselves become objects of economic analysis.

The relation can also alter the salience of what becomes manifest. Two systems may contain similar differences while making different differences available for action. An institution that records only monetary transactions can make financial exchange highly manifest while leaving unpaid care weakly represented. A platform interface can make some prices, ratings, or rankings immediately visible while rendering other dimensions costly to discover. A legal procedure can transform a diffuse conflict into a set of admissible categories. Manifestation is therefore partly a problem of organized availability.

4.7.2 Relational Generation of Manifestation

The manifestation relation becomes generative when relations among its components do more than transmit a preformed appearance. They participate in producing the differentiated form through which something becomes available. This does not require the strong claim that manifestation creates the underlying object. It requires only that the manifested form cannot be adequately explained without the relations through which it is generated.

Definition 4.51 (Relational generation of manifestation)**.** *Relational generation of manifestation* occurs when the organization and interaction of elements within a manifestational configuration participate in producing the form, salience, resolution, classification, or availability through which a difference becomes manifest.

Several kinds of generation can occur. A relation may *select* among differences by making some detectable and others practically invisible. It may *transform* a difference by translating it into another medium, as when a physical signal becomes a numerical reading. It may *aggregate* multiple events into a statistical indicator. It may *classify* heterogeneous cases under a legal or administrative category. It may *amplify* weak variation into a salient signal, or *suppress* variation through thresholds and normalization. It may *sequence* events into a narrative or temporal ordering. It may *stabilize* an otherwise fleeting manifestation by inscription, repetition, storage, or institutional recognition. These are different mechanisms and should not be collapsed into a universal operation.

The relational generation of manifestation is especially clear when the same underlying configuration becomes available differently under changed conditions. A bodily process may manifest as pain, as an imaging signal, as a diagnostic code, as a disability category, or as an insurance claim. None of these manifestations is simply identical to the others. Each is generated through different relations, infrastructures, conventions, and purposes. The multiplicity does not make every manifestation arbitrary. It shows that the same object or process can enter several manifestation relations whose outputs differ because their generative conditions differ.

A similar structure appears in economic life. Productive activity can manifest as wage income, firm revenue, national accounts, household time use, ecological burden, or reputational value depending on the relational apparatus through which it is registered. A transaction can manifest simultaneously as a price, a legal transfer, a tax event, a behavioral data point, and a change in inventory. The manifestations overlap but need not coincide. Each selects and organizes a different dimension of the event.

Claim 4.52 (Relational generation without ontological reduction)**.** *The relational generation of a manifestation does not establish that the manifested object is exhausted by the relations that generate its manifestation. A warranted account of manifestation can therefore remain compatible with ontological suspension concerning the ultimate constitution of what manifests.*

This claim prevents two opposite reductions. One reduction treats manifested form as if it transparently revealed an independently fixed object. The other treats the object as if it were nothing more than the manifestation apparatus that renders it available. GR can reject both shortcuts. A scientific measurement can be instrument-dependent without implying that the measured phenomenon is only an instrument effect. A legal identity can be institutionally generated without implying that every relevant aspect of the person is reducible to legal classification. A market category can be constructed through conventions while still producing effects that constrain actors independently of their individual intentions.

The same reasoning is important for contingency. A contingent encounter may become aesthetically or existentially salient only within a historically formed relational field of expectations, memories, concepts, bodily dispositions, and prior experiences. The field participates in generating how contingency manifests. Yet the relevant relational structure need not begin at the moment of conscious judgment. It can already be operative before the subject recognizes the encounter as contingent. Aesthetic judgment can then become a later manifestation within that structure and, once expressed or acted upon, can feed back into subsequent relations. The example illustrates why manifestation is relationally generated without making perception the origin of relational reality.

4.7.3 Historical Formation of Manifestation Rules

Manifestations are not generated only by immediate relations. The relations governing manifestation can themselves have histories. Languages, measurement conventions, administrative categories, scientific instruments, market protocols, aesthetic canons, educational practices, and institutional procedures develop over time. These histories shape what can become manifest, what distinctions are available, and how manifestations are stabilized or interpreted.

Definition 4.53 (Manifestation rule)**.** A *manifestation rule* is a historically situated regularity, convention, procedure, threshold, classification, transformation, or selection principle that contributes to determining how differences become available within a manifestational configuration.

The term *rule* should not be read as requiring explicit codification. Some manifestation rules are written: accounting standards, legal definitions, laboratory protocols,

survey instructions, platform ranking procedures, or diagnostic criteria. Others are tacit: habits of attention, cultural expectations, aesthetic conventions, professional judgment, or learned bodily sensitivities. Still others are embedded materially in instruments and infrastructures. Their common feature is that they shape manifestation with sufficient regularity to be analytically relevant.

Manifestation rules can emerge through deliberate design, cumulative convention, conflict, adaptation, technological change, institutional inheritance, or combinations of these processes. Their histories therefore matter. A category that appears natural at one moment may be the product of earlier administrative choices. A statistical threshold can reflect technical constraints that later become institutionalized. A visual convention can persist long after the original reason for its design has disappeared. Historical formation can thus become sedimented into present manifestation without remaining visible to current users.

Claim 4.54 (Historicity of manifestation rules)**.** *Manifestation rules can be historically generated, reproduced, contested, and transformed. Their present operation therefore does not imply timeless necessity, and changes in these rules can alter what becomes manifest without requiring the underlying generative system to change in the same way or at the same rate.*

This claim is important for historical comparison. An economic object recorded under one classificatory regime may not be directly comparable with an apparently similar object recorded under another. A change in measured unemployment can reflect economic change, classificatory change, or both. The visibility of unpaid labor can change when survey design changes even if household practices remain partly continuous. A new diagnostic category can produce a sharp increase in recorded cases by reorganizing manifestation conditions. Historical analysis must therefore distinguish changes in what is generated from changes in how generation becomes manifest.

The same issue appears in intellectual history and aesthetics. What counts as a salient problem, elegant proof, beautiful form, or meaningful contingency is mediated by historically formed repertoires of attention and judgment. These repertoires do not mechanically determine judgment. They condition what is available for recognition and provide distinctions through which some encounters become expressible. An aesthetic judgment can therefore be both genuinely emergent and historically mediated. GR treats those properties as compatible.

Manifestation rules can also become self-reinforcing. Once an institution measures a phenomenon through a particular category, actors may adapt to the category; resources may be allocated through it; records may accumulate around it; and later inquiry may inherit the same distinction because data already exist in that form. The rule then participates in generating the relational reality it was initially used to manifest. Classification and object formation can become recursively coupled without becoming identical.

4.7.4 Institutional and Cultural Mediation

Institutions and cultures are especially important mediators because they stabilize manifestation relations across persons and time. They supply categories, roles, stan-

dards, symbols, practices, technologies, authorities, and expectations through which manifestations become publicly recognizable and actionable. Their mediation can increase coordination while also making some dimensions more visible than others.

Institutional mediation is evident in legal, administrative, financial, educational, scientific, and organizational settings. A legal institution can transform a history of conduct into a status, claim, liability, or judgment. A central bank can make monetary conditions manifest through rates, statements, balance sheets, and operational procedures. A university can convert heterogeneous intellectual activity into grades, degrees, publications, rankings, and appointments. A firm can make performance manifest through accounting categories and internal metrics. These manifestations often acquire consequences precisely because institutions authorize and reproduce them.

Cultural mediation operates through partially shared repertoires of interpretation, value, symbolism, attention, narrative, and expectation. Cultural mediation can affect which manifestations are immediately legible, which require explanation, which are trusted, and which are ignored. It can also affect the emotional and aesthetic force of manifestation. The same material configuration can be encountered as sacred, ordinary, threatening, beautiful, wasteful, prestigious, or economically valuable under different cultural relations. GR does not infer from this variability that cultural meaning is unconstrained. Material conditions, histories, institutions, and other relations can sharply delimit the range of viable manifestations.

Claim 4.55 (Mediation without passivity)**.** *Institutional and cultural mediation can participate in generating manifestational form while the manifested object, the mediating structures, and the subjects involved remain capable of constraining and transforming one another. Mediation is therefore a generative relation rather than a one-way transmission channel.*

This reciprocal structure becomes visible when manifestations modify the institutions and cultures through which they were generated. A published economic indicator can alter policy debate and market expectations. A court judgment can reshape the categories used in later adjudication. A public aesthetic judgment can redirect preservation, funding, teaching, and imitation. A religious manifestation can reorganize ritual practice or institutional authority. A newly visible form of vulnerability can generate advocacy, legal reform, or changes in professional classification. What manifests through a mediating system can return as a difference within that system.

The possibility of recursive mediation also clarifies why power matters without making power the sole explanation of manifestation. Institutions can privilege some forms of visibility, define admissible evidence, allocate attention, or authorize classifications. Cultural hierarchies can make some voices more legible than others. Yet manifestation can also escape intended control, generate unintended consequences, or reveal differences that established institutions cannot easily assimilate. The manifestational field is structured, but structure does not imply perfect determination.

For GRE, this point is central to the analysis of value. Market price is a powerful manifestation because institutions, currencies, infrastructures, legal rights, expectations, and accounting practices make it actionable across many relations. Its institutional strength does not entail that price exhausts value. Other values may manifest

through care, ecological resilience, symbolic significance, social recognition, lived capability, or forms that remain weakly commensurable with price. Treating one manifestation as exhaustive can therefore become an epistemic and political act with generative consequences of its own.

4.7.5 Manifestation Mechanisms within Relational Reality

The final step is to locate manifestation mechanisms within the relational reality developed in Section 4.5. A manifestation mechanism is not merely an abstract rule for converting one description into another. It is an organized process through which relevant relations participate in producing a manifestation. Instruments, institutions, habits, classifications, algorithms, rituals, sensory systems, and discursive practices can all function as components of such mechanisms.

Definition 4.56 (Manifestation mechanism)**.** A *manifestation mechanism* is an identifiable organization of relations and processes through which differences are selected, transformed, amplified, suppressed, aggregated, classified, recorded, expressed, or otherwise made available in a manifestational form.

Manifestation mechanisms can themselves become relationally real when they satisfy the criteria of relational emergence, persistence, stability, and causal efficacy. A statistical bureau's classificatory practice can persist across administrations and alter resource allocation. A pricing mechanism can become stable enough to organize expectations and transactions. A diagnostic infrastructure can shape treatment pathways and self-understanding. A platform ranking system can influence attention and behavior while being continually reproduced through technical and organizational relations. In such cases, the mechanism is not only a means through which other objects manifest; it becomes an efficacious object within the generative-relational system.

Claim 4.57 (Relational reality of manifestation mechanisms)**.** *When a manifestation mechanism emerges within a generative-relational system, persists with sufficient stability, and exercises causal efficacy within that system, the mechanism can itself possess relational reality independently of whether the objects it manifests share the same ontological or relational status.*

The qualification at the end of Claim 4.57 is important. A measurement institution can be relationally real even when what it attempts to measure remains ontologically contested. A religious interpretive practice can be relationally real without resolving the ontology of the divine object it concerns. A hallucination-generating process can be relationally real even when the manifested flower lacks the same physical ontology as an ordinarily encountered flower. The reality-status of the mechanism and the reality-status of what manifests through it therefore require separate analysis.

This separation also prevents a common inferential shortcut. The persistence and efficacy of a manifestation mechanism do not guarantee the truth of every manifestation it produces. Stable institutions can classify incorrectly. Reliable instruments can be applied outside their calibrated domain. Cultural conventions can stabilize misleading interpretations. Algorithms can reproduce systematic error. Relational reality concerns the mechanism's efficacy within the system; epistemic warrant concerns the adequacy of the manifestation as evidence for another claim. Chapter 5 will

develop this distinction more fully.

At the same time, recurrent manifestation can alter the mechanism itself. Users adapt to metrics, institutions revise categories after disputes, instruments are recalibrated, algorithms are retrained, and cultural expectations change after repeated encounters. The mechanism therefore participates in a recursive history: it generates manifestations, those manifestations enter subsequent relations, and those relations can reconfigure the mechanism. This recursion is one reason the three registers are better represented as a graph of historically evolving relations than as a fixed chain.

Section 4.7 has therefore shifted the analysis from manifestation as an available form to manifestation as a generative-relational achievement. A manifestation relation connects potential sources of difference with historically situated configurations of availability. Relations can generate manifestational form through selection, transformation, classification, amplification, aggregation, and stabilization. The rules governing these operations can themselves be historical products, while institutions and cultures can mediate manifestation without fully determining it. Finally, manifestation mechanisms can become relationally real when they acquire persistence, stability, and causal efficacy. The next section develops the stronger possibility that the mapping through which relational reality becomes manifest can itself be treated as a relationally real object, provided that its own conditions of stability, persistence, and causal efficacy are established.

4.8 Relational Reality of Manifestation Mapping

Section 4.7 treated manifestation as a generative-relational achievement and introduced manifestation mechanisms whose histories can become part of the conditions of later appearance, classification, measurement, and symbolization. The present section takes one further step. It asks whether the relation through which manifestation is generated can itself become an object of relational reality. The answer is affirmative under conditions that are already familiar from Section 4.5: a manifestation mapping can become relationally real when it emerges within a generative-relational system, persists with sufficient stability over a relevant region or interval of spacetime, and exercises causal efficacy within that system. This claim does not require the mapping to be ontologically fundamental, mathematically exact, consciously represented, or epistemically correct. It requires the mapping to become sufficiently organized and effective to participate in the subsequent generation of relations and manifestations.

The term *mapping* is used cautiously. It does not presuppose a mathematical function with a fixed domain, codomain, and unique output. Many manifestation mappings are partial, probabilistic, multivalued, path-dependent, historically revised, or only locally stable. A perceptual apparatus, an administrative classification, an accounting convention, a legal procedure, a scientific instrument, an algorithmic classifier, a market protocol, or a linguistic convention can all establish structured correspondences through which differences become manifest. In some cases a formal function is an appropriate representation. In others, a rule, relation, stochastic kernel, institutional procedure, embodied disposition, or family of transformations is

more adequate. The ontological point made here is prior to the choice among those representations. (Giere 2004)

Definition 4.58 (Manifestation mapping)**.** A *manifestation mapping* is a relatively organized relation, rule, process, or mechanism through which differences available within a generative-relational system are transformed, selected, classified, amplified, aggregated, translated, or otherwise rendered into one or more manifestational forms under specified conditions.

Definition 4.58 makes the mapping itself analytically visible. Instead of treating a manifestation as if it simply followed from an antecedent object, inquiry can ask what mediates the transition from a field of differences to the form in which those differences become available. This shift is important because the mediator can acquire a history, a domain of validity, a characteristic stability, and causal consequences of its own. Once this occurs, the mapping is no longer merely a convenient description imposed by an analyst. It can become part of the reality through which the system continues to generate later manifestations.

4.8.1 The Manifestation-Mapping Lemma

The relation between manifestation mapping and relational reality can be stated as a direct consequence of the criterion developed in Section 4.5. The statement is called a lemma because it does not introduce a new criterion of reality; it applies the existing criterion to a higher-order object whose role might otherwise remain implicit.

Lemma 4.59 (Manifestation-mapping lemma)**.** *Let a manifestation mapping be generated within a specified generative-relational system. If, over a relevant region or interval of spacetime, the mapping persists with sufficient stability and exercises causal efficacy in the production, organization, interpretation, or subsequent use of manifestations, then the manifestation mapping qualifies as relationally real relative to that system.*

The lemma is intentionally conditional. A proposed mapping does not become relationally real merely because an analyst can write it down. A transient coincidence, an unused classification scheme, a hypothetical function, or a rule that has not entered the operation of the relevant system may remain an analytical representation rather than a relationally real object. The mapping acquires relational reality when the system itself sustains it sufficiently for it to make a causal difference to what subsequently occurs.

This distinction can be illustrated by comparison between an analyst's model and an institutional classification. An economist may construct a mapping that groups heterogeneous transactions into a set of categories for one exploratory analysis. Unless that mapping enters broader practice, its reality may remain primarily representational. By contrast, when a tax authority, statistical office, payment platform, or accounting regime repeatedly classifies transactions according to a rule that affects reporting obligations, eligibility, prices, audits, or later decisions, the mapping can become relationally real. The classification rule participates in producing subsequent relations. Its effects can persist even when individual actors do not understand the rule in detail.

The same logic applies outside explicit institutions. A learned perceptual discrimination can become stable enough to alter attention and action. A linguistic distinction can guide recognition and social response across repeated situations. A ritualized interpretive practice can channel what members of a community notice and how they respond. An algorithmic ranking rule can shape visibility, participation, and incentives. In each case, the mapping is not merely between two descriptions. It is an operative relation embedded in a system.

Remark 4.60 (Higher-order relational objects). The manifestation-mapping lemma illustrates a broader feature of GR: a relation among objects, or a relation among relations, can itself become an analytically relevant object when it acquires persistence, stability, and causal efficacy. Relational reality therefore does not restrict objecthood to substance-like entities.

This remark is especially important for the graph architecture of the three registers. If mappings among relational and manifestational configurations can themselves become relationally real, then the edges of the graph are not always analytically external to the graph. Some edges can stabilize into objects that later participate in additional edges. A classification relation can become an institution; an interpretive convention can become a norm; a measurement protocol can become an infrastructure; an interface rule can become part of a market's operating environment. The system can therefore generate not only new nodes but also relatively stable relations that subsequently function as nodes at another analytical scale.

4.8.2 Stability of the Mapping

Stability is one of the conditions through which a manifestation mapping can become relationally real, but stability should not be confused with exact invariance. A mapping can remain sufficiently stable while its parameters, categories, thresholds, implementation, or local outputs change. The relevant question is whether enough of its organization persists for the mapping to remain identifiable and causally operative within the inquiry's scale.

Definition 4.61 (Mapping stability)**.** A manifestation mapping exhibits *mapping stability* when variations in its conditions, implementation, or inputs remain compatible with sufficient continuity of its organizing relation for the mapping to retain an identifiable role in generating manifestations over the relevant analytical interval.

This definition allows several forms of stability. A legal mapping from circumstances to status can be stable because courts and agencies reproduce a rule even while interpretations evolve. A market protocol can remain stable while prices and participants change continuously. A perceptual mapping can remain stable across ordinary variation in illumination or bodily state. A machine-learning classifier can preserve a recognizable decision regime across a period of use even if its inputs vary widely. Stability concerns the organization of the mapping, not identity of outputs.

The degree of stability required is domain-relative. A high-frequency trading rule may be relationally significant over milliseconds or hours. A monetary classification can persist for decades. A ritual or linguistic mapping may persist across generations while changing gradually. GR therefore does not impose a universal temporal threshold. The relevant interval is set by the system and the explanatory question. What

matters is that the mapping endure long enough, and coherently enough, to influence subsequent relational development.

Stability also has spatial and institutional dimensions. A classification may be stable within one jurisdiction and absent in another. A cultural mapping may operate within a community without extending beyond it. A measurement protocol may be valid only within a calibrated range. A platform's ranking mechanism can be stable inside one technical environment while changing rapidly after a redesign. Treating stability as local prevents a relationally real mapping from being mistaken for a universal law.

Claim 4.62 (Stability without universality)**.** *A manifestation mapping can be sufficiently stable to possess relational reality within a specified system without being invariant across all times, places, scales, institutions, or domains.*

Claim 4.62 is consequential for economic analysis. Economic categories often appear natural after long institutional stabilization. Wage, price, ownership, debt, unemployment, creditworthiness, productivity, and risk can become highly stable manifestations within particular infrastructures. Their stability can make them causally powerful without establishing that the mappings producing them are timeless or ontologically universal. A category may be deeply real in a relational sense precisely because institutions reproduce it, not because the category exists independently of those institutions.

Mapping stability can also be endogenous to repeated use. When actors anticipate how a system maps differences into manifestations, they can adapt their conduct accordingly. Firms alter reports to fit accounting categories; applicants modify behavior in response to scoring systems; researchers adapt experiments to measurement protocols; users optimize content for ranking systems. Repeated adaptation can stabilize the mapping by making surrounding behavior increasingly compatible with it. It can also destabilize the mapping by exploiting its weaknesses. Stability is therefore an historical outcome rather than a purely formal property.

4.8.3 Persistence of the Mapping

Persistence differs from stability. Stability concerns continuity of organization under variation; persistence concerns continued existence or recurrence of the mapping across the relevant spacetime interval. A mapping can persist while becoming less stable, as when a contested classification remains institutionally present but its interpretation fragments. Conversely, a mapping can be locally stable during each use yet fail to persist because the mechanism is abandoned after a short episode. Relational reality requires attention to both dimensions.

Definition 4.63 (Mapping persistence)**.** A manifestation mapping exhibits *persistence* when the relations, practices, mechanisms, or infrastructures that sustain the mapping continue or recur across a relevant spacetime interval such that the mapping remains available to participate in subsequent manifestation.

Persistence can be maintained through material infrastructure, institutional memory, embodied habit, repeated practice, archived rules, software, education, law, ritual, language, or combinations of these. Different supports can substitute for one

another. A monetary mapping between numerical denomination and purchasing capacity, for example, does not persist through one material carrier alone. It can be reproduced through bank ledgers, legal obligations, payment networks, accounting systems, public expectations, pricing practices, and state institutions. The relational object persists through distributed supports whose composition can change.

This distributed persistence matters because the disappearance of one carrier need not dissolve the mapping. Paper certificates can disappear while account-based records remain. A spoken norm can become codified. An institutional category can migrate from paper forms to databases. A scientific measurement practice can move from one instrument generation to another. Persistence therefore belongs to the generative organization rather than necessarily to a single substrate.

Historical transmission also permits mappings to outlive the conditions under which they first emerged. Categories may continue to organize manifestation after the original rationale has weakened. Administrative systems can preserve distinctions whose historical origin is forgotten. Economic indicators can continue to guide policy after production structures have changed. Such persistence is analytically important because the mapping can remain causally efficacious even when actors no longer possess a clear account of its genealogy.

Claim 4.64 (Persistence without conscious maintenance)**.** *A manifestation mapping can persist relationally without being continuously represented, understood, or intentionally maintained by any single subject, provided that the generative-relational system continues to reproduce the mapping through relevant practices, structures, or infrastructures.*

This claim parallels the pre-manifestational status of relational reality discussed earlier. Just as a relationally real object does not require prior perception, a relationally real mapping does not require a subject who explicitly knows the mapping. Some mappings are tacit, distributed, embodied, or infrastructural. Their reality becomes visible through regularities in what systems make available and through the effects that follow from those regularities.

Persistence also makes the history of mappings empirically investigable. One can trace when a distinction entered an institutional vocabulary, when a metric became standardized, when a legal category acquired force, when an algorithmic rule was deployed, or when a perceptual convention became culturally salient. Such histories can reveal that what later appears to be an immediate manifestation was mediated by a mapping that had itself undergone a process of stabilization and transmission.

4.8.4 Causal Efficacy of the Mapping

Persistence and stability alone do not complete the criterion. A mapping becomes relationally real in the stronger GR sense when it also exercises causal efficacy within the relevant system. Causal efficacy can arise at several points. The mapping can influence which differences become available, how they are organized, how actors respond to them, which resources are allocated, what categories are reproduced, and how later mappings are formed.

Definition 4.65 (Causal efficacy of a manifestation mapping)**.** A manifestation map-

ping has *causal efficacy* when its operation makes a difference to subsequent manifestations, actions, relations, constraints, capacities, allocations, classifications, or trajectories within the relevant generative-relational system.

A mapping's causal efficacy need not be deterministic. A credit score may change the probability of receiving credit without uniquely determining the decision. A diagnostic category may alter the range of available treatments without fixing an individual's course. A market price can reorient behavior while different actors respond differently. A cultural symbol can modify salience and expectation without compelling one interpretation. Probabilistic, enabling, constraining, and path-shaping effects can all be causal in the relevant sense when the mapping makes a counterfactually or dynamically significant difference within the system.

Causal efficacy also distinguishes the reality of a mapping from the accuracy of the manifestation it produces. A mistaken classification can still be causally powerful. A biased indicator can redirect resources. A misleading rumor can alter market behavior. A hallucinated object can affect bodily action and memory. An institution can stabilize an erroneous category whose consequences are nevertheless real. The mapping's relational reality therefore cannot be inferred from epistemic correctness, nor can epistemic correctness be inferred from relational reality.

Claim 4.66 (Reality of mapping and epistemic adequacy)**.** *The relational reality of a manifestation mapping and the epistemic adequacy of the manifestations it produces are distinct questions. A mapping can be persistent, stable, and causally efficacious while remaining inaccurate, biased, incomplete, or inappropriate for a particular inferential purpose.*

This distinction is particularly important in GRE. Economic systems are filled with manifestations that guide action because their mappings have become institutionally real: ratings, prices, scores, indicators, legal statuses, performance measures, rankings, and classifications. Their causal power can induce actors to reorganize behavior around them. Once this occurs, a measurement can partially participate in producing the reality it later appears merely to describe. A performance metric can reorganize work; a risk category can change financing conditions; a ranking can redirect attention; a price index can enter contracts; an eligibility threshold can reshape household decisions. The mapping becomes part of the generative field.

Causal efficacy can also operate through reflexivity. Actors can learn the mapping and strategically act upon it. Once a threshold is known, behavior can cluster around the threshold. Once a ranking formula is inferred, participants can optimize for it. Once a legal classification becomes consequential, actors can reorganize transactions to fall inside or outside its categories. Reflexive response does not make the mapping less real. It often provides evidence of its causal incorporation into the system.

At the same time, causal efficacy can contribute to transformation of the mapping itself. Strategic adaptation can expose failures, institutions can revise rules, and accumulated outcomes can alter normative or technical expectations. A manifestation mapping can therefore be both cause and object of later change. This recursive position reinforces the graph architecture: the mapping mediates manifestation, manifested outcomes alter relations, and those relations can return to modify the mapping.

4.8.5 Manifestation Mapping within Relational Reality

The preceding analysis allows manifestation mapping to be located more precisely within the three-register architecture. A mapping is not a fourth register. It is a relation whose analytical status depends on what it does. Some mappings remain hypothetical or representational devices introduced by inquiry. Others become embedded in generative-relational systems and thereby acquire relational reality. Once embedded, they can mediate what becomes manifest while also being transformed by the manifestations and relations they help generate.

Proposition 4.67 (Relational reality of manifestation mapping)**.** *A manifestation mapping belongs to relational reality when its generative-relational emergence, persistence, stability, and causal efficacy are sufficiently established relative to the system and scale under investigation. Its relational reality does not require that the mapping be consciously represented, mathematically exact, epistemically adequate, ontologically fundamental, or universally valid.*

Proposition 4.67 consolidates the section's argument. It also prevents several conflations. First, the mapping's reality is distinct from the ontological reality of what enters or exits the mapping. A perceptual mechanism can be relationally real whether the manifested object is physical, imagined, hallucinatory, remembered, or ontologically unresolved. Second, the mapping's reality is distinct from the reality-status of a particular manifestation. A durable classification system can produce fleeting manifestations, while a transient mapping can occasionally produce a stable recorded output. Third, the mapping's relational reality is distinct from its normative desirability. Persistent and causally efficacious mappings can reproduce exclusion, distortion, domination, or injustice. Reality does not imply legitimacy.

The distinction is also useful for the earlier example of the hallucinatory flower and the ordinarily encountered physical flower. Both can enter manifestational reality, and both can participate in relationally real consequences. Their manifestation mappings can nevertheless differ substantially. One may involve bodily or neurological conditions that generate a flower-like manifestation without a corresponding ordinary external flower; another may involve interactions among an external physical object, sensory apparatus, environmental conditions, memory, and perceptual organization. GR need not place these mappings in one metric space or claim that their structures are directly comparable. It can instead ask whether each mapping is identifiable, persistent, stable, and causally efficacious within its relevant system. Shared relational reality does not require shared generative architecture.

The same caution applies to comparisons among economic mappings. A price mechanism, a religious valuation practice, a legal recognition procedure, an aesthetic judgment, and an algorithmic score can all become relationally real mappings while lacking a justified common metric. Comparison requires an independently warranted relation of comparison. One can sometimes compare causal effects, stability, information loss, accessibility, or institutional reach, but each comparison constructs a domain and selects dimensions. The common label *relationally real* establishes a criterion of reality rather than a universal coordinate system.

This point becomes important for formalization. If an inquiry represents a mani-

festation mapping as

$$\mathcal{M}_C : X \rightsquigarrow Y, \tag{4.1}$$

where C denotes relevant conditions, Equation 4.1 should be interpreted cautiously: the symbol $\rightsquigarrow$ should be read as a deliberately general mapping relation rather than automatically as a single-valued mathematical function. Depending on the domain, $\mathcal{M}_C$ may be deterministic, stochastic, partial, multivalued, path-dependent, or historically variable. The formal representation becomes useful only after the analyst specifies what X, Y, C, and the mapping relation mean in the problem under study. The notation is therefore a compact placeholder for a family of possible structures rather than an ontological claim that manifestation universally follows one mathematical form.

Remark 4.68 (Mapping and graph architecture)*.* When a manifestation mapping becomes relationally real, the graph connecting relational and manifestational registers contains historically generated mediating structures with their own trajectories. The graph is therefore not merely a diagram of static correspondences; its mediating relations can emerge, stabilize, exercise causal efficacy, and transform.

This dynamic graph helps explain why manifestation cannot be treated as the terminal stage of a chain. A relationally real mapping participates in producing a manifestation; the manifestation can enter subsequent action and representation; those consequences can alter the system that sustains the mapping; and the altered mapping can generate different manifestations later. The history of the mapping becomes part of the history of what can appear.

Section 4.8 has therefore elevated manifestation mapping from an implicit bridge to an explicit object of relational analysis. The manifestation-mapping lemma applies the criteria of relational reality to mappings themselves. Stability concerns continuity of organizing relation under variation; persistence concerns continued or recurrent reproduction across a relevant spacetime interval; causal efficacy concerns the difference the mapping makes to later manifestations and relations. When these conditions are satisfied, the mapping is relationally real even while stronger ontological and epistemic questions remain open. The next section turns to a different problem. Once a mapping has been identified, the availability of a manifestation does not guarantee that the mapping can be reversed. Non-invertibility, multiplicity, and loss of relational information therefore become central to any inference from manifestational reality back toward the structures from which manifestation emerged.

4.9 Non-Invertibility of Manifestation

Section 4.8 established that a manifestation mapping can itself become relationally real when it is sufficiently persistent, stable, and causally efficacious within a generative-relational system. The present section examines a different property of such mappings: whether a manifestation can be used to recover, uniquely and adequately, the relational configuration from which it emerged. The central result is a disciplined account of *non-invertibility*. Manifestation may compress, select, transform, aggregate, or contextually reorganize relational differences. Consequently, a manifestational form can be compatible with several relational configurations,

while a given relational configuration can admit several manifestations. These possibilities limit reverse inference from what appears, is recorded, is measured, or is symbolized to the relational reality that participated in generating it. The argument proceeds through many-to-one manifestation, one-to-many manifestation, manifestational equivalence, relational difference beneath manifestational similarity, and the resulting limits of reverse inference.

The term *non-invertibility* is used here in an analytical rather than universally algebraic sense. Some manifestation mappings can be represented by ordinary functions and studied with familiar notions of inverse functions. Others are stochastic, partial, multivalued, historically variable, institutionally mediated, or dependent on conditions that cannot be held fixed across observations. Section 4.8 therefore represented a general manifestation mapping by Equation 4.1, using $\rightsquigarrow$ to indicate a mapping relation whose exact mathematical form remains to be specified locally. Non-invertibility concerns the information and structure that cannot be uniquely recovered when inquiry moves from a manifestational result back toward the relational configurations compatible with it. (Giere 2004)

A convenient formal device is the *compatibility set*. Let $\mathcal{M}_C$ denote a manifestation mapping under relevant conditions C, let X denote a selected space of relational configurations, and let Y denote a selected space of manifestations. For a manifestation $y \in Y$, define the set of relational configurations compatible with y under C by Equation 4.2.

$$\mathcal{P}_C(y) = \{x \in X \mid x \; \mathcal{M}_C \; y\}\,. \tag{4.2}$$

The notation in Equation 4.2 does not assume that X or Y is metric, that $\mathcal{M}_C$ is deterministic, or that every relevant relational configuration has already been exhaustively specified. It identifies a local inverse problem: given a manifestation and a specified manifestation regime, which relational configurations remain compatible with what has become manifest? When the compatibility set contains several materially different configurations, manifestation underdetermines relational reconstruction.

Definition 4.69 (Manifestational non-invertibility)**.** A manifestation mapping is *non-invertible for a specified inquiry* when the available manifestation, together with the mapping conditions and admissible evidence, does not support unique and warranted recovery of the relevant antecedent relational configuration at the scale required by that inquiry.

Definition 4.69 makes non-invertibility relative to an inquiry, scale, and evidential regime. A mapping can be invertible with respect to one coarse variable while remaining non-invertible with respect to a finer relational history. A measurement may uniquely determine a reported category while failing to determine the heterogeneous trajectories that produced that category. A legal status may uniquely identify the institutionally recognized state of a person while leaving the underlying social, economic, and historical relations radically underdetermined. Conversely, additional manifestations or interventions can sometimes narrow the compatibility set. Non-invertibility therefore concerns the relation between available manifestation and warranted reconstruction rather than an assertion that recovery is impossible under every conceivable extension of evidence.

4.9.1 Many-to-One Manifestation

Many-to-one manifestation occurs when materially different relational configurations generate the same, or sufficiently similar, manifestational form under the relevant conditions. This is the most direct source of non-unique reverse inference. If several relational configurations belong to $\mathcal{P}_C(y)$, observing y establishes compatibility with each of them until further evidence differentiates among the alternatives.

Definition 4.70 (Many-to-one manifestation)**.** A manifestation mapping exhibits *many-to-one manifestation* relative to conditions C when two or more relationally distinguishable configurations are compatible with a common manifestational form, or with forms treated as indistinguishable under the operative manifestational criterion.

The source of many-to-one manifestation can differ across domains. A mapping may aggregate several relational configurations into one category. An instrument may register only one dimension of a multidimensional process. An institutional procedure may intentionally suppress distinctions judged irrelevant to its purpose. A perceptual system may resolve several materially different stimuli into one recognizable form. A statistical summary may retain an average while discarding distributional structure. A market price may summarize heterogeneous beliefs, constraints, liquidity conditions, institutional rules, and strategic positions without uniquely revealing their composition. In each case, the manifestation can remain highly useful while carrying less relational information than the configuration from which it emerged.

Compression is therefore one important mechanism of many-to-one manifestation. Compression should be understood broadly. It includes numerical aggregation, categorical classification, perceptual simplification, institutional standardization, linguistic naming, algorithmic feature selection, and other processes through which a richer relational field is rendered into a lower-dimensional or less differentiated manifestational form. The compressed manifestation can be stable and causally powerful. Its stability does not restore the distinctions removed during manifestation.

Many-to-one manifestation can also arise without deliberate compression. Different histories can converge on similar configurations at the point of manifestation. Distinct causal paths can produce the same observed outcome. Heterogeneous social relations can produce similar behavioral regularities. Different institutional arrangements can yield the same reported indicator over a limited interval. Distinct bodily, perceptual, and environmental configurations can generate similar experiences. The manifestational similarity can therefore result from convergence rather than from a single mechanism that intentionally groups diverse inputs.

The distinction between *same manifestation* and *sufficiently similar manifestation* matters. Exact equality is often unavailable or analytically unnecessary. A measurement system can treat values within a tolerance interval as the same reading. A legal regime can place heterogeneous cases in the same category. A human observer can experience two appearances as indistinguishable despite physical differences. A model can treat two distributions as equivalent for a selected decision rule. The operative equivalence criterion belongs to the manifestation regime and should be stated rather than presumed.

Claim 4.71 (Manifestational underdetermination)**.** *When a manifestation is generated through a many-to-one mapping, the manifestation alone underdetermines the antecedent relational configuration. Reverse inference requires additional evidence, constraints, interventions, or assumptions capable of differentiating among the configurations that remain compatible with the manifestation.*

Claim 4.71 does not imply that reverse inference is futile. It specifies its evidential burden. If the compatibility set can be reduced through additional manifestations, historical records, controlled interventions, cross-context comparison, or independent knowledge of the mapping, reconstruction can become more informative. The point is that the manifestation does not carry a unique antecedent merely by virtue of appearing determinate.

This distinction has particular importance for GRE because economic manifestations often appear in standardized forms. A price, score, balance, wage, category, ranking, or aggregate may be numerically precise while remaining relationally underdetermined. Precision of manifestation and uniqueness of generative history are different properties. A highly precise number can summarize a heterogeneous field of relations, just as a coarse category can sometimes correspond to a relatively specific institutional mechanism. The degree of manifestational precision therefore provides limited information about the invertibility of the mapping.

4.9.2 One-to-Many Manifestation

Non-invertibility also arises in the opposite direction. A single relational configuration can generate several manifestational forms across contexts, observers, instruments, symbolic regimes, times, or scales. Section 4.6 already established that manifestational reality is condition-dependent and can take heterogeneous forms. The present subsection makes the consequence for inversion explicit: variation in manifestation need not imply variation in the relational object at the level under investigation.

For a relational configuration $x \in X$, define its admissible manifestation set under conditions C by Equation 4.3.

$$\mathcal{Y}_C(x) = \{y \in Y \mid x \, \mathcal{M}_C \, y\} \, . \tag{4.3}$$

Equation 4.3 allows the manifestation mapping to be multivalued. Even where a deterministic function is appropriate under fixed conditions, variation in C can generate a family of manifestations for the same selected relational configuration. The analyst must therefore distinguish changes in the relational configuration from changes in the conditions through which that configuration becomes manifest.

Definition 4.72 (One-to-many manifestation)**.** A manifestation mapping exhibits *one-to-many manifestation* relative to the selected analytical scale when one relational configuration can become manifest in more than one materially distinguishable form across admissible manifestation conditions.

The qualification *relative to the selected analytical scale* is essential. What appears to be one relational configuration at a coarse scale may contain fine-grained differences that explain manifestational variation. Conversely, an inquiry may have good

reason to treat those differences as irrelevant to its present object. One-to-many manifestation therefore does not establish that an identical microstate generates arbitrary outputs. It states that the relational identity preserved by the inquiry can coexist with plural manifestations.

A monetary relation illustrates the point. The same institutionalized monetary claim may become manifest as a banknote, an account balance, a payment message, an entry in a ledger, a spoken amount, or a displayed price. These manifestations differ materially and symbolically while participating in a relational structure that can remain continuous across them. Likewise, an institutional status can be manifested through a document, database record, uniform, title, access permission, spatial arrangement, or pattern of deference. A relation of trust can become manifest through speech, action, silence, delegation, disclosure, or patterned expectation. The plurality of manifestations does not by itself establish plurality of the relational object.

One-to-many manifestation also appears in scientific and empirical inquiry. A process can leave different traces under different instruments. A latent relation can generate several observable indicators. A historical event can become available through documents, material remains, memories, later institutional records, and statistical consequences. Each manifestation selects and transforms aspects of the underlying relational history. Their differences can be informative precisely because they arise through different manifestation mappings.

This plurality creates a second inverse problem. If one relational configuration can appear in several ways, then inferential procedures that expect a single canonical manifestation can miss relational continuity beneath manifestational difference. A change in representation can be mistaken for a change in the represented relation. A change in instrument can be mistaken for a change in the measured process. A change in symbolic vocabulary can be mistaken for the disappearance of the phenomenon. Conversely, stable terminology can conceal substantial relational transformation. The ontological and epistemic tasks therefore require attention to both directions of mismatch.

Remark 4.73 (Manifestational plurality and identity). Manifestational plurality does not by itself establish either relational identity or relational difference. Whether several manifestations concern one relationally continuous object depends on the persistence, stability, causal organization, and historical continuity that define the relational object at the relevant scale.

Remark 4.73 prevents an opposite overcorrection. The existence of one-to-many mapping does not license the analyst to declare diverse manifestations identical. The relation among them has to be established. The three-register architecture therefore places a burden on both identification and differentiation: similarity of appearance does not establish relational identity, and difference of appearance does not establish relational difference.

4.9.3 Manifestational Equivalence

Many-to-one manifestation requires a concept for cases in which distinct relational configurations cannot be distinguished within a specified manifestation regime. The appropriate concept is *manifestational equivalence*. The term is deliberately weaker

than ontological identity, relational identity, or structural isomorphism. It describes indistinguishability with respect to a specified manifestation mapping and criterion.

Definition 4.74 (Manifestational equivalence)**.** Two relational configurations are *manifestationally equivalent* relative to a specified manifestation regime when the distinctions between them are not expressed in the manifestational forms that the regime recognizes as relevantly distinguishable for the inquiry at hand.

Manifestational equivalence is therefore indexed by a regime. The regime includes the mapping, conditions, resolution, categories, instruments, symbolic resources, tolerances, and analytical purposes that determine what counts as a relevant manifestational difference. Two configurations can be equivalent under one regime and distinguishable under another. The equivalence can also disappear historically when new instruments, categories, practices, or sensitivities make previously unavailable differences manifest.

This relativity does not make manifestational equivalence arbitrary. A regime can have stable procedures and well-specified criteria. Under those criteria, the equivalence may be reproducible and operationally important. Two chemical states can be indistinguishable to one instrument and distinguishable to another; two institutional practices can receive the same administrative code while producing different lived consequences; two economic trajectories can yield the same quarterly aggregate while diverging in distribution, vulnerability, or future capacity. In each case, equivalence is real relative to a manifestation regime while remaining narrower than identity of the relational configurations.

Proposition 4.75 (Locality of manifestational equivalence)**.** *Manifestational equivalence warrants claims of indistinguishability only relative to the specified manifestation regime and criterion. It does not, by itself, warrant ontological identity, relational identity, equal causal structure, equal historical trajectory, or interchangeability across other manifestation regimes.*

Proposition 4.75 is especially important for comparative analysis. A common indicator can create an equivalence class that is useful for one purpose. Treating the same equivalence class as valid for another purpose requires additional justification. Equal income at one date does not imply equal wealth, security, capabilities, obligations, histories, or future opportunities. Equal test scores do not imply identical learning processes. Equal prices do not imply identical market structures. Equal institutional classifications do not imply identical relations of power. The manifestation criterion selects the dimension of equivalence; it does not silently generalize that equivalence to every other dimension.

Manifestational equivalence can itself become relationally consequential. Once an institution treats distinct cases as equivalent, resources, rights, obligations, attention, or sanctions may be allocated according to the shared manifestation. The equivalence relation then becomes part of the generative-relational system. An administrative category can make heterogeneous persons institutionally interchangeable for one procedure. A credit category can group heterogeneous borrowers and alter their future financing conditions. A ranking band can group organizations and affect later demand. A standardized diagnosis can coordinate treatment while also reorganizing self-understanding and institutional response. In these cases, manifestational equiv-

alence begins as a criterion of indistinguishability and can become part of the relational reality that shapes future trajectories.

This recursive possibility reinforces the graph architecture developed throughout the chapter. Manifestational equivalence can be generated by a relationally real mapping; the manifested equivalence can guide action; those actions can reshape subsequent relations; and the resulting relational changes can alter later manifestation mappings. Equivalence is therefore neither a passive label nor a guarantee of deep sameness. It can be an active component in the historical production of similarity and difference.

4.9.4 Relational Difference beneath Manifestational Similarity

The most important ontological consequence of non-invertibility is the possibility that substantial relational difference persists beneath manifestational similarity. A manifestation can be shared while the relations that generated it differ in organization, history, scale, causal mechanism, or normative significance. GR therefore treats the relational structure beneath a manifestation as an open object of inquiry rather than as something uniquely disclosed by appearance.

The example of the hallucinatory flower and the ordinarily encountered physical flower makes the distinction vivid. Both can enter manifestational reality as a flower-like appearance. Both can become causally consequential for attention, movement, memory, language, or subsequent action. Yet the relational configurations through which the manifestations arise can differ substantially. One may involve bodily or neurological conditions that generate a flower-like percept without the ordinary external object; another may involve an external physical flower, environmental conditions, sensory transduction, perceptual organization, memory, and learned categorization. The fact that both are manifestationally available as a flower does not establish a common generative structure, and GR has no need to presume that the two structures belong to a single metric space.

This example also shows why relational reality and manifestational reality should remain distinct. A hallucinatory flower can participate in relational reality if the generated object persists sufficiently and exerts causal efficacy within the relevant system. The relational reality of that object does not depend on identifying its generative structure with the structure of an ordinarily perceived physical flower. Shared manifestational form and shared relational reality-status therefore remain compatible with structural heterogeneity.

The same pattern appears in less unusual cases. Two organizations can report the same productivity indicator while relying on different labor relations, technologies, environmental externalities, or temporal strategies. Two households can report the same income while occupying different debt structures, care obligations, legal statuses, social networks, or exposure to risk. Two communities can exhibit similar rates of participation while differing in trust, coercion, institutional accessibility, or cultural expectations. Two artificial systems can produce similar outputs while relying on different architectures, data histories, or inference procedures. In each case, manifestational similarity narrows some differences while leaving others unresolved.

Claim 4.76 (Relational remainder beneath manifestation)**.** *For a specified manifestation regime, relational differences that do not alter the recognized manifestation constitute a* relational remainder *relative to that regime. Such differences can remain causally and historically significant even while they are absent from the manifestational distinction used by the inquiry.*

The term *remainder* does not imply that the omitted relations are secondary in reality. They are a remainder only relative to a particular manifestation regime. A variable excluded from an indicator can be central to later dynamics. A relation invisible to an administrative category can structure access to resources. A historical difference suppressed by aggregation can determine vulnerability under future disturbance. A symbolic system can render one distinction salient while leaving another difficult to articulate. The remainder is therefore an analytical warning against treating the dimensions made manifest as exhaustive of the relational configuration.

Relational remainder also clarifies why greater manifestational detail does not automatically eliminate non-invertibility. Adding variables can reduce the compatibility set, but every representation selects a domain, scale, resolution, and set of distinctions. A richer manifestation can reveal differences that a coarser regime concealed while still leaving other differences unexpressed. Complete inversion would require a specification of what counts as the full relational configuration and a mapping that preserves every distinction relevant to the inquiry. In many social, economic, historical, and perceptual settings, that requirement is stronger than the available evidence can support.

This point should be kept separate from skepticism. GR does not infer that knowledge is impossible because manifestation can be non-invertible. It infers that knowledge claims should be calibrated to the information preserved by the manifestation regime and to the additional evidence used in reconstruction. An inquiry can learn a great deal from a non-invertible mapping. It can identify equivalence classes, exclude incompatible explanations, estimate probabilities, compare mechanisms, reconstruct partial histories, and test interventions. The loss of unique inversion calls for epistemic discipline rather than epistemic paralysis.

4.9.5 Limits of Reverse Inference

Reverse inference begins from a manifestation and attempts to reconstruct relational structures, histories, mechanisms, or objects compatible with it. The analysis above yields a general constraint: the warranted strength of reverse inference depends on the structure of the manifestation mapping, the size and heterogeneity of the compatibility set, the stability of the conditions, and the availability of independent evidence. Manifestation can support inference without transparently revealing its antecedent relational reality.

Proposition 4.77 (Reverse-inference discipline)**.** *An inference from manifestational reality toward relational reality should state the manifestation regime, identify plausible multiplicity in the compatibility set, distinguish assumptions supplied by the analyst from information preserved by the manifestation, and limit the reconstructed claim to the level supported by the available evidence.*

The principle has several consequences. First, a manifestation should not be

treated as a self-interpreting trace. A number, category, statement, image, behavior, or institutional record becomes evidentially informative through knowledge of the relations and mappings that produced it. Second, reconstruction gains strength when independent manifestations arise through partially different mappings. If several traces with different failure modes converge on a compatible relational account, the compatibility set can become narrower. Third, interventions can sometimes distinguish among otherwise manifestationally equivalent configurations. Changing a condition and observing differential response can reveal structure that passive observation leaves hidden. Fourth, historical reconstruction requires attention to mapping change. A category recorded in one period can have a different generative and institutional meaning in another period even when the visible symbol remains constant.

Reverse inference can also be asymmetric across directions. A mapping may reliably predict a manifestation from a relational configuration while providing weak reconstruction from manifestation to configuration. If a broad range of configurations all produce the same output, forward prediction can be stable while inverse identification remains underdetermined. Conversely, a manifestation can sometimes be highly diagnostic of a narrow class of relational structures even when forward manifestation is probabilistic. The epistemic properties of the forward and reverse problems therefore need separate assessment.

This asymmetry is important for causal interpretation. A causal model can identify how a specified relation would affect manifestation under defined conditions without claiming that every observed manifestation uniquely identifies that cause. Similarly, an institution can reliably translate a legal status into a standardized record while the record alone remains insufficient to reconstruct the full path through which the status was obtained. Predictive adequacy in one direction does not guarantee explanatory uniqueness in the other.

Remark 4.78 (Manifestation and disclosure)*.* A manifestation can disclose genuine aspects of relational reality while remaining non-invertible with respect to the relational configuration as a whole. Partial disclosure and non-unique reconstruction are compatible.

Remark 4.78 protects the chapter from two opposed simplifications. Manifestation is more than arbitrary projection because it can be constrained by, and informative about, relational reality. Manifestation is also less than exhaustive disclosure because the mapping can transform or suppress relational differences. The three-register framework therefore allows a manifestation to be real, constrained, causally consequential, and epistemically useful without treating it as a transparent duplicate of what generated it.

The same discipline applies to symbolic and representational forms, which become central in Section 99. Symbolization can preserve some differences, create new distinctions, stabilize categories, and make relations transmissible across time and space. It can also compress, standardize, and reorganize what becomes manifest. A symbol can therefore increase epistemic reach while adding another mapping whose invertibility requires examination. The transition from manifestation to symbolization should consequently be treated as a further generative relation rather than as a neutral copying operation.

Section 4.9 has established non-invertibility as a structural possibility within the three-register architecture. Many-to-one manifestation generates underdetermination because several relational configurations can be compatible with one manifestational form. One-to-many manifestation generates plurality because a relational configuration can become manifest differently across conditions and regimes. Manifestational equivalence identifies local indistinguishability without converting it into ontological or relational identity. Relational remainder names differences that remain outside a specified manifestation criterion while potentially retaining causal and historical significance. Reverse inference is therefore possible under disciplined conditions, but its strength depends on the mapping, the evidence, and the scale of reconstruction. These results prepare the analysis of symbolization, where manifestations can become stabilized, transmitted, classified, and recursively incorporated into later relational reality.

4.10 Symbolization and Manifestation

Section 4.9 established that manifestation can preserve genuine information about relational reality without providing a uniquely invertible image of the relational configuration from which it emerges. The present section introduces a further mediation: symbolization. Its role is to distinguish manifestation from the processes through which manifestations, relations, subjects, values, and other objects are rendered in symbolic form. Symbolization is analytically important because symbols can preserve distinctions across time and space, make heterogeneous objects administratively or economically comparable, coordinate action among actors who do not share immediate experience, and enter institutions as operative records, categories, rules, and representations. These capacities give symbolic forms unusual generative reach. They also make it especially important to avoid treating symbolization as transparent copying. (Cassirer 1955; Bourdieu 1991; Wittgenstein 2009; Espeland and Stevens 1998)

The argument proceeds in six steps. It first separates manifestation from symbolization and defines a symbolic regime. It then examines symbolic representation as a selective relation rather than an identity between symbol and represented object. The following three subsections consider the symbolization of relations, subjects, and value. The final subsection asks when representations themselves become part of relational reality. Throughout, the method remains consistent with the three-register architecture: symbolization can mediate relational reality without being a prerequisite for relational reality, and symbolic efficacy does not establish that the represented object possesses the ontological status attributed to it.

4.10.1 Manifestation and Symbolization

Manifestation and symbolization overlap in many concrete cases but remain distinct analytical operations. A bodily sensation, a sudden interruption of expectation, a visible pattern, an affective response, a material trace, or a behavioral change can become manifest without first being encoded in a symbolic system. Conversely, a symbolic inscription can persist and circulate beyond the immediate manifestation

through which it was first produced. The distinction therefore protects two claims already established in the chapter: relational reality can precede symbolization, and manifestation is broader than symbolic representation.

Definition 4.79 (Symbolization)**.** *Symbolization* is a generative-relational process through which a difference, object, relation, manifestation, possibility, or constructed category is rendered in a symbolic form whose differentiation and use are organized by a symbolic regime.

The definition is deliberately broader than linguistic naming. Numbers, diagrams, legal categories, monetary denominations, account identifiers, rankings, scores, icons, mathematical expressions, database fields, ritual signs, and conventional gestures can all participate in symbolization when their differences are organized within a system of use. A symbol need not resemble what it represents. Its efficacy can arise from the relations through which a community, institution, technical system, or practice distinguishes the symbol, connects it to other symbols, and treats it as relevant to subsequent action.

Definition 4.80 (Symbolic regime)**.** A *symbolic regime* is a relatively organized set of relations, distinctions, conventions, procedures, media, and practices through which symbolic forms are produced, differentiated, interpreted, transmitted, or made operative within a specified generative-relational system.

A symbolic regime can be highly explicit, as in accounting standards, legal codes, programming languages, or administrative taxonomies. It can also be distributed across practice, as in ordinary language, professional conventions, ritual forms, or culturally stabilized categories. The regime may contain formal rules without being reducible to those rules. Institutional enforcement, habitual use, technological infrastructure, historical inheritance, and embodied competence can all contribute to the persistence of symbolic organization.

Symbolization therefore adds a further mapping to the architecture developed in Sections 4.7–4.9. A manifestation can be selected, segmented, named, quantified, classified, or otherwise encoded. Yet symbolization can also target something that has not been fully manifested to a particular subject. An automated system may classify a transaction, assign an identifier, or generate a score without any human observer first experiencing the underlying relation in an immediate perceptual form. Symbolic mediation is consequently not equivalent to conscious interpretation.

The limited Lacanian analogy introduced in Section 4.2 is useful at precisely this point. Lacanian accounts of the Symbolic do not treat symbolic order merely as labels added after an independently completed field of experience; symbolic relations can organize positions, differences, and possibilities within which later experience and subject formation occur (Johnston 2026). GR does not import Lacan's specific account of language, desire, or subjectivity. The relevant architectural insight is narrower: symbolic mediation can be constitutive of subsequent relations rather than only descriptive of antecedent ones. This is one reason the three registers are represented as a graph rather than a chain.

Claim 4.81 (Symbolization is neither necessary nor terminal)**.** *Relational reality does not require prior symbolization, and symbolization does not constitute a terminal stage of manifestation. Once symbolic forms enter subsequent relations, they can participate*

in further manifestation, stabilization, classification, coordination, and transformation.

Claim 4.81 prevents two opposed reductions. A pre-symbolic relation need not be unreal merely because no vocabulary yet captures it. At the same time, a symbolic representation need not remain external to the object it represents. A new legal name, scientific category, market quotation, diagnosis, public label, or institutional identifier can alter the relations through which the represented object subsequently develops. Symbolization belongs inside generative history when it becomes causally operative.

4.10.2 Symbolic Representation

Symbolic representation is one important use of symbolization, but representation should not be treated as identity. A representation selects differences, organizes them through a symbolic regime, and presents them in a form suited to some practice, audience, institution, medium, or inquiry. The represented object can therefore exceed the representation even when the representation is accurate for its stated purpose.

Definition 4.82 (Symbolic representation)**.** A *symbolic representation* is a symbolically organized object, expression, record, or configuration that stands in a specified representational relation to another object, relation, manifestation, possibility, or constructed target within a symbolic regime.

The term *specified* matters. The same inscription can represent different things under different regimes. A number may denote a price, quantity, rank, probability, account balance, legal threshold, or arbitrary identifier. A word can function as a name, category, command, promise, quotation, or fictional designation. An arrow in a diagram can indicate causation, implication, flow, sequence, correspondence, or merely graphical connection. Representation therefore depends on the relations that organize symbolic use rather than on the mark considered in isolation.

Symbolic representation inherits the non-invertibility examined in Section 4.9. Several relational configurations can be represented by the same symbolic category, while one relational configuration can receive different symbolic descriptions under different regimes. The symbolic form can compress history, suppress differences, aggregate relations, or introduce distinctions that were not previously operative. A category can be highly useful while remaining coarse relative to the relational domain. A detailed representation can preserve more distinctions while still leaving a relational remainder.

This selectivity is not necessarily a defect. Representation is often useful precisely because it reduces complexity. A balance sheet excludes many features of an organization so that specified claims and obligations become legible. A map suppresses most properties of a landscape so that spatial relations relevant to navigation become visible. A legal category narrows heterogeneous histories into a form that permits institutional decision. A statistical variable makes comparison possible by holding some distinctions constant. The relevant question is not whether representation reproduces everything, but what it preserves, what it transforms, what it omits, and what later action is organized through it.

Remark 4.83 (Representational adequacy is purpose-relative)*.* A symbolic represen-

tation can be adequate for one inquiry or practice while remaining inadequate for another. Adequacy therefore requires a stated purpose, scale, domain, and set of distinctions rather than an abstract demand for total correspondence.

Purpose-relative adequacy does not make representation arbitrary. A representation can fail because it omits a causally important distinction, misclassifies the object, applies a rule outside its domain, or produces consequences inconsistent with its stated purpose. The point is instead that symbolic adequacy is evaluated through a relation among representation, target, use, and conditions. No single representation is required to exhaust every relation in which an object participates.

Symbolic representation also introduces a distinction between the reality of the representation and the reality of its referent. A record can exist and be causally effective even if the proposition encoded in it is mistaken. A name can organize collective action even when the named object has uncertain ontological status. A false account balance, erroneous risk classification, or inaccurate administrative record can alter access, behavior, and expectations. The symbolic object and the truth of what it represents are therefore analytically separable.

4.10.3 Symbolized Relations

Relations frequently become actionable through symbolization. Contracts, titles, organizational charts, kinship terms, debt records, network links, legal statuses, platform connections, and institutional roles render some relation sufficiently explicit that it can be stored, communicated, enforced, compared, or incorporated into later decisions. Symbolization can thereby increase the persistence and reach of a relation without exhausting the relation itself.

A symbolized relation is not simply a picture of an antecedent connection. The act of recording, naming, or classifying a relation can change the relation's future trajectory. A debt entered into an enforceable ledger differs from an unrecorded expectation. An employment relation formalized by contract acquires rights, obligations, temporal boundaries, and institutional interfaces that can become causally significant. A platform's designation of two accounts as connected can affect information flow, recommendation, visibility, and later interaction. The symbolic form becomes one of the mediations through which the relation is reproduced.

Definition 4.84 (Symbolized relation)**.** A *symbolized relation* is a relation rendered through a symbolic regime in a form that selects, encodes, or organizes some of its differences and that may subsequently participate in the persistence, interpretation, coordination, or transformation of the relation itself.

Definition 4.84 leaves open whether the symbolic form is constitutive, evidential, descriptive, or merely auxiliary in a particular case. A legal marriage status can partly constitute institutional relations that would not exist in the same form without recognition. A diagram of an informal friendship network may instead be an analyst's representation that has little effect on the represented relations. A public label such as "ally," "competitor," or "debtor" can begin descriptively and later alter expectations enough to become generatively important. The role of symbolization is therefore an empirical and historical question.

Symbolization can also stabilize relations by making them portable across contexts. A credential allows a relation of qualification to travel beyond the place where competence was originally demonstrated. A title allows ownership claims to be recognized by actors who did not witness the original acquisition. A contract allows obligations to persist despite changing memories and personnel. A standardized code allows an institutional relation to be processed by distant offices or automated systems. Symbolization can thus extend relational efficacy across spatial, temporal, and organizational discontinuities.

This portability has limits. The symbolic relation can outlive the conditions that initially made it accurate. A category may persist after the underlying relation has transformed. A database can reproduce an outdated status. A contractual label can conceal asymmetries that the formal description does not register. A network edge can imply a homogeneous connection even when the relation changes in intensity, direction, or meaning. Symbolization increases persistence partly by reducing the number of differences that must be reproduced, and that reduction can later become a source of distortion.

4.10.4 Symbolized Subjects

Subjects are especially vulnerable to confusion between relational reality and symbolic representation because modern institutions operate through names, identifiers, roles, statuses, profiles, records, classifications, and credentials. These symbolic forms make subjects legible to systems that could not otherwise coordinate across large populations and long time horizons. They can also become part of the processes through which subject positions are stabilized.

A person can possess relationally effective subjecthood before or beyond any particular representation. Bodily continuity, memory, practical orientation, recognition by others, participation in institutions, and histories of interaction can sustain a subject across changes in name, account, role, or classification. Conversely, a symbolic subject can be generated institutionally even when the deeper ontological status of subjecthood remains unsettled. A corporation, state agency, software account, autonomous system, or legal estate can be treated as a subject for specified operations without GRE inferring that all such subjects share the same metaphysical or moral status.

Definition 4.85 (Symbolized subject)**.** A *symbolized subject* is a subject-position rendered within a symbolic regime through names, identifiers, categories, roles, records, credentials, profiles, or related representational forms that permit the subject to be recognized or acted upon within specified relations.

The definition refers to a subject-position rather than to the complete subject. This distinction is important. An institutional identifier can be necessary for taxation, payment, healthcare, education, migration, or platform participation while representing only a small subset of the relations through which the person exists. A legal person can be highly effective in contracting and ownership while remaining distinct from a human subject. A computational agent can occupy an operational role in a market or organization without the symbolic role settling questions of consciousness, responsibility, rights, or moral standing.

Symbolized subjecthood can nevertheless become causally powerful. A classification can determine access to benefits, credit, employment, insurance, mobility, or legal procedures. A professional title can organize expectations and authority. A public reputation can affect bargaining position. A profile assembled from behavioral traces can shape which opportunities become visible. Once these symbolic forms enter repeated institutional action, they can become part of the relational reality through which the subject's later possibilities are generated.

The possibility of misrepresentation is therefore normatively and economically significant. A mistaken or reductive representation of a subject can still have real effects if institutions act upon it. The subject may be forced to respond to a symbolic object that has acquired causal efficacy independently of its accuracy. This is another instance in which relational reality and epistemic adequacy must remain distinct: a representation can be relationally real in its consequences while being false, incomplete, outdated, or unjust.

4.10.5 Symbolized Value

Economic life depends heavily on symbolic forms of value. Prices, wages, account balances, exchange rates, ratings, scores, rankings, budgets, asset values, accounting categories, and monetary denominations make heterogeneous activities and objects available to calculation and coordination. Yet the presence of a common symbolic scale should not be confused with proof that the underlying values are intrinsically commensurable.

A price is a particularly important example. It can manifest conditions of exchange under a specified market arrangement and can represent a monetary valuation at a particular time. Once displayed, recorded, anticipated, or used as a reference, the price can also affect bargaining, expectations, investment, production, and later prices. The symbolic form therefore does more than report an antecedent value. It can participate in the generation of subsequent valuation relations.

The same is true of non-price representations. A credit score compresses a set of observations and modeling choices into a symbolic scale that can influence lending. A ranking compresses multiple criteria into an ordering that can alter applications, prestige, and resource flows. A performance indicator can reorganize work around what is measured. An accounting category can make one form of contribution legible while leaving another outside the reporting system. Symbolized value can therefore create pathways through which some differences acquire institutional force.

Definition 4.86 (Symbolic commensuration)**.** *Symbolic commensuration* is the construction or stabilization of a common symbolic scale, ordering, category system, or representational coordinate through which heterogeneous objects or relations can be compared for a specified practice, without thereby establishing that their underlying relational structures or values share an intrinsic common metric.

Definition 4.86 connects symbolization to the non-necessary comparability of relational realities established in Section 4.2. Symbolization can generate a practical comparison relation where none was previously available. Monetary units allow unlike goods to enter exchange calculations. Rankings place heterogeneous organizations in a common order. Composite indicators render different observations comparable by

applying weights and normalization rules. These operations can be useful and consequential. Their success as coordination devices does not establish that the compared objects were already elements of one natural metric space.

Claim 4.87 (Symbolic comparability does not establish relational equivalence)**.** *The successful placement of heterogeneous objects within a common symbolic scale or ordering establishes a practical relation of comparison under that regime; it does not by itself establish equivalence, identity, or intrinsic commensurability among the relational realities represented.*

This distinction matters for GRE because symbolic commensuration can redistribute attention and resources. Once a common scale becomes institutionally important, actors may adapt behavior toward improving the represented value. Objects may be redesigned to fit categories. Activities difficult to symbolize may receive less recognition. A symbolic metric can therefore help create the economic field it initially appears merely to measure. The normative evaluation of such a field requires more than checking whether the metric is consistently applied; it also requires asking which relations become visible, which remain outside the scale, and what generative consequences follow from acting through the representation.

4.10.6 Representation within Relational Reality

The preceding subsections converge on a central implication of the three-register architecture: a representation can itself become part of relational reality. The conditions are the same as for other relationally real objects. A symbolic form, symbolic regime, or representation must emerge within a generative-relational system, persist with sufficient stability over a relevant region or interval, and exercise causal efficacy within that system. Symbolicity alone is insufficient; relational efficacy is what makes the representation relationally real.

Proposition 4.88 (Relational reality of representation)**.** *A symbolic representation or symbolic regime qualifies as relationally real relative to a generative-relational system when it is sufficiently persistent and stable to exercise causal efficacy in the generation, coordination, constraint, interpretation, or transformation of subsequent relations within that system.*

Proposition 4.88 allows representation to be treated symmetrically with the manifestation mappings discussed in Section 4.8. An accounting standard can become relationally real because organizations reorganize reporting, investment, and compliance around it. A currency unit can become relationally real because obligations, prices, and expectations are denominated through it. A legal category can become relationally real because institutions repeatedly act upon it. A public narrative can become relationally real when it persists sufficiently to orient collective action. None of these conclusions requires the representation to be ontologically fundamental or epistemically flawless.

The distinction between causal efficacy and truth is particularly important. A representation can be inaccurate and still cause decisions. A rumor can move a market before being corrected. An erroneous database entry can block access. A mistaken classification can alter treatment by institutions. A misleading indicator can redirect resources. The relational reality of the representation concerns its generated persis-

tence and causal participation, not the truth of every proposition associated with it.

Remark 4.89 (Reality of a representation and truth of a representation). The reality of a representation as an operative object and the epistemic adequacy of what it represents are distinct questions. A representation can be relationally real in its effects while remaining incomplete, inaccurate, contested, or false with respect to its target.

This distinction also prevents a converse mistake. Accurate representation does not automatically imply strong relational efficacy. A carefully verified scientific description can remain causally marginal if it does not enter institutions, practices, decisions, or other subsequent relations. Relational reality depends on how the representation participates in the system, not solely on its correspondence to the represented object.

Symbolic forms therefore occupy a distinctive position in the graph among the three registers. They can arise from manifestations, represent relational realities, encode claims about ontological reality, and become relationally real through their own persistence and causal efficacy. They can also condition later manifestations by organizing what actors, institutions, and technical systems are prepared to recognize. The graph is recursive because a representation produced at one moment can alter the mappings, categories, expectations, and relations through which later reality becomes manifest.

The analysis of symbolization also clarifies why representation cannot be added to the three-register framework as a simple fourth layer above manifestation. Representation is a family of mediated relations that can operate across the graph. A symbolic representation may target a manifestation, a relational object, an ontological claim, another representation, or a possible future configuration. It can remain a transient analytical artifact or become a persistent causal object. Its location is therefore determined by the relations in which it participates rather than by a fixed position in a vertical hierarchy.

Section 4.10 has established six points. Manifestation is broader than symbolization. Symbolization occurs within symbolic regimes whose rules and practices can have histories of their own. Symbolic representation is selective and purpose-relative rather than identical with its target. Relations and subjects can be symbolized in forms that subsequently alter their relational development. Symbolized value can generate practical commensurability without proving intrinsic comparability or relational equivalence. Finally, representations themselves can become relationally real when they persist, stabilize, and causally participate in subsequent generation. These results prepare Section 100, where the book turns from individual mediations to the recursive relations among relational reality, manifestation, representation, and the later relations that they help produce.

4.11 Recursive Relations among Reality, Manifestation, and Representation

Sections 4.5–4.10 separated relational reality, manifestation, manifestation mappings, non-invertibility, and symbolic representation so that each could be analyzed without collapsing into the others. The present section recombines those distinctions into a re-

cursive architecture. Its role is to explain how relational realities can condition what becomes manifest, how manifestations can be stabilized or transformed through representation, and how representations can re-enter the generative-relational system to alter subsequent relations. The resulting structure is neither a linear sequence nor a closed cycle. It is a historically evolving graph in which different pathways can become active, inactive, reinforced, interrupted, or redirected under changing conditions. (Merton 1948; Giddens 1984; Arthur 1989)

The section proceeds in five steps. It first examines the movement from relational reality to manifestation while preserving the possibility that much relational reality remains unmanifested. It then considers the movement from manifestation to representation and the selective operations involved in symbolic articulation. The third subsection treats representation as an input into subsequent relations rather than as a terminal description. The final two subsections distinguish recursive stabilization from recursive transformation. This distinction is important because repeated mediation can reproduce an existing relational reality, but it can also change the conditions under which later reality emerges. Recursion therefore concerns the historical consequences of mediation rather than the mere repetition of a fixed circuit.

Definition 4.90 (Recursive generative mediation)**.** *Recursive generative mediation* is a historically situated process in which a manifestation or representation generated within a generative-relational system subsequently becomes an operative condition, input, constraint, capacity, or object within that system, thereby contributing to the generation of later relations, manifestations, or representations.

Definition 4.90 preserves the graph architecture established in Section 4.2. A manifestation need not arise only after a fully completed relational object, and a representation need not remain outside the relation it describes. Once a manifestation or representation acquires causal participation in subsequent processes, it becomes part of the history from which later configurations emerge. The recursion is generative because later states can differ from earlier states; it is historical because the effects of previous manifestations and representations can accumulate, dissipate, conflict, or become institutionalized over time.

For analytical purposes, one possible local description distinguishes a relational configuration $\mathcal{R}_t$, a manifestational configuration $\mathcal{M}_t$, a representational configuration $\mathcal{P}_t$, and a wider set of relevant conditions $\mathcal{C}_t$ at a time or interval indexed by t. A manifestation relation may be written schematically as

$$\mathcal{M}_t = \Phi_t(\mathcal{R}_t, \mathcal{C}_t), \tag{4.4}$$

while a representational process may be written as

$$\mathcal{P}_t = \Sigma_t(\mathcal{M}_t, \mathcal{R}_t, \mathcal{C}_t). \tag{4.5}$$

The subsequent relational configuration can then be represented schematically by

$$\mathcal{R}_{t+1} = \Gamma_t(\mathcal{R}_t, \mathcal{M}_t, \mathcal{P}_t, \mathcal{C}_t). \tag{4.6}$$

These expressions are not proposed as universal equations of social or economic reality. They provide a compact way to mark three analytical facts: manifestation de-

pends on conditions, representation can depend on more than manifestation alone, and later relational configurations can be affected by what has previously manifested or been represented. The mappings Φ_t, Σ_t, and Γ_t may themselves change historically and may, under the conditions established in Sections 4.5 and 4.8, become relationally real objects within the systems in which they operate.

4.11.1 Relational Reality to Manifestation

The first relation concerns how a relationally real object or configuration becomes manifest under specified conditions. Section 4.5 established that relational reality does not require prior manifestation. An institution, trust relation, debt relation, social expectation, symbolic convention, or historically stabilized sense of self can participate causally in a system even when parts of its operative structure remain outside present awareness, observation, or explicit articulation. Manifestation therefore selects from, responds to, or is generated through relational reality without exhausting it.

Equation 4.4 represents this relation only schematically. The manifestation $\mathcal{M}_t$ is generated through the conjunction of a relational configuration and the conditions under which manifestation becomes possible. Those conditions can include bodily capacities, technical instruments, institutional procedures, cultural categories, attention, spatial position, temporal position, data infrastructure, measurement rules, and prior symbolic expectations. A price becomes manifest through a market and quotation mechanism; an organizational hierarchy can become manifest through decisions, titles, reporting lines, or patterns of deference; trust can become manifest through disclosure, reliance, expectation, or vulnerability; a physical process can become manifest through an instrument whose design selects some differences while suppressing others.

The manifestation relation is therefore selective without being arbitrary. A relational reality can constrain the range of manifestations available under a given regime even when multiple manifestations remain possible. Conversely, a manifestational configuration can suppress, aggregate, or fail to disclose differences that remain causally important in the relational domain. The relational remainder introduced in Section 4.9 is especially relevant here: what remains unmanifested under one configuration may become important under another, and later consequences may reveal that an apparently negligible difference had continuing causal significance.

Claim 4.91 (Manifestational partiality)**.** *A manifestation can be genuinely generated by and informative about a relational reality while remaining partial with respect to the relational configuration, history, and unrealized possibilities through which it emerged.*

Claim 4.91 permits a middle position between transparent disclosure and radical disconnection. Manifestation can carry real information. It can support explanation, evidence, coordination, and intervention. Yet the information preserved by a manifestation depends on the mapping conditions through which it arises. Reverse inference therefore remains disciplined by the plurality of relational configurations compatible with the observed manifestation.

This partiality becomes important in cases of contingency and aesthetic judgment.

A contingent event can become salient to a subject at a particular moment, but the conditions through which that event becomes recognizable as surprising, beautiful, significant, or worthy of attention may have been generated historically before the moment of conscious judgment. Prior encounters, categories, practices, expectations, bodily capacities, institutional histories, and other relations can contribute to a manifestational configuration without first appearing to the subject as explicit objects of awareness. The subsequent judgment concerns a manifestation, but the relational-generative structure enabling that manifestation can precede the judgment. The reality of that structure is therefore not created merely by being noticed.

The same point also protects a distinction between manifestation and ontological access. A manifestation can be generated through a relational reality whose own ontological status remains suspended. The manifestation can then become evidence about relational organization without licensing a stronger claim about ultimate ontology. The graph from relational reality to manifestation consequently remains compatible with the local sufficiency of ontological commitment developed in Sections 4.1 and 4.3.

4.11.2 Manifestation to Representation

A manifestation can subsequently become represented, recorded, named, classified, quantified, narrated, diagrammed, encoded, or otherwise symbolized. Section 4.10 showed that this movement introduces another selective relation. Representation can preserve a manifestation across time, transmit it across space, place it in relation to other manifestations, and make it available to institutions or actors who were absent from the original event. These capacities enlarge the reach of manifestation. They also introduce new sources of transformation.

Equation 4.5 therefore allows $\mathcal{P}_t$ to depend on more than $\mathcal{M}_t$ alone. A representation can incorporate background theories, institutional categories, prior records, legal rules, measurement conventions, or relational knowledge that is not contained in the immediate manifestation. A medical image can be represented differently under different diagnostic categories; an observed transaction can be represented differently under accounting, legal, or statistical regimes; a verbal statement can be classified differently depending on institutional context. Representation is thus not a passive second copy of appearance. It is an organized operation within a symbolic regime.

This operation can make previously dispersed manifestations comparable. A price system places heterogeneous goods within a monetary scale. A ranking places organizations within an ordinal relation. A legal record places heterogeneous histories within a procedural category. A scientific variable can transform observations into comparable measurements. Such symbolic commensuration can enable coordination and analysis while also suppressing differences that do not enter the symbolic scheme. The practical success of representation therefore remains distinct from the claim that the represented realities share one intrinsic metric.

Remark 4.92 (Representation can preserve and transform)*.* Representation can simultaneously preserve selected information from a manifestation and transform the conditions under which that information is interpreted, compared, transmitted, and

acted upon. Preservation and transformation are therefore not mutually exclusive descriptions of the same representational process.

This duality is particularly visible when a representation creates a durable record. A transient manifestation can disappear while its symbolic trace persists. Once preserved, the representation can become available to actors, institutions, or technical systems in later contexts that differ substantially from those of the original manifestation. The later use can therefore generate relations that could not have arisen from the original manifestation alone. Historical records, legal precedents, archives, credit histories, scientific publications, accounting entries, and algorithmic profiles all illustrate ways in which representation can extend the temporal reach of a manifestation.

At the same time, what is represented can feed back into what later becomes manifest. Once actors learn the categories under which they are classified, they may adapt behavior, resist the category, seek inclusion, or reorganize self-understanding. Once organizations know the metrics by which they are evaluated, they may redesign processes to improve those metrics. Once a price becomes publicly quoted, expectations can change before the underlying production relation changes. Representation therefore begins to participate in the conditions of later manifestation even before it qualifies as a stable relational reality in its own right.

4.11.3 Representation to Subsequent Relation

The third relation is the point at which recursion becomes explicit. A representation can enter subsequent relations and thereby alter the generative-relational system from which later realities emerge. Section 4.10 established that a representation can itself become relationally real when it persists with sufficient stability and exercises causal efficacy. The present subsection focuses on what follows once such causal participation occurs.

Equation 4.6 represents the later relational configuration $\mathcal{R}_{t+1}$ as depending, where relevant, on prior relational structure, manifestation, representation, and wider conditions. This dependence need not be direct. Representations can act through institutions, expectations, technologies, incentives, memory, attention, authority, or collective coordination. The same representation can also generate different effects in different relational environments. A legal classification has little force without institutions able to recognize and enforce it; a market quotation acts differently under liquid and illiquid conditions; a self-description has different consequences depending on whether others recognize, contest, or ignore it.

The causal role of representation therefore depends on relational uptake. A symbol becomes generatively consequential when actors or systems are organized so that the symbol can affect later processes. This can occur through explicit interpretation, but conscious interpretation is not required. Automated scoring systems, database constraints, software permissions, payment infrastructures, and algorithmic classifications can produce consequences because technical and institutional relations are organized around symbolic states. A representation can therefore enter subsequent relations through human, institutional, material, or computational pathways.

Proposition 4.93 (Representational recursion)**.** *When a representation generated within a generative-relational system becomes causally operative in later relations, the*

representation becomes part of the historical conditions through which subsequent relational and manifestational realities are generated. Its later effects are therefore not external commentary on the system but part of the system's generative history.

Proposition 4.93 has important consequences for economic analysis. A credit score can affect access to credit, and the resulting access or exclusion can alter later financial behavior that contributes to future scores. A market price can affect production and demand, which then affect later prices. An accounting classification can alter organizational investment, which changes the activity later recorded under that classification. A public forecast can affect expectations and decisions that become part of the later economic configuration. In each case, representation and represented reality cannot be analyzed as permanently external to one another.

The same logic applies to subjectivity. A manifested experience can be narrated, named, or institutionally classified. That representation can affect memory, recognition, expectation, and future conduct, thereby participating in the relational conditions through which later subjectivity develops. The self-description is neither simply identical with the subject nor irrelevant to subject formation. It becomes one relation among others through which a relatively continuous subject can be sustained or transformed.

Aesthetic judgment provides another instructive case. A contingent encounter can become manifest as striking or beautiful; the judgment can then be symbolically articulated, recorded, taught, cited, or institutionalized. Such representations can redirect attention, confer prestige, organize preservation, influence research selection, and shape the conditions under which later observers encounter the object. The judgment therefore participates in a history that can alter the relational reality surrounding the object without implying that the object's earlier relational reality depended on having already been judged.

4.11.4 Recursive Stabilization

Recursive mediation can stabilize a relational reality when later manifestations and representations repeatedly reinforce the relations through which that reality persists. Stabilization is not mere repetition. Each iteration can occur under slightly different conditions, involve different actors, or produce different manifestations while nevertheless preserving enough structure for the relational object to remain recognizable and causally effective across time.

Definition 4.94 (Recursive stabilization)**.** *Recursive stabilization* is the process through which manifestations or representations generated by a relational reality subsequently reinforce, reproduce, coordinate, or restore relations that contribute to the persistence and stability of that relational reality over a relevant spacetime interval.

Money provides a familiar illustration. Monetary relations generate prices, account balances, banknotes, receipts, quotations, and other manifestations and representations. These forms then guide exchange, accounting, debt settlement, planning, and expectation. Repeated use contributes to the persistence of the monetary relation itself. The relational reality of money is therefore reproduced partly through manifestations and representations generated within monetary relations and later

re-entering those relations.

Trust can display a similar pattern without requiring explicit symbolic articulation at every stage. Repeated reliable interaction can generate manifestations of trust such as reliance, disclosure, delegation, or reduced monitoring. Some of these manifestations may be represented through promises, reputational records, narratives, or institutional certifications. Those representations can then support further reliance and coordination. The resulting recursive stabilization can make trust more persistent, although the process remains vulnerable to contradiction, changing conditions, and competing relations.

Institutional categories can also stabilize recursively. A category used to allocate rights, resources, or responsibilities can shape behavior around the category. The resulting behavior can then appear to confirm the category's practical importance, leading to further institutional use. The recursion may be administratively useful, but stabilization alone does not establish epistemic adequacy or normative legitimacy. A poorly founded category can become highly stable when institutional relations repeatedly reproduce it.

Claim 4.95 (Stability does not validate the stabilized representation)**.** *Recursive stabilization can increase the persistence and causal efficacy of a representation or relational object without establishing that the representation is epistemically adequate, normatively desirable, or ontologically fundamental.*

Claim 4.95 is especially important for GRE because economic systems frequently reward what they have already made legible. A metric used for allocation can cause actors to optimize for the metric; the resulting concentration of activity can make the metric appear increasingly representative of the field. A market category can attract capital, talent, and institutional attention; the resulting expansion can make the category appear more naturally given than it was at its emergence. Recursive stabilization can therefore generate historical depth and causal reality around initially contingent classifications.

This mechanism also helps explain why relational realities can exhibit self-reinforcing tendencies without becoming immutable attractors. Stabilization can be local, conditional, and reversible. Competing representations, institutional changes, shocks, new technologies, altered expectations, or previously suppressed relational differences can weaken the recursive support. The relevant analytical question is therefore which feedback pathways currently sustain the relational object, over what interval, and under what conditions those pathways may cease to reproduce it.

4.11.5 Recursive Transformation

Recursion can also transform rather than stabilize. A manifestation or representation can introduce a difference that changes the relations through which later manifestations and representations are produced. In such cases, the system does not simply reproduce an existing relational reality more strongly or weakly. The effective configuration of relations, constraints, capacities, categories, or manifestation rules changes.

Definition 4.96 (Recursive transformation)**.** *Recursive transformation* is the process

through which a manifestation or representation generated within a generative-relational system contributes to changing the relations, constraints, capacities, mappings, or symbolic regimes that condition subsequent relational and manifestational realities.

A new representation can transform the field by creating a distinction that later actors begin to organize around. A legal recognition can change who is able to contract, own, inherit, claim protection, or appear before an institution. A new accounting category can redirect investment and alter organizational boundaries. A scientific classification can reorganize research attention and intervention. A public articulation of an experience can provide a vocabulary through which previously dispersed manifestations become connected, compared, and institutionally recognized. In each case, representation contributes to changing the generative conditions rather than merely preserving an antecedent state.

Transformation can also occur through failure or contradiction. A representation may repeatedly fail to account for observed manifestations. Those mismatches can generate pressure to revise the symbolic regime, alter the manifestation mapping, or reconstruct the underlying relational model. The appearance of anomalies is itself conditioned by available representational resources, but once recognized, anomalies can become relationally consequential by reorganizing inquiry and intervention. Recursion therefore includes pathways in which the system revises the means through which it manifests and represents itself.

The distinction between stabilization and transformation should remain analytical rather than absolute. A recursive process can stabilize some relations while transforming others. The introduction of a standardized metric may stabilize a field of comparison while transforming organizational behavior. A legal reform may transform formal rights while stabilizing deeper resource asymmetries. A new identity category may stabilize recognition for some actors while transforming relations of affiliation and exclusion. GRE therefore requires the scale and object of stabilization or transformation to be specified rather than inferred from the existence of recursion alone.

Proposition 4.97 (Historical recursion of the three-register graph)**.** *In a generative-relational system, manifestations and representations can become historical conditions of later relational reality when they enter subsequent relations with sufficient causal efficacy. The three-register architecture is therefore recursively historical: later relations can depend partly on how earlier relational realities became manifest, represented, interpreted, preserved, and acted upon.*

Proposition 4.97 summarizes the principal result of the section. The graph among ontological, relational, and manifestational reality cannot be adequately understood as a static taxonomy. Relational reality can precede manifestation, yet manifestation can alter later relational reality. Representation can preserve or transform manifestation, yet representation can itself become relationally real. Symbolic regimes can mediate what later becomes manifest, and changing relations can alter the symbolic regimes through which earlier realities were understood. Historical time therefore enters not as an external parameter added after the ontology, but as part of the generative conditions through which the relations among registers evolve.

This recursive architecture also clarifies the limited use of the Lacanian analogy introduced earlier in the chapter. The relevant similarity lies less in matching ontological reality, relational reality, and manifestational reality one-to-one with the Real, Imaginary, and Symbolic than in refusing a simple hierarchy in which one register merely reflects another. Symbolic and manifestational forms can reorganize later relations; relations can condition later manifestation; and some dimensions of reality can remain resistant to the available symbolic or manifestational regime. GR preserves this graph-like intuition while assigning its own criteria of relational reality, causal efficacy, persistence, and historical emergence.

Section 4.11 therefore completes the first major movement of Chapter 4. Sections 4.1–4.11 have established an ontologically restrained three-register architecture in which relational realities can emerge before perception or symbolization, manifestations arise through historically formed mappings, representations can preserve and transform what manifests, and recursive mediation can stabilize or transform subsequent relations. The next movement turns from the architecture itself to particular classes of object that occupy it. Section 101 begins with subjects, asking how subjecthood can be distinguished across ontological, relational, manifestational, and institutionally represented forms without presuming that manifestational equivalence establishes subject identity.

4.12 Subjects across the Three Levels

The three-register architecture developed in Sections 4.2–4.11 becomes especially consequential when the analytical object is a subject. Economic, legal, institutional, interpersonal, and technical practices routinely treat subjects as if their identity were straightforward: a person signs a contract, an organization owns an asset, an account receives a payment, an employee performs a role, or an artificial system selects an action. Yet the apparently simple noun *subject* can refer to markedly different realities. It can refer to an ontological claim about what kind of being exists, a relationally stabilized locus of causal participation, a manifestation through which subjecthood becomes perceptible or experienceable, or an institutional representation through which a system identifies and acts upon a participant. The role of this section is to separate these senses while showing how they can recursively mediate one another. Its objective is to provide an ontologically restrained account of subjecthood adequate to GRE without reducing subjects to representations or presuming that every operationally similar subject shares the same underlying structure. The discussion proceeds from ontological subjecthood to relationally effective subjecthood, manifestational subjecthood, institutional representation, human and artificial subjects, and finally manifestational equivalence without subject identity. (Mead 1934; Ricoeur 1992; Goffman 1959; Honneth 1995)

The distinction extends rather than replaces the conception of the economic subject developed in Chapter 3, Section 75. Chapter 3 treated an economic subject as a relatively stabilized locus of economically consequential participation. The present section asks what kind of reality such a locus has and how that reality can diverge from the ways in which the subject appears, understands itself, or is represented by institutions. A worker, corporation, household, state agency, platform account,

or artificial system can therefore be approached through several registers at once. These approaches need not converge into one exhaustive description. Their analytical value lies partly in making divergence visible.

Definition 4.98 (Register-sensitive subjecthood)**.** *Register-sensitive subjecthood* is an analytical treatment of a subject that distinguishes among claims concerning its ontological status, its relationally stabilized and causally effective participation, its modes of manifestation, and its symbolic or institutional representation, while allowing these dimensions to mediate one another historically.

Definition 4.98 does not imply that every empirical inquiry requires four separate models of the same subject. It supplies a discipline of distinction. When the dimensions coincide sufficiently for the research question, a simpler representation can be appropriate. When they diverge, however, treating them as identical can conceal economically and normatively important mechanisms. A person can remain relationally consequential while disappearing from an administrative record; an institutional profile can persist after the relations that originally produced it have changed; a self-description can alter subsequent conduct; an artificial system can occupy a stable operational position without this position settling questions of consciousness or moral personhood. The registers therefore help specify which kind of subjecthood is being claimed in any particular analysis.

4.12.1 Ontological Subjecthood

Ontological subjecthood concerns the strongest question in the section: what, if anything, the subject is independently of a particular manifestation, classification, role, record, or analytical representation. The formulation is intentionally open. Different ontologies can locate subjecthood in an embodied organism, a persisting person, a conscious field, a process of self-organization, a bundle of capacities, a relationally constituted agent, a narrative continuity, or some combination of these and other structures. GR does not need to adjudicate this entire field before investigating economically consequential subjecthood. The principle of ontological suspension established in Section 4.3 therefore applies with particular force.

The analytical importance of the ontological question remains even when it is suspended. A legal person, a remembered self, a behavioral profile, a biological organism, and an institutional role may all be associated with what ordinary language calls the same subject, yet they select different persistence conditions. The organism can persist through loss of a role. A legal identity can persist through substantial biological and psychological change. A role can persist through replacement of its occupant. A digital profile can persist after the person it represents has ceased to participate in the relevant system. These differences indicate that subject persistence cannot be inferred from a single criterion before the relevant register has been specified.

The sense of “I” provides a particularly instructive case. A continuing self-experience can become relationally real when it emerges through bodily, mnemonic, interpersonal, linguistic, historical, and other relations, persists with sufficient stability, and causally organizes later conduct. The existence of such relational reality does not by itself settle whether there is an ontologically independent, indivisible, or permanently self-identical entity corresponding to that experience. Conversely,

ontological suspension concerning the ultimate status of the self does not weaken the causal reality of self-experience when it organizes memory, commitment, expectation, responsibility, attention, or action. The three-register architecture therefore allows inquiry into the reality of selfhood without forcing immediate passage from causal efficacy to metaphysical conclusion.

The same restraint applies to collective subjects. A corporation can own property, employ workers, enter contracts, borrow, sue, be sued, accumulate reputation, and survive replacement of many of its members. These properties make corporate subjecthood highly consequential in relational and institutional registers. Whether the corporation should also be treated as an ontologically irreducible collective subject is a stronger question. GRE can investigate the generative consequences of corporate action while leaving this stronger issue open unless the research problem makes it operative.

Remark 4.99 (Ontological subjecthood and analytical reference)*.* Suspending a final ontology of the subject does not make the term *subject* empty. It requires the analysis to specify the properties, persistence conditions, capacities, and relations relevant to the inquiry rather than treating ordinary-language identity as a complete ontological account.

Remark 4.99 is especially important for interdisciplinary work. Economics, law, psychology, computer science, biology, and political theory can refer to apparently similar subjects while selecting different properties as causally or normatively relevant. GRE can connect these descriptions where warranted, while preserving the possibility that their objects are only partially overlapping.

4.12.2 Relationally Effective Subjecthood

Relationally effective subjecthood concerns a different question: whether a subject has emerged as a sufficiently persistent and stable locus of participation to exercise causal efficacy within a generative-relational system. This formulation applies the relational-reality criterion from Section 4.5 directly to subjecthood. A subject is relationally effective when actions, expectations, obligations, memories, permissions, capacities, risks, or other consequences can accumulate around a recognizable locus and when that locus subsequently affects the development of the system.

Definition 4.100 (Relationally effective subject)**.** A *relationally effective subject* is a subject-position or subject-configuration that emerges within a generative-relational system, persists with sufficient stability over a relevant spacetime region or interval, and exercises causal efficacy within that system through the organization of action, expectation, attribution, capacity, constraint, responsibility, or subsequent relation formation.

The definition permits considerable heterogeneity in how subjecthood is stabilized. Biological continuity can matter for a human subject. Legal registration can matter for a corporation. Memory and recognition can matter for interpersonal identity. Repeated interaction can stabilize a household or community role. An account, mandate, technical identity, and authorization structure can stabilize the operational position of an artificial system. The common analytical feature is not a common substance but the emergence of a causally consequential locus around which relations

become organized.

This criterion also clarifies why relational subjecthood can precede explicit self-awareness or symbolic recognition. An infant can participate in relations of care, expectation, attachment, dependency, and resource allocation before possessing the symbolic capacities required for a mature self-description. A worker can occupy a structurally consequential position before recognizing its wider institutional significance. A population can be differentially affected by an institutional arrangement before a political or scholarly vocabulary exists through which that position is named. Subjecthood in the relational register therefore does not wait for complete manifestation to the subject itself.

Relational subjecthood can nevertheless be transformed through manifestation. A person who becomes aware of being trusted may act differently because that trust has become manifest. A worker who learns how an institution classifies a role can reinterpret obligations or opportunities. A community that acquires a shared description of its position can coordinate around that description. The manifestation does not create the entire relational history ex nihilo; it enters that history and can reorganize its subsequent development. Subjecthood therefore exemplifies the recursive mediation described in Section 4.11.

Persistence in this register remains relative to the relevant process. A market transaction may require only short-lived identification. Credit, employment, reputation, liability, insurance, inheritance, or long-term cooperation require longer continuity. Some systems construct subject persistence through identifiers, records, biographies, organizational membership, addresses, credentials, or legal continuity. Others rely more strongly on embodied recognition, memory, or recurring interaction. The duration and mechanism of persistence are therefore empirical properties of the relational system rather than fixed attributes of subjecthood in general.

The relational criterion also permits subjecthood to be distributed. A decision attributed to one organization can depend on committees, software, routines, legal mandates, data infrastructures, professional norms, and external constraints. A subject can remain a useful locus of attribution even when the causal organization supporting that locus is internally heterogeneous. The analytical task is then to distinguish the stabilized subject-position from the wider relational architecture that enables it. Relative individuation and relational dependence can coexist.

Claim 4.101 (Relational subjecthood without exhaustive individuation)**.** *A subject can become sufficiently individuated for causal, institutional, or economic analysis while remaining dependent on a wider relational configuration for the persistence, capacities, and boundaries through which that individuation is sustained.*

Claim 4.101 protects GRE from two opposite simplifications. Subjecthood need not be treated as fully pre-given before relation, and relational dependence need not dissolve every subject into an undifferentiated field. The degree and mechanism of individuation are themselves objects of inquiry.

4.12.3 Manifestational Subjecthood

Manifestational subjecthood concerns the ways in which a subject becomes available within a manifestational configuration. The subject may become manifest to itself, to another subject, to an institution, to an instrument, to a public, or to a computational system. These modes can include bodily appearance, speech, action, affect, memory, narrative, performance, biometric signal, statistical pattern, recorded behavior, visual image, or other forms through which some aspect of subjecthood becomes accessible.

Definition 4.102 (Manifestational subjecthood)**.** *Manifestational subjecthood* denotes the reality of a subject insofar as some aspect of that subject becomes available, distinguishable, experienceable, recordable, measurable, interpretable, or otherwise present within a specified manifestational configuration.

Manifestational subjecthood can be fleeting. A facial expression may reveal a momentary affective state without becoming a persistent identity. A statement may disclose an intention that changes shortly afterward. A measurement may reveal one bodily or behavioral feature while leaving many others inaccessible. The entry condition for manifestational reality therefore differs from the persistence condition required for relational reality. A manifestation can be real as manifestation even when it does not stabilize into a durable subject-position.

The first-person case deserves particular care. Self-awareness is a manifestation of subjecthood, yet the relational conditions from which it emerges can precede the moment of explicit awareness. Memory, bodily continuity, habits, language, recognition by others, prior commitments, and institutional histories can participate in stabilizing a subject before those conditions become thematized by the subject. A reflective judgment such as “this is who I am” can then become a new manifestation that feeds back into the relational system. It can alter conduct, expectation, affiliation, memory selection, and the interpretations supplied by others. The manifestational and relational registers thus become recursively coupled without becoming identical.

Manifestation to others can diverge from manifestation to oneself. A person can experience continuity while being institutionally treated as discontinuous because of lost records or changed identifiers. Conversely, an institution can preserve a stable identity while the subject experiences profound discontinuity in self-understanding. A public performance can stabilize one recognizable persona while private experience remains substantially different. The three-register framework allows these differences to be described without requiring one manifestation to stand automatically as the complete truth of the subject.

Manifestations can also conflict. Spoken self-description, observed behavior, physiological measurement, administrative classification, and third-party testimony may disclose different aspects of a subject and can be produced through different manifestation mappings. Their disagreement does not necessarily imply that one simple hidden subject could be reconstructed by choosing the single correct manifestation. Section 4.9 already established that manifestation is generally non-invertible. The subject case makes the implication concrete: multiple manifestations can remain jointly informative while preserving a relational remainder that no one manifestation exhausts.

Remark 4.103 (Plural manifestation of a subject). Different manifestations of a subject can carry different forms of evidential, practical, or institutional relevance. Their plurality does not by itself establish either contradiction or equivalence because each manifestation can depend on a different mapping, audience, purpose, timescale, and relation to the subject's history.

This plurality becomes especially important in economic life. Creditworthiness, productivity, reliability, vulnerability, preference, risk, need, and identity may each be manifested through different procedures. Economic institutions frequently act on these manifestations as though they captured the subject itself. GRE instead asks which aspect became manifest, through which conditions, and with what consequences for later relations.

4.12.4 Institutionally Represented Subjecthood

Institutionally represented subjecthood is a more specific case in which manifestations are selected, symbolized, recorded, and made operational within an institutional system. A legal name, taxpayer identifier, employee number, account, credit file, eligibility category, citizenship status, corporate registration, professional credential, platform profile, or risk score can become a representation through which institutions recognize and act upon a subject. Such representations are often economically decisive because they determine access, liability, authority, visibility, payment, exclusion, or the accumulation of records across time.

Definition 4.104 (Institutionally represented subject)**.** An *institutionally represented subject* is a symbolically or technically stabilized representation through which an institution identifies, classifies, tracks, authorizes, constrains, rewards, sanctions, or otherwise acts upon a purported subject within a specified domain of operation.

The word *purported* is analytically important. The institution's representation can refer adequately to a relationally effective subject, can refer only partially, can lag behind changes in the subject, can combine several subjects, can split one subject across multiple records, or can persist after the relevant relation has ended. The representation and the represented subject are therefore distinguishable objects even when institutional practice treats them as interchangeable.

Represented subjecthood can itself acquire relational reality. An account profile can influence whether a payment is accepted. A credit record can alter borrowing possibilities. A legal status can determine which contracts become available. A credential can organize access to occupations. A platform category can change visibility and expected conduct. Once these representations become persistent, stable, and causally efficacious within the relevant system, they satisfy the relational-reality criterion in their own right. Their causal reality remains distinct from the accuracy or justice of the representation.

This distinction is especially important where institutional systems act faster than subjects can contest their representations. A classification can shape subsequent opportunities and thereby help generate the behavior that later appears to confirm the classification. A profile can influence which information, prices, tasks, or social contacts become available, changing the relational environment from which later manifestations emerge. The representation can therefore participate in producing the

future subject-position that it was initially intended only to describe.

The recursive structure also permits resistance and revision. Subjects can correct records, challenge classifications, strategically present themselves, acquire new credentials, create alternative institutions, or refuse particular categories. Institutions can redesign identifiers, revise eligibility rules, or abandon representations that produce systematic error. Institutionally represented subjecthood is therefore historically alterable even when its practical effects are substantial.

Claim 4.105 (Representational efficacy and subject accuracy)**.** *The causal efficacy of an institutional representation of a subject can vary independently from the representation's descriptive adequacy to the subject it purports to represent.*

Claim 4.105 extends the distinction developed in Section 4.10. A highly influential profile can be incomplete or mistaken; a highly accurate description can remain institutionally irrelevant. Economic analysis therefore needs separate accounts of representational accuracy, institutional uptake, and causal consequence.

4.12.5 Human and Artificial Subjects

The distinction among registers becomes particularly useful when human and artificial subjects occupy adjacent operational positions. Chapter 3 introduced a working distinction between *human subjecthood* and *artificial operational subjecthood*. The present chapter can now state why that distinction matters ontologically. Two systems can become manifest through similar outputs, occupy similar institutional roles, or even be treated as interchangeable for a bounded task while differing substantially in embodiment, historical formation, dependence relations, vulnerability, ownership, persistence conditions, and the wider structures through which their capacities are generated.

A human subject is relationally situated through bodily existence, care, development, language, memory, social recognition, material dependence, institutional position, and historical participation. Many economically relevant properties of human subjecthood are inseparable from vulnerability and finite embodiment: needs must be met through time, bodily capacities can change, care relations can become necessary, and economic loss can affect lived possibilities. These observations do not provide a complete ontology of the human person. They identify dimensions that are causally and normatively relevant to economic analysis and that should not disappear merely because another system can reproduce a selected manifestation of human performance.

Artificial operational subjecthood can arise when an artificial system becomes a sufficiently stable and causally consequential locus of delegated or institutionally recognized action. A system can select transactions, generate offers, route resources, negotiate within constraints, produce classifications, communicate with counterparties, or maintain a persistent operational identity. Where these functions persist and affect subsequent relations, the artificial system can be relationally real as an operational subject-position. This claim does not require GRE to settle whether the system is conscious, possesses first-person experience, qualifies as a legal person, or has independent moral standing.

The relevant relations surrounding artificial operational subjecthood can include model architecture, training data, deployment infrastructure, ownership, authorization, interface design, objective specification, maintenance, oversight, and liability. These relations can differ radically from those that sustain human subjecthood. Even where a human and an artificial system generate the same answer to a query, execute the same trade, or satisfy the same institutional test, equality of manifestation under that test provides limited information about equality of relational structure.

The same caution applies in the opposite direction. Difference in underlying structure does not imply that artificial systems are economically negligible. A system can occupy a causally central position precisely because institutions, firms, markets, or individuals organize their activity around its outputs. The analytical task is therefore to identify the kind of subject-position that has emerged, the relations that sustain it, the manifestations through which it becomes legible, and the institutions through which its actions are attributed.

Claim 4.106 (Operational subjecthood and ontological restraint)**.** *Attribution of operational subjecthood to an artificial system records a stabilized and causally consequential position within a generative-relational system. It does not, without additional argument, establish experiential, ontological, juridical, or moral equivalence with human subjecthood.*

Claim 4.106 permits GRE to analyze technologically mediated economies without choosing between two unhelpful extremes: treating artificial systems as mere inert tools regardless of their operational role, or treating functional substitution as sufficient evidence of full subject identity. The three-register architecture keeps the empirical consequences of artificial action visible while preserving stronger questions for the domains in which they can be responsibly examined.

4.12.6 Manifestational Equivalence without Subject Identity

The preceding distinctions culminate in the problem of manifestational equivalence. Two subjects can become indistinguishable with respect to a specified manifestation while remaining different in relational organization and with their ontological relation unresolved. The equivalence is therefore local to the manifestation criterion, the conditions under which it is produced, and the purpose for which the comparison is made.

Definition 4.107 (Local manifestational equivalence of subjects)**.** Two subjects are *locally manifestationally equivalent* when, under a specified manifestational configuration and comparison criterion, the manifestations relevant to the inquiry are indistinguishable or sufficiently equivalent for that purpose. Such equivalence does not by itself establish relational identity, ontological identity, equal historical formation, equal capacities outside the comparison domain, or equal normative standing.

The definition applies to human–human, human–artificial, artificial–artificial, organizational, and other comparisons. Two people can produce identical answers while arriving at them through different memories or reasons. Two firms can display the same price while relying on different cost structures and financing relations. Two artificial systems can produce the same output while differing in architecture, training history, ownership, or failure modes. A human and an artificial system can

generate behavior that is indistinguishable through a particular interface while belonging to substantially different relational structures. The manifestation therefore supports an equivalence claim only at the level for which the comparison criterion has been specified.

This point is stronger than the familiar observation that appearances can deceive. A manifestation can be completely accurate with respect to the property it manifests and still remain insufficient for subject identity. If two systems genuinely have the same measured response time, the equality need not be illusory. It simply establishes equality of that measured property. The inference from local equality to global identity requires additional mappings and additional evidence. Non-invertibility therefore arises even when the manifestation itself is reliable.

The relation between an illusory flower and an ordinarily perceived physical flower provides a useful limiting example from the wider architecture of this chapter. Both can become manifest, can enter attention and memory, and can produce subsequent action. Under suitable conditions, the experienced flower can also acquire relational reality through its causal participation in the subject's system. Yet shared manifestational properties such as apparent color, shape, or salience do not establish shared generative structure. The same discipline applies to subjects: similarity in one manifestational domain does not supply a universal metric through which their full relational structures become commensurable.

Manifestational equivalence can nevertheless have powerful institutional consequences. If an institution recognizes subjects only through a narrow interface, subjects that are equivalent under that interface may receive the same permissions, prices, rankings, opportunities, or liabilities. The institution can thereby convert local equivalence into a consequential social fact. Conversely, a representation that distinguishes subjects through an institutionally salient criterion can generate different treatment even when the subjects remain equivalent along many other dimensions. The design of manifestational criteria is therefore itself part of the generative-relational economy.

Claim 4.108 (Subject identity exceeds local manifestational equivalence)**.** *Local manifestational equivalence licenses an equivalence claim only within the specified manifestational domain and comparison criterion. Extension from that equivalence to relational or ontological subject identity requires independent justification.*

Claim 4.108 provides a compact rule for later GRE analysis. It prevents operational tests, institutional classifications, market signals, or behavioral outputs from silently becoming complete ontologies of the subjects they classify. It also preserves the legitimate analytical use of equivalence where a bounded comparison is sufficient. A payment system may need only authorization equivalence; a contractual process may need legal-capacity equivalence; a production model may need task-performance equivalence. The mistake lies in allowing the local criterion to expand beyond the scope it was designed to establish.

Subjects across the three registers can now be understood as historically coupled without becoming reducible to one another. Ontological subjecthood names the strongest and often partly suspended question of what the subject is. Relationally effective subjecthood identifies sufficiently persistent, stable, and causally efficacious

loci of participation. Manifestational subjecthood concerns the modes through which aspects of those subjects become available. Institutional representation stabilizes selected manifestations into symbolic or technical forms through which systems act. Human and artificial subjects can occupy overlapping operational domains while retaining potentially substantial relational and ontological differences. Manifestational equivalence can support bounded coordination and comparison while leaving subject identity open.

This register-sensitive account also prepares the next section. Value and meaning are frequently attributed to, generated by, experienced through, represented for, and circulated among subjects. The same discipline that prevents subject representation from replacing the subject will therefore be required when GRE turns to value and meaning across the three levels.

4.13 Value and Meaning across the Three Levels

Value and meaning are central to economic life because subjects, institutions, and communities act through distinctions concerning what matters, what counts, what is worth preserving or exchanging, and what objects, events, relations, or representations signify. The three-register architecture developed in this chapter permits these phenomena to be examined without collapsing them into either objective properties or subjective reports. The role of this section is to specify how value and meaning can be approached across ontological, relational, and manifestational registers. Its objective is to distinguish the relational reality of value and meaning from stronger claims concerning their ultimate ontological status, normative validity, or semantic truth, while preserving the causal and historical importance of valuation and interpretation. The discussion proceeds from relationally emergent value and meaning to their manifestation, symbolic mediation, partial commensuration, and historical transformation. The method is analytical and reconstructive: the section applies the ontology developed in Sections 4.2–4.11 to evaluative and meaningful phenomena while keeping heterogeneous forms of value and meaning open to later domain-specific analysis. (E. Anderson 1993; Appadurai 1986; Bourdieu 1984; Reber et al. 2004)

Chapter 2, Section 43 reconstructed several existing traditions concerning value, valuation, plural forms of value, and commensurability. The present section has a different task. It asks what kind of reality value and meaning can possess within GR. The answer cannot be supplied by declaring that value is simply subjective, objective, social, or symbolic. A value can be historically generated yet highly stable; it can organize action before being explicitly articulated; it can acquire symbolic representation in prices, rankings, rituals, or categories; and its representation can subsequently alter the relations through which value is generated. Meaning exhibits a parallel complexity. An interpretation can emerge through language, practice, memory, expectation, embodiment, and institutional history; it can become causally consequential before it is formulated propositionally; and its later articulation can transform the field of relations in which it continues to operate.

The resulting framework therefore separates three questions. The ontological question concerns whether value or meaning has a status independent of the par-

ticular relational and manifestational configurations through which it becomes available. The relational question concerns whether evaluative or meaningful structures have emerged with sufficient persistence, stability, and causal efficacy to become relationally real within a generative-relational system. The manifestational question concerns the forms through which value or meaning becomes perceptible, articulable, measurable, symbolizable, or otherwise available under particular conditions. These questions can interact without yielding identical answers.

Definition 4.109 (Register-sensitive value and meaning)**.** *Register-sensitive analysis of value and meaning* distinguishes among their possible ontological status, their relational emergence and causal efficacy, and the particular forms through which they become manifest or represented, while allowing these dimensions to mediate one another historically.

Definition 4.109 preserves two forms of restraint. First, the existence of relationally real value does not by itself establish that whatever is valued is normatively good. Second, the existence of relationally real meaning does not by itself establish that the interpretation is semantically true, referentially successful, or epistemically justified. A society can stabilize harmful forms of valuation. A community can organize action around a false interpretation. These formations can nevertheless be causally real because they structure conduct, institutions, expectations, and subsequent relations. GRE therefore requires a vocabulary capable of studying the reality of value and meaning without treating causal stabilization as moral or epistemic vindication.

4.13.1 Value as Relationally Emergent

Value becomes relationally relevant when something acquires evaluative significance through a generative-relational system and that significance participates in the organization of subsequent action. The relevant relations can include desire, need, use, care, recognition, exchange, scarcity, obligation, attachment, institutional classification, historical memory, ecological dependence, collective identity, or aesthetic orientation. Different forms of value can therefore arise through markedly different structures. The relational account does not require these structures to be reducible to a common mechanism or a single scalar quantity.

Definition 4.110 (Relationally emergent value)**.** *Relationally emergent value* is evaluative significance that emerges within a generative-relational system, persists with sufficient stability over a relevant spacetime region or interval, and exercises causal efficacy by orienting selection, preservation, exchange, allocation, attention, commitment, refusal, or subsequent relation formation.

The definition applies the general relational-reality criterion from Section 4.5. It does not imply that every transient preference is already a relationally real value. A fleeting attraction can become manifest without acquiring sufficient persistence or causal force to organize later relations. By contrast, a durable commitment to a person, a sacred object, a professional norm, a currency, a landscape, an institutional mission, or a form of knowledge can become relationally real when the evaluative orientation survives across situations and affects future conduct.

Relationally emergent value can precede explicit valuation. A child can be embedded in relations of care before possessing a developed vocabulary of value. A com-

munity can sustain practices that preserve a landscape before articulating a formal environmental ethic. A researcher can repeatedly orient attention toward a problem experienced as promising or beautiful before producing an explicit account of why it matters. In these cases, the evaluative structure is already participating in the organization of action even though its later symbolic formulation remains incomplete.

This pre-manifestational possibility is especially important for aesthetic judgment. An object does not need to become explicitly judged as beautiful before the relational-generative-historical conditions that make such a judgment possible begin to exist. The history of training, perceptual formation, disciplinary practice, memory, cultural repertoire, bodily disposition, and previous encounters can already structure susceptibility to a later manifestation of beauty, elegance, significance, or importance. The eventual judgment therefore emerges within a field whose evaluative organization partly precedes conscious recognition.

Relational emergence also permits value to be plural without assuming that every plurality can be converted into one metric. Money, friendship, legal equality, ecological continuity, scientific insight, bodily integrity, cultural memory, and aesthetic experience can all acquire relational reality as forms of value while belonging to different evaluative domains. Some domains support stable conversion procedures; others permit only partial comparison; still others may lack a warranted common ordering for the relevant inquiry. The existence of multiple relationally real values therefore does not itself establish commensurability.

Claim 4.111 (Relational reality and normative validity)**.** *The relational reality of a value establishes that the evaluative formation is sufficiently persistent, stable, and causally efficacious within a relevant generative-relational system. It does not by itself establish the normative validity, justice, desirability, or universal authority of that value.*

Claim 4.111 is indispensable for GRE. Market value, status value, ideological value, discriminatory valuation, and exploitative institutional priorities can become highly stable and causally consequential. Their relational reality is an object of explanation, not a certificate of legitimacy. Normative assessment requires additional arguments concerning justice, capability, freedom, care, ecological consequence, rights, or other relevant standards. The three-register architecture therefore keeps descriptive ontology and normative evaluation connected without allowing one to substitute for the other.

The ontological status of value can remain more open. A moral realist, constructivist, pragmatist, relational theorist, or other philosophical position may offer different accounts of whether some values obtain independently of their historical realization. GR does not need to resolve those disagreements in order to study how value becomes causally effective in economic systems. Ontological suspension is especially useful here because it permits strong claims about the historical reality of valuation while leaving stronger metaethical questions available for separate treatment.

4.13.2 Meaning as Relationally Emergent

Meaning concerns the significance through which an object, event, relation, sign, practice, or possibility becomes situated within a field of interpretation and action.

It can involve semantic reference, practical significance, narrative orientation, institutional interpretation, affective salience, symbolic association, or a subject's understanding of what an encounter means for subsequent conduct. These modes should not be reduced to a single linguistic model. A gesture can carry meaning without being a sentence; a price can signal scarcity or prestige; a ritual can organize belonging; a legal category can determine institutional consequence; and an unexpected event can acquire significance before its interpretation becomes verbally explicit.

Definition 4.112 (Relationally emergent meaning)**.** *Relationally emergent meaning* is significance generated through a relational configuration that persists with sufficient stability and exercises causal efficacy by organizing interpretation, expectation, attention, memory, orientation, communication, or subsequent action within a generative-relational system.

Meaning in this sense can be relationally real before it is fully symbolized. A familiar place can carry significance through repeated embodied and interpersonal relations without that significance being translated into a proposition. A social role can orient expectation before participants articulate its rules. A contingent encounter can become structured as potentially significant through a subject's history before the subject becomes reflectively aware of what the encounter means. Symbolic language may later stabilize and communicate such meanings, but symbolization is one mediating pathway rather than a universal prerequisite.

The distinction between relational meaning and semantic truth is parallel to the distinction between relational value and normative validity. A rumor can acquire meaning and alter behavior even when its propositional content is false. A mistaken diagnosis can reorganize a person's expectations, institutional treatment, and future decisions. A fictional character can possess enduring cultural meaning without being an ontologically existing historical person. A religious symbol can become highly consequential within a community while its associated metaphysical claims remain subject to independent inquiry. The causal reality of meaning therefore concerns what the interpretation does within a system, while truth concerns a different relation whose criteria depend on the relevant epistemic domain.

Claim 4.113 (Meaning and truth)**.** *The relational reality of a meaning records the persistence, stability, and causal efficacy of an interpretive formation. It does not by itself establish the truth, referential adequacy, or epistemic justification of the interpretation through which that meaning is organized.*

Claim 4.113 protects the framework from a form of relational relativism. GR can recognize that meanings are historically and relationally generated while also allowing evidence, logical consistency, causal inquiry, testimony, measurement, and other epistemic practices to constrain claims about truth. Relational generation explains how an interpretation becomes operative; it does not make every operative interpretation equally warranted.

Value and meaning also interact without becoming identical. Something can be meaningful without being positively valued. A traumatic site can carry intense meaning while being associated with aversion. A market price can be valuable as information for one actor while symbolizing exclusion for another. A mathematical conjecture can possess meaning within a disciplinary history before a community attributes

high research value to it. Conversely, something can be valued instrumentally while carrying little broader meaning for the subject who uses it. GRE therefore benefits from treating evaluative orientation and interpretive significance as partially coupled dimensions rather than interchangeable terms.

4.13.3 Manifestation of Value

Relationally emergent value becomes manifest through heterogeneous forms. A price, ranking, vote, award, credential, investment decision, act of preservation, ritual gesture, refusal to sell, allocation of time, emotional response, legal protection, or pattern of care can each manifest evaluative significance under particular conditions. None of these manifestations is automatically exhaustive. A market price can manifest one institutionally stabilized form of valuation while leaving other forms of value unexpressed. A conservation designation can manifest institutional recognition while only partially representing the attachments, ecological dependencies, or historical meanings through which the protected object matters.

Definition 4.114 (Manifestation of value)**.** A *manifestation of value* is a perceptual, behavioral, affective, institutional, symbolic, quantitative, or other form through which an evaluative significance becomes available within a specified manifestational configuration.

The definition preserves the distinction from Section 4.6: manifestation does not require the persistence or stability required for relational reality. A momentary expression of delight can manifest value even if the evaluation does not persist. Conversely, a relationally stable value may remain only partially manifested at any particular moment. The mapping from evaluative structure to manifestation is therefore neither complete nor necessarily invertible.

Economic analysis often relies on manifestations of value because many evaluative processes become observable through choices, bids, prices, quantities, scores, surveys, ratings, or institutional decisions. Such manifestations can be informative, but Section 4.9 implies a discipline of inference. Similar prices can arise from different evaluative structures; similar preferences expressed in a survey can be sustained by different histories; and the same underlying commitment can generate different behavior under changing constraints. An observed manifestation should therefore be treated as evidence about value under specified assumptions rather than as an automatic identity between the measure and the value itself.

Symbolization can further transform the evaluative field. Once a value is assigned a numerical score, price, label, ranking, or category, the symbolic representation can become part of the system through which later valuation occurs. Rankings can redirect attention. Prices can reorganize expectations. Certification can create prestige. Accounting categories can determine which contributions become visible. Repeated symbolic representation can therefore stabilize one evaluative dimension while weakening, obscuring, or transforming others.

This process can create practical commensurability among heterogeneous objects. A price system, index, scoring rubric, or ranking scheme can place previously heterogeneous objects within a shared representational space. Section 4.10 characterized this process as symbolic commensuration. The common metric can become

highly consequential without establishing that the underlying values were intrinsically commensurable before the mapping was imposed or negotiated. GRE should therefore distinguish the existence of a functioning conversion interface from the stronger claim that the converted values share a common evaluative structure.

Remark 4.115 (Manifested value and commensuration)*.* A successful symbolic conversion can make heterogeneous values operationally comparable for a specified purpose. The existence of that comparison does not establish complete equivalence among the relational structures from which those values emerge.

This distinction becomes central for later GRE analysis of allocation, return, exploitation, compensation, and justice. An institution can compensate one loss through money because monetary conversion is legally or practically available while the affected subject continues to experience an irreducible remainder. The existence of exchange does not establish that nothing was lost in translation.

4.13.4 Manifestation of Meaning

Meaning likewise becomes manifest through multiple channels. Speech, writing, gesture, image, bodily orientation, narrative, ritual, classification, architecture, interface design, statistical representation, silence, and patterned action can all make significance available. Manifestational plurality is especially important because the same relational meaning can become differently available across subjects and contexts, while similar symbolic forms can sustain different meanings in different histories.

Definition 4.116 (Manifestation of meaning)**.** A *manifestation of meaning* is a form through which relationally generated significance becomes perceptible, interpretable, communicable, recordable, or otherwise available within a particular manifestational configuration.

The definition makes room for both symbolic and non-symbolic manifestations. A facial expression can make distress manifest before it is named. The spatial organization of a courtroom can manifest authority without requiring a verbal proposition. A recurring economic practice can manifest expectations that participants have never written down. A scientific diagram can render a relation visible in a form unavailable to ordinary perception. Symbolization becomes especially powerful because it allows meanings to be stabilized, transmitted, recombined, compared, archived, and recursively reintroduced into later relations.

The mapping from meaning to manifestation remains context-sensitive and non-invertible. The same sentence can carry different meanings in different histories. Different languages can manifest overlapping meanings without exact structural equivalence. Silence can signify consent in one institutional context and resistance in another. A numerical indicator can be interpreted as evidence of performance, risk, failure, or injustice depending on the relational field in which it appears. Reverse inference from manifestation to meaning therefore requires knowledge of the historical and relational conditions through which the manifestation becomes interpretable.

Meaning can also mediate value. A commodity's price can change when its meaning changes from ordinary good to collectible object. A place can acquire economic value after becoming symbolically associated with heritage. A technology can be-

come desirable because it signifies modernity, status, autonomy, or belonging. Conversely, valuation can reshape meaning by directing preservation, repetition, institutional recognition, and educational transmission toward some interpretations rather than others. The relation between value and meaning is therefore recursive and historically generative.

Aesthetic judgment again offers a useful limiting case. The manifestation of beauty is not reducible to the verbal statement that something is beautiful. Aesthetic salience can appear affectively or perceptually before reflective judgment, while the relational conditions enabling that appearance may have been generated over a much longer history. Once articulated, the judgment can further alter attention, prestige, memory, canon formation, research investment, and transmission. The manifestation therefore both discloses and participates in the future generation of evaluative and meaningful reality.

4.13.5 Historical Transformation of Value and Meaning

Value and meaning are historically transformable because the relations, manifestation mechanisms, representations, subjects, and institutions through which they are generated can change. A value can persist while its manifestation changes. A symbolic representation can persist while the relational value beneath it weakens or shifts. A meaning can survive through translation into new media, or a stable sign can acquire substantially different meanings across periods. Historical analysis must therefore distinguish continuity of representation from continuity of relational structure.

The recursive architecture from Section 4.11 supplies a useful model. At one time, a relationally emergent value or meaning contributes to a manifestation. That manifestation can be represented, recorded, institutionalized, taught, priced, ranked, or contested. The representation then becomes part of the later relational environment in which subjects form new valuations and interpretations. Historical transformation therefore need not occur through replacement of one complete value system by another. It can proceed through gradual changes in the relations among practices, symbols, institutions, subjects, and memories.

Money illustrates the point clearly. Monetary value depends on historically stabilized relations among institutions, legal arrangements, accounting practices, expectations, exchange, and recognition. Monetary symbols then participate in reproducing those relations. A unit of account can persist while its purchasing power, political significance, technological embodiment, and relation to trust change. The representation remains recognizable, yet the relational field through which it is valuable evolves.

The same structure applies to prestige, professional credentials, cultural objects, legal rights, religious symbols, scientific problems, and forms of identity. A credential can remain formally identical while the labor market changes the opportunities it generates. A cultural symbol can retain its visual form while becoming associated with different collective histories. A research problem can acquire greater value after new techniques make it tractable or after a disciplinary community interprets it as theoretically central. Historical change therefore concerns both the objects valued

and the relations through which valuation itself becomes possible.

Claim 4.117 (Historical plasticity of value and meaning)**.** *The persistence of a value or meaning across time can coexist with substantial transformation in the relations, manifestation mechanisms, representations, and subjects through which it is generated and reproduced. Apparent continuity at one register therefore does not establish structural continuity across the others.*

Claim 4.117 also clarifies why GRE should preserve records of category change. If an institution measures "merit," "risk," "productivity," "quality," or "need" across decades, continuity of vocabulary can conceal changing evaluative structures and meanings. A time series may remain numerically continuous even while the social object represented by the variable changes. Conversely, terminology can change while a deeper relational structure remains comparatively stable. Historical comparability therefore requires reconstruction of the manifestation mappings and valuation practices that connect periods.

The three-register view consequently prevents both reification and dissolution. Value and meaning need not be treated as timeless substances in order to be real. Their historical and relational emergence does not make them causally negligible, arbitrarily subjective, or reducible to discourse. When they acquire sufficient persistence, stability, and causal efficacy, they can become relationally real. When they appear through prices, judgments, classifications, emotions, symbols, practices, or institutions, they acquire manifestational forms whose structure can be studied independently. Questions of ultimate value, normative validity, semantic truth, and ontological fundamentality remain distinguishable and can be addressed where the inquiry requires them.

This register-sensitive account prepares the transition to social facts and institutional reality. Values and meanings frequently become durable precisely because institutions stabilize classifications, expectations, obligations, roles, and authorized interpretations across persons and time. Section 103 therefore turns from evaluative and meaningful reality to the institutional structures through which relational realities can become collectively reproducible and causally persistent.

4.14 Social Facts and Institutional Reality

Social facts and institutions provide some of the clearest cases in which the three-register architecture can be applied to economic reality. Money, property, legal status, organizational office, debt, professional qualification, citizenship, contractual obligation, and corporate personality can organize action with considerable durability even though their efficacy cannot be identified with the material objects through which they are manifested. Chapter 2, Section 40 reconstructed several existing accounts of social facts, institutional stabilization, legal constitution, symbolic authority, and historical revisability. The role of the present section is different. Its objective is to specify how such phenomena can possess relational reality within GR, how institutional stabilization alters the persistence and causal reach of social facts, and how legal, monetary, and organizational realities traverse ontological, relational, and manifestational registers. The method is register-sensitive: the section distinguishes

the material and other ontological conditions on which institutions may depend, the relational configurations through which institutional objects persist and act, and the texts, records, symbols, performances, classifications, and interfaces through which institutional realities become manifest.

The central claim is modest but consequential. Social construction does not imply diminished reality. When a socially generated object persists with sufficient stability and exerts causal efficacy within the generative-relational system that sustains it, it can satisfy the criterion of relational reality developed in Section 4.5. Its relational reality does not settle whether it possesses an independent ontological existence, whether its representation is epistemically adequate, or whether the institution is normatively legitimate. A legal status can be relationally real while unjust. A monetary unit can be relationally real without being an ontologically fundamental object. An organizational classification can be causally effective even when it misdescribes the people to whom it is applied. The ontology of institutional life therefore requires several distinctions that become obscured when "socially constructed" is treated either as a synonym for unreality or as a complete theory of what social objects are. (Berger and Luckmann 1966; Searle 1995; North 1990; Ostrom 2005)

Definition 4.118 (Institutional reality)**.** *Institutional reality* denotes the relational reality acquired by socially generated objects, statuses, rules, roles, classifications, procedures, or organized capacities when they are stabilized through sufficiently persistent configurations of recognition, practice, authorization, record, material support, expectation, enforcement, or resource allocation and thereby become causally efficacious within the relevant generative-relational system.

Definition 4.118 intentionally includes several possible stabilizing mechanisms rather than reducing institutions to one source. Some institutional realities depend strongly on formal authorization. Others are sustained primarily through convention, habit, organizational routine, infrastructural dependence, or mutually adjusted expectations. Many combine several of these mechanisms. The definition also leaves open whether the relevant institutional object possesses an ontological status beyond its relational realization. The analytical burden is first to identify how it is generated, how it persists, what stabilizes it, and how it affects subsequent relations.

4.14.1 Social Facts

A social fact, in the present framework, is not defined merely by the existence of a shared belief. Shared representations can contribute to its formation, but the relational reality of a social fact requires more than mental agreement. The fact must become sufficiently stabilized within a social field to organize conduct, expectations, opportunities, obligations, identities, access, or resource flows. The relevant relations may include mutual recognition, legal authorization, customary practice, material infrastructure, records, sanctions, market coordination, professional routines, or repeated interaction. What is socially factual is therefore tied to a configuration capable of making a difference within the system.

Definition 4.119 (Relationally real social fact)**.** A *relationally real social fact* is a socially generated object, status, rule, distinction, or expectation that persists with sufficient stability across a relevant spacetime interval and exercises causal efficacy

within the social system through which it is sustained.

This definition preserves the general GR criterion while making the social mode of generation explicit. A marriage, debt, academic credential, property title, rank, office, or currency denomination may be relationally real because actors, organizations, databases, legal procedures, infrastructures, and expectations collectively sustain a configuration through which subsequent action is differentiated. The relevant efficacy may occur even when a particular subject is unaware of the fact. A person can acquire a tax liability without having noticed it, be subject to a legal restriction without understanding its doctrinal basis, or hold a claim recorded in an institutional system before becoming aware that the record exists. Subjective apprehension is therefore neither a necessary nor a sufficient condition of relational reality.

The same point helps distinguish social facts from manifestational facts. A passport, contract, certificate, database entry, court order, price display, uniform, title, or public ceremony can manifest an institutional status. Yet the manifested object is not automatically identical with the relational structure through which the status persists. A printed certificate can be destroyed while the qualification remains institutionally recognized through other records and practices. Conversely, a visually convincing certificate can exist without the institutional relations required to make its represented status effective. Manifestation can disclose, transmit, stabilize, or transform a social fact, but it does not exhaust the social fact's relational reality.

Social facts can also precede explicit symbolization in a local context. Repeated patterns of deference, exclusion, obligation, entitlement, or informal authority may become sufficiently stable to shape conduct before participants develop a settled vocabulary for them. Once named, codified, measured, or represented, these patterns can enter the recursive dynamics described in Section 4.11. The new manifestation may render an existing relation more legible, but it can also reorganize that relation by enabling contestation, coordination, enforcement, comparison, or institutional redesign.

Claim 4.120 (Social fact without universal awareness)**.** *The relational reality of a social fact does not require universal recognition or simultaneous awareness among the subjects affected by it. It requires a sufficiently stable generative-relational configuration capable of sustaining the fact and mediating causal consequences within the relevant system.*

Claim 4.120 matters for large institutional systems. Modern societies routinely coordinate relations among participants who possess highly unequal knowledge of the rules, databases, classifications, procedures, and infrastructures that shape their actions. Institutional reality can therefore be distributed across persons, documents, software, offices, routines, and material arrangements rather than residing in a single collective representation. The resulting social fact may be real for the system even though no individual actor possesses a complete representation of the relations that sustain it.

Social facts need not be mutually commensurable merely because they share the same relational-reality criterion. A religious office, a financial claim, a kinship relation, a legal title, and an academic credential may all be relationally real while being generated through different mechanisms and embedded in different comparison

structures. Even objects bearing similar labels across jurisdictions or historical periods may not be structurally equivalent. Cross-institutional comparison therefore requires an explicitly justified mapping rather than an assumption that shared terminology identifies a common metric space.

4.14.2 Institutional Stabilization

Institutionalization concerns the transition from recurrent social relations toward more durable configurations in which expectations, roles, procedures, classifications, sanctions, and resources become mutually reinforcing. The transition is rarely a single event. It can involve repetition, record keeping, formalization, professionalization, infrastructural investment, legal recognition, routinized enforcement, education, socialization, technological embedding, or the accumulation of precedent. Different combinations can produce different degrees and forms of institutional stability.

Definition 4.121 (Institutional stabilization)**.** *Institutional stabilization* is the historical process through which a socially generated configuration acquires sufficient persistence, reproducibility, and causal reliability that its roles, rules, statuses, procedures, or organized capacities can structure subsequent relations beyond the immediate interactions in which they first emerged.

Institutional stabilization can extend a relational reality across time and space. A bilateral promise can depend heavily on the memory and continued willingness of the two participants. A standardized contract recorded within a legal and administrative system can remain efficacious through changes in personnel, location, ownership, or organizational membership. Stabilization therefore changes not only duration but also the architecture through which persistence is achieved. Memory can be externalized into records; authorization can be attached to offices rather than persons; sanctions can be routinized; procedures can be standardized; and material infrastructures can preserve practical continuity across generations of participants.

This extension of persistence should not be confused with immutability. An institution can be highly stable while remaining historically revisable. Indeed, some institutions stabilize procedures through which their own rules can be amended, offices replaced, assets transferred, or statuses terminated. A constitution, corporate charter, professional code, or monetary regime can therefore include relations of authorized transformation within the institutional reality itself. Stability and revisability are compatible when the procedures governing change are themselves sufficiently stabilized.

Institutional reality can also become recursively self-supporting. A rule shapes behavior; repeated behavior creates expectations; expectations increase the cost of deviation; organizations invest in infrastructure built around the rule; records accumulate; professional roles emerge to interpret and administer it; and these developments make the rule more consequential for later participants. Such recursion can deepen relational reality without converting historical contingency into necessity. What has become difficult to change may still have been generated through a path that could have developed differently.

The three-register architecture helps separate several components of stabilization.

A building, server, ledger, biometric device, courtroom, banknote, or communications network may provide material conditions. A role, entitlement, debt, office, legal relation, or monetary claim may be relationally real within the institution. A statute, record, symbol, dashboard, credential, verdict, price, or ceremony may manifest and represent the relevant relation. Institutional persistence often depends on the coupling among these registers rather than on any one of them in isolation.

Remark 4.122 (Institutional object and institutional manifestation)*.* The persistence of an institutional object can survive the loss or replacement of particular manifestations, while changes in manifestation can nevertheless transform the institutional object when the manifestation itself enters the relations that reproduce it.

This remark captures an important asymmetry. A corporation can survive replacement of its logo, offices, employees, directors, databases, or paper records because its relational continuity is distributed across multiple mechanisms. Yet a change in registration, governance rules, legal classification, or ownership records can alter the corporation precisely because these manifestations are institutionally operative. Manifestation is therefore neither merely superficial nor automatically constitutive; its role depends on the generative relations in which it participates.

4.14.3 Legal Reality

Law offers a particularly clear illustration of relational reality mediated through manifestation. Legal systems depend heavily on texts, judgments, filings, signatures, classifications, procedures, and public acts. These are manifestational forms. Their legal efficacy, however, depends on historically stabilized relations among institutions, officials, subjects, records, recognized procedures, interpretive practices, enforcement capacities, and expectations. The written form of a rule is therefore important without being sufficient to explain the reality of law.

Definition 4.123 (Legal relational reality)**.** *Legal relational reality* is the relational reality acquired by legal statuses, rights, duties, powers, disabilities, procedures, and institutional acts when they are sustained through a sufficiently stable legal-institutional configuration and become causally capable of structuring action, authorization, access, sanction, liability, or resource distribution.

A property right illustrates the distinction. The physical object that becomes property does not contain the right as one of its material attributes. The right is sustained through relations among recognized holders, registries, courts, contractual practices, administrative procedures, social expectations, and enforcement capacities. It may be manifested through a title, deed, digital register, possession, boundary marker, or judicial decision. These manifestations can be indispensable to particular legal systems, but the right's relational reality consists in the stabilized configuration through which claims and actions acquire differential consequences.

Legal acts can also generate new relational realities through authorized manifestation. A judgment, registration, marriage declaration, incorporation filing, appointment, or transfer can change what relations exist because the relevant system assigns generative force to the act. The manifestation is then performative in a specific institutional sense: its efficacy arises from its position within an authorized relational configuration rather than from the words or marks alone. The same utterance or

document outside the relevant institutional relations may lack the corresponding effect.

This generative feature helps explain why legal reality cannot be reduced either to symbolic representation or to physical enforcement. A court order can remain legally real during an interval in which enforcement has not yet occurred. Conversely, coercive conduct can occur without possessing the legal status claimed for it. Legal reality therefore involves relations of validity, authorization, interpretation, institutional competence, and expected consequence that can be analytically distinguished from both textual manifestation and material force.

The framework also permits a distinction between legal reality and legal justice. A discriminatory status, exclusionary rule, or procedurally valid decision can become relationally real when institutions sustain and enforce it. Its causal reality does not establish moral legitimacy. Conversely, a normatively compelling claim may lack institutional realization and therefore possess little or no legal relational reality within a particular jurisdiction at a particular time. GRE can study the economic consequences of this gap without treating the existing legal order as normatively self-validating.

Claim 4.124 (Legal efficacy without ontological identity)**.** *A legal object can possess substantial relational and causal reality without requiring the analyst to posit a distinct ontological substance corresponding to the legal category. Its reality can be traced through the relations that generate, stabilize, manifest, interpret, and enforce it.*

This claim illustrates ontological suspension in practice. Competing philosophies of law may disagree about the ultimate nature of legal normativity, institutional facts, or legal obligation. The relational analysis can remain productive across part of that disagreement by identifying how legal objects become effective in historically specific systems. Where deeper ontological commitments alter the explanation, the disagreement becomes operative and should be addressed explicitly rather than prematurely resolved.

4.14.4 Monetary Reality

Money provides an especially useful case because its manifestations are easy to confuse with the relational object itself. Coins, banknotes, account balances, ledger entries, payment messages, and displayed prices are manifestations through which monetary relations become available and actionable. Their material or digital existence is important, but the monetary reality of a unit, balance, or claim depends on a wider relational configuration involving issuers, banks, payment systems, legal rules, accounting practices, expectations, exchange relations, taxation, contracts, and institutional trust.

Definition 4.125 (Monetary relational reality)**.** *Monetary relational reality* is the relational reality acquired by monetary units, balances, claims, prices, and payment capacities when they are stabilized within a generative-relational system sufficiently to coordinate valuation, settlement, obligation, exchange, accounting, or resource allocation and to exert causal effects on subsequent economic relations.

This definition does not require every monetary form to share the same institu-

tional architecture. Commodity money, state-issued currency, bank deposits, community currencies, digital payment balances, and other monetary arrangements can differ in their stabilization mechanisms. The relevant inquiry concerns the relations through which a particular monetary object is recognized, transferred, accounted for, redeemed, taxed, enforced, trusted, or otherwise made consequential. Similar manifestations can conceal different relational structures, just as similar relational functions can be realized through different manifestations.

A banknote therefore offers only a partial view of monetary reality. The note can be materially destroyed without eliminating the currency. A counterfeit note can closely reproduce the manifestation while lacking the institutional relations that normally sustain the represented monetary claim. A digital balance can persist without any particular physical token corresponding to each unit. These examples reinforce the non-invertibility developed in Section 4.9: observation of a manifestation does not by itself reveal the relational structure that gives it monetary efficacy.

Monetary reality also demonstrates manifestational mediation. Prices, balances, ratings, exchange rates, accounting categories, and policy announcements do more than make an antecedent monetary system visible. Once circulated, they can alter expectations, spending, lending, investment, collateral relations, contractual decisions, and institutional responses. A manifested monetary quantity can therefore enter the generative field that helps produce later monetary and economic relations. The symbolic and relational registers remain distinct while becoming recursively coupled.

The familiar question of whether money is "real" is therefore decomposed into more precise questions. The physical substrate of a note or computer system raises one ontological issue. The stabilized monetary relation raises another. The displayed balance or printed denomination concerns manifestation and representation. The causal effects of monetary recognition concern relational reality. Normative questions concerning distribution, exclusion, monetary governance, or justice require further evaluation. The three-register architecture avoids forcing these questions into one binary judgment.

4.14.5 Organizational Reality

Organizations extend institutional reality through coordinated capacities that exceed the continuity of particular members. A university, corporation, ministry, association, or cooperative can retain identity across changes in personnel, offices, technologies, assets, and internal procedures. This continuity is neither purely symbolic nor reducible to a fixed material substrate. It depends on relations that reproduce membership, authority, decision procedures, ownership, records, routines, responsibilities, resources, and external recognition across time.

Definition 4.126 (Organizational relational reality)**.** *Organizational relational reality* is the relational reality of an organized collective configuration that persists through stabilized relations of membership, authority, procedure, resource control, role differentiation, record, and external recognition, thereby acquiring capacities and causal effects that cannot be identified with any single current participant or manifestation.

The definition does not imply that organizations act independently of people, tech-

nologies, infrastructures, or environments. It identifies a level at which organized relations become sufficiently stable that actions can be attributed to an institutional configuration across turnover in the specific relata realizing it. A company can enter a contract before one manager leaves and remain bound after another arrives. A university can award a degree through procedures distributed across departments, registries, committees, information systems, and legal recognition. The organization persists because relevant relations are reproduced, not because an unchanging substance passes through time.

Organizational personality provides a particularly clear example of the distinction among registers. A legal person can be manifested through a registered name, identifier, seal, website, letterhead, bank account, or contractual signature. The legal representation enables coordinated action, but the organization's relational reality includes governance relations, employees, assets, liabilities, routines, authorizations, counterparties, and historical commitments that extend beyond any one symbol. The organization may therefore possess relational continuity even when particular representations change.

At the same time, organizational representations can reshape the organization. A new accounting category can redirect managerial attention. A performance metric can reorganize incentives. A revised organizational chart can redistribute authority if it is institutionally implemented. A mission statement can remain largely ceremonial or become relationally consequential depending on how it enters hiring, budgeting, evaluation, and decision procedures. The causal significance of representation is thus an empirical property of the generative-relational system rather than an automatic consequence of textual existence.

Organizational reality also clarifies why agency attribution requires care. An organization can possess operational capacities that justify treating it as an analytical subject for particular inquiries, while responsibility, experience, intention, and moral standing may remain distributed or contested. Section 4.12 therefore remains relevant: manifestational or operational unity does not establish identity across every dimension of subjecthood. The three-register architecture permits the analyst to study organizational action without assuming that organizational and human subjectivity are equivalent.

4.14.6 Causal Reality of Social Constructions

The examples above converge on a broader ontological point. A social construction can be causally real because construction refers to a mode of generation rather than to an absence of reality. Once a category, status, institution, or representation becomes embedded in stable relations, it can constrain and enable action, redirect resources, allocate rights, organize expectations, change bodies and environments, reproduce inequality, create capabilities, or alter the conditions under which later relations emerge. The historical contingency of its origin does not cancel these effects.

Claim 4.127 (Causal reality of social construction)**.** *A socially constructed object can possess relational reality when the generative-relational system that sustains it gives the object sufficient persistence, stability, and causal efficacy. Social construction therefore describes a possible history and mechanism of emergence rather than a criterion*

of unreality.

This claim does not imply that every social construction becomes relationally real. A proposed category that fails to circulate, an unenforced rule that leaves practice unchanged, an ephemeral rumor, or an institutional reform that remains purely nominal may lack sufficient persistence or causal efficacy. Nor does it imply that the same constructed object has equal reality across systems. A credential can open access in one institutional field and be ignored in another. A currency can be effective within one payment network and practically unusable outside it. Relational reality remains domain-sensitive and historically situated.

The causal effects of social constructions can also outlive the representations through which they were initially generated. A historical classification may disappear from official vocabulary while its accumulated effects remain embedded in property distributions, organizational routines, infrastructures, reputations, or spatial arrangements. Conversely, a representation can survive after the relations that once made it effective have weakened. This temporal divergence between manifestation and relational efficacy is another reason to resist identifying institutional reality with visible symbols alone.

Institutional reality can further alter its own conditions of reproduction. Once a legal category, currency, organization, or administrative classification becomes established, later actors encounter a relational field already structured by it. They invest, learn, comply, resist, innovate, migrate, or organize around the inherited configuration. Their responses can stabilize the institution, transform it, produce new representations, or generate alternative relations. Institutional reality is therefore historical not only because it has an origin, but because each period of reproduction changes the conditions inherited by the next.

This recursive temporality is especially important for GRE. Economic analysis frequently treats institutions as background constraints or parameters. The generative-relational view instead permits institutions themselves to be investigated as historically produced realities that subsequently participate in producing economic subjects, opportunities, values, incentives, resource distributions, and future institutional forms. A property regime, monetary system, labor classification, welfare category, organizational structure, or accounting convention does not merely constrain choices made within an otherwise unchanged field. It can help generate the field within which later choices, relations, and forms of value become possible.

Remark 4.128 (Reality, legitimacy, and truth). The relational reality of an institution establishes neither its normative legitimacy nor the truth of the representations through which it operates. Causal efficacy, epistemic adequacy, legal validity, social recognition, and normative justification remain distinct dimensions that may interact without collapsing into one another.

The remark preserves a central discipline of the three-register architecture. A discriminatory classification may be institutionally real and normatively objectionable. A mistaken risk score may be epistemically poor and causally powerful. An informal norm may be socially effective without legal validity. A legal entitlement may be valid yet weakly realized in practice. A public representation may accurately describe an institution yet have little causal influence. Analytical precision requires these possi-

bilities to remain separately visible.

The ontological significance of social facts and institutions can therefore be stated without metaphysical inflation. Their reality is not diminished by the fact that they emerge historically through relations, and their relational reality does not compel a claim that they exist independently of those relations. They occupy a domain in which stabilized relations acquire causal efficacy, manifestations become operative components of reproduction, and historically generated objects can confront later actors with substantial practical force. This account prepares the next section's turn from relatively stabilized institutional objects toward process, event, and becoming, where persistence itself must be situated within continuing transformation.

4.15 Process, Event, and Becoming

The preceding sections have developed relational reality largely through objects, subjects, values, institutions, manifestations, and representations that achieve sufficient persistence and stability to become causally efficacious. The role of the present section is to clarify the temporal form of such reality. Its objective is to show how GR can analyze processes, events, and becoming without treating persistence as immobility, without reducing events to instantaneous points, and without turning process language into a final metaphysics. The discussion proceeds through five steps. It first specifies processual reality, then develops an account of events, examines stability within becoming, defines relational transformation, and finally considers how historically generated changes can require new ontological categories within an inquiry. The method remains consistent with the chapter's ontological suspension: temporal and processual descriptions are treated as analytically serious claims about organization and causal efficacy while stronger claims about the ultimate temporal constitution of reality remain open unless the inquiry independently warrants them.

The central difficulty is that relational reality requires persistence and stability, while generative-relational systems are continually changing. These conditions are compatible once stability is understood dynamically. A monetary system persists while transactions, balances, technologies, regulations, and participants change. An organization persists while personnel, routines, assets, and strategies are revised. A sense of self can persist while memory, embodiment, social recognition, and self-description develop. The reality of such configurations lies partly in their capacity to reproduce an organized pattern through change. Processual analysis therefore does not displace the criterion of relational reality developed in Section 4.5; it clarifies one way in which that criterion can be satisfied across time. (Whitehead 1929; Mead 1932; Davidson 2001; Sewell 1996)

Definition 4.129 (Processual reality)**.** *Processual reality* denotes the relational reality of an organized pattern of change whose temporally extended configuration persists with sufficient stability and causal efficacy to participate in the subsequent development of the generative-relational system in which it occurs.

Definition 4.129 makes the process itself, rather than any single temporal slice, the relevant analytical object. A process can include changing components, variable relations, discontinuities, and internal differentiation while remaining identifiable at the

scale of inquiry. Its persistence therefore concerns continuity of organization, trajectory, or generative function rather than exact repetition of state. The definition also remains scale-sensitive. What appears as a relatively stable object at one temporal resolution can appear as an active process at another. A firm can be represented as an institutional entity in one model and as a changing configuration of contracts, routines, capacities, expectations, and material flows in another. Both descriptions can be analytically useful when their scale and purpose are explicit.

4.15.1 Processual Reality

Processual reality becomes important whenever the causal significance of an object depends on the organized continuation of change. A market, learning trajectory, supply chain, technological regime, administrative procedure, or relation of trust may be poorly described by a sequence of independent states because later states depend on how earlier configurations were generated. Historical order, memory, accumulated commitments, adaptation, and feedback can therefore be constitutive of the object under study. The process is relationally real when this temporally extended organization persists sufficiently to shape what can occur next.

The distinction between state and process is analytical rather than absolute. A state description compresses a configuration at a selected temporal resolution. A process description retains some of the transformations through which configurations succeed one another. The appropriate representation depends on the research question. A bank balance at a particular time may be adequately represented as a state for one inquiry, while the sequence of transfers, authorizations, interest accruals, obligations, and institutional validations through which that balance was produced may be indispensable for another. GR therefore treats temporal compression as a methodological choice whose omitted relations should remain visible when they matter to explanation.

Processual reality also clarifies why persistence need not mean substrate identity. Some processes persist through turnover in the entities that realize them. A payment network can continue while servers, software versions, account holders, and organizational personnel change. A legal procedure can retain recognizable continuity while statutes, interpretive conventions, and administrative technologies are revised. A language practice can persist through generations of speakers. In such cases, continuity is carried by a sufficiently stable organization of relations and transformations rather than by an unchanging set of relata.

Claim 4.130 (Dynamic persistence)**.** *A relational reality can persist through substantial change in its constituent states, relata, and manifestations when the organization of transformation remains sufficiently stable to preserve causal continuity at the scale relevant to the inquiry.*

Claim 4.130 is intentionally scale-relative. The same history can support continuity at one scale and rupture at another. A corporation may remain legally continuous through a major restructuring even though employees experience the restructuring as the end of an earlier organizational form. A monetary regime may preserve a currency name while changing the institutions, convertibility rules, settlement technologies, or policy mechanisms that sustain it. The analytical task is therefore to specify

which organization persists, for whom or for what system, across which interval, and with what causal consequences.

Processual reality also accommodates rhythms, cycles, and recurrent dynamics without assuming exact periodicity. Many economic processes are reproduced through recurring but variable practices: payroll, taxation, budgeting, maintenance, certification, price revision, inventory replenishment, and contractual renewal. Their relational reality can depend on repeated coordination whose timing and content change within bounded ranges. Stability here is statistical, institutional, or organizational rather than identical repetition. The relevant process persists because enough of its generative structure is reproduced to maintain causal continuity.

Some processes possess several interacting timescales. Regulatory change can occur slowly relative to trading, infrastructural replacement slowly relative to software updates, and demographic change slowly relative to organizational decisions. GR can represent these differences without assuming that one timescale is ontologically fundamental. The important question is how processes operating at different rates constrain, amplify, or reorganize one another. A slowly changing legal framework can stabilize fast transactions; repeated fast transactions can accumulate pressures that eventually transform the legal framework. Temporal structure is therefore relational and potentially recursive.

The processual view has an additional consequence for manifestation. A process may be relationally real before it is manifested as a coherent process to any subject. Individual observations can appear disconnected until a historical pattern becomes recognizable through later comparison, measurement, narration, or modeling. The manifestation of the process can then feed back into it. Once inflation is represented through an index, organizational decline through a performance metric, or ecological change through a monitoring series, subjects may alter behavior in response to the manifestation. The process existed relationally before its explicit representation in such cases, while its later manifestation becomes one of the relations shaping its subsequent development.

4.15.2 Events

Processes unfold through temporally differentiated changes, some of which acquire a distinctive status as events. An event in GR need not be instantaneous, spectacular, or wholly discontinuous. It is better understood as a temporally bounded reconfiguration whose occurrence makes a consequential difference to the development of a relational system. The event can be brief or extended, visible or initially unrecognized, intentionally produced or emergent from distributed interactions. Its analytical importance lies in the reorganization it introduces into subsequent possibilities.

Definition 4.131 (Relational event)**.** A *relational event* is a temporally delimited reconfiguration within a generative-relational system that produces a causally consequential difference in the organization, constraints, capacities, or trajectories of subsequent relations.

Definition 4.131 distinguishes an event from arbitrary temporal segmentation. Any interval can be bounded by an analyst, but eventhood requires a difference that matters to the system under study. Signing a contract can become an event because obli-

gations, permissions, expectations, and future options are reorganized. A payment default can become an event because it changes credit relations, legal possibilities, reputational classifications, and later financing. A policy announcement can become an event when actors reorganize behavior around it. A software release can become an event if it changes operational capacities or participation conditions. The boundary of the event is therefore partly analytical and partly constrained by the causal structure of the system.

Eventhood can be retrospective. A change that initially appears minor can later be recognized as consequential because subsequent relations amplify it. A local technical modification may become a turning point after complementary technologies, regulations, practices, or expectations align around it. Conversely, an occurrence widely represented as momentous can have limited relational consequences if the surrounding system absorbs it without substantial reorganization. Manifestational salience and relational eventhood can therefore diverge.

This divergence matters for historical analysis. Public discourse often privileges events that are visible, narratively convenient, institutionally recorded, or symbolically dramatic. GR allows an analyst to distinguish the manifestational prominence of an occurrence from its relational significance. A highly publicized announcement may remain weakly causal, while a quiet administrative change, altered database schema, revised eligibility rule, or gradual infrastructural threshold may reorganize access and behavior across a large system. Event analysis therefore requires attention to causal consequences as well as to representation.

Events can also emerge without a single author. A financial panic, collective shift in expectations, congestion cascade, labor shortage, reputational collapse, or technological convention may become event-like through distributed interactions. The event is then generated by a relational configuration whose participants may possess only partial knowledge of the overall process. This distributed generation is compatible with the relational-reality criterion because causal efficacy can be system-level even when no actor intends or fully represents the resulting reconfiguration.

Remark 4.132 (Event and manifestation)*.* A relational event can precede its explicit recognition, while a manifested occurrence can acquire additional event-like consequences through the responses its manifestation generates. Eventhood and manifestation therefore interact recursively without being identical.

Remark 4.132 extends the graph architecture developed earlier in the chapter. A threshold crossing may reorganize a system before subjects recognize it. Later measurement, naming, announcement, or narration can then become a second source of causal change. The event's relational reality and its manifestational history should therefore be reconstructed separately when both matter.

4.15.3 Stability within Becoming

The concept of becoming names the continuing production of difference through time. GR uses the term cautiously. It does not require a metaphysical doctrine in which process is declared more fundamental than entity, nor does it imply that every configuration changes at the same rate or in the same manner. Becoming identifies the analytical fact that generative-relational systems can produce new states, relations,

capacities, constraints, meanings, manifestations, and objects through their histories. Stability must therefore be understood within this ongoing production of difference.

A stable relational reality is often maintained through active reproduction. Money remains effective because infrastructures settle payments, institutions enforce claims, subjects continue to price and transact, records are maintained, and expectations are reproduced. An organization remains continuous because roles are reassigned, records updated, resources replenished, decisions implemented, and membership boundaries reproduced. Trust can persist because interaction repeatedly confirms or repairs expectations. Stability is therefore frequently achieved through work, adjustment, feedback, repair, and renewal.

This point motivates a distinction between static and dynamic stability. Static stability would describe limited change around a configuration under specified conditions. Dynamic stability describes persistence of organization through continuing transformation. The distinction is analytical; many systems exhibit mixtures of both. A legal rule may remain textually unchanged while its interpretation evolves. A platform may continually update software while preserving a recognizable participation architecture. A household may maintain a pattern of care through changing tasks, needs, and members. The relevant form of stability depends on what must remain sufficiently organized for causal continuity to persist.

Claim 4.133 (Stability within becoming)**.** *Stability in a generative-relational system can consist in the continued reproduction of an organized relational pattern through change. Persistence therefore remains compatible with becoming when the transformations themselves sustain sufficient continuity of structure, constraint, capacity, or causal orientation.*

Claim 4.133 prevents a false choice between stable reality and historical transformation. The same relational reality can be persistent and continually reproduced. At the same time, reproduction is never guaranteed. Small modifications can accumulate, external conditions can change, internal contradictions can intensify, new relations can enter the system, and earlier stabilizing mechanisms can lose efficacy. Dynamic stability can therefore weaken, recover, or pass into transformation.

The temporal extent of stability also matters. A configuration can be stable over a short interval and unstable over a longer one. A speculative price regime may persist long enough to organize investment decisions even if it later collapses. An emergency institution can be relationally real during a crisis despite its intended temporariness. A temporary identity category can shape access and conduct while it remains institutionally operative. Relational reality therefore does not require indefinite duration. It requires sufficient persistence relative to the causal processes under analysis.

Becoming also complicates identity. If a relational reality changes continuously, the question of whether it remains the same object cannot always be answered by a single invariant criterion. Legal continuity, organizational continuity, functional continuity, experiential continuity, material continuity, and historical continuity may diverge. GR therefore treats identity through change as an inquiry-relative reconstruction. The analyst should specify which continuities matter to the question and which transformations count as preserving or ending the object under study.

This approach is especially relevant to subjectivity. The continuing experience of

"I" can be relationally real even though embodiment, memory, social position, commitments, and self-description change. Its reality need not depend on an immutable ontological core. At the same time, ontological suspension prevents the relational account from proving that no such core exists. GR can therefore analyze continuity of self through changing relations while leaving stronger metaphysical conclusions open.

4.15.4 Relational Transformation

Relational transformation occurs when change modifies the organization through which a relational reality is generated, stabilized, or made causally effective. The concept therefore concerns more than variation in the values of fixed variables. A relation may change in strength, direction, meaning, institutional form, temporal ordering, or scale; relations among relations may be reorganized; new relata may enter; earlier ones may disappear; and the mechanisms through which manifestations feed back into the system may themselves change.

Definition 4.134 (Relational transformation)**.** *Relational transformation* denotes a historically situated change in the organization of a generative-relational system that modifies the conditions through which relational realities emerge, persist, interact, manifest, or exercise causal efficacy.

Definition 4.134 distinguishes transformation from ordinary state change. A price change within an otherwise stable market arrangement may alter a state without transforming the relational architecture. A change in settlement rules, ownership structure, access rights, information infrastructure, or category system can transform the relations through which prices are generated and acted upon. The distinction remains scale-dependent, but it directs attention toward changes in generative conditions rather than toward magnitude alone.

Relational transformation can be cumulative. Repeated small changes can modify expectations, routines, infrastructures, and classifications until a system operates under materially different generative conditions. The absence of a single dramatic event does not preclude transformation. Gradual digitization of payment systems, for example, can change the relations among money, identity, privacy, institutions, and access through accumulated infrastructural revisions. Similarly, gradual adoption of algorithmic evaluation can reorganize employment, credit, insurance, education, or welfare relations even when no single deployment constitutes the entire transformation.

Transformation can also be path-dependent. Earlier relations shape which later changes are feasible, costly, intelligible, or institutionally legitimate. Historical residues can remain operative after the representations associated with them disappear. Infrastructures, legal precedents, accumulated skills, property distributions, organizational routines, and categories can constrain later possibilities. The transformed system therefore carries aspects of its history into new configurations even when its manifestational vocabulary changes substantially.

The recursive architecture of Sections 4.10 and 4.11 becomes especially important here. Representations can become mechanisms of transformation when classifications, measurements, models, narratives, or interfaces alter behavior and institu-

tional response. A newly introduced performance score can reorganize organizational incentives; a legal category can create new rights and duties; a public risk classification can alter investment; an economic indicator can change policy behavior. Once such representations become causally embedded, transformation occurs partly through manifestational mediation.

Relational transformation can also dissolve relational realities. A currency can lose the relations that sustain its practical efficacy. A legal office can be abolished. A social norm can weaken until it ceases to organize conduct. A trust relation can collapse. Dissolution does not imply that the earlier reality was illusory. A relational reality can have been historically real, causally consequential, and later absent. The ontology developed here is therefore temporally indexed: reality within a generative-relational system can emerge, persist, transform, and cease.

Remark 4.135 (Historical reality and dissolution). The later disappearance of a relational reality does not retroactively remove its earlier causal reality. Historical existence and present persistence are distinct questions.

This remark matters for economic history and institutional analysis. Defunct currencies, dissolved corporations, abolished legal statuses, vanished markets, and obsolete technologies can remain causally significant through accumulated effects, inherited infrastructures, debts, memories, distributions, and institutional residues. Their present relational reality may have ended while consequences generated during their persistence continue to structure later systems.

4.15.5 Emergence of New Ontological Categories

Relational transformation can eventually strain the categories through which an inquiry describes what exists. Existing categories may continue to capture some features of a changing system while becoming inadequate for others. New kinds of institutional object, operational subject, property relation, value form, technical agency, or manifestation can arise through combinations of relations that earlier classifications did not anticipate. The emergence of such objects creates an ontological problem for analysis: the investigator must decide whether an existing category can be extended, whether several categories should be distinguished, or whether a new category is warranted.

The phrase *new ontological category* is used here with ontological restraint. It does not mean that the analyst has discovered a new fundamental constituent of reality. It means that the system presents a sufficiently stable and causally consequential form whose existing analytical classification is inadequate for the inquiry. Category formation is therefore a response to emergent reality under specified evidential and methodological conditions. The category can later be revised, divided, merged, or abandoned as the object and the inquiry develop.

Definition 4.136 (Emergent ontological category)**.** An *emergent ontological category* is an analytically warranted category introduced when a historically generated configuration displays sufficiently distinctive persistence, organization, causal capacities, or modes of manifestation that the categories previously available to the inquiry no longer provide an adequate account of the relevant reality.

Definition 4.136 links ontology to historical inquiry without reducing reality to naming. The category is analytically introduced, but the warrant for introducing it is constrained by the properties and effects of the configuration being studied. A new term alone does not create a new ontological category. Conversely, a novel relational reality may begin to operate before a vocabulary for it exists. This preserves the distinction between relational reality and symbolization established earlier in the chapter.

Contemporary artificial systems offer one illustration. The emergence of systems capable of sustained interaction, autonomous-seeming task execution, representation, coordination, and intervention can strain categories built around tools, agents, organizations, and human subjects. GRE need not settle this difficulty by declaring such systems persons or by reducing them to ordinary instruments. Section 4.12 introduced artificial operational subjecthood precisely as a differentiated analytical category whose scope is narrower than human subjecthood. The category becomes useful when it tracks stable capacities and causal roles that existing descriptions obscure, while ontological and normative questions beyond that scope remain suspended.

Economic institutions can generate similar categorical pressure. Digital assets, platform-mediated labor relations, algorithmically administered claims, hybrid public-private infrastructures, and machine-mediated forms of coordination can combine properties previously distributed across several categories. Whether they warrant genuinely new analytical categories depends on the structure of the inquiry. GRE therefore treats category formation as a disciplined response to emergent configurations rather than as conceptual novelty for its own sake.

The same discipline applies to historical categories. A category that once tracked a stable relational reality can lose adequacy as the system changes. Retaining the old name may conceal transformation if its referent has acquired substantially different generative conditions and causal capacities. Conversely, rapid renaming can exaggerate novelty where relational continuity remains strong. Category revision therefore requires comparison of historical organization, persistence, causal efficacy, manifestation, and transformation rather than lexical difference alone.

Claim 4.137 (Category emergence under ontological suspension)**.** *The emergence of a new analytical ontological category can be warranted by historically generated differences in organization and causal efficacy without requiring a claim that the category identifies a new fundamental kind of being.*

Claim 4.137 connects the present section back to ontological suspension. GR can revise what it counts as an object, process, event, subject, institution, or form of value when reality under inquiry changes or when earlier descriptions prove inadequate. This flexibility is compatible with ontological seriousness because revision responds to evidence about persistence, difference, causal efficacy, and generative structure. It is also compatible with metaphysical restraint because local analytical differentiation does not automatically become a universal ontology.

Process, event, becoming, transformation, and category emergence therefore provide a temporal extension of the chapter's three-register architecture. Relational realities can persist through organized change; events can redirect trajectories before or after they become manifest; manifestations and representations can become causal

components of transformation; and new configurations can eventually require revised categories of analysis. Stability and becoming are thus mutually informative rather than mutually exclusive. The result prepares the transition to Section 105, which introduces a category-theoretic view as one possible formal language for describing objects, morphisms, mappings, and equivalences across relational and manifestational domains while preserving the ontological restraint established throughout the chapter.

4.16 A Category-Theoretic View

The preceding sections have developed an ontology in which relational realities emerge, persist, manifest, become represented, and transform through historically structured systems. The role of the present section is to introduce category theory as one possible formal language for describing selected aspects of this architecture. Its objective is not to claim that relational reality is fundamentally categorical. Rather, category-theoretic language can help distinguish objects from mappings, preserve compositional structure, compare different descriptive domains, and make explicit when two paths of mediation are treated as equivalent or when they remain distinct. The section proceeds from objects and morphisms to categories of relational and manifestational reality, then considers functorial manifestation, loss and excess of information, equivalence, symbolic mediation, changing manifestation rules, multiple realization, and diagrammatic path dependence. Throughout, the formal vocabulary is treated as a methodological expedient whose appropriateness depends on whether the relations under study actually support the compositional assumptions imposed by the model.

Category theory is attractive for GR partly because it directs attention away from intrinsic properties alone and toward relations, mappings, transformations, and preservation across descriptions. Yet this attraction requires restraint. A category is a mathematically specified structure with objects, morphisms, identity morphisms, and associative composition. A generative-relational system need not present itself in this form without analytical construction. The investigator must decide what counts as an object, which transformations count as morphisms, when two morphisms are composable, and what form of equality or equivalence is appropriate. These decisions can illuminate structure, but they also select and compress reality. Category-theoretic analysis therefore belongs within the chapter's broader principle of open ontological commitment: it can support rigorous local claims without acquiring metaphysical authority beyond the structures it successfully represents. (Mac Lane 1998; Awodey 2010)

Definition 4.138 (Category-theoretic representation)**.** A *category-theoretic representation* of a generative-relational domain is an analytically constructed category whose objects and morphisms represent selected configurations and admissible relations or transformations in that domain, with identity and composition specified in a manner appropriate to the inquiry.

Definition 4.138 emphasizes representation rather than identity. The category is a model of selected structure. It can preserve relations that matter to the inquiry while

leaving other features unrepresented. This makes category theory especially useful for the three-register architecture, where the same object can be described within different domains and where manifestation, representation, and transformation often involve mappings between domains rather than a single common metric space.

4.16.1 Objects, Morphisms, and Relational Description

A category consists, minimally, of objects and morphisms between them. For objects A, B, and C, morphisms can be written

$$f : A \to B, \qquad g : B \to C, \tag{4.7}$$

Equation 4.7 introduces the basic source–target notation used in this section. A composite $g \circ f : A \to C$ is defined when the codomain of f matches the domain of g. Each object has an identity morphism, and composition is associative wherever it is defined. These requirements are simple, but their interpretation in a generative-relational analysis is not automatic.

An object can represent a stabilized relational configuration, an institutional state, a manifestation, a symbolic representation, a process considered at a selected scale, or another analytically bounded unit. A morphism can represent a transformation, translation, admissible relation, institutional operation, manifestation process, or structure-preserving map. The same empirical material can support more than one categorical representation because the choice of object and morphism depends on the analytical question.

For example, firms can be represented as objects and contractual transformations as morphisms in one model. In another model, contractual arrangements themselves can become objects, while legal or organizational transformations act as morphisms among them. A third representation can treat manifestations of those firms—financial reports, registrations, ratings, or platform profiles—as objects within a manifestational category. Category theory therefore does not decide in advance what the economically relevant object is. It disciplines relations among whatever objects the inquiry has justified selecting.

Remark 4.139 (Object selection). Categorical objecthood is an analytical role, not a declaration of fundamental ontological objecthood. The same relational reality can occupy different formal roles under different resolutions and research questions.

This point matters because objectification can conceal internal structure. Treating an organization as a single categorical object may be useful for studying interorganizational transformations while suppressing internal power relations, departments, subjects, and material infrastructures. Treating those internal elements as separate objects can recover some of that structure but may suppress other scales. The categorical model therefore inherits the boundary and scale problems already identified in GRE. Formal clarity does not remove the need to justify what has been made visible and what has been compressed.

4.16.2 Relations as Morphisms and Relations among Relations

The language of morphisms is naturally attractive to a relational framework, but GR should resist a simple identification between every relation and every morphism. In an ordinary category, morphisms possess specified domains and codomains and participate in associative composition. Many empirical relations are symmetric, partial, probabilistic, context-sensitive, historically contingent, or difficult to compose. Some can nevertheless be represented categorically by choosing an appropriate category; binary relations, for example, can themselves be treated as morphisms in a category whose composition is relational composition. In other cases, transformations rather than relations in the broad GR sense provide the more suitable morphisms.

The useful methodological question is therefore whether a selected relational domain supports a compositional representation. When it does, composition can expose how relations among relations generate higher-order consequences. If $f : A \to B$ and $g : B \to C$ represent two admissible transformations, then $g \circ f$ represents the result of applying them in sequence. The composite can be analytically important even when neither transformation alone determines the final configuration. Contract formation followed by registration, classification followed by allocation, or measurement followed by administrative decision can all be represented through composition when the domain and codomain assumptions are justified.

Relations among relations can also require higher-order structures. A change in the rule by which one morphism is interpreted, a comparison between two mappings, or an intervention on a manifestation rule is not simply another relation among the original objects. Category theory offers several ways to represent such higher-order structure, including functors and natural transformations. GR need not adopt the most elaborate formalism by default. The important insight is that the relation connecting two objects and the transformation of that relation belong to distinguishable analytical levels.

Claim 4.140 (Compositional warrant)**.** *A categorical representation of a relational domain is warranted only to the extent that the selected objects, morphisms, identities, and compositions preserve structures relevant to the inquiry. Formal composability should not be inferred merely from the presence of empirical relations.*

This claim protects the method against decorative formalization. A category-theoretic diagram becomes informative when its compositions correspond to meaningful sequences or transformations in the domain. Where composition is ambiguous, history-dependent, or only partially defined, the model should represent that limitation rather than assume away the problem.

4.16.3 Categories of Relational Reality

The strict criterion of relational reality developed in Section 4.5 can be combined with category-theoretic representation without identifying the two. Let a category $\mathcal{R}$ represent a selected domain of relational realities. Its objects can stand for relational configurations that satisfy the relevant persistence, stability, and causal-efficacy conditions at the scale of inquiry. Its morphisms can represent transformations, admissible relations, or structure-preserving changes among those configurations.

The resulting category does not contain relational reality in its entirety. It contains only those distinctions that the model has made categorical. A monetary relation, institution, trust relation, self-model, or organization can possess internal histories and causal structures that are absent from the chosen object. The category becomes analytically useful when the omitted features are not required for the question being asked or when they are represented at another level.

A category of relational reality can also be local. Different subsystems can support different object types and transformation rules. A category appropriate to legal relations need not be identical to one used for technological systems, subjective continuity, or financial networks. The possibility of relating these categories through functors can be more informative than forcing all of them into a common metric or a single universal object space.

Definition 4.141 (Relational category)**.** A *relational category* is a category constructed for an inquiry in which objects represent selected relationally real configurations and morphisms represent admissible relations or transformations whose composition preserves structures relevant to that inquiry.

The definition deliberately leaves open what counts as preservation. In one study, preservation can concern legal validity; in another, organizational continuity, causal accessibility, information flow, contractual structure, or some other relation. The category gains explanatory value from the explicitness of these choices rather than from conformity to a single ontology.

4.16.4 Categories of Manifestational Reality

Manifestational reality admits a parallel but distinct categorical treatment. Let $\mathcal{M}$ denote a category whose objects represent manifestations available under a specified manifestational regime and whose morphisms represent admissible transformations, translations, comparisons, or transitions among those manifestations. The objects of $\mathcal{M}$ can include observations, measurements, classifications, reports, symbolic forms, perceptual states, institutional records, or other manifestations selected by the inquiry.

A manifestational category is not merely a category of representations. Section 4.6 distinguished manifestation from symbolization, and Section 4.10 distinguished symbolic representation from manifestational reality more broadly. A bodily response, an observed pattern, a measurement trace, a legal inscription, and a linguistic description can therefore belong to different manifestational subdomains while all remaining manifestations in the broader GR sense.

The categorical distinction between $\mathcal{R}$ and $\mathcal{M}$ provides a disciplined way to express a point developed throughout the chapter: relational and manifestational realities need not share the same objects or the same structure. A relational configuration can support multiple manifestations, and several relational configurations can become manifest in indistinguishable ways under a limited regime. Instead of treating these mismatches as defects in a single space, category-theoretic analysis can represent them as properties of mappings between distinct categories.

Remark 4.142 (Heterogeneous domains)*.* The usefulness of separate relational and

manifestational categories lies partly in permitting heterogeneity. A mapping between domains can be studied without presuming that the domains share a common metric, coordinate system, or ontology.

This is especially important for the non-necessary comparability of relational realities. Two relationally real objects can belong to categories whose internal morphisms, equivalences, and invariants differ substantially. Comparison then requires an explicit functor, correspondence, or other mapping rather than an assumed common scale.

4.16.5 Manifestation through Functorial Mapping

A functor provides one formal model of manifestation across categorical domains. Suppose $\mathcal{R}$ is a relational category and $\mathcal{M}$ a manifestational category. A functor

$$F : \mathcal{R} \longrightarrow \mathcal{M} \tag{4.8}$$

Equation 4.8 names the functor that will serve as the local manifestation model. It assigns each modeled object A in $\mathcal{R}$ an object $F(A)$ in $\mathcal{M}$ and each modeled morphism $f : A \to B$ a morphism $F(f) : F(A) \to F(B)$ while preserving identity morphisms and composition.

The preservation of composition is the substantive assumption. If a relational transformation f followed by g is represented by $g \circ f$, functoriality requires the manifestation of that composition to agree with the corresponding composition of manifested morphisms:

$$F(g \circ f) = F(g) \circ F(f). \tag{4.9}$$

Equation 4.9 can be analytically powerful because it identifies a condition under which relational composition is preserved through manifestation. It can also fail. A manifestational regime may erase sequence, reorder operations, introduce threshold effects, or depend on contextual information absent from the source category. Functoriality should therefore be treated as a model property to be investigated rather than a universal fact about manifestation.

Definition 4.143 (Functorial manifestation)**.** *Functorial manifestation* is a model of manifestation in which selected relational objects and morphisms are mapped into a manifestational category while identities and relevant compositional structure are preserved.

This definition does not require manifestation in general to be functorial. It identifies a useful special case. Administrative systems often aspire to such preservation: a legally valid sequence of operations is expected to produce a corresponding sequence of records; an accounting transformation is expected to be reflected in a consistent ledger transformation; a data pipeline is expected to preserve specified relations among inputs and outputs. Failures of preservation can then become analytically visible as breaks between relational process and manifestation.

4.16.6 Non-Faithful Manifestation and Loss of Relational Information

A functor is faithful when it maps distinct morphisms between the same pair of source objects to distinct morphisms in the target. Non-faithfulness therefore provides one precise formal model of relational distinctions that become indistinguishable in manifestation. Suppose $f, g : A \to B$ are distinct morphisms in $\mathcal{R}$ but

$$F(f) = F(g). \tag{4.10}$$

Equation 4.10 states the relevant collapse: the manifestational category fails, under this model, to preserve the distinction between the two relational transformations.

This formal structure corresponds closely to the relational remainder developed in Section 4.9. Different causal histories, institutional pathways, or social relations can produce the same recorded outcome. Two workers can receive the same wage through substantially different relations of bargaining power and security. Two firms can receive the same credit classification despite different dependency structures. Two subjects can produce the same interface response while differing in histories, capacities, or internal organization. In each case, a manifestational system can preserve an outcome while collapsing distinctions among the morphisms that generated it.

Claim 4.144 (Non-faithfulness and relational loss)**.** *When a manifestation functor is non-faithful, distinct modeled relational transformations can become manifestationally indistinguishable. The resulting loss of distinction concerns the selected manifestation regime and does not imply that the source transformations were relationally identical.*

Faithfulness is only one form of information preservation. A functor can distinguish morphisms while still mapping distinct objects to the same object, depending on the category and model. Conversely, object-level differences can remain visible while important internal relations are lost. GR therefore uses faithfulness as a precise local concept rather than as a complete measure of manifestational adequacy.

The category-theoretic language also clarifies why improving measurement can require more than adding variables. If a regime systematically identifies distinct relational pathways, richer data may leave the collapse intact unless the mapping itself is redesigned. The epistemic problem can therefore reside in the structure of manifestation rather than only in the quantity of manifested information.

4.16.7 Non-Full Manifestation and Unmanifested Relational Possibilities

Fullness requires a different interpretation. A functor $F : \mathcal{R} \to \mathcal{M}$ is full when every morphism in $\mathcal{M}$ between $F(A)$ and $F(B)$ is the image of at least one morphism in $\mathcal{R}$ between A and B. A non-full functor therefore indicates that the target category contains morphisms between manifested objects that are not induced by morphisms represented in the source category.

This point should be distinguished carefully from an *unmanifested source possibility*. In a strict functor, every source morphism receives an image. Non-fullness therefore does not, by itself, mean that a relational morphism exists but fails to man-

ifest. Rather, it means that the manifestational domain admits transformations or relations that are not accounted for by the modeled source relations. These can arise from measurement procedures, symbolic recombination, institutional processing, artifacts, interpretive operations, or relations introduced by the manifestation system itself.

To represent relational possibilities that are not manifested at all, the model must be modified. One option is to define the manifestation functor only on a subcategory $\mathcal{R}_{\text{vis}} \subseteq \mathcal{R}$ of relational configurations and morphisms that are accessible under the relevant regime. Relational possibilities in $\mathcal{R}$ outside that subcategory remain unmanifested relative to the regime. Another option is to use a partial, lax, stochastic, or correspondence-based structure where strict functorial assignment is inappropriate.

Remark 4.145 (Fullness and invisibility)*.* Non-fullness and relational invisibility are different structural problems. Non-fullness concerns target morphisms lacking source antecedents in the model; unmanifested relational possibilities concern source structure excluded from, undefined under, or inaccessible to the manifestation mapping.

This distinction is methodologically useful because the two problems call for different interventions. If relevant source relations are invisible, the manifestational regime may require expanded access or a different mapping. If the target generates relations not grounded in the source model, the analyst must study the generative contribution of measurement, classification, symbolic processing, or institutional mediation itself. In GR terms, manifestation can add structure rather than merely transmit it.

4.16.8 Isomorphism, Equivalence, and Manifestational Indistinguishability

Category theory offers several notions of sameness, and GR benefits from keeping them distinct. Two objects A and B in a category are isomorphic when there are morphisms between them whose compositions yield the respective identity morphisms. Isomorphism therefore captures sameness of categorical structure relative to the category, not numerical identity. Two categories can be equivalent even when they are not isomorphic as categories, provided they preserve the relevant structure up to natural isomorphism.

Manifestational indistinguishability is weaker. Section 4.9 defined manifestational equivalence locally to a regime. In categorical terms, two relational objects can satisfy $F(A) = F(B)$ or otherwise become isomorphic or observationally equivalent in $\mathcal{M}$ without being isomorphic in $\mathcal{R}$. Likewise, two source categories can generate equivalent manifestations while differing in relational organization.

Claim 4.146 (Manifestational equivalence is not relational isomorphism)**.** *Equivalence or isomorphism in a manifestational category does not, without additional assumptions on the manifestation mapping, establish isomorphism, equivalence, or identity in the relational category.*

The additional assumptions can be strong. A fully faithful functor preserves and reflects important morphism structure between modeled objects, but even full faith-

fulness does not automatically settle every ontological question outside the representation. GR therefore treats categorical equivalence as always relative to a selected formal domain.

This discipline is particularly important for economic equivalence. Equal price, equal legal category, equal score, equal statistical profile, or equal platform status can create manifestational equivalence under a practical regime. Such equivalence can have real effects because actors and institutions respond to it. Yet the equality need not erase differences in histories, dependencies, capacities, vulnerabilities, or generative conditions. Category theory provides precise language for separating equivalence under a mapping from identity of what is mapped.

4.16.9 Functors between Symbolic and Relational Descriptions

Symbolic regimes can also be modeled categorically. Let $\mathcal{S}$ denote a category of selected symbolic objects and transformations: classifications, legal codes, identifiers, prices, scores, textual descriptions, or other symbolic forms. An encoding or representation functor can map selected relational configurations into $\mathcal{S}$, while an interpretation or institutional enactment mapping can connect symbolic objects back to relational consequences.

The two directions should not be assumed to be inverses. A symbolic representation can compress several relational realities into one category, and an interpreted symbol can generate relations that were not present before the symbolization. A credit score, legal status, diagnostic category, occupational code, or monetary denomination can therefore be both a representation of prior relations and a causal input into later relations. The categorical picture is consequently recursive rather than merely representational.

One can schematically distinguish a relational category $\mathcal{R}$, symbolic category $\mathcal{S}$, and later relational category $\mathcal{R}'$ with mappings

$$\mathcal{R} \xrightarrow{E} \mathcal{S} \xrightarrow{I} \mathcal{R}', \tag{4.11}$$

Equation 4.11 separates the two mappings explicitly: E represents a selected encoding or symbolization and I represents the institutional, interpretive, or practical mediation through which symbols enter later relations. The notation does not imply that $\mathcal{R}'$ is determined by symbols alone. Other histories, material conditions, subjects, and constraints can contribute to its generation.

The value of the categorical representation lies in its ability to make preservation questions explicit. Which distinctions survive E? Which symbolic morphisms become causally operative under I? Which compositions commute, and which depend on the order or path of mediation? These are empirical and theoretical questions, not consequences of the notation itself.

4.16.10 Natural Transformations and Changing Manifestation Rules

The chapter has repeatedly emphasized that manifestation mappings can change historically. Category theory offers a formal language for comparing two functors that

map the same source category into the same target category. If $F, G : \mathcal{R} \to \mathcal{M}$ represent two manifestation regimes, a natural transformation $\eta : F \Rightarrow G$ assigns to each source object A a morphism

$$\eta_A : F(A) \to G(A) \tag{4.12}$$

in a way compatible with the morphisms of $\mathcal{R}$. Equation 4.12 therefore represents the objectwise component of a change between two manifestation regimes rather than an isolated conversion.

In applications, F and G can represent different measurement systems, classification regimes, institutional reporting rules, interfaces, or symbolic conventions. The components η_A then represent transformations between the manifestations produced under the two regimes. Naturality is a strong structural condition: it requires these transformations to cohere with the modeled relations among source objects rather than being arbitrary object-by-object conversions.

Definition 4.147 (Coherent change of manifestation regime)**.** A *coherent change of manifestation regime* is a model in which two manifestation functors are connected by transformations that preserve the relational compatibility conditions represented by a natural transformation.

Not every historical change satisfies this condition. A new accounting standard, legal classification, algorithmic interface, or statistical methodology can reorganize categories so substantially that no natural transformation between old and new regimes provides an adequate model. The failure of naturality can itself be informative: it signals that translation between regimes depends on path, context, exception, or reinterpretation not captured by a uniform structural mapping.

This makes natural transformations useful for analyzing comparability over time. A time series constructed under changing measurement systems may appear continuous while the transformation between regimes fails to preserve the relevant relational structure. Conversely, a carefully calibrated change can preserve enough structure to support meaningful historical comparison. Category theory therefore turns the vague question of whether two regimes are "comparable" into a more explicit inquiry about what transformations preserve which relations.

4.16.11 Multiple Realization and Functorial Equivalence

Multiple realization describes situations in which different underlying relational configurations realize the same or sufficiently equivalent higher-level organization, function, or manifestation. The three-register framework already permits this possibility because manifestational equivalence does not imply relational identity. Category theory offers several ways to formalize the relation without collapsing the realizing systems into one object.

Distinct objects A and B in $\mathcal{R}$ can be mapped to the same manifestational object or to isomorphic objects in $\mathcal{M}$. More strongly, distinct subcategories of relational realization can be mapped into equivalent manifestational structures. This can model cases in which different technologies, organizational arrangements, biological substrates, cultural practices, or computational architectures support similar manifested capacities.

Multiple realization should be distinguished from arbitrary substitution. Two realizations count as equivalent only relative to specified functions, relations, or manifestations. A payment service implemented through different technical infrastructures can appear equivalent to users for a selected transaction set while differing in resilience, surveillance, governance, energy use, or legal dependency. An artificial system and a human subject can produce locally equivalent outputs while differing profoundly in relational histories and forms of subjecthood. The relevant equivalence therefore belongs to the specified category and mapping, not to the entities without qualification.

Claim 4.148 (Locality of functorial equivalence)**.** *Functorial equivalence among realizations is always relative to the categories, morphisms, and invariants selected by the inquiry. It does not entail equivalence with respect to omitted relational, causal, normative, experiential, or ontological structure.*

This claim preserves the book's resistance to premature equivalence. A formal equivalence can be powerful precisely because its scope is explicit. It identifies what is preserved while leaving open what differs.

4.16.12 Commutative and Non-Commutative Diagrams of Representation

One of category theory's most useful habits is to ask whether different compositional paths yield the same result. A commutative diagram represents paths whose composite morphisms are equal within the model. In a representation problem, commutativity can express consistency between direct and mediated descriptions. If a relational configuration can be manifested directly or first symbolized and then translated into a manifestation, commutativity states that the two modeled paths agree.

Such agreement should not be presumed. Economic and institutional systems are often path-dependent. Classification before valuation can yield a different result from valuation before classification. Legal recognition followed by market participation can generate different relations from market participation followed by later recognition. A symbolic description produced before an intervention can affect the intervention itself, while a description produced afterward has a different causal role. In these cases the relevant diagram is non-commutative: the order and path of mediation matter.

Definition 4.149 (Representational path dependence)**.** *Representational path dependence* occurs when two admissible compositional paths connecting corresponding source and target configurations produce distinguishable outcomes within the modeled domain.

Non-commutativity is particularly important for the recursive architecture of Section 4.11. Once a manifestation or representation becomes causally operative, changing the order of manifestation, classification, recognition, or intervention can change the later relational configuration. Diagrammatic non-commutativity therefore provides one formal language for historical mediation.

At the same time, commutativity can be a normative or engineering objective rather than an empirical fact. An administrative system can be designed so that

equivalent procedural paths yield equivalent outcomes; an accounting architecture can seek consistency across transformations; a legal procedure can attempt to preserve rights across different channels. The diagram then encodes a desired invariant whose empirical realization must be tested.

4.16.13 Limits of the Category-Theoretic View

Category theory provides a powerful language of structure, composition, equivalence, and translation, but its usefulness within GR has identifiable limits. First, categorical analysis depends on prior choices of objects and morphisms. These choices can clarify a domain while reifying boundaries that remain contested or historically variable. A category can therefore be internally rigorous and still poorly matched to the relational reality it is intended to represent.

Second, ordinary categories encode composition abstractly but do not automatically represent probability, intensity, duration, geometry, uncertainty, power, cost, or causal strength. Such information can be added through enriched, probabilistic, metric, higher-order, or other categorical structures, but the additional formalism must earn its relevance. GRE should not escalate mathematical complexity merely because a richer category can be defined.

Third, some generative relations admit composition only partially, depend on context, or are themselves transformed through composition. Historical sequence can change the meaning of later operations; institutional exceptions can defeat uniform mapping; stochastic processes can make a single deterministic morphism inappropriate. In these settings, strict categories and strict functors may be approximations. Partial categories, correspondences, profunctors, lax structures, higher categories, or non-categorical models may provide better representations, but no formal family receives automatic priority.

Fourth, categorical equivalence can preserve structure while leaving material, experiential, historical, and normative differences outside the model. A fully faithful representation of selected relations can still omit who bears risk, whose experience is recognized, what resources are consumed, or which histories made the structure possible. Formal invariance therefore does not substitute for substantive economic inquiry.

Remark 4.150 (Methodological status of category theory)*.* Within GR and GRE, category theory is best treated as a language for disciplined structural comparison and composition. Its successful application establishes properties of the represented domain under specified modeling assumptions; it does not by itself establish that reality is fundamentally categorical.

The category-theoretic view nevertheless contributes something distinctive to the chapter. It allows relational and manifestational domains to remain heterogeneous while still being connected through explicit mappings. It distinguishes loss of relational distinctions from excess structure introduced by manifestation. It separates isomorphism, equivalence, and manifestational indistinguishability. It provides a formal language for coherent changes of mapping rules, multiple realization, and path-dependent representation. Most importantly, it makes visible the conditions under which a comparison preserves structure and the points at which such preser-

vation fails.

These contributions prepare the move to Section 106. Category theory can relate heterogeneous domains without requiring a shared metric, but it does not eliminate differences of scale or the possibility that similar higher-level realities are realized through different lower-level configurations. Scale-relative reality and multiple realization therefore require separate treatment. The categorical language developed here will remain available as one analytical resource while the next section returns to the ontological problem itself: how reality can be stable and causally efficacious at one scale while being differently constituted at another.

4.17 Scale-Relative Reality and Multiple Realization

The preceding section introduced category theory as one formal language for relating heterogeneous domains without requiring a common metric or an identity of underlying structure. The role of the present section is to address a more general ontological problem that remains even when no categorical formalism is used: the same generative-relational system can present different relatively stable objects, relations, processes, and functions at different scales, and similar higher-level functions can be realized through heterogeneous lower-level configurations. The objective is to clarify how GR can speak of scale-relative reality without making reality arbitrary, and how it can recognize multiple realization without treating functional similarity as ontological identity. The section proceeds through scale-relative entityhood, scale-relative relationality, multiple realization of similar functions, heterogeneous realization, and cross-scale reality. Throughout, scale is treated as an analytically specified resolution constrained by the organization and causal structure of the system, rather than as a freely chosen perspective detached from what the system can sustain.

Scale enters GR in several forms. It can be spatial, temporal, organizational, institutional, functional, informational, or relational. A household can be treated as an economic subject at one organizational scale while being analyzed as a changing set of interpersonal, legal, affective, material, and monetary relations at another. A firm can appear as a single contracting entity in one model and as a distributed process of governance, routines, assets, labor, software, infrastructures, and expectations in another. A price can be treated as a scalar variable at one analytical resolution while another inquiry reconstructs the market-making, institutional, informational, and symbolic relations through which that price becomes possible. None of these descriptions is automatically more real because it is finer grained. The relevant question is which organization persists and exerts causal efficacy at the scale required by the inquiry. (P. W. Anderson 1972; Bar-Yam 2004; Simon 1962)

This position differs from a simple micro–macro hierarchy. A scale is not defined only by size, and a finer resolution does not necessarily reveal a privileged ontological base. A legal status can operate at an institutional scale that is not reducible to physical size; a norm can persist across many material realizations; a computational function can be implemented through architectures with different internal organizations; and a subject can occupy several overlapping relational scales simultaneously. Scale-relative analysis therefore concerns the resolution at which organization, per-

sistence, constraint, and causal efficacy become analytically distinguishable.

Definition 4.151 (Analytical scale)**.** An *analytical scale* is a specified resolution of a generative-relational system at which selected entities, relations, processes, boundaries, and causal differences are treated as distinguishable for the purposes of an inquiry.

Definition 4.151 makes scale an explicit component of representation. It does not imply that the analyst creates the relevant reality by choosing a scale. The chosen resolution must remain answerable to the system. If a purported object fails to persist, stabilize, or exercise causal efficacy at the selected resolution, treating it as a relationally real entity becomes difficult to justify. Conversely, a configuration can be relationally real even when a finer-grained description reveals continual replacement, turnover, or transformation among its constituents.

4.17.1 Scale-Relative Entityhood

Entityhood in GR is therefore often scale-relative. A configuration can function as an entity when enough of its organization is stabilized to support identification, interaction, and causal participation at a selected resolution. This entityhood does not require that the configuration be simple, internally homogeneous, or materially indivisible. It requires that treating it as a unit preserve causal and relational differences relevant to the inquiry.

Definition 4.152 (Scale-relative entityhood)**.** *Scale-relative entityhood* denotes the status of a configuration that exhibits sufficient persistence, stability, boundary coherence, and causal efficacy to be treated as a distinguishable relational object at a specified analytical scale, even when finer or alternative scales reveal it as internally heterogeneous, processual, or distributed.

A corporation illustrates the point. At one scale it can enter contracts, own assets, incur liabilities, employ workers, issue securities, and survive changes in membership. At another scale it is constituted through legal rules, governance procedures, organizational routines, technologies, buildings, documents, labor, interpersonal relations, and expectations. The higher-level entity does not disappear because its lower-level realization is heterogeneous. At the same time, the lower-level relations cannot be inferred exhaustively from the fact that the corporation persists as a legal and economic entity. Scale-relative entityhood therefore preserves both the causal reality of the higher-level object and the incompleteness of any single-scale description.

The same pattern appears in money. A unit of account can be analyzed as a stabilized relational object within a monetary system, while its realization depends on material tokens, ledgers, settlement infrastructures, legal rules, central-bank practices, commercial banking, expectations, software, and repeated acts of pricing and payment. A monetary unit is neither reducible to any one of these components nor independent of the system that sustains it. Its entityhood is scale-relative because it becomes causally tractable at the level at which monetary claims, prices, debts, and payments operate.

Scale-relative entityhood also applies to subjects. The continuing sense of “I” discussed in Section 4.12 can possess relational reality at a scale of autobiographical con-

tinuity and practical agency while being realized through changing bodily, neural, mnemonic, linguistic, social, and institutional processes. The fact that these lower-level realizations change does not by itself negate the relational reality of the self-model that persists sufficiently to guide action. Conversely, persistence of the practical self does not settle whether an ontologically independent and unchanging self exists. The three-register architecture and ontological suspension remain intact.

Scale-relativity therefore differs from nominalism about entities. GR does not treat entities as mere names imposed on an otherwise undifferentiated flow. Some boundaries are institutionally authorized, materially reinforced, operationally reproduced, or causally consequential. Others are weak, temporary, contested, or analytically convenient. The task is to identify the mechanisms through which entityhood is stabilized and the range over which treating the configuration as an entity preserves explanatory adequacy.

Claim 4.153 (Constraint on scale-relative entityhood)**.** *A scale-relative entity claim is warranted only insofar as the proposed entity exhibits sufficiently stable organization and causal efficacy at the selected scale; changing the scale can alter the adequacy of the entity description without making the underlying inquiry arbitrary.*

Claim 4.153 prevents two opposite errors. One is reductionism, in which a higher-level object is dismissed because it can be decomposed. The other is reification, in which a convenient aggregate is treated as independently real even when its internal heterogeneity materially changes explanation. A national unemployment rate, a firm's productivity, a household preference, or a platform's market share can be useful higher-level objects, but the explanatory adequacy of each depends on whether aggregation preserves the differences relevant to the problem.

Scale-relative entityhood also has a temporal dimension. An entity can be stable at one temporal resolution and transient at another. A coalition can organize a negotiation for several months without becoming a durable institution. A market panic can persist long enough to reorganize credit even if it dissipates rapidly in historical time. A technical standard can remain stable for decades while individual implementations change continuously. Persistence must therefore be evaluated relative to the causal timescales of the relations being studied.

4.17.2 Scale-Relative Relationality

Relations are also scale-relative. A relation observed at one scale can summarize a large number of lower-level interactions, while a lower-level relation can become invisible or irrelevant at a higher resolution. For example, an employer–employee relation can be represented as a contractual relation in one model, while another inquiry decomposes it into wage-setting procedures, supervisory practices, legal rights, informal expectations, technical dependencies, bargaining capacities, and histories of recognition or conflict. Neither representation is automatically superior. Each preserves different relations and suppresses others.

Scale-relative relationality matters because GR places relations at the center of explanation without assuming that all relations must be represented at the finest available resolution. An economic system would become analytically unusable if every molecular, neurological, linguistic, contractual, technological, and institutional inter-

action had to be represented simultaneously. Relational analysis therefore requires principled compression. The question is whether the compressed relation retains the causal and generative structure relevant to the inquiry.

Definition 4.154 (Scale-relative relation)**.** A *scale-relative relation* is an analytically specified relation whose relata, structure, and causal significance are defined at a selected resolution and whose adequacy depends on whether it preserves the relational differences relevant to the inquiry.

A relation at one scale can itself become a relatum at another. A long-term contractual relation between two firms can be treated as one edge in a supply network even though the relation is internally complex. A local credit network can become a component of a regional financial structure. A household can become a relatum in a tax system. An institution can become a node within an international regime. This nesting is not merely representational convenience when the higher-level configuration develops persistence and causal efficacy of its own.

Relations across scales can also constrain one another. A regulatory regime can shape permissible transactions among individual firms; repeated firm-level practices can gradually alter regulatory expectations; a platform's architecture can condition interactions among users; accumulated user practices can produce pressures that change the platform's rules. GR therefore avoids a one-directional picture in which causal explanation always moves from smaller to larger units. Cross-scale causal organization can involve amplification, constraint, feedback, path dependence, and institutional mediation.

The possibility of scale-relative relationality also clarifies why relational realities need not share a common metric. A relation between two persons, a relation between institutions, and a relation between a legal category and an administrative procedure can all be causally important without being distances in one numerical space. Moving across scale can require translation among heterogeneous forms of relation rather than rescaling a single measure. The category-theoretic view of Section 4.16 provides one possible formal language for such translations, but the ontological point is broader: relational connectedness does not imply metric homogeneity.

Remark 4.155 (Relational compression)*.* A higher-scale relation can be analytically legitimate even when it compresses many lower-scale relations, provided that the compression preserves the distinctions necessary for the explanatory or evaluative task and does not conceal lower-scale heterogeneity that materially changes the conclusion.

Remark 4.155 is especially important for GRE. Economic analysis routinely works with households, firms, sectors, markets, institutions, and states. GRE does not reject these units because they are relationally constituted. It asks when their internal constitution matters and when a stabilized higher-scale relation is an adequate object of inquiry. The answer can change across questions. A firm can be a useful unit in a trade model and an inadequate unit in an analysis of workplace power. A household can be useful in a consumption model and inadequate in an analysis of intra-household allocation. Scale selection therefore carries explanatory and normative consequences.

4.17.3 Multiple Realizations of Similar Functions

Scale-relativity becomes especially important when similar higher-level functions are realized through different lower-level configurations. A payment function can be supported by cash, bank deposits, card networks, mobile ledgers, or other infrastructures. A coordination function can be performed through hierarchy, market exchange, professional norms, algorithmic allocation, or combinations of these. A memory function can be distributed across human recollection, written records, databases, institutional routines, and technical archives. Similar manifested capacities can therefore emerge from heterogeneous relational organizations. (Fodor 1974; Kim 1992)

Definition 4.156 (Multiple realization)**.** *Multiple realization* occurs when two or more materially, organizationally, relationally, or otherwise structurally distinct configurations support a sufficiently similar function, capacity, manifestation, or higher-scale relational reality relative to explicitly specified criteria.

Definition 4.156 makes similarity criterion-dependent. Two systems can realize the same payment function for ordinary retail exchange while differing in privacy, settlement finality, resilience, energy demand, governance, legal recourse, accessibility, or exposure to surveillance. Two organizations can produce similar outputs while distributing authority, risk, labor, and recognition differently. Two subjects can produce locally indistinguishable responses while possessing different histories, internal organizations, capacities, or forms of experience. Multiple realization therefore supports local equivalence without implying general equivalence.

This distinction is continuous with the chapter's treatment of non-invertibility. Similar manifestations do not uniquely determine the relational configuration that produced them. Multiple realization provides a structured reason for this underdetermination: different realizations can converge on a similar manifested function. The inverse problem becomes especially difficult when only the higher-level output is observed and the lower-level realization is hidden, changing, or institutionally inaccessible.

Multiple realization also prevents a simple reduction of function to substrate. If the same higher-level function survives replacement of many lower-level components, the function can acquire a degree of relational autonomy at the scale where it is reproduced. This autonomy is relative rather than absolute. The higher-level reality still depends on realization, but it may not depend on one unique realization. A legal office can persist through changes in officeholders, buildings, record systems, and administrative technologies; a currency can persist through changes in physical tokens and settlement infrastructure; an organization can preserve functions through substantial turnover in members and routines.

Claim 4.157 (Locality of realized equivalence)**.** *When distinct configurations realize a similar function or manifestation, the resulting equivalence is limited to the criteria under which the similarity is established. It does not entail equivalence of causal history, internal relation, normative consequence, material dependence, or ontological status.*

Claim 4.157 gives multiple realization the same discipline that Section 4.16 gave formal equivalence. A comparison must state what is preserved. In economics, this prevents functional substitutability from becoming a claim of social or ethical substi-

tutability. An automated system can substitute for a human worker in a specified productive task while changing employment relations, accountability, knowledge distribution, bargaining power, surveillance, or the meaning of participation. Functional similarity is therefore one relation among many.

Multiple realization can also occur historically within one relational reality. A monetary system, educational institution, welfare programme, scientific practice, or communication network can preserve a recognizable higher-level function while its material and organizational realization changes over time. Historical continuity then consists partly in the reproduction of function across changing realizations. Whether the change constitutes continuity, transformation, or replacement depends on which relations and capacities are treated as constitutive at the scale of inquiry.

4.17.4 Heterogeneous Ontological Realizations

The language of multiple realization can tempt a stronger conclusion: that a higher-level reality is independent of the ontological character of its realizers. GR does not require this conclusion. Realizations can be heterogeneous without being irrelevant. Material, biological, technical, institutional, symbolic, and experiential differences can affect which functions are possible, how reliably they are sustained, what costs they impose, and what forms of causal efficacy they acquire.

For this reason, the phrase *heterogeneous ontological realization* is used cautiously. It does not assert that GR has already established a complete ontology of the realizing domains. It marks cases in which the lower-level configurations supporting a higher-level relational reality require substantially different descriptive vocabularies or ontological commitments. A legal norm can depend on texts, institutions, authorized roles, practices, sanctions, interpretations, and embodied subjects. A digital asset can depend on electrical infrastructure, software states, cryptographic operations, legal recognition, organizational governance, and user expectations. A religious object can depend on material artifacts, ritual practice, collective memory, symbolic systems, embodied experience, and institutional continuity. The higher-level relational reality can span these heterogeneous realizations without being identical to any single one.

Definition 4.158 (Heterogeneous realization)**.** A *heterogeneous realization* is a realization in which the sustaining components or processes belong to analytically distinct domains whose relevant structures cannot be adequately represented by a single homogeneous descriptive vocabulary without significant loss.

Definition 4.158 does not imply that the domains are metaphysically incommensurable. It states a methodological condition: the inquiry currently requires more than one descriptive register to preserve the organization relevant to explanation. Ontological suspension remains appropriate when stronger claims about the ultimate relation among those domains are unnecessary.

Heterogeneous realization matters for the three-register architecture because manifestation can occur through one domain while relational stabilization depends on several. A monetary balance may manifest as a number on a screen while its relational reality depends on legal claims, institutional records, technical infrastructures, settlement capacities, and expectations. A person's institutional identity may

manifest through a credential while its effects depend on legal recognition, database entries, organizational practice, social interpretation, and the subject's own history. A manifestationally simple object can therefore possess a relationally heterogeneous realization.

This point also constrains ontological inference. The fact that a higher-level function is multiply realized does not prove that the realizations are ontologically interchangeable. Conversely, the fact that realizations differ ontologically does not prevent them from supporting a locally similar relational reality. GR therefore separates at least three questions: whether a function is preserved, whether the realizing structures are relationally equivalent, and whether their ontological status is the same. These questions can receive different answers.

Heterogeneous realization has normative consequences as well. Two infrastructures that provide similar user-facing functions can distribute environmental cost, labor burden, vulnerability, control, or exclusion differently. Two organizational forms can produce similar outputs while structuring autonomy and authority differently. Ontological and relational heterogeneity can therefore matter even when manifestational equivalence is strong. GRE must resist the tendency to treat functional output as an exhaustive description of economic reality.

4.17.5 Cross-Scale Reality

The preceding arguments imply that relational reality can be distributed across scales. A higher-scale object can be realized through lower-scale configurations while becoming sufficiently stable to constrain, enable, or reorganize those very configurations. This reciprocal organization is what the present subsection calls cross-scale reality. The term does not designate a separate fourth register of reality. It describes relations among realities whose persistence and causal efficacy are distinguishable at different analytical scales.

Definition 4.159 (Cross-scale reality)**.** *Cross-scale reality* denotes a configuration in which relationally real structures identified at different analytical scales participate causally in one another's generation, stabilization, constraint, or transformation.

A legal institution provides a simple example. Repeated actions, documents, decisions, records, and recognized roles sustain the institution. Once stabilized, the institution constrains which actions count as valid, who possesses authority, what procedures are available, and which future relations can be formed. The higher-scale institution is realized through lower-scale practices, while the lower-scale practices are reorganized by the institution they sustain. A monetary system similarly depends on transactions and records while simultaneously shaping the terms under which transactions are possible. An organization depends on individual actions while roles, procedures, and collective resources constrain those actions.

Cross-scale reality therefore avoids the assumption that causal explanation must terminate at the finest scale. A finer-grained description can reveal mechanisms through which a higher-level structure is realized, but the higher-level structure can still be causally indispensable because it organizes the space of lower-level possibilities. The statement that a rule is implemented through individual actions does not eliminate the causal significance of the rule when actors orient themselves to it, insti-

tutions enforce it, and it structures future choices. The relation between realization and efficacy is recursive rather than eliminative.

This does not require a strong doctrine of "downward causation." GR can remain neutral about metaphysical debates concerning causal levels. The analytically necessary claim is weaker: descriptions at different scales can capture causally relevant organization that is lost if analysis is restricted to one scale. If changing a higher-level institutional relation systematically changes lower-level possibilities, and if lower-level interactions reproduce or transform that higher-level relation, then a cross-scale account can be explanatorily warranted regardless of how the ultimate metaphysics of causation is later formulated.

Claim 4.160 (Cross-scale causal adequacy)**.** *A cross-scale explanation is warranted when causal differences at one analytical scale cannot be adequately represented without reference to relatively stable organization identified at another scale, and when the relations connecting those scales can be specified sufficiently for the inquiry.*

Claim 4.160 places a burden on cross-scale explanation. Analysts should identify the relations connecting scales rather than invoke "macro" or "micro" levels as unexplained causes. The relevant connectors can include rules, incentives, infrastructures, information, classifications, authority, material dependencies, learning, imitation, resource flows, technical interfaces, or repeated practices. Different problems require different mechanisms.

Scale selection also affects manifestation. A pattern can be manifest at one scale while remaining invisible at another. An individual may experience a series of unrelated administrative decisions while a population-level analysis reveals a systematic distribution. A macroeconomic indicator can display stability while household-level experiences diverge sharply. A platform can appear reliable to users while infrastructural monitoring reveals growing fragility. Manifestational reality is therefore scale-sensitive, and disagreements about "what is happening" can sometimes arise because different observers, institutions, or instruments manifest different scales of the same relational system.

The graph architecture developed earlier in the chapter remains applicable. A manifestation at one scale can enter relations at another scale. A population statistic can reorganize policy; an individual case can become a symbolic event that changes institutional rules; a market index can alter firm behavior; a local failure can trigger system-wide redesign. Scale and register are therefore distinct dimensions. Ontological, relational, and manifestational realities can each be investigated at several scales, and mappings among registers can themselves operate across scale.

The consequence for GRE is methodological rather than merely ontological. Economic inquiry should specify the scale at which an object is claimed to be real, the realization relations that sustain it, the higher- and lower-scale structures omitted by the representation, and the conditions under which equivalence across realizations is asserted. A stable aggregate should not be decomposed merely because decomposition is possible, but neither should aggregation conceal heterogeneity that changes causal or normative conclusions. The appropriate scale is therefore part of the argument.

Scale-relative reality and multiple realization also clarify why ontological cat-

egories can change historically. New technologies, institutions, infrastructures, classifications, and productive arrangements can stabilize objects and functions at scales that were previously unavailable or analytically insignificant. A platform, digital identity, algorithmic market, multinational supply network, or machine-learning agent can become a relatively stable object only under historical conditions that sustain the relations required for its persistence and efficacy. The categories through which an inquiry describes economic reality can therefore acquire or lose salience as the systems themselves change.

This observation prepares Section 107. The next problem is not only that the same reality can be described at several scales, but that the categories available for identifying subjects, objects, relations, capacities, and institutions are themselves historically formed. Scale-relative analysis preserves a plurality of valid resolutions; historical materiality asks how some resolutions and categories become practically consequential in the first place. Together, the two arguments support an ontology that is structured and causally serious without being frozen into a timeless inventory of entities.

4.18 Historical Materiality of Ontological Categories

The preceding sections have progressively loosened the assumption that an ontology for economic inquiry can be given as a timeless inventory of ready-made entities. Relational realities can emerge and dissolve; manifestations can alter the systems they disclose; representations can become causally operative; subjects, institutions, and values can be stabilized through historically specific relations; and the adequacy of an entity description can vary across scale. The role of the present section is to make the historical consequence of these claims explicit. Its objective is to show that the categories through which GR and GRE distinguish subjects, objects, relations, capacities, institutions, and processes can themselves possess a historical materiality. This does not mean that reality is created at will by vocabulary, nor that every ontological distinction is merely conventional. It means that the kinds of relatively stable realities available to economic analysis, the practical boundaries through which they are reproduced, and the categories adequate to describing them can change as productive capacities, institutions, infrastructures, classifications, and forms of social organization change. The discussion proceeds through historical category formation, productive forces and ontological salience, institutional stabilization, transformation of subject and object categories, and the disciplined revisability of ontological categories.

Historical materiality therefore concerns more than the history of ideas about what exists. It also concerns the history of the relational systems within which some distinctions become materially reproducible and causally consequential. The category of a corporation, for example, is not only a word used by analysts. It is connected to legal personality, accounting, ownership, contracting, record keeping, governance, and organizational continuity. The category of a wage worker is similarly connected to historically specific relations of labor, property, contract, production, and reproduction. A category can thus be historically constituted at two levels at once: as a conceptual distinction within inquiry and as a distinction stabilized in the organization of the world being investigated. Keeping these levels

distinct is essential. A historically formed concept can refer badly to reality, while a historically stabilized relational object can remain causally real even when existing concepts represent it inadequately.

Definition 4.161 (Historical materiality of an ontological category)**.** The *historical materiality of an ontological category* denotes the dependence of a category's practical applicability, boundaries, salience, or causal relevance on historically formed generative-relational conditions, including productive capacities, institutions, infrastructures, classifications, practices, and modes of representation.

Definition 4.161 is deliberately weaker than the claim that all ontological reality is historically produced. GR does not need that stronger metaphysical thesis. The definition instead identifies a property of inquiry and of relational reality: some categories become adequate because historical processes stabilize objects or relations that satisfy the category's conditions; some lose adequacy because those objects or relations transform; and some acquire new meanings because the systems through which they operate change. Ontological suspension therefore remains compatible with historical materiality. One can investigate how a category becomes materially and institutionally operative without claiming that every aspect of the reality to which it refers is exhausted by that history.

4.18.1 Historical Formation of Categories

Economic categories have histories because economies have histories. Property, labor, money, household, firm, market, commodity, debt, employment, platform, data, and capital are not analytically interchangeable across all social formations. Some of these terms can be used at high levels of abstraction across long periods, but their concrete relations, legal forms, technical infrastructures, and causal roles can differ substantially. Historical political economy has long emphasized that economic categories can be specific to forms of production and social organization rather than natural kinds that retain an invariant content across history (Marx 1867; Polanyi 1944). GR adopts this historical discipline without requiring that every later ontological claim be reduced to a single theory of historical development.

A category can form historically in several ways. New relational objects can emerge. Existing objects can acquire new causal roles. Institutional boundaries can stabilize distinctions that were previously fluid. Measurement and recording systems can make previously diffuse differences operational. Technical infrastructures can connect dispersed processes into a new functional whole. Political and legal arrangements can create statuses with durable consequences. Repeated representation can also reorganize the object represented, producing recursive stabilization of the category itself. These pathways often overlap, but they should not be collapsed into one mechanism.

Consider the modern firm. Treating the firm as an economic subject is analytically useful because legal, accounting, organizational, technological, and contractual relations make it possible for a changing population of persons and assets to persist as a recognizable unit. The category becomes materially consequential because contracts are signed in its name, liabilities are assigned to it, accounts are kept for it, and future action is coordinated through it. Yet the category does not have one invariant

realization. A family enterprise, public corporation, cooperative, platform company, and multinational group can differ sharply in governance, ownership, scale, internal authority, and technical organization while remaining recognizable under a broader category of firm for some inquiries.

The same applies to labor. "Labor" can designate human activity at a high level of abstraction, but wage labor, coerced labor, unpaid care, self-employment, professional service, platform-mediated work, and machine-assisted production occupy different relational structures. A historical change in the organization of production can therefore alter which distinctions matter to explanation. An ontology of economic activity that treats all productive contribution as one homogeneous object may remain useful for one aggregate calculation while becoming inadequate for questions about authority, reproduction, dependency, or distribution.

Historical category formation should also be distinguished from simple linguistic change. A new word can appear without a corresponding new relational reality, and a relational reality can emerge before a stable vocabulary exists for it. Section 4.5 established that relational reality does not require prior perception or symbolization. The historical formation of an ontological category can therefore lag behind the formation of the reality it later names. Conversely, institutional naming can precede and help stabilize the object named. Legal recognition of a corporate form, administrative classification of a population, or technical standardization of a digital object can contribute to the relations through which the corresponding reality subsequently persists.

Claim 4.162 (Dual historicity of ontological categories)**.** *The historicity of an ontological category can arise both from changes in the reality to which the category is applied and from changes in the conceptual, institutional, and representational practices through which that reality is distinguished; these two histories can interact without being identical.*

Claim 4.162 prevents two reductions. One would treat categories as passive labels that simply follow changes in an independently organized world. The other would treat the world as if it were produced entirely by classification. GR instead permits recursion. A changing economic system can demand new categories, and an institutionalized category can later reorganize the relations it classifies. Hacking's historical ontology and work on classificatory practices provides a useful precedent for this latter possibility, particularly where classifications interact with the persons and practices organized around them (Hacking 2002). The present argument extends the point cautiously to a wider range of economic objects while preserving the distinction between classificatory mediation and the full generative structure of those objects.

This dual historicity also means that category boundaries can be contested. Disputes about whether a worker is an employee or independent contractor, whether a digital token is money, property, security, or access credential, whether a platform is a marketplace or an employer, or whether an artificial system counts as an economic agent can be partly conceptual and partly institutional. Such disputes often matter because different classifications activate different rights, liabilities, measurements, expectations, and causal pathways. The contest is therefore not merely semantic. Once linked to institutions, a category can become a mechanism through which resources and possibilities are distributed.

4.18.2 Productive Forces and Ontological Salience

Historical materiality becomes especially visible when productive capacities change. The term *productive forces* is used here in a broad and deliberately non-exclusive sense to include techniques, skills, infrastructures, tools, scientific knowledge, organizational capacities, energy systems, computational resources, and other means through which production and coordinated activity become possible. Marxian traditions give productive forces a central place within historically specific relations of production, but GRE need not adopt a deterministic sequence in which technical development alone explains institutional or ontological change. Productive capacities interact with law, ownership, culture, ecology, political authority, knowledge, and social reproduction. Their relevance in this section is narrower: changes in productive capacity can alter which objects, relations, and scales become stable enough to acquire ontological salience for economic inquiry.

Definition 4.163 (Ontological salience)**.** *Ontological salience* denotes the degree to which a kind of object, relation, process, or capacity becomes sufficiently persistent, causally consequential, and differentiable within a historical system that distinguishing it materially improves explanation, intervention, or evaluation.

Ontological salience is not identical to ontological reality. Something can be real while remaining marginal to the inquiry, and something can be highly salient in representation while its underlying reality is weak or mischaracterized. Salience concerns why a distinction becomes difficult to omit without explanatory loss. When railways, electrical grids, telecommunications networks, digital platforms, or large computational systems become infrastructures of economic coordination, categories corresponding to network position, interoperability, platform access, computational capacity, or data dependency can acquire a practical importance that was absent under earlier productive arrangements.

Technical change can also create new scales of stable organization. A geographically dispersed supply chain becomes a tractable economic object only when transport, communication, contracting, standards, finance, and information systems sustain coordination across distance. A real-time algorithmic market presupposes technical and institutional infrastructures through which orders, prices, identities, risk controls, and settlement can be processed at speeds and scales unavailable to earlier markets. A machine-learning agent can become an operationally significant economic object only when computational infrastructures, training processes, interfaces, institutional permissions, and organizational practices support sustained action. These objects are not made real by technology alone; technology participates in the generative-relational configurations that allow them to persist and act.

Productive forces can also alter the salience of older categories. Mechanization changes the relation between labor time, skill, machinery, and output. Automation can separate productive contribution from direct human execution. Digital replication changes the relation between use and scarcity for some informational goods. Remote communication changes the spatial organization of work. Large-scale data processing changes the practical role of classification and prediction. None of these transformations automatically invalidates categories such as labor, property, commodity, or firm, but each can change what must be specified for those categories to

remain analytically adequate.

The relation between productive forces and ontological salience is therefore generative rather than deterministic. New capacities can open a possibility space without fixing the institutional form that will stabilize within it. Similar technologies can be embedded in different ownership structures, legal regimes, organizational forms, cultural practices, and normative orders. Conversely, institutions can delay, redirect, or selectively amplify technical possibilities. GR therefore treats productive forces as one set of historically material conditions among several, not as an autonomous engine that determines the ontology of the economy.

Remark 4.164 (Material possibility and historical stabilization). A productive capacity can make a relational form possible without making that form inevitable. Ontological salience emerges when technical possibility becomes joined to sufficiently stable institutional, organizational, symbolic, ecological, and practical relations to produce durable causal effects.

Remark 4.164 is particularly important for contemporary AI. The existence of a model capable of generating language does not by itself settle whether it constitutes an economic subject, an instrument, an organizational component, an autonomous service, or some combination of these under different conditions. Those categories depend on the relations through which the system is authorized, controlled, represented, contracted with, integrated into workflows, and made responsible or nonresponsible for consequences. Technical capability changes the category problem; institutional stabilization helps determine which category becomes operative.

4.18.3 Institutions and Stabilized Reality

Institutions give historical categories durability by linking distinctions to recurrent practices, rules, records, sanctions, rights, expectations, and authorized procedures. Section 4.14 treated institutions as relationally real when they satisfy the full criterion of persistence, stability, and causal efficacy. The present concern is how institutionalization contributes to the historical materiality of the categories through which such realities are recognized and reproduced.

Institutional categories do more than describe. A property title establishes a recognized relation among persons, objects, claims, and authorities. A corporate registration makes a legal subject available for contracting and liability. An employment classification can activate wage rules, insurance obligations, tax treatment, bargaining rights, or exclusions. A national-accounting category can shape how economic activity is measured and compared. A technical standard can determine which objects interoperate. Once these classifications are embedded in durable procedures, their consequences extend beyond the moment of naming.

North's institutional analysis emphasizes that formal rules, informal constraints, and enforcement characteristics structure incentives and economic interaction (North 1990). Searle's account of institutional facts likewise draws attention to how socially recognized statuses can support powers, rights, duties, and functions that are not reducible to the physical properties of the objects involved (Searle 1995). GR need not adopt either framework as a complete ontology of institutions to retain the insight that institutional recognition can stabilize relational realities and make

category boundaries causally consequential.

Institutional stabilization can produce what might be called category infrastructure. Registries, legal codes, accounting systems, databases, credentials, standards, forms, identifiers, professional practices, and administrative routines make categories reproducible across time and across many local interactions. They reduce the need to renegotiate the existence and meaning of a category in each encounter. A corporation need not be recreated conceptually whenever it enters a contract; a recognized currency unit need not be redefined in each payment; a credential can travel across organizations because institutional infrastructures preserve enough of its meaning to make it actionable.

Definition 4.165 (Category infrastructure)**.** A *category infrastructure* is a relatively persistent assemblage of rules, records, standards, practices, technologies, and authorized interpretations through which a classificatory distinction is reproduced and made causally operative across situations.

Category infrastructure helps explain why some classifications become relationally real while others remain ephemeral. A spontaneous label may influence a local interaction but disappear quickly. A classification linked to records, eligibility rules, technical interfaces, and repeated organizational practice can persist and reorganize future relations. Its materiality lies partly in the infrastructures that carry it. This does not make the classification epistemically correct or normatively legitimate. A mistaken, discriminatory, or obsolete category can remain causally powerful when institutions continue to act upon it.

Institutional stabilization also produces inertia. Once organizational routines, contracts, software systems, forms, statistical series, and legal rights are built around a category, revising that category can become costly. Historical categories can therefore outlive the conditions under which they were initially useful. A classification may persist because infrastructures presuppose it, even as the underlying relational reality becomes more heterogeneous. This lag creates a recurring epistemic and political problem: the category remains materially real in its effects while becoming increasingly inadequate as a description.

The recursive architecture of Sections 4.10 and 4.11 is visible here. A category becomes symbolized and institutionalized; institutions then act through the category; those actions reshape subjects, resources, and opportunities; the altered relations generate new manifestations; and subsequent representations may either reinforce or challenge the category. Historical materiality therefore includes the accumulated consequences of prior classifications. Categories carry histories not only because their meanings change, but because earlier meanings leave infrastructures and distributions behind.

4.18.4 Historical Transformation of Subject and Object Categories

The distinction between subject and object is itself historically articulated within economic systems. GR does not imply that every subject is reducible to a role or that every object is created by institutions. It does, however, treat practical subjecthood and objecthood as potentially relationally stabilized. Section 4.12 already distinguished ontological subjecthood, relationally effective subjecthood, manifestational subject-

hood, and institutionally represented subjecthood. Historical materiality adds that the conditions under which particular forms of subjecthood become economically operative can change.

The wage worker, consumer, shareholder, debtor, insured person, welfare recipient, platform user, data subject, content creator, contractor, and machine operator are not simply different names for a timeless economic individual. Each role selects different relations, rights, obligations, capacities, vulnerabilities, and forms of representation. A person can occupy several of these positions simultaneously, and the same person can move among them over time. Historical change can create new subject positions or reorganize the causal importance of old ones.

Classifications of persons can also be recursive. Hacking's analysis of interactive kinds is especially relevant where classifications enter institutions and self-understanding, although GR does not assume that every economic category behaves in this way (Hacking 2002). A credit category can alter borrowing opportunities and future financial behavior. An employment category can alter legal protection and bargaining position. A professional credential can alter access to institutions and the subject's own expected trajectory. A platform reputation score can mediate visibility and opportunity. In each case a representation of the subject becomes part of the relational system through which later subjecthood is produced.

Objects undergo analogous transformations. Land can be a lived environment, territory, ecological system, taxable parcel, commodity, collateral, commons, sacred site, or development asset under different relational configurations. Data can be treated as record, evidence, asset, input, personal information, property-like resource, public infrastructure, or object of governance. A digital account can become an access credential, payment instrument, identity proxy, contractual interface, or bundle of institutional claims. The physical or informational substrate can remain partly similar while the relational object changes because different institutions and practices stabilize different causal roles.

Claim 4.166 (Historical transformation of economic objecthood)**.** *An economic object's relational reality can transform when the relations that stabilize its boundaries, capacities, rights, uses, or causal roles change, even where some underlying material substrate remains continuous.*

Claim 4.166 helps avoid two extremes. One would assume that the stable material substrate fixes the economic object once and for all. The other would imply that a change of description alone creates a new object. GR instead asks whether the change in relations is sufficient to alter persistence, causal capacities, recognized boundaries, or the possibilities generated by the object. Reclassification matters most when it becomes embedded in relations that materially change what can happen next.

Subject and object categories can also exchange analytical roles. A firm can be a subject in a market model and an object of regulation. A worker can be an agent in a labor-supply model and an object of algorithmic classification. An algorithm can be treated as an object owned by a firm, a process embedded in organizational decision making, or an operational subject when it performs sustained actions within authorized interfaces. These shifts do not by themselves settle metaphysical subjecthood. They show that the subject/object distinction used in economic inquiry is partly task-

and relation-dependent, and that historical changes can make previously marginal orientations practically important.

This point becomes particularly significant under automation and AI. A system can manifest outputs associated with human economic agency while remaining embedded in ownership, infrastructural dependence, governance, and technical realization that differ substantially from human subjecthood. GRE therefore needs categories capable of recognizing artificial operational agency without inferring experiential, moral, juridical, or ontological equivalence from functional similarity. The historical emergence of such systems makes the inadequacy of a simple human-agent/tool dichotomy increasingly visible, but the appropriate replacement categories remain open to empirical and normative development.

4.18.5 Ontological Categories as Historically Revisable

If ontological categories possess historical materiality, they must also be revisable. Revisability, however, should not be confused with conceptual voluntarism. Analysts cannot simply redefine an inconvenient reality out of existence. A useful revision must respond to changes in causal organization, evidential access, institutional structure, explanatory purpose, or normative problem. Historical revisability is disciplined by the realities the categories are intended to track.

Definition 4.167 (Historical revisability of ontological categories)**.** The *historical revisability of an ontological category* is the requirement that its boundaries, criteria, and explanatory role remain open to modification when changes in relational organization, manifestation, evidence, institutional practice, or analytical purpose materially alter the adequacy of the category.

Several forms of revision are possible. A category can be subdivided when previously compressed differences become causally significant. Several categories can be joined for a particular higher-scale analysis when their differences cease to matter to the inquiry. A category can change its defining criteria. Its temporal or spatial scope can be narrowed. A formerly central category can become secondary while another becomes more salient. A category can also remain in use while its ontological interpretation becomes more restrained. Revisability therefore does not imply constant replacement; it includes refinement, rescaling, qualification, and explicit limitation.

Historical revisability is especially important where administrative and analytical categories have become infrastructures. Because institutional categories can shape the reality they classify, revision can change the object of inquiry as well as the representation of that object. Altering an employment classification can change rights and organizational incentives. Revising a monetary definition can change reported aggregates and policy interpretation. Changing a diagnostic or eligibility category can reorganize access to resources. The epistemic act of revision can thus become an intervention in relational reality.

This recursive possibility makes provenance important. Analysts should be able to ask when a category was introduced, through which institutions it became operative, what relations it compresses, which populations or objects it excludes, what technical or legal infrastructures depend on it, and how its meaning has changed. Historical ontology in this sense is not an antiquarian supplement to economic analysis. It is

part of understanding what present categories do.

Claim 4.168 (Discipline of historical revision)**.** *Revision of an ontological category is warranted when an alternative distinction preserves or improves causal, relational, manifestational, or evaluative adequacy for the inquiry, and when the reasons for altering the category can be traced to changes in evidence, organization, scale, purpose, or historically material conditions rather than to terminological preference alone.*

Claim 4.168 gives revisability a burden of argument. A new category should show what explanatory difference it makes. An old category should not be discarded merely because it is historically constituted; historical constitution is compatible with durable causal reality. Money, firms, legal persons, markets, and institutional roles can remain indispensable objects of analysis even when their forms are historically specific. Conversely, long use does not guarantee continuing adequacy. A category can be deeply institutionalized and still fail to represent emerging relations that have become causally significant.

The distinction between relational reality and normative validity is again essential. A historically stabilized category can be unjust, exclusionary, or misleading while remaining causally real. Its normative criticism does not erase its effects. Likewise, a normatively attractive category does not become relationally real merely because it would be desirable for institutions to recognize it. GRE must therefore be able to analyze categories that ought to change without pretending that they have already changed, and to analyze emergent categories without treating emergence as justification.

Historical materiality also places a limit on claims of universal ontology within economics. Categories that function well in one historical configuration may require translation elsewhere. “Household,” “property,” “employment,” “market,” or “firm” can refer to relationally different arrangements across institutional and cultural contexts. Comparative analysis therefore needs to establish which structural correspondences justify using a common category and which differences require separate treatment. Shared terminology should not silently produce equivalence.

At the same time, historical materiality does not eliminate the possibility of cross-historical abstraction. Some categories can be useful precisely because they capture recurring relational forms at a sufficiently general level. Exchange, constraint, dependency, production, reproduction, coordination, obligation, and causal efficacy can sometimes travel across contexts more readily than narrower institutional categories. The appropriate level of abstraction depends on the question. GR’s methodological primitives and the three-register architecture are intended to support this movement across levels without claiming that every concrete economic object has a timeless form.

The resulting position is a historically responsive ontology rather than either a fixed catalogue or unrestricted constructivism. Reality constrains categories; categories can mediate reality; institutions can stabilize categories; productive capacities can change what becomes materially possible and salient; and historical transformation can require new distinctions. Ontological suspension remains active throughout: the historical emergence of a relational object does not decide whether it possesses some stronger ontological status, while the absence of a final metaphysics does not

weaken the claim that historically formed objects and categories can be causally real.

This historical perspective prepares the next methodological step. If categories, scales, and even some objects of inquiry are historically conditioned, relational-generative analysis should be treated as a disciplined analytical expedient rather than as a declaration that all reality possesses one final relational form. Section 108 therefore turns from the historical materiality of categories to the methodological standing of relational-generative analysis itself: what it enables, when it is warranted, and where its use should remain provisional.

4.19 Methodological Standing of Relational-Generative Analysis

The preceding sections have developed an ontological architecture in which relational realities can emerge, persist, stabilize, and exercise causal efficacy; manifestations can disclose and transform those realities; representations can become operative within subsequent relations; categories can vary across scale and history; and formal languages can clarify selected structural features without exhausting the realities they represent. The role of the present section is to state the methodological consequence of that architecture for Generative Relational Theory (GR) and Generative Relational Economics (GRE). Its objective is to clarify the standing of relational-generative analysis as a disciplined analytical expedient: a way of selecting relations, histories, transformations, and downstream consequences for inquiry when those selections improve explanation, without converting the analytical selection into a universal metaphysical thesis. The discussion proceeds through relational selection, generative selection, methodological economy, ontological plurality, and the limits of relational-generative abstraction.

The term *expedient* is used here in a technical and non-pejorative sense. An analytical expedient is a constructed mode of access whose adequacy depends on the problem, scale, evidence, and explanatory purpose. Scientific and interpretive inquiry routinely proceed through such constructions: a boundary is drawn around a system, a variable is selected, a comparison class is defined, a temporal interval is chosen, a mechanism is isolated, or a representation is adopted because the resulting description makes some pattern or causal relation intelligible. The construction can be highly disciplined and empirically constrained while remaining different from a claim that reality possesses exactly the same boundaries or form independently of inquiry. (Fraassen 1980; Giere 2004)

Definition 4.169 (Relational-generative methodological expedient)**.** A *relational-generative methodological expedient* is an explicitly scoped analytical construction that represents an object, process, or domain through selected relations, generative histories, constraints, transformations, and downstream effects in order to improve explanation, comparison, interpretation, or intervention, while leaving stronger ontological claims open unless they receive independent warrant.

This definition preserves two commitments simultaneously. Relational-generative analysis can make substantive claims about causal organization, persistence, historical formation, and transformation. At the same time, the analytical grammar through

which these claims are organized remains answerable to the inquiry rather than automatically elevated into the final structure of reality. Relation and generativity therefore function as strong analytical commitments where they carry explanatory work and as revisable selections where another representation better addresses the problem.

This position extends the open ontological commitment established in Section 4.1. Ontological suspension concerns the strength of reality claims; methodological expedience concerns the form through which inquiry approaches those realities. The two disciplines reinforce one another. A researcher can take relations seriously enough to explain causal organization while suspending the stronger proposition that relations are metaphysically prior to every relatum. A researcher can analyze generative histories without assuming that every relevant property is best explained by tracing its production. GR therefore gains explanatory depth from relational and generative reasoning while retaining room for substance-oriented, process-oriented, phenomenological, institutional, formal, or domain-specific descriptions when those descriptions are locally adequate.

4.19.1 Relational Selection

Relational analysis begins by selecting relations as explanatory objects. This selection directs attention toward dependence, coupling, positioning, mediation, recognition, exchange, constraint, coordination, conflict, transmission, inheritance, and other structures through which the capacities or trajectories of an object depend partly on its situation within a wider configuration. The selection is especially useful where isolating an entity would conceal the mechanisms through which its apparent properties are produced or maintained.

A firm provides a familiar example. Treating the firm as a unit can be entirely appropriate for questions about aggregate output, accounting performance, or contractual liability. A relational analysis becomes useful when the inquiry concerns how the firm's capacities depend on employees, suppliers, legal rules, infrastructures, creditors, platforms, customers, data flows, ownership, organizational routines, and political conditions. The relational description does not abolish the firm as an entity. It changes the resolution of the inquiry so that some of the relations constituting or conditioning the entity become analytically explicit.

The same principle applies to subjects. Section 4.12 distinguished ontological, relationally effective, manifestational, and institutionally represented subjecthood. A relational analysis of a worker, consumer, debtor, citizen, researcher, or artificial operational subject asks which capacities are produced, recognized, constrained, or amplified through relations. Such analysis can reveal dependencies that are obscured when the subject is treated as a self-contained bearer of fixed preferences or capabilities. Yet the usefulness of the relational view does not require the stronger claim that the subject possesses no reality apart from relations. The analytical question is whether relational organization contributes materially to the phenomenon under investigation.

Claim 4.170 (Relational selection)**.** *A relational representation is methodologically warranted when differences in relations, positions, interfaces, or configurations make*

a material explanatory difference to the capacities, persistence, manifestation, or transformation of the object under study.

Claim 4.170 places a burden on relational vocabulary. Merely redescribing an entity with the word "relation" adds little. The analysis should identify which relations are relevant, how they are distinguished, what evidence supports their relevance, and what explanatory difference follows from including them. A relation can be direct or mediated, persistent or transient, symmetric or asymmetric, material or symbolic, institutional or interpersonal, observable or inferred. The selection should match the mechanism and scale of the inquiry.

Relational selection also involves boundary choice. Any empirical analysis includes some relations while treating others as background. A study of labor relations may foreground contract, supervision, wage dependence, household reproduction, or platform mediation while leaving distant ecological or geopolitical relations outside the immediate model. The excluded relations do not thereby become unreal. They remain outside the chosen analytical boundary unless evidence shows that they materially alter the phenomenon being explained. The adequacy of a relational analysis therefore depends partly on whether its boundary captures the relations that make a consequential difference to the local question.

This boundary discipline matters because an indefinitely expanded relational description can become analytically empty. Every object can be placed within an enormous history of material, biological, social, institutional, linguistic, and ecological relations. Inquiry requires selection. GR contributes by making the selection explicit and revisable rather than by demanding maximal relational inclusion. The relevant relation is the relation that carries explanatory, interpretive, evaluative, or intervention significance at the scale being studied.

The three-register architecture further constrains relational selection. An analyst should distinguish relations inferred from manifestations from the relational reality being inferred, and should identify where symbolic or institutional representations mediate the evidence. Section 4.9 showed that reverse inference from manifestation can remain underdetermined. Relational analysis therefore gains rigor when it states which relations are directly observed, which are institutionally recorded, which are reconstructed historically, and which are hypothesized as latent generative structures.

4.19.2 Generative Selection

Generative analysis introduces a second selection. It asks how a configuration produces, enables, constrains, stabilizes, transforms, or dissolves subsequent objects, capacities, relations, manifestations, meanings, and possibilities. The focus therefore extends beyond the description of a present relational structure toward the consequences and historical trajectories that the structure helps generate.

Generativity is particularly useful when an apparently static allocation has dynamic consequences. A distribution of income, ownership, educational access, computational capability, legal status, or institutional authority can alter what actors are later able to learn, build, negotiate, represent, preserve, or contest. The initial configuration may therefore matter not only because of what is distributed at one moment

but because it changes the field of later generation. GRE uses this perspective to investigate trajectories of capability, value, power, knowledge, institutional formation, and relational reproduction.

The generative perspective should remain scoped. Some questions are adequately answered by description, classification, or equilibrium comparison. Others require historical explanation of formation. Still others require causal analysis of what follows from a configuration. The value of generative analysis appears when downstream production or transformation is part of the substantive problem. It is therefore a methodological choice oriented toward a class of questions rather than a requirement that every analysis be converted into a genealogy of everything that preceded it.

Definition 4.171 (Generative relevance)**.** A relation, configuration, event, or representation has *generative relevance* for an inquiry when its presence, organization, persistence, or transformation contributes materially to the production, stabilization, modification, or suppression of later states, capacities, relations, manifestations, or possibilities that fall within the inquiry's explanatory scope.

Definition 4.171 connects generativity to causal and historical significance while preserving scale. A minor interaction may have generative relevance for a local relation and little relevance for a national institution. A legal classification may reorganize one market while leaving another largely unaffected. A technological infrastructure may generate new operational capacities without substantially altering some normative relations. The analyst therefore specifies the downstream object and timescale rather than treating generativity as an undifferentiated property.

Generative selection also introduces temporal asymmetry into analysis. A present structure can be understood partly through the trajectories it opens and closes. This does not imply deterministic prediction. Generative systems can contain contingency, feedback, path dependence, critical transitions, heterogeneous responses, and interactions with conditions outside the analytical boundary. The claim that a configuration generates possibilities is therefore compatible with multiple future trajectories. GRE's interest lies in how the configuration changes the distribution, accessibility, or organization of those possibilities.

This distinction is useful for intervention. A policy may improve a manifest outcome at one moment while weakening capacities required for later adaptation. Another intervention may have modest immediate effects while changing institutional relations that support later generation. A generative analysis brings these temporal consequences into view. It remains possible that another method captures the same phenomenon more efficiently; the methodological status of generativity therefore depends on the explanatory gain it provides for the problem at hand.

Generative analysis also requires attention to the history of the mechanisms it studies. Section 4.18 established that categories and causal organizations can themselves possess historical materiality. A generative mechanism observed in one institutional configuration may change when legal rules, productive capacities, classifications, infrastructures, or symbolic regimes change. The method therefore treats mechanisms as potentially historical objects rather than assuming invariant laws merely because a recurrent pattern has been identified.

4.19.3 Methodological Economy and Provisional Use

A useful analytical framework should explain enough while assuming only what the inquiry requires. Relational-generative analysis follows this principle of methodological economy. It introduces relations when relational organization changes the explanation, generativity when downstream formation matters, and stronger formal or ontological commitments only when they provide additional warranted explanatory value. This economy protects the framework from accumulating conceptual machinery that exceeds the question.

Proposition 4.172 (Local sufficiency of relational-generative analysis)**.** *For a specified inquiry, relational-generative analysis is locally sufficient when the selected relations, generative mechanisms, boundaries, scales, and temporal horizons support the explanatory or interpretive task without requiring stronger commitments whose addition would not materially improve the analysis.*

Proposition 4.172 parallels the principle of local ontological sufficiency developed earlier in the chapter. The aim is neither theoretical minimalism for its own sake nor maximal formal completeness. The aim is proportionality between the analytical apparatus and the problem. A study of institutional trust may need historical relations, symbolic mediation, and recursive feedback without requiring category theory. A study of manifestation mappings may benefit from category-theoretic language without requiring a field-theoretic model. A study of pricing dynamics may use quantitative causal models while leaving questions about ultimate social ontology suspended.

Provisional use follows from this proportionality. An analytical representation can be adopted because it works well for a defined purpose and later revised when the purpose, evidence, or system changes. Provisionality concerns the standing of the representation rather than the seriousness of the inquiry. A provisional model may support strong local findings when its assumptions and scope are explicit. Conversely, a model presented with metaphysical confidence can remain weak if its empirical or conceptual fit is poor.

This stance is particularly important for interdisciplinary work. GR draws on economics, political economy, sociology, philosophy, law, complex systems, computation, history, and other domains. Each discipline carries characteristic objects and methods. Methodological economy allows GRE to borrow a representation for a specified task without absorbing the entire ontology of the source discipline. A network can represent interaction structure; a dynamical system can represent temporal evolution; an institutional analysis can represent rule-bound organization; a phenomenological account can clarify manifestation; a historical reconstruction can establish path-dependent formation. Their local contributions can coexist even where their background assumptions differ.

Provisionality also protects cumulative research. A framework that requires every contribution to settle the full ontology of its objects would impose an unrealistic burden and discourage empirical work. Researchers can instead state the level of commitment required by their study. One contribution may establish that a classification has relational reality because it is persistent and causally efficacious. Another may investigate the manifestation mechanisms through which that classification becomes salient. A third may contest its normative legitimacy. A fourth may propose a

stronger ontology. The contributions can accumulate because the shared analytical distinctions remain clear even where metaphysical commitments differ.

Methodological economy therefore favors modularity. Claims about relational reality, manifestation, representation, value, subjecthood, scale, and historical category formation can be connected without requiring that every module be used in every study. GRE functions more effectively as a research programme when investigators can select the components required by the question while preserving compatibility with the larger architecture.

4.19.4 Relational Analysis and Ontological Plurality

Treating relation as an analytical choice also guards against relational reductionism. Relational reductionism would arise if a successful relational explanation were taken to establish that entities, properties, experiences, material structures, or domain-specific mechanisms possess no analytically independent significance. GR has no methodological need for that extension. An entity can be relationally constituted in some respects and still require description at the level of its internal organization. A process can depend on relations while retaining material constraints that are poorly represented through relational vocabulary alone. A manifestation can be relationally generated while possessing phenomenological features that require another mode of access.

The three-register architecture itself supports this plurality. Ontological reality exceeds what any one manifestation or representation captures. Relational reality identifies one criterion of causal reality within generative-relational systems. Manifestational reality identifies conditions of availability. These distinctions already imply that one analytical vocabulary is unlikely to exhaust every relevant question. Relational-generative analysis therefore operates within an ontology that permits plural modes of access.

Caution 4.173 (Relational reductionism)*.* Relational reductionism occurs when explanatory success at the level of relations is extended into the unsupported conclusion that other analytically relevant structures, properties, experiences, or domain-specific mechanisms can be fully replaced by relational description.

Caution 4.173 is distinct from the ontological inflation identified in Section 4.1. Ontological inflation concerns movement from analytical success to stronger reality claims. Relational reductionism concerns compression of heterogeneous explanatory objects into one preferred vocabulary. The two can occur together, but each requires separate discipline.

Consider monetary reality. A relational analysis can explain how legal recognition, expectations, accounting, payment infrastructures, state capacities, and exchange practices stabilize money. This does not make the material and technical properties of payment systems irrelevant. A banknote has physical constraints; a digital payment system depends on hardware, energy, code, security, and communication infrastructure; monetary policy operates through institutionally specific mechanisms. Relational explanation is strongest when it articulates these components rather than translating them into an abstract relation that loses their causal specificity.

The same applies to subjectivity. The relational reality of a continuing sense of self can be analyzed through memory, recognition, bodily continuity, narrative, institutional identity, and interaction. Such analysis leaves room for psychological, neurological, phenomenological, and philosophical accounts that address different dimensions of the same subject. Relational analysis can identify coupling among these dimensions without claiming jurisdiction over every question they raise.

Ontological plurality also preserves the possibility of domain-specific primitives. Physics, biology, law, economics, and phenomenology may require different operational distinctions. GR can investigate relations across those domains while allowing each to retain objects that are locally indispensable. Cross-domain translation therefore becomes an empirical and conceptual task. Similar relational patterns can support analogy without implying that the underlying objects are of the same ontological kind.

This position is consistent with the non-necessary comparability established in Section 4.5. Two relationally real objects can remain structurally incommensurable. A methodological commitment to relation does not create a common metric merely because both objects are represented relationally. The analyst must establish the mapping, equivalence criterion, or comparison space independently. Relational vocabulary supplies a grammar for asking about correspondence; it does not guarantee correspondence.

4.19.5 Limits of Relational-Generative Abstraction

The final methodological task is to identify where relational-generative abstraction loses information or explanatory traction. Every abstraction suppresses detail. The relevant question is whether what has been suppressed matters to the inquiry. GR therefore treats limitations as part of the specification of an analysis rather than as an external objection added after the model is complete.

Several limits recur. First, relation selection can omit materially consequential internal structure. A network representation may capture who interacts with whom while missing the content, temporality, embodiment, or institutional meaning of the interaction. Second, generative analysis can become overly expansive if every remote historical antecedent is treated as part of the mechanism. Third, system boundaries can hide external dependencies that later prove causally important. Fourth, manifestation data can underdetermine the relational structure from which they arose. Fifth, symbolic representations can impose commensuration on realities whose differences matter. Sixth, scale selection can stabilize an entity that dissolves when examined at another resolution. These are not reasons to abandon relational-generative analysis; they are conditions under which its claims require qualification or supplementation.

Definition 4.174 (Abstraction boundary)**.** An *abstraction boundary* specifies the relations, internal structures, scales, timescales, manifestations, and contextual conditions that an analysis treats as outside its active explanatory representation while recognizing that some excluded elements may remain real and potentially causally relevant.

Definition 4.174 gives methodological exclusion a positive form. An analysis can

say what it brackets. A model of market transactions may bracket household care relations; a study of household reproduction may bracket global financial structure; a formal manifestation mapping may bracket embodied phenomenology; an institutional analysis may bracket molecular mechanisms. The boundary becomes problematic when excluded elements materially change the results while remaining unacknowledged. Explicit abstraction boundaries make such revision easier.

A second limit concerns normative inference. Generative success, relational stability, persistence, and causal efficacy remain descriptive or explanatory properties until a normative argument is supplied. A highly stable institution can generate severe exclusion. A powerful symbolic regime can coordinate activity while distorting recognition. A generative process can expand one form of value while destroying another. GRE therefore keeps evaluative judgment distinct from the fact that a system reproduces itself effectively.

A third limit concerns epistemic access. Relational-generative models often infer structures from traces, outcomes, records, classifications, or manifestations. Sections 4.8 and 4.9 established that manifestation mappings can be relationally real and still non-invertible. An analytically elegant relational structure can therefore remain underdetermined by available evidence. Methodological expedience does not license filling this gap with preferred theory. The model should mark where inference depends on assumptions, priors, idealizations, or inaccessible historical conditions.

A fourth limit concerns performativity and recursion. Once a relational-generative representation enters institutions, it can begin to alter the reality it describes. A risk model can change lending; a labor classification can change rights and incentives; a measure of productivity can reorganize work; a theory of markets can influence market design. The analytical expedient can therefore become a manifestational or relational object within the system. Reflexive monitoring is required when representation changes the generative field.

Claim 4.175 (Revisability of abstraction)**.** *A relational-generative abstraction should be revised, supplemented, or replaced when excluded structures, alternative scales, changing historical conditions, new manifestations, or competing representations materially alter the explanatory conclusions for which the abstraction was adopted.*

Claim 4.175 gives methodological pluralism an operational criterion. The question is not whether relational-generative analysis is universally correct. The question is whether it remains adequate for the inquiry and whether another representation captures consequential structure that it omits. Revision can deepen the relational model, combine it with another method, change scale, alter boundaries, or suspend the relational-generative representation altogether for a particular task.

The resulting methodological position is therefore strong without being exclusive. GR and GRE use relations to investigate dependence, organization, mediation, and position; they use generativity to investigate emergence, reproduction, transformation, and future possibility. These selections support substantive claims when the relevant structures are evidenced and causally consequential. Their success does not require a final declaration that reality consists only of relations or that every phenomenon is best understood through its generative history. Relational-generative analysis earns its place through explanatory performance, explicit scope, and capacity for revision.

Section 108 thus clarifies the methodological standing of the framework developed throughout Chapter 4. Relation and generativity function as disciplined analytical selections; ontological suspension preserves room for stronger or alternative ontologies; methodological economy limits conceptual machinery to what the question requires; and explicit abstraction boundaries make the costs of simplification visible. The next section develops the positive implication of this position by examining compatibility with alternative ontological commitments, including substance-oriented, process-oriented, relation-oriented, and domain-specific ontologies.

4.20 Compatibility with Alternative Ontological Commitments

The ontological architecture developed in Chapter 4 is intended to support substantive inquiry without requiring every investigation to adopt one comprehensive metaphysical doctrine. The role of the present section is to specify how Generative Relational Theory (GR) and Generative Relational Economics (GRE) can remain compatible with alternative ontological commitments while preserving the analytical distinctions already established among ontological reality, relational reality, manifestational reality, representation, scale, and historical emergence. Its objective is to replace a vague appeal to pluralism with explicit conditions of compatibility. The discussion proceeds through ontological pluralism, substance-oriented, process-oriented, relation-oriented, and domain-specific ontologies, followed by criteria for translation, coexistence, and operative disagreement.

Compatibility in this context is weaker than identity and stronger than mere tolerance. Two ontological frameworks can be compatible for a specified inquiry when their commitments can coexist without contradiction at the level required by that inquiry, when their vocabularies can be related through an explicit translation or division of explanatory labor, or when disagreement concerning stronger claims remains non-operative for the local analysis. Compatibility can therefore be partial, asymmetric, scale-dependent, or question-dependent. A framework may be compatible with GR for one class of claims while conflicting with it for another. (Whitehead 1929; Quine 1948; Archer 1995)

Definition 4.176 (Local ontological compatibility)**.** Two ontological commitments are *locally compatible* with respect to a specified inquiry when their jointly retained claims do not generate an operative contradiction for the objects, scales, causal relations, manifestations, or explanatory tasks under study, and when any translation between their terms is stated at the level actually warranted.

Definition 4.176 places scope at the center of compatibility. It avoids treating ontological frameworks as packages that must be accepted or rejected in their entirety. A substance-oriented account may provide a useful specification of relatively enduring entities while a process-oriented account explains their transformation. A relation-oriented account may clarify dependence among those entities while a legal ontology specifies institutionally recognized persons, offices, rights, and obligations. The resulting analysis can be coherent when the commitments are assigned clear roles and when a local translation does not silently become a claim of universal equivalence.

This position extends the methodological standing established in Section 4.19. Relational-generative analysis earns its place through explanatory performance, explicit scope, and revisability. Compatibility with alternative ontologies follows from the same discipline. GR can use an ontology strongly where its commitments matter and suspend stronger disputes where they do not. Such suspension preserves disagreement rather than dissolving it. A physicalist, phenomenological, processual, institutional, or relation-oriented account can therefore remain distinct even when each contributes to a shared analysis.

4.20.1 Ontological Pluralism

Ontological pluralism, as used here, concerns the possibility that different domains, scales, questions, or modes of access require different ontological vocabularies. It does not entail that every ontology is equally adequate, that contradictions are harmless, or that reality changes freely with description. Pluralism instead recognizes that an inquiry can encounter heterogeneous kinds of object and that one vocabulary may illuminate some structures while obscuring others.

The three-register architecture already creates a disciplined form of plurality. Ontological reality concerns what obtains independently of a particular manifestation; relational reality concerns what emerges, persists with sufficient stability, and exercises causal efficacy within a generative-relational system; manifestational reality concerns what becomes available under a specified manifestational configuration. These distinctions do not determine whether the ultimate constituents of a domain are substances, processes, relations, fields, events, organisms, informational structures, or something else. They organize questions that can be posed across several such commitments.

Pluralism also appears across scale. Section 4.17 showed that a configuration can be represented as an entity at one scale and as a distributed process or relation at another. The availability of both descriptions does not imply that each is equally useful for every task. A corporation may be treated as a juridical entity for contract and liability, as an organizational process for internal coordination, as a network for supply-chain dependence, and as a historical institution for long-run transformation. Each view can identify real features while selecting a different resolution.

Claim 4.177 (Plurality with constraint)**.** *Ontological plurality is analytically productive when each adopted vocabulary identifies a specified object or scale, preserves the causal and evidential constraints relevant to that object, and exposes rather than conceals the points at which translation across vocabularies becomes uncertain or fails.*

Claim 4.177 makes pluralism answerable to evidence and explanation. A plurality of models does not provide a license to move opportunistically among incompatible claims. Where two ontologies produce different causal expectations, different identity criteria, or different accounts of persistence, the disagreement becomes operative and should be investigated. Where they differ only in stronger metaphysical commitments that do not change the local analysis, ontological suspension can preserve both possibilities.

This approach also guards against premature synthesis. A translation between two ontologies can be useful without establishing that they refer to the same structure

in the same way. The category-theoretic language introduced in Section 4.16 offers one formal illustration: a mapping can preserve selected structures while leaving other structures unmapped. Ontological comparison should be treated similarly. The analyst should identify what is preserved, what changes, and what remains outside the translation.

4.20.2 Substance-Oriented Ontologies

Substance-oriented ontologies give analytical priority to entities that possess some degree of persistence, identity, or bearer-like continuity across change. GR can accommodate such entities when their identification is empirically or conceptually useful. Relational-generative analysis does not require every object to dissolve into relations. It asks whether the capacities, persistence, or transformation of the object depend materially on relations and generative histories.

This compatibility is especially important in economics. Persons, firms, assets, commodities, contracts, infrastructures, and states are frequently treated as units with relatively stable identities. Many economic questions require precisely such units. Accounting, ownership, liability, inventory, demographic measurement, and contractual analysis become difficult when every entity is redescribed at every moment as a fully decomposed relational configuration. A substance-oriented representation can therefore provide an appropriate local ontology for a specified task.

GR adds two questions to that representation. First, what supports the persistence and identity criteria by which the entity remains identifiable? Second, which capacities attributed to the entity are generated or transformed through relations? These questions can deepen a substance-oriented analysis without invalidating the entity. A firm can remain a firm while its productive capacity depends on labor, law, finance, technology, suppliers, and customers. A person can remain an embodied individual while economic agency depends partly on education, recognition, legal status, infrastructure, and social reproduction.

Remark 4.178 (Entity persistence and relational constitution). A relatively enduring entity can be treated as an analytical bearer of properties while some of those properties, capacities, or identity conditions are explained relationally. Compatibility therefore depends on distinguishing the persistence of the entity from the provenance of every feature attributed to it.

This distinction prevents two opposite reductions. Entity-centered analysis can become insufficient when it treats relationally generated capacities as intrinsic and history-free. Relational analysis can become insufficient when it treats the identification of entities as analytically dispensable even where persistent units carry causal, legal, biological, or institutional significance. Local compatibility permits the two descriptions to coexist when their scopes are explicit.

A stronger metaphysical substance doctrine may eventually conflict with a stronger metaphysical relational doctrine. GR need not resolve that conflict in advance. Under ontological suspension, the operative question is whether the dispute changes the causal, historical, or manifestational claims required by the inquiry. If it does, the disagreement should be made explicit. If it does not, the analysis can proceed while preserving the stronger disagreement for another level of inquiry.

4.20.3 Process-Oriented Ontologies

Process-oriented ontologies emphasize becoming, transformation, activity, event, and temporal organization. Section 4.15 already established that GR can treat processes and events as analytically primary where extended transformation carries the explanatory burden. This orientation is highly compatible with generative analysis because generativity concerns how configurations produce, reproduce, transform, and dissolve subsequent configurations over time.

Compatibility nevertheless requires precision. A generative account need not claim that process is metaphysically prior to every object. An entity can be analyzed through the processes that sustain it while retaining an entity-level identity for other purposes. Dynamic persistence provides one bridge. A phenomenon can remain sufficiently stable to count as a relationally real object even when its stability depends on ongoing processes of maintenance, repair, reproduction, recognition, or exchange.

Economic institutions illustrate this point. Money, organizations, markets, property arrangements, and occupational categories persist through repeated practices, legal acts, accounting routines, infrastructural operations, and expectations. Their persistence can therefore be processually sustained. A process-oriented view helps explain how stability is achieved rather than treating stability as a primitive fact. GR can adopt that explanation while continuing to refer to money, organizations, or institutions as relationally real objects at the scale where their causal efficacy is coherent.

Process orientation also supports the historical dimension of GRE. Generative consequences may unfold across multiple timescales, and later relations can incorporate the products of earlier processes. The recursive architecture of Section 4.11 becomes especially useful here: manifestations and representations can enter subsequent processes and alter the conditions of later emergence. Historical becoming is therefore compatible with temporary stabilization.

Claim 4.179 (Process-compatible persistence)**.** *The persistence required for relational reality is compatible with process-oriented ontology when stability is produced through sufficiently continuous or recurrent processes that preserve an object's causal efficacy over the relevant spacetime interval.*

Claim 4.179 avoids equating persistence with immobility. It also preserves the strict relational-reality criterion. A transient process can be manifestationally real without yet constituting a persistent relational object; a recurrent or self-maintaining process may itself satisfy the persistence, stability, and causal-efficacy conditions required for relational reality. The relevant analytical unit can therefore be an enduring object, an organized process, or a coupled object-process description.

4.20.4 Relation-Oriented Ontologies

Relation-oriented ontologies assign strong explanatory or metaphysical significance to relations, relational positions, or structures of dependence. GR has an obvious affinity with this family of views because relational emergence is central to its analytical vocabulary. The affinity remains deliberately limited by ontological suspension. Relational analysis can be indispensable without establishing that relations are uni-

versally prior to relata or that every domain is exhaustively relational.

A relation-oriented ontology becomes especially useful where objects acquire capacities through position, coupling, recognition, dependence, or interaction. Trust, authority, institutional office, market access, indebtedness, legal standing, and organizational role provide examples in which the relevant reality cannot be adequately specified through isolated intrinsic properties alone. The relational configuration contributes directly to what the object can do and to how it affects subsequent processes.

GR's definition of relational reality, however, is more selective than a general declaration that everything is relational. An object becomes relationally real when it emerges within a generative-relational system, persists with sufficient stability over a relevant region or interval of spacetime, and exercises causal efficacy within that system. The criterion therefore identifies a mode of reality within a system rather than asserting a complete metaphysical inventory of the world.

This selectivity allows GR to remain compatible with weaker and stronger relation-oriented ontologies. A weak relational ontology may claim that some properties are essentially relational. A stronger version may treat relations as ontologically fundamental. GR can work with either where the local analysis concerns structures both frameworks recognize. The stronger dispute can remain suspended until it becomes operative.

The distinction between relational reality and manifestational reality is also important here. A relation can be causally operative before a subject perceives or symbolizes it. Conversely, manifestations and symbols can enter the relation and reshape it. Relation-oriented ontology therefore gains a historical and recursive dimension without requiring manifestation to constitute all relational reality. The graph architecture among the registers remains available under several strengths of relational metaphysical commitment.

4.20.5 Domain-Specific Ontologies

Many inquiries rely on ontologies whose terms are specific to a domain. Law distinguishes persons, offices, rights, duties, jurisdictions, instruments, procedures, and recognized acts. Economics distinguishes assets, liabilities, commodities, firms, households, prices, contracts, and forms of capital. Biology, psychology, computation, ecology, and engineering each employ their own objects and identity criteria. These domain ontologies can carry substantial explanatory and practical force even when their relations to ultimate ontology remain unsettled.

GRE therefore requires a disciplined interface between domain-specific ontology and GR's broader analytical architecture. Domain terms should retain the distinctions that make them operationally meaningful. A legal person should not be translated automatically into a network node; a price should not be reduced automatically to a symbol; a corporation should not be reduced automatically to a set of interpersonal relations; an artificial operational subject should not be assumed to share the ontology of a human subject because both can occupy similar economic interfaces.

The three-register architecture can organize these domain terms without replacing

them. A legal status can be analyzed as relationally real when institutional relations stabilize it and it causally affects what actors can do. Its certificates, registry entries, judgments, and identifiers belong to manifestational and representational processes. Questions about the ultimate ontology of personhood, normativity, or institutional facts can remain open where the economic analysis does not require their resolution.

Domain-specific ontologies also matter for intervention. Institutions act through operational categories. Tax systems, courts, firms, welfare agencies, payment networks, and computational platforms require classifications that determine eligibility, ownership, responsibility, access, or transfer. Such categories can become relationally real because they structure subsequent action. Their practical necessity does not guarantee epistemic adequacy or normative legitimacy. GRE can therefore study the generative effects of domain categories while keeping their truth, justice, and ontological fundamentality distinct.

Definition 4.180 (Domain-ontology interface)**.** A *domain-ontology interface* is an explicit mapping between a domain's operational objects and GR's analytical distinctions that preserves the domain-specific identity conditions required for the inquiry while identifying where relational emergence, manifestation, representation, scale, or historical transformation materially affect those objects.

Definition 4.180 treats translation as selective. The objective is to preserve enough structure for cross-domain inquiry without erasing what makes the source domain distinctive. Some translations may be close; others may preserve only a few relations; still others may fail because the relevant objects lack a warranted common comparison space. The non-necessary comparability developed earlier in the chapter therefore applies equally to ontological vocabularies.

4.20.6 Conditions of Compatibility

The compatibility developed in this section can be summarized through a set of conditions. These conditions are methodological criteria for joint use rather than axioms of a final ontology. They specify when alternative commitments can enter a GR or GRE analysis without conceptual collapse.

First, the object and scale of each ontology should be explicit. A vocabulary suited to embodied persons may operate differently from one suited to organizations, legal offices, or computational agents. Second, identity and persistence criteria should be stated where they matter. What counts as the same firm, subject, institution, process, or relation can vary across domains and scales. Third, causal claims should remain attached to the mechanisms recognized by the relevant ontology rather than being translated into a generic relational idiom that loses mechanism-specific content.

Fourth, mappings across ontologies should specify what they preserve. A translation may preserve causal ordering, functional role, legal status, manifestational form, organizational position, or selected relational structure while losing other dimensions. Fifth, residual structure should remain visible. A successful local correspondence does not imply global equivalence. Sixth, stronger disagreements should be classified by whether they are operative for the inquiry. Ontological suspension is appropriate where disagreement does not alter the retained claims; explicit adjudication becomes necessary where competing commitments generate different expec-

tations, identity conditions, or interventions.

Claim 4.181 (Compatibility discipline)**.** *Alternative ontological commitments can be jointly used within GR or GRE when their scopes, identity criteria, causal roles, translation rules, and residual disagreements are explicit, and when stronger metaphysical disagreements are suspended only to the extent that they remain non-operative for the inquiry.*

Claim 4.181 makes compatibility an active analytical task. It requires more than placing several vocabularies side by side. The analyst must specify how they interact and where they diverge. This requirement is especially important in interdisciplinary research, where the same term can carry different identity criteria across law, economics, computation, psychology, or political theory.

Compatibility also has temporal conditions. An ontology that is locally adequate at one historical stage may become less adequate when new entities, infrastructures, practices, or manifestations emerge. Section 4.18 showed that ontological categories can possess historical materiality. The compatibility relation among ontologies can therefore change as well. A distinction that once aligned across institutional and technical domains may later fracture; new interfaces can create forms of subjecthood or organization that require revised mappings.

A final condition concerns normativity. Ontological compatibility does not settle normative compatibility. Two frameworks may describe the same institution coherently while supporting different judgments about legitimacy, justice, welfare, or responsibility. GRE should preserve that distinction. The ontological question concerns what kinds of objects and relations the analysis recognizes and how they persist or act. Normative evaluation requires additional premises and arguments.

The resulting position is a constrained ontological pluralism. GR offers a common analytical architecture for distinguishing ontological, relational, and manifestational reality; tracing generative histories; identifying causal efficacy; and examining recursive mediation. That architecture can interface with substance-oriented, process-oriented, relation-oriented, and domain-specific ontologies without treating them as interchangeable. Compatibility is earned locally through explicit scope, preservation of relevant structure, and disciplined treatment of residual disagreement.

Section 109 therefore extends ontological suspension into a positive method of interdisciplinary coexistence. Alternative ontologies can contribute different resolutions of the same domain, or address different domains altogether, while GR provides a vocabulary for asking how those resolutions connect, where they fail to connect, and when their disagreements become causally or analytically operative. The next section narrows the chapter's claims by specifying the limits of GRE's ontological commitments and the kinds of metaphysical, empirical, and normative conclusions that the present architecture does not by itself establish.

4.21 Limits of GRE Ontological Claims

The ontological architecture developed in this chapter makes substantive claims about emergence, persistence, stability, causal efficacy, manifestation, representation, scale, and historical transformation. Its usefulness depends equally on

specifying the claims that do not follow from those commitments. The role of the present section is therefore to establish the boundary of GRE's ontological claims before the chapter turns from reality to knowledge. Its objective is not to weaken the three-register architecture, but to distinguish what the architecture warrants from stronger conclusions that require additional metaphysical, empirical, epistemic, or normative argument. The discussion proceeds through the boundary of established claims, ontological underdetermination, the limits of formal ontology, limits of cross-domain generalization, and openness to ontological revision.

A theory can become less precise when the scope of its strongest concepts expands faster than the evidence supporting them. This risk is particularly important for a framework that uses terms such as *reality*, *emergence*, *causal efficacy*, and *subjecthood*. GRE therefore treats explicit limitation as part of ontological discipline. A claim that money, an institution, a self-model, a form of trust, or another object is relationally real says something substantive: the object has emerged within a generative-relational system, persists with sufficient stability over a relevant spacetime region or interval, and exercises causal efficacy within that system. The claim does not by itself determine the object's ultimate ontological constitution. Similar restraint applies to manifestational reality, symbolic representation, formal modeling, and cross-scale analysis. (Fraassen 1980; Giere 2004; Longino 1990)

Definition 4.182 (Ontological claim boundary)**.** An *ontological claim boundary* is the explicitly stated limit separating the commitments warranted by a GR or GRE analysis from stronger claims concerning ultimate constitution, exhaustive classification, universal applicability, epistemic truth, or normative validity that require additional argument.

Definition 4.182 makes limitation internal to the method rather than an afterthought. A strong local claim can coexist with restraint concerning stronger questions. GRE can, for example, assert the causal reality of a monetary institution while suspending the question of whether institutional reality is reducible to physical, psychological, informational, legal, or other structures. It can analyze the relational reality of an experienced continuity of self without claiming to have settled the ontology of consciousness. It can treat a religiously mediated object as relationally real within a system when the persistence, stability, and causal-efficacy conditions are satisfied without inferring from that relational reality either the independent ontological existence or non-existence of the object in question.

This distinction is also important for the architecture of the three registers. Ontological reality, relational reality, and manifestational reality organize different questions. They are not asserted to be an exhaustive partition of everything that can exist, nor are they three substances from which reality is composed. Their graph-like relations are likewise analytical commitments rather than a universal causal diagram imposed on every domain. The framework earns explanatory force by preserving these distinctions while allowing their concrete realization to remain open.

4.21.1 Boundary of Established Claims

The first limit concerns what the chapter has actually established. The three-register architecture distinguishes ontological, relational, and manifestational questions; it

specifies a strict criterion for relational reality; it treats manifestation as condition-dependent and potentially recursive; and it allows representations, mappings, institutions, categories, and subjects to become causally operative within generative-relational systems. These commitments provide a disciplined ontology for GRE inquiry. They leave several stronger questions unresolved.

GRE does not establish that relation is the fundamental substance of reality. Relational-generative analysis can be indispensable for a specified economic object while stronger metaphysical questions remain suspended. Section 4.19 therefore treated relational-generative analysis as a scoped methodological commitment, and Section 4.20 showed how this commitment can coexist locally with substance-oriented, process-oriented, relation-oriented, and domain-specific ontologies. The explanatory importance of relations does not by itself establish their metaphysical priority.

The chapter also does not establish that every persistent pattern is relationally real. Persistence and stability are necessary components of the criterion developed in Section 4.5, but causal efficacy within the relevant generative-relational system remains essential. A regularity that merely recurs in an analyst's description may lack the causal participation required for relational reality. Conversely, a relational reality can be dynamically maintained rather than static. Stability concerns maintained organization over an inquiry-relevant region or interval, not immobility.

Causal efficacy does not establish epistemic truth. Section 4.10 showed that representations can become relationally real through their consequences even when they are partial, inaccurate, or false concerning their targets. A classification can alter eligibility, a mistaken belief can reorganize conduct, and an inaccurate metric can redirect resources. Their effects are real without making their representational content true. The same distinction applies to manifestational salience: what becomes strongly visible or institutionally legible need not provide an exhaustive or privileged disclosure of the underlying relational configuration.

Causal efficacy also does not establish normative validity. Money, legal categories, institutional hierarchies, identities, classifications, and value regimes can become highly stable and causally powerful while remaining ethically contested or unjust. Persistence can indicate successful reproduction rather than justification. The ontology developed here therefore supplies objects for normative analysis but does not convert historical survival, institutional recognition, or generative power into moral endorsement.

Nor does relational reality require prior perception, awareness, or symbolization. This point creates a limit in the opposite direction: the absence of manifestation to a particular subject does not justify the conclusion that no relationally real structure exists. Contingency provides an important example. A historical-generative configuration through which a contingent encounter becomes possible can already be relationally organized before that contingency is consciously recognized, aesthetically judged, or symbolically articulated. The later manifestation may reveal, select, amplify, or transform part of that structure without creating the entire relational reality at the moment of perception.

Claim 4.183 (Non-entailment discipline)**.** *Within GRE, persistence does not by itself*

entail relational reality; relational reality does not entail ontological fundamentality; manifestation does not entail exhaustive disclosure; causal efficacy does not entail epistemic truth; and historical stabilization does not entail normative validity.

Claim 4.183 is a compact statement of the chapter's claim boundary. Its purpose is not skeptical. Each term remains capable of supporting strong conclusions within its appropriate domain. The discipline lies in resisting movement from one kind of warranted claim to another without an explicit bridge.

The same restraint applies to comparison. Two objects can both satisfy the criterion for relational reality without occupying a common metric space, a common ordering, or even a justified common comparison domain. The hallucinatory flower discussed earlier and an ordinarily perceived physical flower may each be relationally real in relevant systems while differing radically in generative structure. Shared reality-status therefore establishes neither structural similarity nor commensurability. Any comparison must specify what relation, mapping, invariant, or practical criterion makes the comparison meaningful.

4.21.2 Ontological Underdetermination

The second limit arises because the evidence available to an inquiry may support several ontological interpretations. The non-invertibility of manifestation developed in Section 4.9 provides one route to this result. Different relational configurations can generate similar manifestations, while similar relational configurations can manifest differently under changing conditions. Even when an observed pattern is robust, reconstruction from manifestation toward underlying organization can remain underdetermined.

Ontological underdetermination is broader than manifestational non-invertibility. The same relationally effective organization can sometimes be described through different ontological vocabularies. A firm can be modeled as a juridical entity, an organizational process, a contractually structured nexus, a network of dependencies, or a historically reproduced institution. These descriptions need not be equivalent, and each can reveal structures hidden by the others. Yet available evidence may fail to determine which vocabulary, if any, captures the ultimate constitution of the object.

Definition 4.184 (Ontological underdetermination)**.** *Ontological underdetermination* obtains when the evidence, causal regularities, manifestations, and successful explanatory relations available within a specified inquiry remain compatible with more than one materially distinct ontological interpretation.

Definition 4.184 is inquiry-relative. Additional evidence, a different scale, a new intervention, or a stronger explanatory demand can reduce underdetermination. The concept therefore differs from a permanent declaration that ontological questions are undecidable. It identifies a present relation between evidence and claim strength.

Underdetermination is especially relevant to the examples that motivate ontological suspension. Consider the continuity of the experienced "I." GRE can investigate how bodily continuity, memory, recognition, narrative, institutional identity, and repeated action participate in stabilizing a relationally real self. Such analysis can explain important causal consequences of selfhood while several ontologies of con-

sciousness and personal identity remain compatible with the retained evidence. The relational analysis is not empty because the metaphysical question remains open; neither does explanatory success in the relational domain settle that question automatically.

A similar point applies to money. Monetary reality can be studied through institutional authority, legal designation, accounting systems, expectations, payment infrastructures, conventions, and material tokens. These relations can sustain an object with substantial persistence and causal efficacy. Several ontological interpretations of institutional facts can nevertheless remain available. GRE needs to resolve among them only when their differences become operative for the economic question under study.

Underdetermination also explains why the ontological register cannot be identified with whatever remains after relational and manifestational analysis. Ontological reality is not a residual box containing an unknown substrate. It names the question of what obtains beyond the commitments licensed by a particular manifestation or relational model. In some inquiries, stronger ontological claims can be justified; in others, suspension remains the more disciplined position.

Claim 4.185 (Strength calibration under underdetermination)**.** *When materially distinct ontological interpretations remain compatible with the evidence and explanatory relations available to an inquiry, GRE should calibrate its claims to the structure jointly supported by those interpretations unless the stronger disagreement becomes operative for explanation, prediction, intervention, or evaluation.*

Claim 4.185 preserves both explanatory ambition and metaphysical restraint. It permits the analysis to advance where common structure is well supported while keeping stronger disagreements visible for later investigation.

4.21.3 Limits of Formal Ontology

Formal languages can sharpen ontological reasoning by making identity criteria, mappings, compositional rules, invariants, state spaces, constraints, and transformation structures explicit. This chapter has used such resources selectively, including dynamical language, mapping notation, scale-relative descriptions, and a category-theoretic view. Their precision can expose assumptions that ordinary prose leaves implicit. Their limits are equally important.

A formal representation does not establish that its mathematical objects are the literal constituents of the domain. A graph can represent relational dependence without implying that a society is fundamentally a graph. A state space can represent possible configurations without implying that the represented system possesses that space as an independent metaphysical object. A category can encode objects and morphisms relevant to an inquiry without establishing categorical ontology. A field model can capture distributed interaction without proving that the social domain is fundamentally a field.

This distinction follows from the chapter's treatment of mappings. Formalization selects objects, relations, equivalence criteria, boundaries, and admissible transformations. Those selections can be analytically justified while remaining choices of

representation. Different formalisms can preserve different structures of the same domain. Their comparative success is an empirical and explanatory matter rather than a direct route from mathematical elegance to ontological truth.

Formal ontology also encounters the problem of representation-induced identity. Once an analyst chooses a state description or category of objects, elements that differ outside that formalization may become identical inside it. This can be useful. An economic model may intentionally treat two heterogeneous realizations as equivalent because they perform the same relevant function. Section 4.17 described such local equivalence under multiple realization. The loss of distinction should nevertheless remain visible. Formal equality inside a model can represent a justified abstraction without entailing ontological identity outside it.

Remark 4.186 (Formal exactness and ontological strength)*.* Greater exactness within a formal representation increases clarity concerning the commitments of that representation. It does not, by itself, increase the ontological strength of the claim connecting the representation to the world.

Remark 4.186 is especially important in interdisciplinary work. Mathematical sophistication can make assumptions more precise while leaving the empirical warrant for those assumptions unchanged. A beautifully defined equivalence relation, functor, potential function, attractor, or metric still requires a defensible interpretation linking it to the domain.

Formal systems can also create commensurability that the source domain did not possess in advance. Section 4.10 described symbolic commensuration; mathematical representation can perform an analogous operation. Assigning values to a common coordinate, metric, utility, score, or latent space can make comparison possible for a specified purpose. The resulting comparison may be operationally powerful and even institutionally consequential. Its existence inside the formalism does not prove intrinsic commensurability among the represented realities.

GRE therefore treats formal ontology as an instrument for disciplined representation, inference, and comparison. It can contribute to ontological inquiry by exposing structure, generating testable implications, and revealing invariant or transformational relations. It remains answerable to the domain and to the evidential conditions under which its objects are interpreted.

4.21.4 Limits of Cross-Domain Generalization

A further limit concerns the transfer of ontological categories across domains. GR is intentionally broad enough to support inquiry into economic, legal, political, educational, technological, ecological, and other relational systems. Breadth creates the temptation to assume that concepts established in one domain transfer unchanged to another. GRE resists that inference.

The criterion for relational reality is deliberately general, but its operationalization is domain-sensitive. Persistence for a market convention can have a different temporal scale from persistence for an ecological relation, a legal office, a computational process, or an interpersonal trust relation. Causal efficacy can also take different forms: changing resource flows, altering legal possibilities, constraining behavior,

reorganizing attention, modifying biological processes, or transforming symbolic expectations. The general criterion gains content only through domain-specific mechanisms.

The same limitation applies to subjecthood. Human persons, corporations, states, algorithms, animals, and collective organizations can occupy causally important positions in economic systems. Similarity in economic function or manifestational output does not establish identical forms of subjecthood. Section 4.12 therefore distinguished human subjecthood from artificial operational subjecthood and treated manifestational equivalence as local. Cross-domain generalization should preserve such differences rather than elevate a shared interface into universal identity.

Value and meaning provide another case. A common symbolic scale can create practical commensuration among heterogeneous values, while the underlying value structures remain non-equivalent. Likewise, a concept of meaning developed for linguistic interpretation cannot automatically be extended to every biological, computational, or institutional process that exhibits patterned response. Domain transfer requires an explicit account of what is preserved and what changes.

Definition 4.187 (Cross-domain transfer condition)**.** A *cross-domain transfer condition* specifies the properties, relations, causal roles, identity criteria, scales, and evidential assumptions that must be preserved for an ontological or relational concept to be used across distinct domains without silently changing its meaning.

Definition 4.187 makes generalization a constructive task. A concept can travel, but its travel requires a map. Sometimes the transfer will preserve a substantial common structure. Sometimes only an analogy survives. Sometimes the domains lack a warranted common space of comparison. The possibility of failure is part of disciplined generalization.

This restraint also protects GR from becoming a vocabulary that redescribes everything in the same terms. If every phenomenon is called a relation, field, attractor, emergence, or generative process without domain-specific criteria, explanatory content diminishes. A broad framework remains useful when its general concepts constrain inquiry while allowing local sciences and disciplines to supply mechanisms, measurements, categories, and evidence that cannot be derived from the framework alone.

For GRE, the economic domain remains primary. Connections to law, politics, ecology, psychology, computation, education, and other domains can be necessary because economic relations cross those boundaries. The ontological interface should nevertheless respect the concepts through which those domains identify their own objects. Cross-domain synthesis is warranted where the interfaces are explicit; conceptual annexation is not.

4.21.5 Openness to Ontological Revision

The final limit is temporal. GRE's ontological categories are intended to remain revisable when new evidence, new forms of organization, new scales, new modes of manifestation, or new conceptual distinctions alter what the framework can adequately describe. This openness follows from the historical materiality developed

in Section 4.18 and from ontological suspension developed in Section 4.3. A historically situated research programme should not treat its present ontology as immune to the processes it studies.

Ontological revision can occur at several levels. A previously useful object category can become inadequate when its internal heterogeneity becomes causally important. A relation once treated as background can become a central mechanism. A manifestational distinction can cease to track the relational structure it was designed to represent. A new technological or institutional configuration can generate objects for which existing identity criteria are unstable. A formal model can reveal overlooked invariants, while empirical evidence can show that an assumed invariant is historically contingent.

Revision does not require abandoning earlier concepts whenever novelty appears. Many categories remain useful across substantial historical change. The relevant question is whether the retained category continues to preserve the distinctions needed for explanation, intervention, and evaluation. Revision becomes warranted when anomalies are systematic, when causal mechanisms fall outside the existing object structure, when previously excluded differences become consequential, or when alternative ontological descriptions achieve materially stronger explanatory adequacy.

Claim 4.188 (Ontological revisability)**.** *GRE should revise an ontological commitment when sustained evidence or explanatory failure shows that the commitment no longer preserves distinctions necessary for identifying relevant objects, causal relations, persistence conditions, manifestations, scales, or transformations within the inquiry.*

Claim 4.188 makes revisability conditional rather than fashionable. Ontological novelty is not inferred merely from new terminology, new technology, or a new representation. Revision should answer to changes in explanatory adequacy and to the realities under investigation.

The three-register architecture itself is subject to this principle. Ontological reality, relational reality, and manifestational reality currently provide a productive set of distinctions for the GR research programme. Their usefulness does not grant them immunity from criticism. Future inquiry may require finer subdivisions, different mappings among registers, domain-specific extensions, or alternative concepts that preserve relevant phenomena more adequately. Such revision would be compatible with the framework's present commitments because openness has been built into those commitments from the beginning.

This openness also prevents ontological restraint from becoming intellectual passivity. Suspension is provisional where inquiry can proceed, and stronger ontological questions can be reopened when they become operative. Formalization can be strengthened when measurement and mechanism justify it. Cross-domain concepts can be generalized when preservation conditions are demonstrated. Alternative ontologies can be compared more sharply when they generate different empirical or practical consequences. The boundary established in this section therefore marks a frontier for further inquiry rather than a prohibition against stronger claims.

Section 110 completes the chapter's explicit account of ontological scope. GRE commits to enough reality to analyze generative systems seriously: relations can produce

stable and causally efficacious objects; manifestations and representations can participate recursively in later reality; subjects, institutions, value, meaning, processes, and categories can acquire historically situated forms of reality; and these structures can be compared across scales when warranted. The framework simultaneously leaves ultimate constitution, exhaustive ontology, universal commensurability, complete formal capture, and unrestricted cross-domain transfer open to additional argument. With that boundary in place, the remaining problem is epistemic: given realities that can exceed, precede, and be transformed by their manifestations, how can an inquiry responsibly know them? Section 111 turns to that transition.

4.22 Reality, Access, and Epistemic Reconstruction

The ontological work of this chapter produces an epistemic problem rather than an epistemic solution. GR has distinguished ontological reality, relational reality, and manifestational reality; specified the conditions under which an object may be treated as relationally real; shown that manifestation is generated through historically and relationally formed conditions; and established that manifestations and representations can recursively alter subsequent relational reality. These commitments clarify what kinds of realities an inquiry may address, but they also make clear why knowing those realities cannot be reduced to reading their visible expressions at face value. The role of this final section is therefore to state the epistemic consequences of the three-register architecture and to prepare the research programme developed in Chapter 5. Its objective is not to provide a complete epistemology in advance, but to identify the structure of the problem: reality can exceed manifestation, manifestation can disclose without exhausting, representation can mediate without transparently copying, and inference must reconstruct relations through historically situated traces.

This transition matters because ontological restraint changes what counts as an adequate epistemology. Once GRE suspends stronger claims about ultimate constitution where they are unnecessary, knowledge cannot be defined as possession of a final metaphysical description. At the same time, ontological suspension does not license a retreat to unconstrained interpretation. Relational realities remain capable of persistence, stability, and causal efficacy; manifestations remain constrained by the configurations through which they emerge; and representations can be compared with evidence, revised, and tested against subsequent consequences. The epistemic task is consequently neither transparent access nor arbitrary construction. It is the disciplined reconstruction of realities whose accessibility is mediated, partial, historical, and potentially recursive. (Giere 2004; Longino 1990; Hacking 2002)

The chapter's preceding distinctions also imply that epistemology must preserve the difference between an object and the conditions under which that object becomes knowable. A monetary relation is not identical to an accounting entry that records it. A legal position is not exhausted by the administrative category through which it becomes legible. A configuration of trust may already be relationally real before it is explicitly acknowledged. A contingent structure can shape what later becomes aesthetically salient before a subject recognizes the encounter as contingent or beautiful. In each case, evidence may arise through manifestation, but the evidential form and

the relational reality to which it refers remain analytically distinct. Knowledge therefore requires attention not only to what appears, but also to the relations that make appearance possible and to the transformations introduced by observation, symbolization, measurement, and representation.

Claim 4.189 (Epistemic consequence of the three-register architecture)**.** *If relational reality can precede particular manifestations, if manifestation is generated through condition-dependent relations, and if manifestations and representations can alter subsequent relational reality, then knowledge of a generative-relational system requires inquiry into both the realities under study and the relations through which evidence of those realities becomes available.*

Claim 4.189 gives the transition its basic form. The manifestation relation is not an invisible channel that epistemology can ignore. It becomes part of the object of inquiry. A trace can be informative because of how it was generated; a classification can be evidentially limited because of what its institutional production excludes; a repeated manifestation can acquire diagnostic value because the relevant mapping is sufficiently stable; and the same manifestation can become misleading when the mapping changes historically. Epistemic evaluation therefore extends from the manifested content to the generative conditions of manifestation itself.

4.22.1 Reality and Access

The first epistemic consequence concerns access. The three-register architecture does not assume that what is real is immediately available to inquiry. Ontological reality may remain partly or substantially under suspension. Relational reality can exist without having been perceived, named, measured, or symbolized by a particular subject. Manifestational reality marks a mode in which some aspect of a configuration becomes available under specified conditions, but availability itself is selective. What becomes accessible depends on embodiment, instrumentation, institutions, categories, interfaces, histories of attention, scales of observation, temporal position, and other relations that condition manifestation.

Access is therefore better treated as a relation than as a binary possession. An inquiry can have strong access to one aspect of a relational configuration and weak access to another. It can observe current outcomes while lacking historical trajectories. It can possess detailed administrative records while missing informal relations that organize those records' production. It can measure transactions precisely while having limited access to care, coercion, tacit obligation, fear, trust, or unrecorded exchange. It can encounter a stable manifestation while remaining uncertain about the multiplicity of relational structures compatible with it. The epistemic problem is shaped by the configuration of access rather than merely by the amount of information accumulated.

Definition 4.190 (Relational epistemic access)**.** *Relational epistemic access* denotes the historically and materially situated set of relations through which an inquiry can obtain, preserve, compare, interpret, or intervene upon manifestations and traces relevant to a specified epistemic target.

Definition 4.190 treats access itself as analyzable. It can be widened by new instruments, archives, institutions, languages, computational methods, or relationships

of trust. It can be narrowed by secrecy, destruction of records, strategic concealment, exclusion from institutions, measurement design, linguistic barriers, unequal resources, or the disappearance of the relevant manifestations. Access can also be distributed. Different actors can hold different traces of the same relational configuration, while no single observer possesses a complete view. The conditions under which evidence is collected thus become part of the history of what can later be known.

This conception also separates absence of access from absence of reality. A relation can be hidden, latent, weakly manifested, or manifest through forms unavailable to a particular inquiry. The absence of a recorded manifestation may therefore have several possible interpretations. The relevant relation may not exist; it may exist without producing the expected trace; the trace may have been produced but not preserved; the observer may lack access to it; or the manifestation rule itself may have changed. The epistemic significance of absence depends on the manifestation and recording relations that connect the target to the evidential field.

The converse problem also matters. Abundant access to manifestations does not necessarily yield correspondingly strong access to relational structure. A platform can generate billions of behavioral observations while leaving motivations, external relations, unobserved constraints, institutional conditions, and counterfactual possibilities underdetermined. Administrative systems can accumulate detailed categories whose precision exceeds the adequacy of the ontology they presuppose. Computational abundance can increase the resolution of a manifestational field while reproducing the same blind spots at greater scale. Epistemic strength therefore depends on the relation between evidence and target, not merely on the volume of evidence.

Ontological suspension intensifies rather than weakens this requirement. When GRE declines to settle what an object ultimately is, it must be particularly explicit about what is actually accessible and what inferential bridge connects that access to the claim being made. The framework can know a relational reality through its persistence, causal consequences, historical traces, responses to intervention, or convergent manifestations without pretending that such knowledge exhausts the object's ontology. Knowledge can therefore be substantive while remaining scoped.

4.22.2 Manifestation and Evidential Access

Manifestation supplies a principal interface through which relational realities become evidentially accessible. The term *interface* is useful only if it is not mistaken for a neutral screen. Section 4.7 showed that manifestations emerge through generative-relational conditions, while Section 4.8 showed that sufficiently stable manifestation mappings can themselves become relationally real. An evidential manifestation therefore carries information about a target through a process whose own structure, stability, and history can affect what the evidence means.

Definition 4.191 (Evidential interface)**.** An *evidential interface* is a manifestation relation, or organized set of manifestation relations, through which features of a specified epistemic target become available for observation, recording, comparison, interpretation, or intervention.

An evidential interface can be bodily, linguistic, institutional, legal, statistical, com-

putational, material, or composite. Pain may become accessible through speech, gesture, physiology, clinical examination, or patterns of action. Monetary relations may become accessible through prices, account balances, contractual records, settlement systems, observed exchanges, or institutional interventions. Trust may become accessible through repeated cooperation, expressed commitments, vulnerability, withdrawal, testimony, or responses under changing conditions. None of these manifestations is identical to the relational reality under study, and each preserves some distinctions while transforming or omitting others.

The evidential value of a manifestation consequently depends partly on knowledge of its production. A stable thermometer reading is informative because a sufficiently understood relation connects relevant physical conditions to the displayed value under specified conditions. A legal registry is informative because institutions generate, preserve, and update entries according to rules whose operation can be investigated. A survey answer is informative under a different manifestation regime involving question wording, interpretation, memory, incentives, social desirability, sampling, and response conditions. Treating all three simply as "observations" would conceal important differences in their generative pathways.

This approach also clarifies why directness is often a poor measure of epistemic quality. A manifestation can feel immediate while being generated through complex learned, embodied, institutional, or technological mediation. Conversely, a highly mediated trace can provide strong evidence when the relevant mapping is well characterized and independently tested. GRE therefore gives priority to reconstructing the evidential relation over ranking evidence by an intuitive scale from direct to indirect. The important questions concern what generates the trace, under what conditions, with what stability, and which relational differences the interface can preserve.

Manifestational plurality can strengthen inquiry when partially independent interfaces constrain the same target from different directions. Testimony, behavior, administrative records, historical documents, material traces, and intervention responses may each preserve different features and possess different failure modes. Convergence among them can reduce the compatibility set described in Section 4.9. Yet convergence is not automatic confirmation. Several manifestations can share the same upstream classification system, institutional incentive, database, or cultural convention and therefore reproduce a common error. Epistemic plurality requires attention to dependence among evidential interfaces rather than merely counting the number of observations.

The historical character of interfaces is equally important. The same symbol, indicator, behavior, or institutional record can change meaning when its manifestation relation changes. A category can persist linguistically while its legal criteria are revised. A price series can span periods in which market institutions, currencies, quality standards, or reporting practices differ. An expression of identity can operate differently after new institutions make that expression consequential. Historical epistemology therefore requires reconstruction not only of traces but of the changing rules through which those traces became possible.

Remark 4.192 (Evidence and manifestation)*.* A manifestation becomes evidence for a specified claim only through an inferential account linking the manifestation, its generative conditions, and the epistemic target. Manifestational reality is therefore

broader than evidence, while evidence is manifestation interpreted within a warranted epistemic relation.

Remark 4.192 prevents the ontology of manifestation from silently becoming an epistemology. A manifestation can be real without being evidentially useful for a particular question. It can also be causally powerful while epistemically misleading. The transition to epistemology begins when inquiry asks what a manifestation licenses us to infer.

4.22.3 Representation and Inference

Representation introduces another layer of mediation. Section 4.10 distinguished symbolization from manifestation and showed that symbolic forms can stabilize categories, produce practical commensurability, and become causally effective in their own right. For epistemology, the central problem is that representations do not merely store already settled knowledge. They select variables, categories, units, scales, boundaries, temporal resolutions, equivalence relations, and conventions through which manifestations become inferentially tractable.

An economic model, statistical indicator, legal category, archival description, qualitative code, graph, narrative, database schema, or computational state representation therefore participates in the structure of inference. Each makes some distinctions explicit and leaves others implicit or unavailable. A representation can preserve the relations relevant to one problem while distorting those relevant to another. The adequacy of representation is consequently task-sensitive without becoming arbitrary: the relevant question is whether the representation preserves, transforms, or suppresses differences that matter for the claim under investigation.

The non-entailment discipline of Section 4.21 applies directly here. Formal exactness does not establish ontological identity. Predictive success does not by itself establish unique causal reconstruction. Institutional uptake does not establish truth. A representation can become relationally real because decisions, expectations, rights, or resource allocations are organized around it while remaining epistemically inadequate concerning its target. This possibility is particularly important in economics, where prices, ratings, rankings, risk scores, classifications, forecasts, and models can feed back into the systems they describe.

Inference must therefore distinguish at least three relations: the relation between a relational reality and its manifestations, the relation between manifestations and their representations, and the relation between those representations and the conclusions drawn from them. Weakness or transformation can enter at each stage. A model can faithfully encode a dataset whose measurement process is biased. A dataset can accurately preserve recorded manifestations while those manifestations are weak indicators of the target. A representation can preserve relevant evidence while an inferential procedure overstates what the evidence supports. Epistemic assessment requires locating uncertainty rather than compressing it into a single undifferentiated confidence judgment.

Claim 4.193 (Layered inferential accountability)**.** *An epistemic claim concerning relational reality should remain accountable to the conditions that generated the relevant manifestations, the operations that represented those manifestations, and the inferen-*

tial rules through which the representation supports the claim.

Claim 4.193 does not require every inquiry to reconstruct an unlimited chain of mediation. It requires the chain to be extended far enough that omitted transformations are unlikely to reverse or materially alter the conclusion. This boundary is itself inquiry-relative. A descriptive task may require only a stable reporting relation. A causal claim may require intervention, temporal ordering, mechanism, or comparison among competing generative accounts. A normative decision may additionally require explicit value assumptions, legitimacy conditions, and treatment of affected subjects whose realities are poorly represented by the available data.

Representation can also change the object of inference. Once a category is published, a score assigned, a forecast circulated, or a model institutionalized, agents can respond. The representation then becomes part of the generative-relational system and can alter later manifestations. An epistemology adequate to GRE must therefore track performativity and recursion. Evidence generated after a representation becomes operative may partly reflect the representation itself. The line between observation and intervention can become historically entangled.

This entanglement is not an exceptional defect of social inquiry. It is a structural possibility wherever manifestational and representational forms enter subsequent causal relations. The epistemic task is to identify when that recursion is material. Chapter 5 will therefore treat representation not only as a medium of knowledge but also as a possible generator of later reality.

4.22.4 Inverse Reconstruction

The preceding points converge on an inverse problem. Inquiry commonly encounters manifestations, traces, records, behaviors, symbols, and outcomes and seeks to reconstruct the relational realities, histories, and generative mechanisms compatible with them. Section 4.9 established that manifestation can be non-invertible: multiple relational configurations may produce similar manifestations, while one relational configuration may produce different manifestations under changing conditions. Epistemology must determine what can responsibly be reconstructed despite that non-uniqueness.

The inverse problem is not simply a technical difficulty produced by insufficient data. Additional data can narrow a compatibility set, but non-invertibility can arise from the structure of the manifestation relation itself. Distinct histories may converge on the same current state. Different institutional arrangements may produce the same aggregate statistic. Different motivations can yield the same observed action. Different causal pathways can generate the same outcome. A single relation can manifest differently across cultural, historical, technological, or bodily conditions. Even an extremely detailed manifestational description may therefore leave relational structure underdetermined.

Definition 4.194 (Relational inverse problem)**.** A *relational inverse problem* arises when an inquiry seeks to reconstruct one or more relational configurations, histories, or generative mechanisms from available manifestations and traces for which more than one materially distinct reconstruction remains compatible with the evidence and maintained assumptions.

Definition 4.194 shifts the epistemic aim away from an automatic demand for unique inversion. Sometimes unique reconstruction can be achieved under strong and justified constraints. In other cases, the appropriate epistemic object is a set of plausible relational configurations, an equivalence class, a partially ordered family of explanations, a distribution over possibilities, or a set of invariants shared across competing reconstructions. The form of knowledge should match the identifiability permitted by the evidence.

This point is especially important for historical and social inquiry. A surviving archive is not the past itself. It is a historically generated manifestational field shaped by preservation, destruction, classification, institutional power, material durability, access, and later interpretation. A current institution can preserve traces of earlier relations while also reorganizing them. A subject's present testimony can carry memory, reinterpretation, later categories, and current stakes. Reconstruction therefore requires attention to the history of the evidential interface, not only the content of surviving evidence.

Intervention can sometimes strengthen inverse reconstruction because different candidate relational structures can respond differently when conditions change. Comparative cases, natural variation, experiments, policy changes, historical discontinuities, and perturbations can expose differences hidden under ordinary conditions. Yet intervention itself can transform the system, and the relation between intervention response and antecedent structure requires argument. GRE therefore treats intervention as one epistemic resource among others rather than a universal solution to non-invertibility.

The inverse problem also explains why heterogeneous methods can be epistemically complementary. Historical reconstruction can identify trajectories concealed by cross-sectional data. Ethnographic or interpretive inquiry can recover meanings and relations compressed by administrative categories. Statistical methods can estimate regularities across cases. Network and dynamical models can expose structural dependencies. Computational simulation can test whether proposed mechanisms are capable of generating observed patterns. Legal analysis can reconstruct institutional rules that shape manifestational regimes. None of these methods possesses automatic priority. Their contribution depends on which dimensions of the compatibility set they constrain and which assumptions they introduce.

Claim 4.195 (Epistemic adequacy under non-invertibility)**.** *When unique reconstruction is not warranted, epistemic adequacy consists partly in preserving the plurality of materially compatible relational explanations, identifying the evidence that distinguishes among them, and calibrating claims to the invariants or differences that the available access can support.*

This claim makes uncertainty structurally informative. Multiple compatible explanations indicate where manifestation fails to preserve distinctions, where access is limited, or where additional assumptions are carrying the inference. The objective is not to celebrate indeterminacy but to locate it. An explicit compatibility set can guide new observation, archival search, intervention, comparison, or model revision more effectively than a premature single reconstruction.

The inverse problem also returns us to the example of relational realities that need

not share a common metric space. If two objects are both relationally real, epistemic comparison still requires a warranted comparison relation. Reconstruction cannot assume in advance that heterogeneous domains can be reduced to one metric, one ranking, or one common representation. Sometimes the relevant knowledge concerns structural correspondence; sometimes temporal dependence, functional equivalence, causal interaction, or qualitative difference; sometimes no defensible comparison is yet available. Epistemology must justify the comparison structure rather than inheriting it from the convenience of representation.

4.22.5 Relational Epistemology

The resulting epistemic orientation can now be stated provisionally. GRE requires an epistemology capable of knowing relationally generated, historically changing, multiply manifested, and recursively represented realities without assuming transparent access or final ontological settlement. Such an epistemology must treat evidence, observation, categories, models, archives, and methods as situated within relations while still allowing disciplined claims about realities that exceed those relations of access.

Definition 4.196 (Relational epistemology in GRE)**.** *Relational epistemology in GRE* denotes the study and practice of warranted knowledge concerning relational and generative realities through situated manifestations, traces, representations, comparisons, interventions, and historical reconstructions, together with explicit analysis of the relations that make those forms of access possible and consequential.

Several commitments follow from Definition 4.196. First, knowledge claims are situated without being reduced to perspective. The position of an observer, institution, instrument, archive, or model affects access, but relational reality can constrain and correct the account produced from that position. Second, mediation is epistemically constitutive rather than merely contaminating. Instruments, languages, institutions, categories, and representations can make otherwise inaccessible realities knowable; their mediation must be analyzed rather than imagined away. Third, historical change applies to epistemic relations themselves. Methods, categories, observation systems, and standards of evidence can acquire histories, and their adequacy can change as the realities under study and the interfaces of manifestation change.

Fourth, epistemic plurality can be productive when methods preserve different dimensions of the relational configuration and expose one another's blind spots. This plurality does not mean that all interpretations are equally warranted. Claims remain answerable to evidence, causal structure, internal coherence, historical reconstruction, comparative performance, and the consequences of intervention where relevant. Fifth, uncertainty should be located and structured. The inquiry should distinguish uncertainty about the target, uncertainty about the manifestation relation, uncertainty introduced by representation, uncertainty arising from missing evidence, and uncertainty created by competing explanations.

Sixth, epistemology in GRE is recursively connected to praxis. Research can change what it studies by classifying, measuring, publishing, intervening, allocating attention, or altering institutional expectations. The production of knowledge can therefore generate new relational realities. This fact does not eliminate the possibility of

knowledge; it adds another causal relation that must sometimes be included in the analysis. Epistemic responsibility includes attention to how inquiry enters the generative field.

The three-register architecture developed in this chapter consequently supplies neither a metaphysical closure nor a simple ladder from reality to knowledge. It supplies a structured problem-space. Ontological reality marks questions whose final settlement can remain open. Relational reality identifies emergent, sufficiently persistent and stable, causally efficacious objects within generative-relational systems. Manifestational reality identifies modes through which aspects of those realities become available under particular conditions. Manifestation can precede neither relation nor ontology by conceptual necessity, and manifestation can recursively reshape the relational field once it becomes operative. Symbolic representations can stabilize, compare, compress, transform, and institutionalize manifestations while acquiring causal efficacy of their own. Across these registers, mappings can be partial, plural, historically variable, and non-invertible.

The epistemic problem follows directly. How can an inquiry identify relations that are only partly manifest? How can it distinguish traces from the structures that generate them? How can it learn manifestation rules and detect when those rules change? How can it reason across boundaries and scales, reconstruct the identity and persistence of relations, analyze higher-order or field-like organization, attribute generative effects, and preserve historical trajectories? How should it treat unequal access, strategic concealment, missing records, performative classifications, computational representations, and evidence that changes because the system has learned to respond to observation? These are not secondary methodological details. They are consequences of the ontology developed here.

Chapter 5 takes these consequences as its starting point. It begins with the epistemic problem created by ontological suspension, then develops the inverse problem of manifestation, knowledge of manifestation relations, the distinction between relation and trace, symbolization and representation, performative representation, partial observation, boundary and scale, relational identity, higher-order relations, relational fields, generative relations, attribution, trajectories, uncertainty, comparison, and epistemic revision. The movement of Part II is therefore complete at the level required for transition: Chapter 4 has clarified the kinds of reality GRE permits itself to discuss and the limits of those claims; Chapter 5 asks how warranted knowledge of those realities can be constructed under conditions of mediation, plurality, history, and incomplete access.

The transition can be stated compactly. GRE begins neither with the expectation of transparent reality nor with the conclusion that mediation makes reality inaccessible. It begins with a more demanding proposition: reality and access are related but distinct; the relations between them are themselves historically generated and potentially knowable; and responsible knowledge requires reconstructing those relations with the same care that GRE brings to the economic realities they disclose.

Chapter 5

Epistemology of Generative Relational Economics

This chapter develops the epistemology required for Generative Relational Economics (GRE) after the ontological distinctions of the preceding chapter have been established. Its role within Part II is to move from a view of reality to a disciplined account of knowledge of that reality. The previous chapter distinguished ontological, relational, and manifestational reality while preserving ontological suspension where stronger commitment is unnecessary. The present chapter asks how inquiry can move from manifestations, traces, representations, observations, records, models, and interventions toward warranted claims about relations and generative processes. Its objective is to specify the epistemic conditions under which GRE can make claims that are sufficiently warranted, appropriately scoped, historically situated, contestable, and revisable, while leaving broader theories of knowledge and stronger claims of transparent access outside the commitments required here.

The central difficulty arises from mediated access. Relational realities can become manifest through bodily, institutional, legal, linguistic, statistical, technological, or other conditions of manifestation, yet manifestation does not uniquely reveal the relational structure from which it arises. Similar manifestations may be compatible with different relational configurations, and similar relations may become manifest differently across contexts, scales, historical periods, or representational systems. The epistemic task therefore has the structure of an inverse problem. Inquiry often encounters what has become observable or representable and attempts to reconstruct the relations, fields, trajectories, and generative processes that may have contributed to it. Such reconstruction can be rigorous, but its warrant depends on explicit assumptions concerning manifestation, evidence, representation, boundary, scale, temporality, and alternative explanation.

Ontological suspension makes this epistemic discipline especially important. GRE can investigate relations without deciding in advance whether every analytically useful relation corresponds to an independently fundamental entity. It can also acknowledge relational realities whose persistence and causal efficacy depend partly on institutions, recognition, convention, classification, or symbolic mediation. These freedoms increase rather than reduce the burden of epistemic specification. A relation that is legally recognized, statistically represented, administratively legible,

behaviorally enacted, or computationally inferred can be real in one relevant sense while remaining misrepresented in another. A representation can be causally effective without being epistemically adequate, and a relation can be weakly represented while still being relationally consequential. The chapter accordingly separates questions of existence, manifestation, representation, causal efficacy, generativity, and normative evaluation wherever their conflation would strengthen a claim beyond its evidence.

The chapter's method is architectural. It begins from the target claim and identifies recurring epistemic problems that research designs may have to address when they study relational or generative phenomena, allowing different evidential forms and methodological traditions to enter according to their claim-relative contribution. These include non-invertibility of manifestation, partial observation, unequal access, boundary and scale selection, relational identity through change, higher-order structure, field reconstruction, generative attribution, historical trajectory, evidential heterogeneity, uncertainty, epistemic justice, machine mediation, and revisability. Formal definitions and propositions are introduced where they clarify the structure of these problems, but they remain analytical devices whose usefulness depends on the empirical and interpretive context in which they are applied.

The first movement, Sections 5.1–5.9, establishes the conditions of epistemic access to relations. Section 5.1 formulates the epistemic problem that follows from ontological suspension and identifies relational reality as an epistemic target reached through manifestational and representational mediation. Section 5.2 develops the inverse problem of manifestation and the consequences of non-invertibility, manifestational equivalence, contextual dependence, and multiple relational explanations. Section 5.3 then makes manifestation relations themselves objects of inquiry, because inference from manifestation to relation depends partly on what is known about the processes through which manifestation occurs. Sections 5.4 and 5.5 distinguish relations from their traces and from the symbolic, legal, administrative, statistical, linguistic, and computational representations through which those traces become usable in inquiry.

That movement also treats representation and observation as active conditions rather than neutral windows. Section 5.6 examines circumstances in which representations become performative: classifications, legal categories, administrative records, statistical descriptions, or algorithmic outputs can enter the relational system and affect subsequent relations. Section 5.7 develops partial observation, observer position, unequal access, distributed observation, concealment, and temporal gaps. Section 5.8 then shows that relational claims are indexed to boundaries and scales whose selection can materially alter what becomes visible and what remains outside the analysis. Section 5.9 closes the first movement by addressing identity and persistence, because longitudinal knowledge requires criteria for deciding when a changing relation should be treated as continuous, transformed, newly formed, or dissolved.

The second movement, Sections 5.10–5.14, extends epistemic inquiry beyond individual relations toward relational configurations and generative processes. Section 5.10 distinguishes relations among relations, collective relations, nested relations, multilayer configurations, and hyperrelational forms while preserving the additional uncertainty introduced by higher-order reconstruction. Section 5.11 devel-

ops the epistemology of relational fields and requires a field claim to establish more than relational density: distributed organization and position must matter to the target under investigation. These discussions provide the structural basis for Section 5.12, which defines generative relations relative to specified effects such as capacity formation, relation formation, structural transformation, constraint generation, altered future possibilities, or changes in the conditions of subsequent transformation.

The distinction between relational existence and generative effect is central to the chapter. Evidence that a relation exists does not by itself establish what the relation generates. Section 5.13 therefore develops the epistemic problem of generative attribution through mechanisms, counterfactual dependence, multiple causation, distributed generation, delayed effects, branching pathways, and emergent outcomes. The chapter therefore uses a plural architecture of causal and generative warrant. The appropriate burden depends on the kind and strength of the attribution being made. Section 5.14 then adds historical depth by distinguishing relational trajectories, generative trajectories, path dependence, genealogy, historical counterfactuals, and re-epistemization. Historical knowledge is treated as revisable reconstruction under changing evidence and categories rather than as retrospective access to a fixed and fully recoverable past.

The third movement, Sections 5.15–5.22, turns from the objects of relational and generative knowledge toward the evidential and institutional conditions of warranted inquiry. Section 5.15 differentiates documentary, administrative, legal, behavioral, testimonial, ethnographic, network, longitudinal, and computationally inferred evidence according to the relational properties they can support and the characteristic mediations through which they are produced. Section 5.16 then specifies the additional evidential burden associated with generative claims, including downstream effects, capacity formation, structural transformation, value propagation, recirculation, and foreclosure. Evidential pluralism in these sections requires claim-sensitive judgment about what each evidential form can reveal, what it may conceal, and how convergent or conflicting evidence should alter the warranted claim while preserving differences among evidential forms.

Section 5.17 organizes uncertainty into a multidimensional confidence profile rather than a single undifferentiated score. Relational, manifestational, generative, boundary, scale, temporal, model, and explanatory uncertainty can vary independently, and a defensible claim should preserve those differences where they matter. Section 5.18 adds epistemic justice by examining how visibility, voice, representational authority, classification, institutional legibility, evidence-production capacity, and generative attribution are unequally distributed. Justice-sensitive inquiry retains evidential standards while asking whether the conditions under which evidence becomes producible, preservable, credible, and actionable systematically exclude relevant relations or contributors.

Machine mediation intensifies several of these concerns. Section 5.19 examines machine observation, algorithmic classification, computationally inferred relations, AI-assisted reconstruction, machine-generated representation, epistemic asymmetry, representational authority, and contestability. Computational scale and precision can enlarge epistemic reach while also introducing opacity, inherited categories, uneven

provenance, and new recursive effects when outputs become operational within the systems being studied. Machine systems are therefore treated as components of an epistemic architecture rather than as independent guarantors of knowledge.

The chapter closes by making revisability an explicit property of GRE inquiry. Section 5.20 develops revision through new evidence, intervention, historical transformation, category failure, reflexive observation, and preservation of serious alternative interpretations. Section 5.21 consolidates the chapter into a set of epistemic commitments: partial knowledge, explicit representation, explicit boundary and scale, explicit uncertainty, mechanism-sensitive attribution, evidential pluralism, historical sensitivity, revisability, and epistemic humility. Section 5.22 then translates these commitments into methodological design burdens. The transition is deliberate. Epistemology specifies what a defensible relational or generative claim requires; methodology must organize inquiry so that evidence capable of supporting, qualifying, contesting, or revising such claims can actually be produced.

Across these movements, the chapter advances a position of bounded epistemic ambition. GRE is permitted to ask large questions concerning distributed relations, historically evolving institutions, heterogeneous forms of evidence, and generative transformations across scales. It is also required to state the conditions under which those questions become answerable. Strong formalization, extensive data, institutional recognition, computational sophistication, or representational precision can improve inquiry while the mediations through which knowledge is produced remain explicit. A narrow claim with explicit scope and strong evidential fit can therefore possess greater epistemic warrant than a more comprehensive claim whose boundary, representation, or inferential pathway remains obscure.

The resulting epistemology is demanding while remaining compatible with incomplete knowledge. It permits provisional relational maps, partial reconstruction, competing explanations, graded generative attribution, and historically revisable knowledge while preserving criteria by which stronger and weaker claims can be distinguished. The chapter therefore supplies GRE with an epistemic position appropriate to an open research programme: knowledge can be situated while preserving standards of warrant, plural while preserving evidential differentiation, formally articulated while retaining ontological restraint, and revisable while retaining epistemic content. With this architecture in place, the book can move from the conditions of warranted knowledge to the practical organization of research praxis and methodology.

5.1 The Epistemic Problem after Ontological Suspension

Chapter 4 established an ontological architecture that is deliberately strong enough to support substantive inquiry and deliberately restrained enough to avoid converting analytical usefulness into final metaphysical settlement. Ontological reality, relational reality, and manifestational reality identify distinct registers of analysis; relational reality can precede perception and symbolization; manifestation is generated through historically and materially conditioned relations; and representations can enter the systems they describe and alter subsequent relations. These commitments

create the starting problem of the present chapter. If reality can exceed what is manifest, if manifestation can be selective and non-invertible, and if representation can be both evidential and performative, then epistemology cannot be reduced to the accumulation of visible facts. The role of this section is to formulate that problem precisely. It develops five connected tasks: knowledge under ontological suspension, specification of relational reality as an epistemic target, the evidential role of manifestational reality, representation as mediated access, and disciplined inference across the three registers.

The argument proceeds from a distinction between *ontological settlement* and *epistemic warrant*. GRE does not require a final account of what an object ultimately is before inquiry can establish that some configuration persists, exhibits a sufficiently stable organization, produces causal effects, or changes under specified interventions. Scientific and philosophical debates concerning ontological commitment, empirical adequacy, model-based representation, and the social conditions of evidential judgment already show that useful inquiry can distinguish the strength of an empirical or representational claim from the strength of a metaphysical one (Quine 1948; Fraassen 1980; Giere 2004; Longino 1990). GRE extends that discipline into a relational setting. The absence of final ontological settlement does not erase the possibility of knowledge; it increases the need to state what is being claimed, through which evidential relations, and with what residual uncertainty.

Claim 5.1 (Epistemic consequence of ontological suspension)**.** *Ontological suspension permits substantive epistemic claims when the epistemic target, evidential access, inferential relation, and scope of the claim are sufficiently specified. Suspension limits the strength of ontological conclusion; it does not by itself diminish the evidential strength of a well-supported relational or manifestational claim.*

Claim 5.1 provides the chapter's initial discipline. A researcher may be highly confident that a monetary arrangement structures access to resources, that a legal category alters feasible action, that an institutional ranking changes subsequent behavior, or that a trust relation has stabilized across repeated interactions while remaining agnostic about the ultimate metaphysical constitution of money, law, institutional identity, or selfhood. The claim can be strong at the level it addresses and suspended at another. Epistemic restraint therefore concerns the calibration of claims rather than a generalized weakening of knowledge.

This calibration also prevents a recurrent movement from uncertainty at one level to skepticism at every level. Uncertainty about ontological fundamentality does not imply uncertainty about observed manifestations. Uncertainty about the unique relational structure underlying a manifestation does not imply that the manifestation itself is doubtful. Conversely, confidence in a manifestation does not establish confidence in a unique relational explanation. The three-register architecture therefore supplies an epistemic differentiation: different claims can carry different degrees and kinds of warrant even when they concern the same event, object, or process.

5.1.1 Knowledge under Ontological Suspension

Ontological suspension is epistemically productive when it prevents an inquiry from demanding stronger settlement than its explanatory task requires. The relevant ques-

tion is not whether inquiry can proceed in the absence of any ontology; Chapter 4 has already rejected such a position. GRE identifies objects, relations, persistence conditions, causal effects, manifestations, scales, and historical transformations, and each of these choices carries ontological commitments. The epistemic question is narrower: which of those commitments must be settled for a particular claim to become warranted, and which may remain open without damaging the inference?

This distinction can be understood through the difference between *target commitment* and *ultimate commitment*. A target commitment identifies what the inquiry is attempting to know: for example, the organization of a labor relation, the persistence of a monetary convention, the distribution of access to computational capacity, or the institutional reproduction of a legal status. An ultimate commitment would answer a stronger question concerning what kind of being such an object finally possesses. The first is unavoidable for research. The second becomes necessary only when competing ontological accounts alter explanation, measurement, intervention, or evaluation.

Definition 5.2 (Epistemic target)**.** An *epistemic target* is the explicitly delimited object, relation, process, configuration, mechanism, trajectory, or property about which an inquiry seeks warranted knowledge under specified spatial, temporal, scalar, and conceptual conditions.

Definition 5.2 makes delimitation part of epistemic responsibility. A statement such as "trust increased" remains under-specified until the inquiry clarifies whose trust, within which relational domain, across what interval, through what manifestations, and relative to which criteria of persistence or change. The same requirement applies to economic claims. "Capital became more powerful" can refer to ownership concentration, control over future investment, institutional claims on income streams, influence over technological development, command over generative infrastructure, or several interacting mechanisms. The epistemic target must therefore be constructed with enough precision that evidence can bear on it.

Ontological suspension then operates selectively. If two metaphysical interpretations generate the same expectations for the target under the inquiry's present scale, evidence, and intervention possibilities, their disagreement can remain suspended. If they imply different persistence conditions, different causal mechanisms, or different responses to intervention, the disagreement becomes epistemically operative and must be reopened. This preserves the distinction developed in Chapter 4 between non-operative and operative ontological disagreement while giving it a direct epistemological consequence.

The approach differs from a simple instrumentalism. GRE does not treat objects and relations as disposable fictions merely because their ultimate ontology remains unsettled. A relational reality may possess stable causal efficacy within the system under study. The monetary unit used in an accounting system, the institutional category through which a person receives or loses an entitlement, or the recognized identity of an organization can produce consequences that remain explanatorily indispensable. Epistemic warrant can therefore attach to a relationally real object without requiring that object to be fundamental in a stronger metaphysical sense.

A second consequence concerns historical change. The categories through which

an epistemic target is identified can themselves have histories. Hacking's work on historical ontology and Kuhn's account of historically organized scientific practice provide different precedents for taking the historical formation of concepts, objects, and problem structures seriously (Hacking 2002; Kuhn 1962). GRE therefore treats target specification as revisable. A category that once captured the relevant organization can become inadequate when new relations, technologies, scales, or manifestations become causally important. Revisability does not make the target arbitrary; it makes the history of its adequacy part of epistemic inquiry.

Remark 5.3 (Scoped knowledge)*.* A claim can be strongly warranted within a specified epistemic target and evidential domain while stronger claims concerning ultimate ontology, exhaustive mechanism, universal scope, or normative validity remain suspended.

Remark 5.3 will recur throughout this chapter. GRE's epistemology is intended to support strong local knowledge without quietly converting local warrant into universal closure.

5.1.2 Relational Reality and Epistemic Targeting

Relational reality introduces a distinctive epistemic target because the relevant object need not be directly observable, consciously recognized, or symbolically articulated. Chapter 4 defined a relationally real object through emergence within a generative-relational system, sufficient persistence and stability across a relevant spacetime domain, and causal efficacy within that system. Each component creates an evidential burden. An inquiry must identify evidence of emergence, evidence of continuity or patterned persistence, evidence that the object retains enough organization to be distinguished across change, and evidence that it makes a difference to subsequent processes.

The epistemic target is therefore rarely an isolated entity. It includes the relational configuration through which the object emerges and the domain within which its causal efficacy is assessed. Consider money. A token, inscription, or account balance can be observed directly, but the relational reality of money depends on broader arrangements of recognition, law, exchange, accounting, expectation, institutional enforcement, and practical use. Observing a note or a number is evidence of a manifestation. Knowing the monetary relation requires reconstruction of the system in which that manifestation acquires persistence and efficacy.

The same point applies to objects with less obvious material manifestation. Trust can become relationally real before either party states that trust exists. A sense of continuing self can organize action before it is reflectively narrated. A religious object can organize obligations, spaces, temporal rhythms, and collective practices while its ultimate ontological status remains suspended. A contingent configuration can shape what later becomes aesthetically salient before the subject recognizes the contingency or articulates an aesthetic judgment. In each case, the epistemic challenge is to avoid identifying the absence of explicit manifestation with the absence of relational reality.

Definition 5.4 (Relational epistemic target)**.** A *relational epistemic target* is an epistemic target whose identity, persistence, causal role, or transformation depends ma-

terially on the generative-relational configuration within which it emerges and acts.

Definition 5.4 does not imply that every relevant cause is relational in the same sense. Bodies, infrastructures, material resources, ecological conditions, computational hardware, and other objects may enter the configuration under domain-specific ontologies. The definition concerns what must be reconstructed for the target to be adequately known. If the economic reality of a firm's authority depends on legal recognition, contracts, organizational routines, labor relations, financing, and expectations, then knowledge of that authority cannot be reduced to inspection of any single component.

Relational targeting also changes how absence is interpreted. Failure to observe an explicit claim of authority does not show that authority is absent. Failure to observe monetary exchange does not show that monetary dependence is absent. Failure to record a relation in an administrative database does not show that the relation does not organize action. At the same time, the framework does not authorize inference of hidden relations whenever evidence is missing. The relevant burden is constructive: an inquiry should specify what manifestations or traces a proposed relational reality would be expected to generate, under what conditions those manifestations may fail to appear, and which alternative relational structures remain compatible with the available evidence.

This requirement places mechanism and history near the center of epistemic targeting. A relational reality can be identified more securely when different evidential routes converge on its persistence and causal role: repeated behavior, institutional records, testimony, counterfactual variation, intervention, historical traces, and changes that follow the relation's stabilization or dissolution. Convergence does not guarantee unique reconstruction, but it can narrow the compatible relational field and strengthen a scoped claim.

The target may also be distributed. No participant need possess a complete representation of the relation in which they participate. Markets, administrative systems, infrastructures, supply chains, reputational fields, and scientific communities can contain locally informed actors whose combined practices generate structures that exceed each actor's explicit knowledge. Epistemology must therefore distinguish the knowledge possessed by participants from the knowledge an inquiry attempts to reconstruct about the relational configuration as a whole.

5.1.3 Manifestational Reality and Evidential Access

Manifestational reality supplies the principal domain through which inquiry encounters relational reality, but manifestation and evidence are not synonymous. A manifestation becomes evidence only relative to an epistemic target and an account of how the manifestation is generated. A market price can be evidence about exchange conditions, but its interpretation depends on institutional rules, market structure, temporal aggregation, strategic behavior, and what the price fails to record. A legal document can be evidence of a recognized status, but knowledge of effective legal power may also require enforcement practice, administrative discretion, and access to remedies. A behavioral trace can be evidence of interaction without uniquely revealing intention, trust, coercion, or preference.

The distinction can be stated explicitly.

Definition 5.5 (Evidential status of a manifestation)**.** The *evidential status of a manifestation* is the warranted relation by which a manifestation is treated as bearing information about a specified epistemic target under an articulated account of its generation, preservation, selection, and interpretation.

Definition 5.5 places the evidential burden on the relation between manifestation and target. The same manifestation can have different evidential significance for different questions. A wage payment can provide strong evidence that a payment occurred, moderate evidence concerning a contractual employment relation, weaker evidence concerning the worker's experienced autonomy, and almost no direct evidence concerning the complete structure of household care or future bargaining power. Evidential strength therefore cannot be assigned to the datum independently of the claim.

This position is compatible with a broader philosophy-of-science distinction between observed phenomena and stronger claims concerning the structures that explain them. Van Fraassen's constructive empiricism emphasizes the difference between empirical adequacy and stronger realist commitment, while Giere's model-based account treats representation as purposive and selective rather than as simple identity between model and world (Fraassen 1980; Giere 2004). GRE does not adopt either position wholesale. Their relevance lies in a shared caution: evidential accessibility and ontological exhaustiveness should not be conflated.

Manifestational access is also conditioned. Instruments, categories, languages, administrative rules, interfaces, bodily capacities, and historical circumstances determine what can become legible. Longino's contextual empiricism is useful here because evidential relevance depends partly on background assumptions and on the critical contexts through which those assumptions can be challenged (Longino 1990). In GRE, such background conditions are not merely external philosophy-of-science considerations. They can themselves be relationally real parts of the system under investigation. A statistical classification can determine which people become visible to an institution; an interface can determine which actions can be registered; a legal category can determine which harms become actionable; a platform metric can determine which activities are recognized as valuable.

Consequently, an inquiry should examine the conditions under which manifestations are produced, not only the manifested content. A stable manifestation relation can support repeated inference. A changing manifestation relation can make an apparently stable time series epistemically misleading. A new measurement technology can reveal previously inaccessible differences while simultaneously changing behavior. The same symbolic category can preserve continuity in records even when the relational reality it once tracked has transformed. Evidential access therefore has a history.

Claim 5.6 (Manifestation-evidence distinction)**.** *A manifestation acquires evidential force for a relational claim only through a warranted account of the relations connecting the manifestation to the epistemic target. Manifestational presence alone does not determine the strength or uniqueness of the inference.*

Claim 5.6 does not make evidence inaccessible. It clarifies where evidential work

occurs. Repeated manifestations, independent traces, intervention responses, mechanism knowledge, and historical continuity can strengthen the relation between manifestation and target. The later sections of this chapter will differentiate direct, indirect, latent, hidden, documentary, behavioral, testimonial, ethnographic, formal, and computational forms of evidence. Section 112 establishes the common structure within which those differences matter.

5.1.4 Representation and Mediated Access

Representation introduces another layer between manifestation and epistemic claim. A manifestation can be recorded, classified, translated, measured, aggregated, modeled, narrated, visualized, or encoded. Each operation can preserve some relations, suppress others, create new comparabilities, and add assumptions that were not present in the manifestational field itself. Representation is therefore an epistemic resource and an epistemic transformation.

A distinction between manifestation and representation is particularly important in economic inquiry. A transaction is one event; an administrative record of the transaction is another object; a statistical aggregation of many recorded transactions is another; a model estimated from the aggregate is another; and a policy interpretation of the model introduces yet another representational layer. These layers can be tightly connected, but they should not be treated as interchangeable. An error, selection rule, classification change, or aggregation procedure introduced at one stage can propagate through the later stages while leaving the final representation internally precise.

Quine's holistic account of empirical testing and Longino's contextual account of evidential relevance both provide precedents for treating observation and inference as embedded within wider conceptual and social structures rather than as isolated pairings between single statements and neutral facts (Quine 1951; Longino 1990). GRE adds a generative-relational concern: the representational apparatus can become causally active within the domain it represents. A credit score can alter access to credit; a ranking can alter applications and funding; a diagnosis can reorganize self-understanding and institutional treatment; a forecast can alter investment; and a legal classification can change the feasible actions of the classified subject. Representation can therefore mediate knowledge and later become part of the relational reality whose future manifestations are observed.

Definition 5.7 (Representational mediation)**.** *Representational mediation* denotes the set of operations through which manifestations or traces are selected, encoded, classified, transformed, aggregated, modeled, narrated, or otherwise organized into forms used for epistemic inference.

The definition makes representation analyzable without assuming that every representation is distorting. Mediation can increase epistemic capacity. A map can reveal spatial relations that are difficult to perceive locally. A statistical model can expose patterns across large populations. An archive can preserve traces beyond the lifetime of their producers. A legal record can stabilize a claim across institutional contexts. A simulation can make counterfactual structure explorable. The epistemic value of representation depends on what relations are preserved, what transforma-

tions are introduced, and what target the representation is used to investigate.

This also means that representational accuracy has several dimensions. A representation can reproduce observed manifestations accurately while mischaracterizing the relations that generated them. It can preserve a causal mechanism while omitting distributive consequences. It can capture average behavior while suppressing heterogeneity. It can represent a historical configuration adequately for one period and poorly after the underlying relations change. Epistemic evaluation should therefore specify the dimensions along which adequacy is claimed rather than treating representation as globally faithful or unfaithful.

In GRE, representational mediation acquires particular importance because the objects of political economy are frequently constituted partly through the representations used to govern them. Prices, property titles, balance sheets, national accounts, credit ratings, legal statuses, employment categories, performance indicators, and algorithmic scores are simultaneously representations and operative institutional objects. The epistemology of such domains must therefore distinguish evidence about a relational reality from representations that participate in producing that reality.

5.1.5 Inference across Registers and Epistemic Restraint

The final problem concerns inference across the three registers. The architecture developed in Chapter 4 permits several legitimate inferential movements, but none is automatically reversible. A manifestation can support a claim about relational reality when the manifestation relation is sufficiently understood. A relational configuration can support predictions about likely manifestations under specified conditions. A representation can preserve selected features of manifestations and permit comparison across cases. Evidence concerning persistent causal organization can also motivate stronger ontological questions. The epistemic danger appears when a warranted movement in one direction is silently converted into identity across registers.

Three forms of overreach are especially important. The first is *manifestational overreach*: treating what appears under one set of conditions as an exhaustive account of the relational reality. The second is *representational overreach*: treating a successful symbolic, statistical, computational, or formal representation as identical with the target. The third is *ontological overreach*: treating a well-supported relational explanation as sufficient proof of ultimate metaphysical constitution. The nonentailment discipline of Chapter 4 becomes an epistemic discipline here.

Definition 5.8 (Cross-register inference)**.** A *cross-register inference* is an inference in which evidence or claims articulated primarily at one register of reality are used to support a claim concerning another register. Its warrant depends on the explicitly or implicitly posited relations connecting the registers under the relevant historical, material, and manifestational conditions.

Definition 5.8 makes the inferential bridge visible. For example, inferring relational trust from repeated cooperative behavior requires assumptions about the relation between behavior and trust. Inferring institutional authority from legal documentation requires assumptions about recognition and enforcement. Inferring preference from choice requires assumptions concerning feasible alternatives, information, strategic behavior, and constraint. Inferring an underlying generative structure

from a statistical pattern requires assumptions about causal architecture and alternative explanations. Each inference can be warranted, but the warrant is located in more than the observed manifestation alone.

Non-invertibility makes this problem systematic. Different relational realities can generate similar manifestations, and one relational reality can generate heterogeneous manifestations across contexts. The inverse problem therefore produces a set of compatible explanations rather than a guaranteed unique solution. Epistemic progress can consist in reducing that set, discriminating among alternatives, identifying invariants, discovering new manifestations, changing the conditions of observation, or intervening on the system. Complete inversion is only one possible epistemic achievement and often an unrealistic one.

Claim 5.9 (Epistemic restraint across registers)**.** *The strength of a claim inferred across registers should be limited by the demonstrated stability, specificity, and scope of the relations that connect the evidential manifestation or representation to the epistemic target.*

Claim 5.9 gives GRE a practical rule for epistemic calibration. A highly specific and stable manifestation relation can support comparatively strong inference. A historically unstable, institutionally mediated, strategically manipulated, or weakly understood relation requires wider uncertainty. Multiple independent evidential routes can strengthen the claim when their errors and assumptions are sufficiently distinct. Apparent convergence among representations generated from the same underlying classification or dataset provides less independent support than its numerical multiplicity might suggest.

The rule also preserves room for knowledge that is historical and partial. A past relation may be reconstructable only through surviving traces whose production was unequal. A marginalized actor's experience may be poorly represented in official archives but partially recoverable through testimony, material traces, later records, or the consequences of institutions. A new scientific instrument can disclose structures inaccessible to earlier observers. An AI system can reorganize vast amounts of evidence while inheriting the exclusions embedded in its sources. Epistemic warrant therefore depends partly on understanding the history and distribution of access to manifestations.

Section 112 establishes the basic epistemic problem that follows from the ontology of Chapter 4. GRE can pursue knowledge without final ontological settlement because epistemic claims can be targeted, scoped, and warranted at different levels. Relational reality supplies an object of inquiry whose evidence may precede explicit recognition; manifestational reality provides access without guaranteeing exhaustive disclosure; representation expands and transforms that access; and inference across registers requires explicit bridges rather than assumed identity. The next section develops the most immediate technical consequence of this architecture: the inverse problem of manifestation, in which an inquiry must reconstruct relational configurations from manifestations that may be compatible with more than one generative history.

5.2 The Inverse Problem of Manifestation

Section 5.1 established that manifestation supplies epistemic access without guaranteeing exhaustive disclosure of relational reality. The present section develops the most immediate consequence of that position: inquiry frequently proceeds in the inverse direction, beginning from what has become manifest and attempting to reconstruct the relational configurations, histories, and generative conditions compatible with it. The role of this section is to formulate that reconstruction problem as an epistemic problem rather than merely a formal property of manifestation mappings. Its objective is to clarify what can be known when several relational configurations remain compatible with the same manifestation, when one configuration can manifest differently across contexts, and when the mapping itself changes historically. The discussion proceeds through relational reconstruction, non-invertibility, manifestational equivalence, multiple relational explanations, contextual dependence, and historical dependence. The method is inferential: it treats reconstruction as a constrained comparison among compatible relational accounts whose warrant can increase without requiring unique recovery of a single complete antecedent configuration.

The inverse problem should be distinguished from ordinary uncertainty about whether an observation is correct. A manifestation can be accurately recorded and still fail to identify uniquely the relational configuration that generated it. A price can be measured precisely while remaining compatible with heterogeneous market structures, expectations, constraints, and institutional conditions. A legal status can be documented unambiguously while leaving open several paths through which it was produced and several relations through which it is maintained. A behavioral regularity can be reproducible while admitting different accounts of trust, coercion, habit, incentives, or institutional filtering. The epistemic difficulty therefore concerns the relation between manifestation and reconstruction, not simply noise in the manifestation itself. This problem belongs to a wider family of underdetermination problems in which evidence constrains explanation without necessarily selecting a unique account (Duhem 1954; Quine 1951; Stanford 2023).

Definition 5.10 (Inverse epistemic problem of manifestation)**.** The *inverse epistemic problem of manifestation* is the problem of determining which claims about relational reality are warranted from one or more manifestations when the relations connecting relational configurations to those manifestations may be selective, many-to-one, one-to-many, context-dependent, historically variable, or only partially known.

Definition 5.10 makes the epistemic target central. An inquiry need not reconstruct every relation that participated in the history of a manifestation. It may seek only the relations relevant to a specified causal question, institutional mechanism, distributional pattern, or generative consequence. Invertibility is therefore too strong as a universal standard. The more appropriate question is whether the target of inquiry is *identifiable enough* under the available manifestations, assumptions, and conditions to support the intended claim.

5.2.1 From Manifestation to Relational Knowledge

Movement from manifestation to relational knowledge requires an inferential bridge. Section 5.1 called such movement a cross-register inference. The inverse problem makes its structure explicit. Let Y denote a selected manifestational domain, X a selected domain of relational configurations, and C the material, historical, institutional, perceptual, or technical conditions under which manifestation occurs. For an observed manifestation $y \in Y$, the epistemic task is to determine which elements of X remain compatible with y under C and which features of those elements can be warranted from the available evidence.

A useful starting object is the compatibility set developed in Chapter 4. For present epistemic purposes, however, the set should include the evidential and modeling assumptions through which compatibility is judged. Let E denote the available evidential corpus and A the explicit auxiliary assumptions of the inquiry. The epistemically admissible compatibility set is represented in Equation 5.1.

$$\mathcal{K}(y \mid C, E, A) = \{x \in X \mid x \text{ remains compatible with } y \text{ under } C, E, A\}. \tag{5.1}$$

Equation 5.1 is intentionally general. It does not assume that compatibility is probabilistic, metric, deterministic, or reducible to one formal model. In one inquiry, compatibility may be defined by a causal model and a likelihood. In another, it may depend on archival consistency, institutional sequence, legal records, qualitative traces, or process evidence. The equation serves to expose the epistemic structure: the observed manifestation constrains the candidate relational domain, but auxiliary assumptions and available evidence also shape what remains admissible.

This formulation makes two kinds of epistemic progress visible. The first is *eliminative progress*: additional evidence or stronger constraints remove relational configurations from $\mathcal{K}$. The second is *structural progress*: even when several configurations remain, inquiry discovers features shared across them. A researcher may be unable to identify one complete generative history while becoming highly confident that every serious account requires, for example, a particular institutional dependency, a threshold effect, a gatekeeping relation, or a temporal ordering. Relational knowledge can therefore increase through identification of invariants across compatible reconstructions.

Definition 5.11 (Relational identifiability)**.** An epistemic target is *relationally identifiable* relative to manifestations, conditions, evidence, and auxiliary assumptions when the admissible compatibility set is sufficiently constrained that the target property or relation takes a determinate, or appropriately bounded, form across the configurations that remain epistemically viable.

Relational identifiability in Definition 5.11 is weaker than complete inversion. A target can be identifiable even when the full configuration is not. If every viable reconstruction contains the same access restriction, the restriction can be well supported despite disagreement about other relations. If several histories produce the same observed institution but all require a durable asymmetry in control over a resource, that asymmetry may be identifiable even when the exact historical pathway

is not. The epistemic aim is therefore calibrated reconstruction rather than maximal reconstruction by default.

This also places model choice under scrutiny. Models can narrow the compatibility set by imposing structure, but narrowing through assumption should not be confused with narrowing through evidence. A representation can produce a unique estimate because the model excludes alternatives by construction. The uniqueness of the output then reflects both evidence and imposed structure. Model-based scientific representation is therefore epistemically powerful precisely when the relation between target, idealization, and representational purpose remains explicit (Giere 2004).

5.2.2 Non-Invertibility

Non-invertibility becomes epistemically significant when the manifestations available to inquiry fail to support unique recovery of the target relational configuration at the required scale. Chapter 4 treated this as a structural property of manifestation mappings. Chapter 5 adds the inferential consequence: non-invertibility creates a disciplined space of possible reconstructions and therefore requires explicit management of underdetermination.

Several sources of non-invertibility should be distinguished. *Compression* occurs when the manifestation preserves fewer distinctions than the relational configuration contains. *Aggregation* occurs when several units or relations contribute to a common manifest value. *Convergence* occurs when different generative trajectories reach similar manifest states. *Contextual transformation* occurs when the same relational configuration becomes manifest differently under changing conditions. *Selective observation* occurs when only some relations generate traces accessible to the inquiry. *Representational standardization* occurs when heterogeneous manifestations are translated into a common administrative, statistical, legal, or computational form. These mechanisms can coexist.

The epistemic implication is not that every explanation is equally plausible. Evidence can sharply constrain the compatibility set while leaving more than one serious relational account. The classical problem of underdetermination is useful here because it separates multiplicity of compatible explanation from unrestricted arbitrariness (Duhem 1954; Quine 1951; Stanford 2023). GRE adds two qualifications. First, the competing accounts may differ not only in theory but in the relational histories they reconstruct. Second, the mappings that produce evidence can themselves be historically generated and causally operative within the system under investigation.

Claim 5.12 (Non-invertibility and calibrated knowledge)**.** *Manifestational non-invertibility limits the uniqueness and scope of relational reconstruction, while remaining compatible with strong knowledge of properties that are stable across the admissible compatibility set or independently supported through additional evidential relations.*

Claim 5.12 prevents two opposite errors. One error treats a determinate manifestation as if it carried a unique relational antecedent. The other treats non-unique reconstruction as if it eliminated knowledge altogether. The appropriate response is to state which parts of the reconstruction are stable, which remain conditional, and

which depend on assumptions that alternative accounts do not share.

Intervention can sometimes improve identifiability by generating new manifestations under deliberately altered conditions. Comparative cases can serve a similar function when they vary relations that competing explanations treat differently. Historical evidence can discriminate between mechanisms that predict the same present manifestation but require different sequences. Qualitative evidence can reveal relations erased by standardized indicators. Formal analysis can characterize equivalence classes of models or mechanisms. These methods do not share a single epistemic form, yet each can reduce or reorganize the compatibility set. Methodological plurality therefore becomes a response to relational underdetermination rather than a generic preference for variety.

5.2.3 Manifestational Equivalence

The inverse problem becomes especially difficult when distinct relational configurations are manifestationally equivalent relative to the criteria of an inquiry. Chapter 4 defined manifestational equivalence as local indistinguishability under a specified manifestation regime. The epistemic task is to determine what, if anything, that equivalence licenses about the underlying relations.

Definition 5.13 (Epistemic manifestational equivalence)**.** Two relational configurations are *epistemically manifestationally equivalent* for an inquiry when the manifestations available under the inquiry's operative conditions and distinctions do not provide sufficient grounds to discriminate between them with respect to the specified epistemic target.

This definition is deliberately inquiry-relative. Two configurations can be equivalent for a narrow target and distinguishable for another. Two firms may be equivalent with respect to an observed quarterly profit while differing sharply in debt exposure, labor organization, ecological dependence, and technological trajectory. Two households may have the same income while differing in unpaid care burdens, legal vulnerability, asset ownership, and access to social networks. Two AI systems may produce indistinguishable outputs on a benchmark while relying on different training histories, architectures, compute requirements, or governance arrangements. The manifestation criterion determines the domain of equivalence; it does not erase relational difference outside that domain.

Manifestational equivalence should also be distinguished from measurement error. Perfect measurement of the operative manifestation may leave the equivalence intact. Increasing precision can reduce uncertainty around y without reducing multiplicity in $\mathcal{K}(y \mid C, E, A)$. If the measurement captures only a projection of the relational configuration, more precise measurement of that projection does not automatically recover omitted dimensions. Epistemic improvement may require a different manifestation, a new intervention, a changed scale, or access to another trace rather than greater precision of the same indicator.

This distinction is important for political economy because standardized measures often become authoritative precisely through their apparent comparability. Prices, incomes, productivity measures, credit scores, rankings, standardized legal categories, and algorithmic classifications create manifestational domains in

which heterogeneous relations become comparable for practical purposes. Such comparability can be administratively or economically powerful while remaining epistemically incomplete. A common scale can organize action without establishing that the underlying relational configurations are commensurable in every dimension.

Remark 5.14 (Equivalence and epistemic humility)*.* Manifestational equivalence warrants restraint concerning relational difference; it does not warrant a presumption of relational identity. The absence of discriminating manifestation is an epistemic condition, not proof that no relevant difference exists.

Remark 5.14 is especially important where some relations are systematically less likely to leave durable traces. Informal labor, care work, coercion, tacit exclusion, undocumented exchange, affective dependence, and relations involving actors with limited institutional voice can be weakly represented in official records. A manifestational regime can therefore produce equivalence partly because it lacks distinctions through which certain relational differences become legible. The inverse problem is consequently linked to the social distribution of epistemic visibility.

5.2.4 Multiple Relational Explanations

When several relational explanations survive the available evidence, GRE requires criteria for comparing them without pretending that one must always be selected immediately. The objective is neither permanent suspension nor premature closure. It is to make the remaining alternatives explicit and identify what additional evidence, interventions, or conceptual distinctions would materially discriminate among them.

Multiple explanations can differ in several ways. They can identify different relations as causally central, assign different roles to the same relation, specify different historical sequences, draw boundaries around the system differently, or treat a manifestation as generated at different scales. They can also agree on a local mechanism while disagreeing about its wider embedding. Two explanations of wage change, for example, might agree that bargaining institutions matter while differing on whether technological change, labor-market concentration, legal structure, organizational strategy, or macroeconomic conditions explain the institutional shift that preceded the observed outcome.

A relational comparison should therefore examine more than goodness of fit to the manifestation. It should ask whether the explanation preserves relevant temporal order, accommodates independent traces, survives comparison across contexts, specifies the mechanism through which relations generate the manifestation, and remains coherent when the analysis changes scale. Explanations should also expose rather than hide their auxiliary assumptions. Longino's account of evidential reasoning is useful here because it emphasizes that the relevance and interpretation of evidence depend on background assumptions that become more reliable when subjected to critical scrutiny from alternative perspectives (Longino 1990).

Proposition 5.15 (Comparison of relational reconstructions)**.** *When several relational reconstructions remain compatible with the available manifestations, GRE should compare them through the target-relevant structure they preserve, the independent evidence they accommodate, the assumptions they require, their sensitivity*

to scale and context, and the discriminating consequences they generate for further inquiry or intervention.

Proposition 5.15 allows several outcomes. One reconstruction may become substantially better supported. Several may remain viable but share a common relational core. Different reconstructions may be useful at different scales or for different targets. A disagreement may remain unresolved because the surviving evidence does not discriminate among the alternatives. These outcomes should be reported differently. The epistemic vocabulary should preserve the difference between identification, bounded inference, comparative support, and unresolved plurality.

The possibility of a common core is particularly important. Suppose several explanations disagree about the exact mechanism through which a platform acquired market dominance, but every viable account requires asymmetric control over access to a critical infrastructure. The broader claim about infrastructural asymmetry may then be better supported than any single complete historical reconstruction. GRE can therefore advance through partial relational invariants even where the full inverse problem remains open.

5.2.5 Context Dependence

Inverse reconstruction is conditioned by the context in which manifestation occurs. A manifestation relation that is highly discriminating in one context can become weakly informative in another. The same behavior can indicate trust where exit is feasible and indicate compliance where sanction is severe. The same price can emerge under competitive exchange, administered pricing, scarcity, speculation, subsidy, or strategic restriction. The same legal category can carry different practical consequences depending on enforcement, institutional capacity, and adjacent rights. Context therefore enters the inverse problem as part of the generative conditions of manifestation.

Context should not be treated as an unlimited residual category. For epistemic purposes, relevant context consists of conditions whose variation materially changes the relation between the target configuration and the manifestation. These conditions can be institutional, technological, cultural, ecological, legal, spatial, temporal, or relational. Identifying them is part of the reconstruction problem. A good explanation should specify which contextual differences are expected to alter manifestation and which are irrelevant to the target claim.

This requirement also limits unrestricted transfer of inference across populations or domains. A manifestation relation established in one institutional setting cannot be assumed to retain the same specificity elsewhere. A survey item, performance indicator, transaction record, or behavioral proxy can acquire different meanings when incentives, classifications, norms, or available alternatives change. Perspectival and model-based accounts of scientific representation are relevant because representations are constructed for purposes and from positions that select some relations while omitting others (Giere 2004; Longino 1990).

Claim 5.16 (Contextual portability of inverse inference)**.** *An inverse inference is portable across contexts only to the extent that the conditions governing the relevant manifestation relation remain sufficiently stable, or the differences among contexts are*

explicitly modeled and supported by evidence.

The claim prevents an observed regularity from being elevated too quickly into a context-independent relational law. It also permits legitimate generalization when invariants are demonstrated. GRE is not committed to contextual uniqueness. It is committed to making the conditions of portability part of the epistemic claim.

Context can also be actively altered by inquiry. Publication of a metric can change the behavior measured by that metric. A legal classification can reorganize conduct. A forecast can alter expectations. An AI-generated representation can modify subsequent decisions. In such cases, the manifestation relation at a later time partly reflects earlier epistemic activity. The inverse problem must therefore account for reflexive contexts in which observation, representation, and intervention become part of the generative field.

5.2.6 Historical Dependence

Historical dependence gives the inverse problem a further dimension. The same manifest form can arise from different historical sequences, and the same symbol or category can change its relational meaning over time. Reconstruction therefore concerns not only which configuration is compatible with a manifestation, but which trajectory could have generated and sustained that configuration under historically specific conditions.

A present manifestation frequently contains only compressed traces of its history. An institution can preserve rules whose originating conflict is no longer visible. A market convention can remain stable after the conditions that first produced it have changed. A category can continue to be recorded even while its institutional meaning shifts. A relation can become self-reinforcing, so that its present persistence depends less on the mechanism that initiated it than on later feedbacks. Present-state evidence therefore may be insufficient for distinguishing origin, stabilization, and reproduction.

Historical reconstruction expands the evidential field by incorporating sequence, timing, archival traces, testimony, material residues, prior classifications, and changes in the manifestation regime itself. It also introduces losses that cannot always be repaired. Records can be destroyed, never created, selectively preserved, or generated through institutions that gave some actors far greater capacity to leave durable traces than others. The compatibility set for a historical inverse problem can therefore remain permanently wider than the set that would have been available to a contemporary observer with richer access.

Definition 5.17 (Historically indexed inverse problem)**.** A *historically indexed inverse problem* reconstructs a relational configuration or trajectory from manifestations whose production, preservation, interpretation, and evidential significance are themselves functions of historical conditions that may change across the period under study.

Definition 5.17 prevents current interpretive categories from being projected backward without qualification. A record must be understood partly through the manifestation and representational relations under which it was produced. A category

recorded identically at two dates can refer to different institutional realities. A silence in an archive can mean absence, non-recording, suppression, destruction, or lack of institutional recognition. Historical evidence therefore requires reconstruction of the conditions under which traces became possible.

Historical dependence also makes revision an ordinary feature of knowledge. New archives can become available, new techniques can make previously inaccessible traces legible, later events can reveal relations whose earlier significance was unclear, and new concepts can permit distinctions that prior inquiry did not formulate. Such revision does not imply that historical claims are arbitrary. It means that the admissible compatibility set and the criteria for comparing reconstructions can change as evidence and epistemic resources change.

The inverse problem of manifestation consequently provides a bridge between the ontology of Chapter 4 and the more detailed epistemology developed in the remainder of Chapter 5. Relational knowledge begins from manifestations that constrain without necessarily determining their antecedent configurations. Non-invertibility produces underdetermination but still permits strong claims about identifiable properties and shared relational structure. Manifestational equivalence is local to an epistemic regime rather than proof of relational identity. Multiple explanations can be compared through preserved structure, independent evidence, explicit assumptions, and discriminating consequences. Context governs the portability of inverse inference, while history governs both the production of manifestations and the survival of traces. The next section turns from the inverse problem itself to knowledge of the manifestation relations on which such reconstruction depends.

5.3 Knowledge of Manifestation Relations

Sections 5.1–5.2 established that manifestation can provide evidential access to relational reality while leaving the inverse reconstruction problem underdetermined. The present section develops a further requirement that follows from this position: inquiry must seek knowledge not only of manifestations and relational targets, but also of the *relations through which those manifestations are generated*. The role of this section is to make manifestation relations themselves objects of epistemic inquiry. Its objectives are to distinguish knowledge of manifest content from knowledge of the manifestation relation, identify evidence that can support claims about such relations, specify when manifestation rules may be treated as sufficiently stable for inference, analyze changes in those rules, reconstruct them historically, and represent uncertainty about the mapping between relational and manifestational reality. The discussion proceeds methodologically from object specification to evidence, stability, change, history, and uncertainty. Throughout, manifestation relations are treated as historically situated and potentially causally operative components of generative-relational systems rather than as transparent channels standing outside the realities they mediate.

The need for this distinction can be seen whenever the same observed quantity, category, behavior, or representation changes its epistemic meaning because the process that produces it has changed. A stable unemployment rate can arise under al-

tered definitions of labor-force participation. A legal classification can retain the same label while the procedures through which it is assigned change. A platform metric can preserve its numerical form after an algorithmic ranking system has been revised. A recurring expression of trust can be generated by voluntary confidence in one setting and strategic conformity in another. In each case, accurate knowledge of the manifestation does not by itself establish knowledge of the manifestation relation. The epistemic relation between a manifestation and its target therefore depends partly on whether the inquiry understands how, under what conditions, and with what transformations the manifestation is produced.

Definition 5.18 (Manifestation relation as an epistemic target)**.** A *manifestation relation as an epistemic target* is the delimited set of conditions, mechanisms, transformations, selections, mediations, and response regularities through which a specified relational configuration contributes to a specified manifestation within a stated spatial, temporal, scalar, and institutional domain.

Definition 5.18 avoids treating the manifestation relation as a universal function whose form is known in advance. In some domains the relation may be well approximated by a measurement model, response function, or probabilistic mapping. In others it may involve legal procedures, classificatory conventions, organizational routines, interpretive practices, material affordances, or historically accumulated symbolic forms. The epistemic task is to identify the relevant mediations at the level needed by the inquiry. A manifestation relation can therefore be known partially and locally without being reduced to a single formal expression.

This formulation also preserves the graph architecture established in Chapter 4. A manifestation relation is not merely a one-way conduit from relational reality to appearance. The institutions, instruments, categories, and practices through which manifestation occurs can themselves be relationally real and causally consequential. Quantification, standardization, and classification are especially clear cases: the procedures that make social or economic realities legible can organize later conduct, stabilize categories, and alter the very relations subsequently observed. Historical studies of quantification and statistical classification show that apparently neutral representational infrastructures can be institutionally produced and historically variable (Porter 1995; Desrosières 1998). Knowledge of manifestation relations must therefore include, where relevant, knowledge of their participation in subsequent generation.

5.3.1 Manifestation Relations as Objects of Knowledge

Treating manifestation relations as objects of knowledge changes the structure of epistemic inquiry. A researcher ordinarily asks what a manifestation indicates about a target. GRE adds a prior and recurrent question: what warrants the assumption that this manifestation is related to that target in the way the inference requires? The question is not answered merely by naming an indicator, instrument, category, or observation protocol. It requires an account of the relation that makes the manifestation evidentially relevant.

At least four components should be distinguished. The first is the *source domain*: the relational configurations or properties capable of contributing to the manifestation. The second is the *mediating domain*: the material, institutional, perceptual,

computational, symbolic, or procedural conditions that transform or select aspects of the source. The third is the *manifest domain*: the traces, measurements, classifications, behaviors, records, or appearances accessible to inquiry. The fourth is the *scope condition*: the domain within which the inferred relation is expected to hold. These components need not be independent. A legal procedure can belong to the mediating domain while also changing the source relations it classifies; an observer can generate a record while participating in the relation being observed; a statistical standard can produce comparability and thereby alter institutional decisions.

Knowledge of a manifestation relation is therefore not equivalent to possession of a fixed codebook. A codebook can state how categories are currently assigned while leaving the historical emergence, practical implementation, discretionary variation, and feedback effects of classification unspecified. Likewise, an algorithmic documentation page can state an output rule while omitting data-generation processes, upstream filtering, model updates, organizational overrides, and strategic responses by users. The epistemic object is the operative relation in context, not only its official representation.

Claim 5.19 (Manifestation-relation dependence of evidential inference)**.** *The warrant of an inference from a manifestation to a relational target depends partly on the warrant for the manifestation relation presupposed by that inference. Strong confidence in the manifest content cannot by itself compensate for weak knowledge of how that content is generated, selected, transformed, or recorded.*

Claim 5.19 does not require complete knowledge of the manifestation relation before any inference is possible. Many successful inquiries proceed with partial knowledge of measurement mechanisms, institutional processes, or behavioral responses. The claim instead makes the missing knowledge explicit. Where the inference is insensitive to plausible variation in the manifestation relation, partial knowledge may be sufficient. Where small changes in the relation would reverse the conclusion, the relation becomes an especially important epistemic target.

This dependence can itself be scale-relative. At one scale, a standardized price index may function as a sufficiently stable manifestation relation between sampled prices and an aggregate inflation measure. At another, the inquiry may concern how substitution rules, quality adjustments, sampling frames, or consumption heterogeneity shape the index. The first inquiry may legitimately treat the mapping as provisionally fixed; the second makes its internal construction the object of analysis. Epistemic adequacy therefore depends on whether the manifestation relation is specified at the scale at which it materially affects the claim.

5.3.2 Evidence for Manifestation Relations

Evidence for a manifestation relation differs from evidence carried through that relation. Observing that a metric changes is evidence about the metric's value. Establishing that the metric reliably tracks a relational property requires additional evidence about the production of the metric and its connection to the target. This distinction is familiar in scientific modeling and measurement, where representational adequacy depends on purposive relations between models, targets, and selected respects of similarity rather than identity between representation and world (Giere 2004). GRE

generalizes the distinction to institutional, historical, symbolic, and social manifestations.

Several evidential routes can support a manifestation relation. *Repeated covariation* can show that changes in a target-relevant configuration are regularly accompanied by changes in the manifestation. *Intervention evidence* can test whether changing a source condition alters the manifestation in the expected direction. *Mechanism evidence* can identify the mediating process through which the source contributes to the manifest outcome. *Cross-context comparison* can reveal which components of the relation remain stable when surrounding conditions vary. *Calibration* can compare the manifestation against an independently accessible reference. *Process and documentary evidence* can reconstruct institutional procedures, classificatory decisions, instrument design, and implementation. *Negative and discrepant cases* can identify circumstances in which the presumed relation fails. No single route has universal priority; their relevance depends on the epistemic target and the type of manifestation relation involved.

The evidential problem becomes particularly important when the manifestation relation is partly strategic. Survey respondents can adapt answers to perceived expectations. Firms can change reported categories after regulatory thresholds are announced. Platform participants can optimize behavior to ranking metrics. States and organizations can reorganize records in response to performance indicators. In such settings, the manifestation relation contains endogenous responses to observation or evaluation. What appears to be a measurement of an antecedent relation can become part of a feedback process that changes the target itself.

Evidence for manifestation relations should therefore be triangulated where possible. A behavioral trace, an institutional record, a participant account, and an intervention response may each be incomplete, yet their conjunction can constrain the plausible mapping more strongly than repeated observation of one manifestation alone. Longino's emphasis on the role of background assumptions in evidential reasoning is relevant here: evidence becomes more reliable when the assumptions linking observation and conclusion are exposed to criticism from alternative perspectives and bodies of knowledge (Longino 1990). For GRE, manifestation relations are among the central background structures that should be made contestable.

Definition 5.20 (Manifestation-relation warrant)**.** *Manifestation-relation warrant* is the degree to which available evidence supports a specified account of how a relational configuration contributes to a manifestation under stated conditions, including the relevant mediations, scope conditions, and known failure modes.

The definition deliberately avoids reducing warrant to a single numerical confidence score. Some manifestation relations can be estimated probabilistically; others may be supported by process evidence, institutional documentation, historical comparison, or qualitative reconstruction. What matters is that the basis of the warrant is inspectable. A claim about a stable manifestation relation should state what kind of evidence supports stability, what contexts have been examined, and which plausible changes could undermine the inference.

5.3.3 Stability of Manifestation Rules

Inference commonly relies on some degree of stability in manifestation rules. A rule is stable when sufficiently similar relational configurations under sufficiently similar conditions continue to generate manifestations in a way that preserves the distinctions relevant to the epistemic target. Stability does not require exact invariance. Measurement error, contextual modulation, observer variation, and stochastic response may coexist with a mapping that remains stable enough for a particular inference.

The epistemic importance of stability is straightforward. If the relation between target and manifestation changes unpredictably while the inquiry assumes it is fixed, temporal comparison can become misleading. Apparent change in the target can be generated by a changed manifestation rule; apparent continuity can be produced by compensating changes in the source and the mapping. Conversely, a stable manifestation relation can support stronger comparison across observations even when the target itself is dynamic.

Stability should be specified with respect to what is preserved. A classification rule may preserve category membership while changing the threshold by which membership is assigned. A statistical series may preserve its name while changing data sources. A linguistic expression may remain lexically stable while its institutional meaning changes. A market price may remain continuously observable while the microstructure generating it changes. Epistemic claims should therefore avoid treating nominal continuity as evidence of mapping stability.

Definition 5.21 (Epistemic stability of a manifestation rule)**.** A manifestation rule is *epistemically stable* for a specified inquiry when variation in the rule across the relevant domain remains sufficiently bounded that the target-relevant distinctions carried by the manifestation are preserved to the degree required by the claim.

Definition 5.21 makes stability claim-relative. The same mapping can be stable for one inquiry and unstable for another. A survey item may be adequate for tracking broad directional change while too unstable for fine cross-cultural comparison. An administrative category may support short-run monitoring while failing across a major legal reform. A model may preserve local ranking while failing to preserve cardinal magnitude. The relevant standard is whether the manifestation relation preserves the information required by the epistemic target.

Repeated successful use can increase confidence in stability, but historical repetition alone is insufficient. A rule can appear stable because the range of conditions encountered so far has been narrow. Stability claims therefore gain strength when they survive meaningful variation in context, scale, population, institutional setting, or intervention. This is one reason comparative and historical analysis matter even for apparently technical measurement systems.

5.3.4 Change in Manifestation Rules

Manifestation rules can change because instruments change, institutions revise procedures, categories acquire new meanings, observers alter practices, populations adapt strategically, or the underlying relational system reorganizes the mediations

through which it becomes manifest. Such change is epistemically consequential because a discontinuity in the mapping can be mistaken for a discontinuity in the target, while transformation in the target can be hidden by a compensating change in the mapping.

Several forms of change should be separated. *Parametric change* alters the strength or threshold of a familiar relation while leaving its broad structure recognizable. *Procedural change* alters the steps through which the manifestation is produced. *categorical change* alters the distinctions encoded by the manifestation. *infrastructural change* alters the technical or institutional system that makes the manifestation possible. *reflexive change* occurs when actors adapt to the manifestation regime itself, thereby changing the relation between underlying activity and observed trace. These changes need not occur independently.

Historical accounts of scientific and administrative categories provide useful precedents for taking such transformations seriously. Kuhn's account of historically organized scientific practice and Hacking's work on historical ontology both emphasize, in different ways, that concepts, objects of inquiry, and styles of reasoning can change with the practices through which they are constituted and investigated (Kuhn 1962; Hacking 2002). Statistical and administrative histories similarly show that classification and quantification regimes can change the terms through which populations and activities become comparable (Desrosières 1998; Porter 1995). GRE treats these observations as reasons to make the history of manifestation rules part of epistemic analysis rather than as grounds for generalized relativism.

Claim 5.22 (Manifestation-rule change and apparent target change)**.** *Observed change in a manifestation can reflect change in the relational target, change in the manifestation relation, or interaction between both. Epistemic attribution of change therefore requires evidence capable of distinguishing these possibilities to the degree relevant to the inquiry.*

The claim has direct consequences for time-series reasoning. Longitudinal comparability requires more than repeated use of the same label or numerical format. The inquiry should identify whether definitions, sampling frames, measurement technologies, legal procedures, data-generating practices, or strategic responses have changed. Where they have, continuity may need to be reconstructed rather than assumed. In some cases no defensible adjustment can restore comparability, and the epistemically appropriate result is a documented discontinuity.

Rule change can also be a substantive object of GRE. A new manifestation regime may redistribute visibility, recognition, and institutional consequences. When a platform introduces a new reputation score, when a state changes a legal classification, or when an organization adopts a new performance metric, the alteration can change who becomes visible, which relations count, and which actions become consequential. The epistemic history of the mapping therefore intersects with the generative history of the system.

5.3.5 Historical Reconstruction of Manifestation

Historical reconstruction becomes necessary when present manifestations are interpreted through relations that have changed over time. The task is not merely to re-

cover earlier observations. It is to reconstruct, as far as evidence permits, the conditions under which those observations were generated and the distinctions that they could legitimately support at the time. A historical series assembled from surviving records may contain values whose apparent uniformity conceals changes in classification, collection, administrative purpose, or institutional coverage.

Historical reconstruction should therefore treat manifestation relations as trajectories. An archive records not only events but the effects of selection, preservation, categorization, institutional purpose, and survival. A legal register reflects the rules under which statuses were recorded. A price series depends on which exchanges became observable and comparable. A corpus of published research reflects publication practices, disciplinary categories, and technical capacities. Present access to these traces is further mediated by later preservation, digitization, indexing, and interpretation. The epistemic object is thus a historically layered relation between past relational configurations, past manifestation practices, surviving traces, and present reconstruction.

This layered view prevents two opposite errors. The first is *presentist projection*: assuming that a present category had the same meaning, boundary, or measurement relation in the past. The second is *historical skepticism*: concluding that because manifestation relations changed, disciplined comparison is impossible. Reconstruction can often identify periods of relative stability, explicit breaks, overlapping regimes, conversion rules, and residual uncertainty. The goal is to preserve warranted comparability where possible and preserve documented non-comparability where it is not.

Definition 5.23 (Historical reconstruction of a manifestation relation)**.** The *historical reconstruction of a manifestation relation* is the evidence-guided recovery of the conditions, rules, mediations, scope, and transformations through which a past relational configuration became manifest and through which its traces became available to present inquiry.

The definition includes the history of preservation because surviving evidence is itself selective. An event may have generated many manifestations, only some of which were recorded; only some records may have survived; and only some surviving records may be accessible or legible under present categories. Knowledge of the historical manifestation relation therefore includes knowledge of loss, silence, and differential preservation where those factors materially affect inference.

This is also where historical reconstruction connects to later questions of epistemic justice. Some manifestation systems systematically privilege actors with greater institutional visibility, literacy, administrative recognition, or control over record-making. The resulting archive can reproduce those asymmetries. Section 115 will distinguish relation, trace, and evidence more finely; the present point is that the evidential status of a historical trace depends partly on knowledge of the manifestation and preservation relations through which it exists.

5.3.6 Uncertainty about Manifestation Mapping

Manifestation relations are often only partly known. Uncertainty can concern which source relations matter, which mediators intervene, whether the rule is stable, how

actors respond to observation, whether different contexts share the same mapping, or how the mapping changed historically. This uncertainty should be represented explicitly because it propagates into the inverse reconstruction problem developed in Section 5.2.

At least three forms of uncertainty are useful to distinguish. *Structural uncertainty* concerns the form of the manifestation relation: which mediators and transformations belong in the account. *parametric uncertainty* concerns the magnitude, threshold, probability, or sensitivity of a relation whose broad form is accepted. *historical uncertainty* concerns when and how the relation changed, including uncertainty generated by incomplete documentation. A fourth form, *scope uncertainty*, concerns the domain across which a relation can be transported without substantial alteration.

These uncertainties can combine. A researcher may know that an administrative indicator is generated from a defined set of records while remaining uncertain about discretionary implementation across offices. A model may be well calibrated in one period while facing scope uncertainty after institutional reform. Historical sources may document a category change without revealing how quickly practice changed on the ground. GRE should therefore avoid representing mapping uncertainty as a single generic error term when the structure of the uncertainty matters to interpretation.

Claim 5.24 (Propagation of manifestation-mapping uncertainty)**.** *Uncertainty about a manifestation relation propagates into claims inferred through that relation. The propagated uncertainty need not invalidate the claim, but the claim's strength should reflect the range of target-relevant conclusions compatible with serious alternatives concerning the mapping.*

Claim 5.24 creates a direct connection between Sections 5.2 and 5.3. The compatibility set in the inverse problem should expand when several plausible manifestation relations remain open and contract when evidence rules them out. A reconstruction that appears unique under one fixed mapping may become non-unique once mapping uncertainty is admitted. Conversely, some target properties may remain invariant across plausible mappings and can therefore retain strong warrant despite uncertainty about the complete relation.

Epistemic progress can accordingly take several forms. Inquiry can improve knowledge of the target while holding the mapping provisionally fixed; improve knowledge of the mapping while leaving the target uncertain; identify properties robust across several plausible mappings; or discover that an earlier inference depended on a manifestation relation that no longer holds. Such revision is not an embarrassment to relational epistemology. It is one of its expected modes of development.

Knowledge of manifestation relations thus occupies a central position between ontology and empirical method. The three-register architecture makes manifestation possible without reducing reality to what appears; the inverse problem shows why manifestations do not uniquely reconstruct their sources; and the present section shows that the mapping connecting source and manifestation is itself historically situated, evidentially investigable, and uncertain. The next section turns from knowledge of the mapping to the traces through which relations become evidentially accessible. That transition shifts the emphasis from the rules of manifestation to the heteroge-

neous traces that those rules produce, preserve, obscure, or fail to generate.

5.4 Relation, Trace, and Evidence

The preceding sections established that GRE often encounters relational reality indirectly: manifestations are generated through historically variable manifestation relations, and reconstruction from manifestation toward relational structure is generally non-invertible. The present section introduces the evidential vocabulary required to proceed under those conditions. Its role is to distinguish the relation under inquiry from the traces through which that relation becomes accessible and from the evidential status later assigned to those traces. The section develops eight connected distinctions: relation and evidence of relation, direct and indirect traces, observable and inferred relations, latent and hidden relations, and the difference between absence of evidence and evidence of absence. The method is deliberately relational. A trace is treated neither as a transparent fragment of reality nor as an arbitrary sign; its evidential force depends on the generative relation through which it arose, the conditions under which it was preserved or observed, and the inferential target for which it is being used.

This distinction matters because the same material or symbolic object can occupy different epistemic roles. A contract, message log, transfer record, testimony, administrative category, network edge, or repeated behavioral pattern may be produced by a relation, record a relation, mediate a relation, or become part of the relation's later reproduction. Its existence alone therefore does not determine what it evidences. The evidential question concerns how that object was generated, what relation it bears to the target, what alternative relations could have generated a similar trace, and which relevant traces could have failed to appear or survive. Work on scientific objectivity, statistics, historical classification, and contextual empiricism likewise shows that evidence acquires significance through conventions of production, background assumptions, and institutionalized practices of comparison rather than through mere presence alone (Porter 1995; Desrosières 1998; Hacking 2002; Longino 1990).

Definition 5.25 (Trace)**.** A *trace* is a material, behavioral, institutional, symbolic, statistical, computational, testimonial, or other manifestational remainder whose existence or form was generated, conditioned, or made more probable by a relation, process, event, or configuration relevant to an epistemic target.

Definition 5.25 intentionally keeps the category broad. A trace can be intentionally produced, as in a signed agreement or recorded payment, or unintentionally left, as in a pattern of repeated co-presence, a change in resource flows, a sequence of revisions, or a residue in a technical system. It can be contemporaneous with the relation or generated later by consequences of that relation. It can also be partial: a trace may preserve one dimension of a relation while omitting the dimensions most important to another inquiry.

Definition 5.26 (Evidence)**.** *Evidence* is a trace, manifestation, observation, record, testimony, measurement, comparison, or intervention result that is assigned an inferential role with respect to a specified epistemic target under an articulated account of relevance, reliability, and alternative explanation.

The distinction between Definitions 5.25 and 5.26 is foundational for this chapter. A trace can exist without yet functioning as evidence. It becomes evidence only relative to a claim and an inferential practice. Conversely, evidence need not consist of a single preserved object. A pattern across several weak traces can support a relational claim even when none is individually decisive. Evidence is therefore not a substance attached permanently to an item; it is a role that an item or pattern can occupy within an inquiry.

5.4.1 Relation and Evidence of Relation

A relation and evidence of that relation belong to different analytical categories. The relation is part of the target reality under inquiry; the evidence is part of the epistemic access through which a claim about that reality is evaluated. Confusing the two can produce both false confidence and false skepticism. A recorded edge in a database can be mistaken for the social relation itself, while a relation lacking a convenient record can be treated as if it did not exist. GRE therefore preserves a strict distinction between relational existence and evidential manifestation.

The distinction remains necessary even when the relation is highly formalized. A legal record may be constitutive of a legal relation under a given institutional order, yet the record and the relation are still analytically distinguishable. The record may establish status within one domain while failing to capture informal dependence, effective control, lived meaning, or later transformation. Likewise, an account balance can participate in constituting a monetary relation while still remaining only one manifestational component of a wider system of claims, expectations, institutional enforcement, and access. Constitutive traces are therefore possible, but constitution does not eliminate the need to specify which dimension of the relation the trace supports.

Claim 5.27 (Relational–evidential distinction)**.** *Evidence that a relation exists, persists, or changes should be distinguished from the relation itself and from representations that merely encode or summarize it. The stronger the inferential step from trace to relational claim, the more explicit the inquiry should be about the manifestation relation, plausible alternatives, and the dimensions of the target that remain unobserved.*

Claim 5.27 gives GRE a way to handle heterogeneous records without collapsing them into a single evidential hierarchy. A transcript may provide strong evidence for an utterance, weaker evidence for the speaker's durable intention, and still weaker evidence for the long-term structure of a relation. A transfer record may strongly support that a transaction occurred, while providing only partial evidence about coercion, trust, dependence, or the distribution of alternatives surrounding that transaction. The same trace can therefore carry different evidential weight for different targets.

This target-relativity should not be confused with arbitrary interpretation. The relevant relation between trace and target can itself be investigated. Evidence becomes stronger when the trace-generation process is well understood, competing explanations are constrained, observations are independently corroborated, and the inference remains stable under reasonable alternative codings or models. Evidence becomes weaker when the trace can be generated by many materially different con-

figurations, when preservation is selective, or when the observation system systematically excludes parts of the relation under study.

The relation–evidence distinction also matters for historical inquiry. Present researchers often encounter past relations only through surviving traces. Survival adds an additional manifestation relation: what was produced, what was recorded, what was preserved, what was destroyed, what became legible, and what later institutions chose to index or digitize. Historical evidence therefore bears the history of both the target relation and the evidential infrastructure through which present access becomes possible.

5.4.2 Direct Traces

A direct trace is relatively proximal to the relation or event targeted by the inquiry. Proximity can be temporal, procedural, institutional, material, or causal. Examples include a contemporaneous transaction record for a transfer, an authenticated message for a communication event, a legal filing for a formally registered status, a sensor record for a physical interaction, or an observed sequence of actions within a specified setting. The term *direct* is therefore relational and scoped. It does not mean unmediated access to reality.

Definition 5.28 (Direct trace)**.** A *direct trace* is a trace generated through a relatively short and specified manifestational path from the target relation or relational event to the evidential object, such that the principal transformations between target and trace are sufficiently known for the inquiry's purpose.

The definition makes directness a property of the evidential path rather than of a privileged class of objects. A signed contract may be direct evidence that specified parties entered a recorded agreement under a particular legal procedure. The same contract is not direct evidence that the parties experienced equal bargaining power. An interaction log may be direct evidence that two accounts exchanged messages while remaining weak evidence about friendship, authority, dependence, or trust. Directness therefore does not automatically confer broad scope.

Direct traces can be especially useful for establishing occurrence, timing, sequence, and formally recorded participation. They are less automatically informative about unrecorded motivations, counterfactual options, tacit norms, or distributed conditions. GRE should therefore resist a documentary bias in which formally captured relations appear more real simply because their traces are easier to stabilize and inspect. Institutional systems often produce abundant direct traces for what they are designed to recognize and sparse traces for relations outside their categories. The history of statistical and administrative classification illustrates how standardized records can increase comparability while simultaneously organizing what becomes visible (Porter 1995; Desrosières 1998).

Direct traces can also be strategically generated. A declaration, report, score, or official record may be created precisely because actors anticipate later evaluation. The trace then remains direct with respect to the recorded act while its evidential relation to broader conduct requires additional scrutiny. A compliance certificate can directly establish that a certificate was issued; its value as evidence of substantive compliance depends on the inspection regime, incentives, and possibility of strategic

adaptation. Directness thus reduces some inferential distance without eliminating the need for a manifestation-relation analysis.

5.4.3 Indirect Traces

Many economically significant relations leave no single proximal record. Their existence is reconstructed from downstream effects, repeated patterns, correlated changes, institutional responses, or combinations of traces produced through several mediating steps. Such traces are indirect relative to the target relation. Indirectness does not make them inferior by definition. In some inquiries, a distributed pattern across multiple indirect traces can provide stronger evidence than a formally direct record that captures only one declared aspect of the relation.

Definition 5.29 (Indirect trace)**.** An *indirect trace* is a trace connected to an epistemic target through one or more intervening relations, transformations, consequences, or preservation processes whose contribution must be reconstructed for the trace to support the target claim.

Examples include changes in prices used to infer supply constraints, migration patterns used to investigate changing opportunity structures, repeated exclusion outcomes used to investigate an institutional barrier, or downstream changes in behavior used to investigate a trust relation. In each case, the trace may be compatible with several candidate explanations. The epistemic burden therefore shifts toward discriminating among plausible generative paths.

Indirect traces are particularly important for relations that are distributed, tacit, stigmatized, historically remote, or institutionally unrecorded. A relation of dependence may be inferred from repeated asymmetries of exit, access, and response even when no actor explicitly records the relation as dependence. A field-like constraint may be reconstructed from patterned local outcomes that cannot be attributed to a single dyadic command. A historical relation may become visible only through later consequences because contemporaneous record-making omitted the affected actors. These cases show why GRE cannot limit evidence to explicit self-description or formal documentation.

At the same time, indirect traces invite over-attribution when analysts move too quickly from pattern to relation. Several relational structures can generate similar downstream manifestations, as Section 5.2 established. The disciplined response is triangulation across traces generated through partially independent pathways. Documentary evidence, behavior, testimony, longitudinal change, institutional records, and intervention results can constrain one another when their errors and selection processes are not identical. Contextual empiricism is relevant here because what counts as evidentially probative depends partly on background assumptions that themselves require critical examination (Longino 1990).

Remark 5.30 (Combination of weak traces)*.* Several individually weak traces can jointly support a stronger relational claim when their dependence structure is understood and when the traces constrain overlapping alternatives through sufficiently different manifestation pathways. Simple numerical accumulation of mutually dependent traces does not provide the same warrant.

Remark 5.30 prevents a common mistake in large evidential systems. Thousands of records generated from the same classification rule may contain less independent information than a small set of traces produced through distinct mechanisms. Evidential quantity and evidential diversity are therefore analytically different.

5.4.4 Observable Relations

Some relations can be observed in a relatively direct operational sense. A transfer can be witnessed, a conversation can be heard, an exchange can be recorded, a contractual status can be queried, or a physical connection can be inspected. GRE nevertheless treats observability as relation-specific and regime-specific rather than as a universal boundary between known and unknown objects. Observation itself occurs through a manifestational configuration involving an observer, instrument, category, temporal window, and criterion of recognition.

Definition 5.31 (Operationally observable relation)**.** A relation is *operationally observable* for an inquiry when the relation or a constitutive relational event becomes available within the inquiry's observation regime with sufficiently specified criteria of recognition and sufficiently limited inferential distance for the target claim.

This definition allows an exchange event to be observable while the durable economic relation within which it occurs remains partly inferred. Observing repeated transfers does not by itself settle whether the relation is reciprocal, exploitative, charitable, coerced, strategic, or embedded in a longer obligation. Similarly, observing two persons collaborate can establish interaction while leaving the distribution of authority, dependence, recognition, and future obligation underdetermined.

Operational observability can also be created institutionally. Administrative systems render some relations queryable by assigning identifiers, categories, and records. Network platforms can make interaction histories inspectable. Sensors and digital infrastructures can transform previously ephemeral events into persistent traces. Such changes expand evidential access while also altering the relation between observation and conduct. Once actors know that a relation is observed, the observation regime can become part of the relational system. The epistemology of performative observation will therefore require later attention in Sections 116–118.

A further distinction is useful between observing a relational event and observing a relationally real object. A single communication event can be observed, while a stable trust relation requires evidence of persistence, organization, and causal efficacy across a relevant interval. The GR criterion for relational reality therefore places a higher evidential burden on durable relational claims than on the occurrence of isolated relational events.

5.4.5 Inferred Relations

Most relations studied by GRE are at least partly inferred. Inference becomes necessary whenever the target exceeds any single observation: persistent authority, institutional dependence, social trust, exclusion, access asymmetry, generative capacity, field position, and many forms of economic power are reconstructed from multiple manifestations and traces. The inferred character of these relations does not

weaken them ontologically. It describes the epistemic route through which they become known.

Definition 5.32 (Inferred relation)**.** An *inferred relation* is a relational target whose existence, organization, persistence, or causal role is supported through an explicit inferential synthesis of traces, manifestations, observations, models, or interventions rather than through a single sufficiently proximal observation.

Inference can take qualitative, historical, statistical, computational, formal, or mixed forms. A historian may reconstruct an institutional dependence from correspondence, legal records, and resource flows. An ethnographer may infer a tacit hierarchy from repeated interactional patterns and participants' accounts. A network model may infer ties from event data. A causal analysis may infer a relational effect from variation under a specified design. GRE does not assign automatic priority to one form. The relevant standard is whether the inferential method is appropriate to the target and whether its assumptions and residual alternatives are made visible.

Inferred relations should therefore carry an account of identification. An inquiry should state which traces would be expected under the proposed relation, which serious alternatives remain compatible with the evidence, and which additional observations could discriminate among them. This requirement follows directly from the inverse problem. The relation becomes better identified when competing configurations are progressively constrained, even if unique reconstruction remains unavailable.

The distinction between inferred relation and speculative relation is consequently evidential rather than rhetorical. An inferred relation has articulated support and known inferential conditions. A speculative relation may be worth considering as a hypothesis but lacks comparable constraint. GRE benefits from preserving both categories because early-stage inquiry often needs hypotheses that can guide trace collection without treating those hypotheses as established relational reality.

5.4.6 Latent Relations

Some relations are causally operative without being manifest in the observation channel currently used by an inquiry. GRE describes such relations as latent relative to that epistemic arrangement. Latency is therefore an epistemic condition of access, not a statement that the relation lacks relational reality. A relation can persist, constrain action, and shape subsequent generation while remaining unavailable to a particular observer, instrument, category, or temporal window.

Definition 5.33 (Latent relation)**.** A *latent relation* is a relation that may satisfy the relevant conditions of relational reality while remaining unmanifest or insufficiently discriminated within a specified observation regime, even though indirect traces or later manifestations may permit its reconstruction.

The qualification "within a specified observation regime" is essential. A relation latent to one observer can be manifest to another. Informal care relations may be absent from market statistics while plainly visible in household practice. A dependency may be invisible in an organizational chart while apparent in patterns of consultation and approval. A computational relation may be inaccessible in a user interface while

recorded in backend logs. Latency therefore often reflects the partiality of epistemic access rather than the intrinsic invisibility of the relation.

Latent relations are especially important when manifestational systems privilege what is readily quantified. Standardized categories can improve coordination and comparison while leaving relations outside those categories weakly represented (Porter 1995; Desrosières 1998). GRE should therefore treat the absence of a variable, category, or explicit edge from a dataset as a property of the representational system until additional evidence supports a stronger conclusion about the underlying relation.

The notion also helps distinguish pre-manifestational relational reality from mere analyst invention. A relation can be latent before it is consciously recognized if it already persists and exerts causal efficacy within the system. Its later discovery changes epistemic access, and perhaps subsequent relations once the discovery becomes operative, without implying that the relation began to exist only when it was named.

5.4.7 Hidden Relations

Hidden relations form a narrower epistemic problem. A relation is hidden when the observation regime fails to reveal it because relevant traces are inaccessible, suppressed, displaced, masked, or systematically routed outside the observer's evidential field. Strategic concealment is one important mechanism, but hiddenness can also arise from institutional segmentation, technical opacity, confidentiality, unequal access, or the topology of a distributed system. Section 118 will examine observer position and strategic concealment in greater detail; the present section defines the evidential distinction.

Definition 5.34 (Hidden relation)**.** A *hidden relation* is a relation for which evidential access is materially obstructed within a specified inquiry because relevant traces are unavailable, obscured, selectively preserved, strategically concealed, or generated outside the observer's accessible manifestational domain.

Hiddenness differs from latency primarily in the structure of access. Latency emphasizes insufficient manifestation within an observation regime; hiddenness emphasizes obstruction or exclusion from the evidential field. The categories can overlap. A relation may be latent because its effects are subtle and hidden because actors also conceal the traces most likely to reveal it. GRE should therefore use the distinction analytically rather than treat it as a rigid ontology of relations.

Hidden relations create asymmetric epistemic burdens. Actors inside a relation may possess knowledge unavailable to external investigators; institutions may control records required for verification; affected subjects may experience consequences without access to the infrastructures that produce them; and observers with technical privileges may see relational structures that ordinary participants cannot inspect. These asymmetries later become questions of epistemic justice and machine-mediated knowledge, but they begin here as properties of evidential access.

A hidden relation should not be inferred solely from the fact that evidence is missing. The hypothesis of concealment itself requires traces: discontinuities, inconsisten-

cies, restricted access, unexplained selection, testimony, leaked records, differential visibility, or other observations that make obstruction more plausible than simple nonexistence or measurement failure. This requirement guards against converting every unexplained absence into evidence of an invisible structure.

5.4.8 Absence of Evidence and Evidence of Absence

Negative evidence requires a particularly explicit manifestation model. The nonappearance of a trace can support a claim that a relation is absent only when the inquiry has reason to expect that the relation, if present, would probably have generated an observable and preserved trace within the relevant observation regime. Without that expectation, missing evidence remains weakly informative.

Definition 5.35 (Negative evidential warrant)**.** *Negative evidential warrant* is the support that nonappearance of an expected trace provides for the absence, weakness, interruption, or transformation of a target relation when the trace-generation, detection, coverage, and preservation conditions are sufficiently specified.

The definition makes four conditions especially important. First, *trace generation*: would the target relation normally produce the relevant manifestation? Second, *detection*: would the observation system register it if produced? Third, *coverage*: was the relevant temporal, spatial, institutional, or population domain actually observed? Fourth, *preservation*: could the trace have been lost, deleted, censored, or transformed before inspection? Evidence of absence becomes stronger as these conditions become better understood and as the expected trace becomes more reliable under the hypothesized relation.

This distinction is crucial in economic and institutional research. The absence of a complaint is weak evidence that no harm occurred when complaint mechanisms are inaccessible or risky. The absence of a transaction record is weak evidence that no transfer occurred when informal exchange is common. The absence of a network edge is weak evidence of no relation when the network is reconstructed from a partial communication channel. By contrast, the persistent absence of an expected entry in a highly complete registry under a stable mandatory reporting regime can provide stronger negative evidence for a formally registered relation.

Claim 5.36 (Condition for evidential absence)**.** *Absence of evidence becomes evidence of absence to the extent that the inquiry can justify a sufficiently reliable expectation that the target relation, if present at the relevant strength and scope, would have generated a detectable and preserved trace within the observation regime.*

Claim 5.36 also clarifies why evidential silence can be historically and politically structured. Classification systems, archives, administrative routines, and research infrastructures determine which relations reliably produce traces. Hacking's account of historical ontology and the histories of statistical classification examined by Desrosières provide examples of how categories and recording practices can change the objects that become visible to inquiry (Hacking 2002; Desrosières 1998). Silence in an archive or dataset therefore requires knowledge of the record-making relation before it can support a substantive inference.

The same principle applies to repeated nonobservation. More observations in-

crease evidential strength only when they meaningfully increase the probability of detection under the target hypothesis. Repeatedly inspecting the same narrow channel does little to rule out a relation expressed elsewhere. Expanding observer positions, temporal coverage, trace types, and independent manifestation pathways can be more informative than multiplying observations within a single constrained regime.

The relation–trace–evidence distinction therefore supplies a basic grammar for the remainder of Chapter 5. Relations belong to the reality under inquiry; traces are heterogeneous manifestations or remainders generated through relational and historical processes; evidence arises when traces are connected to specified claims through warranted inferential relations. Direct and indirect traces differ by the structure of their manifestational paths rather than by an absolute hierarchy of reliability. Observable, inferred, latent, and hidden relations describe different conditions of epistemic access rather than different degrees of ontological reality. Negative evidence becomes informative only when trace generation and observation are sufficiently understood. These distinctions prepare the next section's treatment of symbolization and representation, where traces are transformed into linguistic, legal, administrative, statistical, and computational forms that can both preserve and reorganize relational knowledge.

5.5 Symbolization and Representation

Section 5.4 distinguished relations from the traces through which they become epistemically accessible and from the evidential roles later assigned to those traces. The present section examines a further transformation: traces, observations, and relational configurations are frequently rendered into symbolic forms that can be stored, communicated, compared, aggregated, interpreted, and acted upon across settings. Its role is to clarify how symbolization and representation participate in relational knowledge without being treated as transparent duplication of the realities they concern. The section proceeds through eight components: manifestation and symbolization, linguistic representation, administrative representation, legal representation, statistical representation, computational representation, symbolized relations, and representation error. The method is comparative. Each representational form is analyzed in terms of what it selects, preserves, compresses, transforms, and makes newly available for inference.

Symbolization matters for GRE because relational inquiry rarely proceeds through unprocessed manifestations alone. A spoken description, a category in a registry, a legal status, a statistical indicator, a graph edge, a model parameter, or a machine-readable embedding can make a relation portable across time, space, institutions, and observers. Such portability expands epistemic reach. It also introduces additional conditions of interpretation. The same relational reality can be symbolized differently under different languages, administrative systems, legal regimes, statistical conventions, and computational architectures. Conversely, similar symbols can refer to relations that differ substantially in their histories, mechanisms, or causal organization. Symbolization therefore becomes part of the epistemic pathway through which relational reality is reconstructed.

Cassirer's philosophy of symbolic forms provides one important lineage for treating symbolic articulation as constitutive of intelligibility rather than as a secondary label placed upon already finished experience, while Bourdieu's analysis of language emphasizes that symbolic forms operate within social relations of authority and differential recognition (Cassirer 1955; Bourdieu 1991). GRE draws on these insights without committing itself to a comprehensive philosophy of symbolic form. The narrower claim developed here is methodological: symbolic systems organize access to relational reality by establishing distinctions, equivalences, references, and conventions through which manifestations become interpretable and transportable.

Definition 5.37 (Symbolization)**.** *Symbolization* is the relational process through which a manifestation, trace, object, relation, process, event, or distinction is rendered in a symbolic form that can be recognized, communicated, stored, compared, transformed, or used within an epistemic or institutional practice.

Definition 5.37 keeps symbolization broader than language. A symbol may be a word, category, code, legal designation, numerical variable, visual mark, network edge, database field, model state, or computational token. What unifies these cases is the establishment of a rule-governed relation through which some differences are preserved and others are suppressed, grouped, or transformed.

Definition 5.38 (Representation)**.** A *representation* is a symbolic, material, formal, linguistic, administrative, legal, statistical, computational, or other constructed configuration used to stand for, describe, model, encode, or make inferentially accessible selected aspects of an epistemic target.

Representation therefore has a target-relative structure. A representation can be highly adequate for one inferential purpose while remaining uninformative for another. Giere's account of scientific representation is useful here because it treats models as purposive representations of selected aspects of reality rather than as literal duplicates of their targets (Giere 2004). GRE generalizes this restraint beyond scientific models. Every representational practice selects a relation between a target, a representational form, and a purpose under which similarity, relevance, fidelity, or usefulness is judged.

5.5.1 Manifestation and Symbolization

Manifestation and symbolization occupy different stages and roles within epistemic access. A manifestation is the way in which some aspect of reality becomes available within a relational configuration of perception, instrumentation, practice, institution, or other mediation. Symbolization renders some aspect of that manifestation into a form that can circulate within a symbolic practice. The two can occur nearly simultaneously, especially in highly institutionalized settings, yet the distinction remains analytically useful.

A price appearing on a trading interface is already heavily symbolized at the point of manifestation. A person's bodily discomfort can become manifest before it is linguistically articulated. An institutional status can be symbolically recorded at the same moment that it becomes administratively manifest. These examples show that manifestation and symbolization can overlap while still answering different questions. Manifestation concerns availability; symbolization concerns the rule-governed

form through which what is available is rendered communicable, recordable, or manipulable.

The distinction also clarifies why pre-symbolic or weakly symbolized relational realities remain possible. A pattern of dependence, trust, vulnerability, attraction, exclusion, or coordinated expectation can become relationally real before participants possess a stable vocabulary for it. Later symbolization can increase epistemic accessibility by supplying names, categories, comparisons, and records. Symbolization can also reorganize the field of attention by making some relations easier to notice and others less legible.

Claim 5.39 (Symbolic mediation of epistemic access)**.** *Symbolization can expand, stabilize, and reorganize epistemic access to relational reality by rendering selected manifestations portable across observers, settings, and times. The resulting symbolic accessibility remains dependent on the selection rules and interpretive conventions through which the representation is produced and used.*

Claim 5.39 explains why symbolic systems are both epistemically enabling and selective. A stable vocabulary can support comparison across cases that would otherwise remain locally intelligible. A coding standard can aggregate records across institutions. A legal category can coordinate recognition across courts and agencies. At the same time, each gain in portability is achieved through a representational decision about which distinctions will count as relevant.

5.5.2 Linguistic Representation

Linguistic representation provides one of the most flexible media for relational knowledge. Language can name entities, specify relations, narrate trajectories, mark modality, attribute causes, preserve testimony, and express uncertainty. It can also embed distinctions that become difficult to see once they are stabilized in ordinary usage. Terms such as *worker*, *owner*, *household*, *market*, *dependency*, *care*, or *trust* can function simultaneously as descriptive conveniences and as historically inherited classifications.

For GRE, linguistic representation should therefore be analyzed at two levels. The first concerns semantic content: what relation or object a linguistic expression is intended to describe. The second concerns the social conditions under which the expression becomes authoritative, ordinary, contestable, or unavailable. Bourdieu's account of linguistic markets is useful here because it emphasizes that linguistic efficacy depends partly on social position, institutional authorization, and the conditions of reception (Bourdieu 1991). A description can thus fail to become publicly consequential even when it captures an important aspect of relational reality, while an institutionally authorized description can become widely reproduced despite serious epistemic limitations.

Linguistic representation is especially important for relations whose traces are dispersed across experience rather than concentrated in formal records. Testimony about dependence, exclusion, coercion, care, trust, or tacit norms often requires narrative articulation before the relevant relational pattern becomes available to others. Such articulation can condense a long trajectory into a linguistic form that permits comparison and inquiry. The evidential value of the account still depends on context,

corroboration, target specification, and the possibility of alternative interpretations.

Language also supports second-order representation. A subject can describe the categories through which an institution describes them, contest those categories, or propose a new vocabulary for a relation previously rendered obscure. Epistemic change can therefore involve changes in the representational language itself. This does not imply that reality changes whenever vocabulary changes. It means that available distinctions influence which relational hypotheses can be formulated, communicated, and tested.

5.5.3 Administrative Representation

Administrative representation converts persons, organizations, events, transactions, locations, resources, and relations into standardized categories suitable for coordination across institutional settings. Registries, forms, identifiers, taxonomies, eligibility rules, case files, accounting fields, and reporting systems create representational infrastructures through which large organizations can act upon realities that no single administrator encounters directly.

The epistemic advantage is substantial. Standardization allows cases to be compared, aggregated, retrieved, and transported across organizational boundaries. The same process can reduce heterogeneous relations to a limited set of recognized attributes. Desrosières' history of statistical reasoning and Porter's study of quantitative objectivity both show how conventions of classification and standardized procedures support impersonal and transportable judgment (Desrosières 1998; Porter 1995). Hacking's historical ontology further emphasizes that categories can acquire histories and participate in reorganizing the fields they describe (Hacking 2002).

Administrative representation therefore generates a specific epistemic asymmetry. Relations that fit the administrative schema can become highly visible, while relations that fall outside the schema can remain weakly represented even when they are causally important. A household may be represented by an address and membership field while care dependencies remain unrecorded. Employment may be represented by contract status while effective control is distributed through subcontracting, platforms, algorithms, and informal expectations. A benefit system may record eligibility categories while omitting relational barriers that shape practical access.

Definition 5.40 (Administrative legibility)**.** *Administrative legibility* is the degree to which an object, relation, event, or condition can be represented within the categories, identifiers, procedures, and record structures through which an administrative system observes and acts.

Administrative legibility is epistemically useful because it supports coordination and comparison. It is also selective because legibility is defined relative to a particular representational infrastructure. GRE therefore treats administrative absence with caution: an unrecorded relation may reflect nonexistence, weak trace generation, exclusion from the schema, incomplete reporting, strategic concealment, or a mismatch between lived relations and recognized categories.

5.5.4 Legal Representation

Legal representation renders relations through categories of status, right, duty, authority, liability, ownership, membership, capacity, obligation, and procedure. Legal systems thereby produce highly structured representations of relational positions. These representations can summarize complex histories into recognized forms: a person is registered as an owner, a corporation as a juridical entity, an agreement as a contract, a relation as employment, or an act as a legally relevant transfer.

Hart's account of primary and secondary rules highlights how legal systems depend on socially organized practices for identifying, changing, and applying valid rules, while Searle's account of institutional facts emphasizes how recognized status functions can support rights, duties, powers, and other institutional consequences (Hart 2012; Searle 1995). GRE can use these accounts to study legal representation while preserving a distinction among the represented relation, the legal category, and the wider relational reality in which the category operates.

Legal representation can be epistemically precise within its own domain. A registry can provide strong evidence of formally recognized ownership. A judgment can establish the legal disposition of a dispute. A statute can specify an authorized category. The same representation may provide only partial access to bargaining power, practical dependence, social recognition, informal obligation, or the full generative consequences of the relation. Legal status and relational structure therefore overlap without being interchangeable.

This distinction becomes particularly important when several legal forms can support similar relational effects or when the same legal form operates differently across material and institutional conditions. GRE should ask which dimensions of a relation a legal category preserves, which it abstracts from, and how much inferential weight the category can bear outside the legal question for which it was designed.

5.5.5 Statistical Representation

Statistical representation renders heterogeneous observations into variables, counts, distributions, indices, correlations, rates, and other numerical forms. This transformation can reveal patterns that remain invisible at the level of individual cases. It can also establish equivalences among cases that differ along dimensions omitted from the representation. Statistical knowledge therefore depends on both measurement and classification.

Desrosières emphasizes that statistical categories rely on conventions that make heterogeneous cases comparable, while Porter shows how standardized quantification can support forms of objectivity that travel across institutional settings (Desrosières 1998; Porter 1995). These insights are particularly important for GRE because relational phenomena are often transformed into variables whose apparent simplicity conceals substantial representational work. A variable labeled *employment*, *income*, *trust*, *household*, *network degree*, or *access* may summarize a complex family of relational judgments.

Statistical representation can operate at several distances from the target. Some variables are direct encodings of standardized records. Others are constructed

indices combining multiple indicators. Still others are latent quantities estimated through models. The evidential burden changes across these cases. A relation inferred from a latent variable requires justification of both the measurement model and the substantive interpretation that connects the statistical construct to the relational target.

Claim 5.41 (Statistical representation and relational compression)**.** *Statistical representation can expand relational knowledge by revealing aggregate patterns and structured variation while simultaneously compressing heterogeneity through classification, measurement, and aggregation. The epistemic adequacy of a statistical representation therefore depends partly on whether the dimensions suppressed by that compression are material to the relational claim under inquiry.*

Claim 5.41 provides a practical criterion for GRE. Compression is not itself an error. Every representation omits detail. The relevant question is whether the omitted structure changes the inference. A national average may be useful for one question and deeply misleading for another when important relational differences are concentrated across regions, classes, institutions, or networks.

5.5.6 Computational Representation

Computational representation extends symbolic transformation into machine-processable structures. Databases encode entities and attributes; graphs encode nodes and relations; simulations encode rules and state transitions; machine-learning systems encode statistical regularities in parameters or latent spaces; agent-based models encode actors, environments, interaction rules, and update processes. These representations enable forms of analysis that exceed unaided human inspection in scale, speed, and combinatorial complexity.

Scientific modeling provides a useful epistemic precedent. Giere treats models as purpose-relative representations of selected aspects of reality, while Winsberg shows how computer simulation mediates among theory, model construction, approximation, computation, and evidence (Giere 2004; Winsberg 2010). GRE extends the same caution to computational representations of economic and social relations. A graph, simulation, classifier, embedding, or prediction model should be interpreted through the choices that generated its objects, variables, relations, loss functions, update rules, and evaluation criteria.

Computational representation can create particularly strong appearances of precision because symbolic categories are translated into exact machine-readable states. Exact encoding, however, does not guarantee exact correspondence with the target. A network edge can be precisely stored while remaining an imperfect representation of friendship, authority, dependence, or information flow. A classifier can assign a precise probability while relying on target categories whose social or institutional meaning is unstable. A simulation can execute deterministic rules whose relation to the modeled system remains uncertain.

Algorithmic systems also blur the boundary between epistemic representation and institutional operation. A computational representation can be used to allocate tasks, rank subjects, determine access, flag risk, or structure incentives. Kellogg, Valentine, and Christin show how algorithms in organizations can participate in directing, eval-

uating, and controlling work (Kellogg et al. 2020). The present section records this possibility while reserving the fuller recursive and performative analysis for Section 117. For epistemology, the immediate point is that an operational representation may later affect the data from which its adequacy is evaluated.

5.5.7 Symbolized Relations

A relation becomes symbolized when some aspect of its structure is rendered into a symbolic form that can be identified and manipulated within an epistemic practice. Symbolization can preserve the identity of relata, relation type, direction, intensity, duration, sequence, legal status, uncertainty, or other properties. Different representations preserve different subsets of these features.

A network graph can preserve adjacency while omitting the qualitative meaning of a tie. A contract can preserve specified obligations while omitting the history of bargaining. A statistical matrix can preserve covariance while omitting local narrative context. A linguistic account can preserve experienced meaning while leaving scale and comparability uncertain. None of these forms is intrinsically superior. Their adequacy depends on the target and the question.

Definition 5.42 (Symbolized relation)**.** A *symbolized relation* is a representation in which one or more aspects of a target relation are encoded into a symbolic structure according to an explicit or implicit representational rule.

Definition 5.42 allows GRE to separate the relational target from the representational object used to study it. The distinction is especially important when a symbolized relation acquires institutional durability. A database edge, legal status, score, category, or label can be preserved long after the relation that originally motivated it has changed. Epistemic inquiry must therefore ask whether the representation continues to track the target, records only a past state, or has become part of a new relational configuration.

Symbolized relations can also be multiply realizable. The same underlying relation may be represented through testimony, legal documents, administrative records, statistical variables, graph structures, and computational states. Agreement across heterogeneous representations can strengthen a claim when the representations rely on sufficiently independent manifestation pathways. Apparent agreement among representations derived from the same underlying record system provides weaker triangulation because their errors may be correlated.

5.5.8 Representation Error

Representation error concerns the mismatch between what a representation preserves or implies and the epistemic target for which it is being used. The concept should remain broader than numerical measurement error. Linguistic categories can mischaracterize a relation; administrative schemas can omit relevant distinctions; legal forms can fail to track practical dependence; statistical indicators can compress consequential heterogeneity; computational models can encode inappropriate categories or unstable proxies.

Definition 5.43 (Representation error)**.** *Representation error* is a target-relative discrepancy introduced when a representation omits, distorts, conflates, misclassifies, mis-scales, or otherwise preserves inadequately a feature of the epistemic target that is material to the claim for which the representation is used.

This definition makes error dependent on both target and use. A representation can omit most details of a system and still be adequate for a narrow question. The same omission can become an error when the inquiry shifts. Representation error is therefore evaluated relative to material relevance rather than descriptive completeness.

Several forms deserve distinction. *Selection error* arises when the representation excludes relations or cases important to the target. *classification error* arises when cases are assigned to categories that fail to preserve relevant differences. *aggregation error* arises when combining observations suppresses structure material to the inference. *semantic error* arises when a symbol is interpreted as referring to a different relation from the one it reliably tracks. *temporal error* arises when a representation is treated as current after the underlying relation has changed. *structural error* arises when the representational form itself presupposes a relation type that differs from the target, for example when a distributed field is forced into pairwise edges or a temporally evolving relation is represented as a static attribute.

Claim 5.44 (Representation adequacy under relational inquiry)**.** *A representation is epistemically adequate for a relational claim to the extent that its selection, encoding, scale, temporal scope, and interpretive rules preserve the target-relevant structure sufficiently for the inference being made, with material sources of representational error identified and bounded where possible.*

Claim 5.44 complements the evidential distinctions of Section 5.4. Evidence can be abundant while representation remains poor. A large administrative dataset can provide many precise observations of categories that fail to capture the relation of interest. Conversely, a sparse qualitative representation can sometimes preserve a relational distinction that a large standardized dataset erases. Epistemic strength therefore depends on the relation among target, trace, representation, and inference rather than on volume or formal precision alone.

Representation error can also be systematic. Institutional categories may repeatedly underrepresent certain relations because the relevant distinctions are absent from the schema. Statistical systems may reproduce the same coding convention across decades. Computational systems may inherit labels and proxies from administrative infrastructures. Once such representations become widely reused, correlated errors can appear as cross-source confirmation. GRE should therefore examine the genealogy of representations as part of epistemic evaluation, especially when several apparently independent datasets or models depend on the same upstream categories.

The section's overall result is a layered account of symbolic mediation. Relational reality can generate manifestations and traces; symbolization renders selected aspects of those manifestations into portable forms; representations organize those symbols for linguistic, administrative, legal, statistical, or computational purposes; and representation error arises when the preserved structure is inadequate for the epistemic target. Symbolic forms can dramatically extend relational knowledge by en-

abling memory, comparison, aggregation, modeling, and communication across distance. Their epistemic force remains tied to the histories, conventions, institutions, and technical procedures through which they are produced. This layered account prepares Section 117, which examines what happens when representations move beyond epistemic mediation and enter the generative-relational system as operative classifications, rules, measurements, and algorithmic interventions.

5.6 Performative Representation

Section 5.5 treated representation principally as an epistemic mediation through which selected aspects of relational reality become portable, comparable, storable, and inferentially usable. The present section examines a further possibility: some representations enter the relational system in which they circulate and contribute causally to subsequent relations, opportunities, expectations, classifications, decisions, and institutional responses. Its role is to distinguish representational description from representational intervention while preserving the separation among epistemic adequacy, causal efficacy, relational stabilization, and normative evaluation. The section proceeds through seven components: representation and subsequent relation, classification effects, legal performativity, administrative performativity, statistical performativity, algorithmic performativity, and recursive representation. The method is relational and process-oriented. Each case is analyzed through the pathway by which a representation acquires uptake, becomes connected to action or institutional procedure, and alters conditions that can later become objects of representation in their own right.

The language of performativity has several intellectual lineages. Austin's analysis of performative utterances established a particularly influential case in which words can participate in the performance of actions under conventional and contextual conditions (Austin 1962). Historical and sociological work later broadened attention toward classifications, measurements, and models whose circulation can alter the practices and objects to which they refer. Hacking's historical ontology emphasizes the historical emergence of categories and objects within practices of classification and reasoning (Hacking 2002). Espeland and Sauder analyze reactivity to public measures, showing how rankings can alter expectations and organizational behavior (Espeland and Sauder 2007). MacKenzie documents cases in which financial models became incorporated into market practices and thereby participated in reshaping the markets they represented (MacKenzie 2006). GRE draws on these lineages while giving the term a narrower relational specification.

Definition 5.45 (Performative representation)**.** A *performative representation* is a representation that, through uptake within a social, institutional, legal, technical, or other relational process, contributes causally to the subsequent configuration, persistence, transformation, or generation of relations relevant to its domain of use.

Definition 5.45 makes performativity conditional. Representations vary in their capacity to affect subsequent relations. A privately written description that remains unread can be epistemically rich while having little practical effect on its target domain. A coarse administrative category connected to eligibility rules can have substantial

causal consequences despite limited descriptive resolution. The relevant question is therefore whether a credible pathway connects the representation to subsequent relational change.

Several conditions commonly strengthen such a pathway. A representation may acquire recognized authority, become embedded in organizational routines, trigger a legal or administrative rule, guide allocation, coordinate expectations among multiple actors, alter incentives, or become repeatedly reproduced in later decisions. Persistence and reach also matter. A classification used once in a local setting can produce a narrow effect, whereas a category embedded across interoperable databases can structure relations across institutions and time. These conditions concern performative efficacy rather than epistemic quality. The distinction becomes central to the analysis that follows.

Claim 5.46 (Separation of representational adequacy and performative efficacy)**.** *The epistemic adequacy of a representation and its performative efficacy are distinct properties. A representation can exert substantial causal influence while preserving the target poorly, and a highly adequate representation can remain causally weak when it lacks uptake or operational connection.*

Claim 5.46 extends the discussion of representation error in Section 5.5. An inaccurate score can still affect access to resources when institutions act upon it. A careful scholarly reconstruction can remain practically inert when no relevant institution, participant, or decision process uses it. Causal efficacy therefore supplies neither a truth criterion nor a normative endorsement. Conversely, epistemic adequacy supplies no guarantee of practical consequence.

5.6.1 Representation and Subsequent Relation

A representation becomes performatively relevant when it enters a pathway through which subsequent relations depend partly on its presence, content, or institutional interpretation. The phrase *subsequent relation* refers here to a relation whose configuration is temporally downstream from the representation and whose formation, modification, persistence, or dissolution is causally influenced by the representation's uptake. The representation can concern the same relation, a neighboring relation, or a higher-order structure that reorganizes several relations at once.

Consider a representation of creditworthiness. The representation may summarize traces of income, repayment, debt, or institutional history. Once lenders use the representation in allocation decisions, the score can influence access to credit, the terms of borrowing, subsequent repayment opportunities, and future records. The representation then occupies two roles. It remains an epistemic object intended to say something about a target, while also becoming a causal input into a changing relational configuration among borrowers, lenders, intermediaries, and institutions. The later configuration can generate traces that are subsequently used to evaluate or update the original representational system.

The same structure can occur without centralized authority. A public reputation category can coordinate expectations among many actors. A widely circulated label can alter whom others approach, avoid, trust, or monitor. A market model can influence trading strategies. A scientific classification can redirect data collection and in-

stitutional attention. The relevant mechanism differs across cases, yet the relational structure is comparable: representation enters practice, practice changes relational conditions, and those changed conditions can later manifest through new traces.

This process also clarifies the relation between performative representation and relational reality. The preceding ontological chapter defined relational reality through emergence, sufficient stability over some spacetime region, and causal efficacy within a generative-relational system. A representation that becomes institutionally stabilized and causally consequential can therefore itself acquire relational reality within the relevant domain. Its relational reality concerns the representation's effective presence in the system. The truth or adequacy of what it represents remains a separate epistemic question.

A useful analysis of performativity should therefore identify at least three objects: the *target relation* that the representation purports to describe; the *operational relation* through which the representation enters action, decision, or coordination; and the *subsequent relation* whose configuration is altered through that operation. These objects can coincide only partially. A legal status may represent one relation while changing several adjacent rights and obligations. A statistical ranking may represent performance while altering recruitment, funding, attention, and internal organizational priorities. A computational score may estimate one target while becoming an input into an allocation process with wider relational consequences.

Proposition 5.47 (Operational mediation of performative effects)**.** *A claim of performative representation is strengthened when the analysis identifies a traceable operational mediation connecting the representation to subsequent relational change, including the actors, rules, infrastructures, expectations, or decision procedures through which the representation acquires causal relevance.*

Proposition 5.47 guards against treating temporal succession as sufficient evidence of performativity. A representation can precede a relational change without contributing materially to it. Epistemic warrant requires evidence concerning the transmission pathway, competing causes, timing, scope, and persistence of the effect. The epistemology of performativity is therefore an attribution problem as well as a representational one. Later sections on evidence, generative relations, and attribution develop this problem more systematically.

5.6.2 Classification Effects

Classification is one of the most common routes through which representation becomes performative. A classification groups cases according to distinctions that make them administratively, legally, statistically, socially, or computationally tractable. Once a category is connected to recognition, expectation, allocation, sanction, entitlement, or organizational procedure, category membership can contribute to the relations available to the classified case.

Hacking's historical ontology is relevant because it directs attention to the historical formation of categories and objects within practices of naming, classification, inquiry, and intervention (Hacking 2002). GRE places particular emphasis on the relational consequences of this process. A classification can make a dispersed pattern publicly recognizable, support coordination around a previously weakly articulated

relation, or provide a vocabulary through which subjects can interpret experience. It can also compress heterogeneity, stabilize a contested boundary, or attach institutional consequences to differences that were previously less consequential.

Classification effects can operate through several pathways. First, institutions can route cases differently after classification. Second, other actors can alter expectations toward a classified person, organization, object, or event. Third, subjects can adapt behavior in anticipation of classification. Fourth, the classification can alter data collection, because institutions begin recording variables that matter to the category. Fifth, repeated use can stabilize the category itself, making it appear increasingly natural or inevitable even when its boundary arose historically from specific institutional purposes.

The economic significance of classification is especially clear when category membership affects conversion possibilities. A person classified as eligible can gain access to an entitlement, service, market, or institutional pathway. An organization classified under a particular legal or administrative type can face different reporting duties or financing possibilities. An object classified as a commodity, protected resource, waste product, cultural object, or regulated good can enter different circuits of valuation and exchange. Kopytoff's analysis of commoditization illustrates how object status can vary across social contexts and histories rather than functioning as an invariant property of the object itself (Kopytoff 1986). GRE treats such changes as transformations in the relational organization through which value and exchange become possible.

Classification effects remain heterogeneous. A category can have strong formal consequences and weak practical uptake. Another can have little formal standing while strongly coordinating expectations. A category can also become performative through anticipation before an official decision is made, for example when actors reorganize behavior around an expected classification threshold. The causal unit is therefore the broader classificatory arrangement, including rules of assignment, visibility, authority, anticipated consequences, channels of contestation, and the temporal persistence of records.

The possibility of classification effects intensifies the epistemic stakes of representation error. Misclassification can alter the target environment and thereby generate traces consistent with the category that produced the intervention. An initially weak representation can thus acquire apparent empirical support after institutions reorganize behavior around it. This possibility does not make all classifications self-confirming. It identifies a specific recursive pathway that relational inquiry should test where classification and intervention are tightly connected.

5.6.3 Legal Performativity

Legal representation supplies a comparatively explicit form of performativity because legal systems connect recognized symbolic acts, categories, and documents to rules governing rights, duties, powers, liabilities, statuses, procedures, and institutional competencies. Austin's account of performative utterances is directly relevant to cases in which conventional acts accomplish legally recognized changes under appropriate conditions (Austin 1962). Hart's analysis of primary and secondary

rules provides a complementary perspective on how legal systems organize conduct and establish rules through which legal validity, alteration, and adjudication are recognized (Hart 2012).

For GRE, the important point concerns the generation or transformation of relations through legally operative representation. A contract can specify obligations that become institutionally recognizable. Incorporation can establish an organizational form with consequences for asset ownership, liability, governance, and third-party relations. Property registration can reorganize claims among holders, users, creditors, successors, and public authorities. Organizational law can structure asset partitioning and relations between firms, owners, managers, and creditors (Hansmann and Kraakman 2000). In each case, a symbolic form participates in producing a relational configuration because institutions recognize the form and connect it to durable rules of action and adjudication.

Legal performativity depends on more than textual existence. A document outside a recognized procedure can fail to alter legal relations. A valid rule can have uneven practical consequences when enforcement, awareness, institutional capacity, or social uptake varies. The performative effect therefore travels through a relational infrastructure composed of authorized procedures, offices, records, enforcement capacities, professional practices, expectations, and conventions of recognition.

This distinction also clarifies the relation between legal reality and wider relational reality. A legal status can be causally effective even when everyday practice only partially conforms to it. Conversely, a stable practical relation can exist without corresponding legal recognition. GRE should therefore distinguish legal representation, legally constituted relations, practically enacted relations, and the wider relational field in which both are situated. Their correspondence is an empirical and historical matter.

Legal representation can further transform epistemic conditions. Once a relation receives a legal form, it often becomes easier to record, archive, contest, compare, and transmit across institutions. Legal performativity can therefore generate new traces at the same time that it restructures rights and obligations. This dual role is important for later inquiry: the evidential record available to the researcher can be partly produced by the legal arrangements whose consequences are being studied.

5.6.4 Administrative Performativity

Administrative systems convert heterogeneous situations into categories, records, statuses, files, priorities, thresholds, and procedural states that can be processed at organizational scale. Section 5.5.3 examined these forms primarily as representations. Their performative dimension emerges when administrative records are connected to allocation, access, sequencing, monitoring, recognition, or institutional response.

An administrative category can determine whether a case enters a queue, receives a benefit, triggers an inspection, qualifies for an exception, or becomes visible to a particular office. A record can also coordinate actions across institutions when interoperable systems reuse the same status or identifier. Administrative representation then becomes an infrastructure for relational coordination. It shapes which actors encounter one another, which procedures become available, how quickly an interac-

tion proceeds, and what documentation must be supplied for further recognition.

Institutional analysis has long emphasized that formal rules and organizational structures shape incentives and patterns of interaction (North 1990). GRE adds a representational question: the operation of a rule frequently depends on how a case has first been rendered administratively legible. The category is therefore part of the pathway through which the institution acts. A mismatch between lived relations and administrative representation can have material consequences even when the formal rule is applied consistently to the recorded category.

Administrative performativity can accumulate over time because records persist. A category assigned at one moment can influence subsequent decisions long after the underlying relation has changed. Later institutions may inherit the recorded status without observing the original context. This creates temporal asymmetry between relational transformation and administrative updating. Historical inquiry should therefore distinguish the time of the represented relation, the time of recording, the time of institutional use, and the time at which consequences become visible.

Large-scale data infrastructures extend this process by enabling records to circulate across organizational boundaries. The World Bank's treatment of integrated data systems illustrates the growing institutional importance of administrative and other data sources for public decision processes (World Bank 2021). From a GRE perspective, integration increases both epistemic reach and performative reach. A category used across many institutional settings can coordinate services and reduce repeated informational costs; the same portability can also propagate a representational error through multiple downstream decisions.

Administrative performativity is therefore inseparable from questions of correction and contestability. A system that acts on records requires mechanisms through which outdated, contextually inappropriate, or erroneous representations can be revised. The epistemic significance of such mechanisms is substantial: they help prevent a representational state from becoming self-reinforcing solely because later institutions repeatedly treat the existing record as evidence of its own correctness.

5.6.5 Statistical Performativity

Statistical representation becomes performative when indicators, rankings, benchmarks, forecasts, classifications, or numerical models are incorporated into behavior, evaluation, coordination, or resource allocation. The history of quantitative objectivity shows how standardized numerical procedures can acquire authority partly because they enable impersonal comparison across cases and institutions (Porter 1995). Desrosières likewise emphasizes the historical construction of statistical categories, conventions, and comparability (Desrosières 1998). These representational infrastructures can later become objects around which institutions organize action.

The performative pathway is particularly visible when measurement becomes evaluation. A numerical indicator used only for descriptive analysis can have limited effect on the target. Once the same indicator enters a funding rule, ranking system, performance review, public comparison, or organizational target, actors gain reasons to attend to the metric. Espeland and Sauder's study of law-school rankings demonstrates this form of reactivity: public measures can alter expectations

and organizational behavior, with commensuration and self-reinforcing expectations contributing to the process (Espeland and Sauder 2007). The measure thereby becomes part of the environment within which the measured organizations act.

Statistical performativity can alter both behavior and category meaning. Actors may direct effort toward measured dimensions, redesign internal procedures to improve recorded performance, invest in data practices that affect future measurement, or reorganize activities around threshold effects. Such responses can improve the target of measurement when the indicator tracks a valued objective sufficiently well. They can also increase divergence between the measured variable and the wider target when optimization concentrates on what the metric captures.

MacKenzie's study of financial economics provides a related case at the level of models rather than simple indicators. Financial models became incorporated into market practices and contributed to changes in the markets to which those models referred (MacKenzie 2006). For GRE, this example is important because it shows that representation can participate in the generation of conditions under which its own assumptions become more or less descriptively successful. Model evaluation in such settings requires historical attention to deployment as well as comparison with an independently evolving target.

The epistemic challenge is especially sharp when a statistical representation changes the data-generating relations that later supply evidence about its adequacy. A ranking can change applicant behavior, institutional investment, and reporting practices. A forecast can alter expectations that influence subsequent transactions. A performance target can change which activities are prioritized and recorded. Later observations then describe a world partly reorganized through earlier measurement. Statistical evaluation should therefore ask whether observed stability reflects a stable target, adaptation to the measure, changes in recording practice, or some combination of these processes.

Claim 5.48 (Reactivity of operationalized measures)**.** *The probability and scope of statistical performativity increase when a measure becomes visible to affected actors and is coupled to consequential decisions, comparative evaluation, resource allocation, reputational effects, or repeated organizational routines.*

Claim 5.48 is deliberately conditional. Quantification alone does not establish reactivity. The causal mechanism depends on how the measure enters a relational field and what capacities actors possess to respond to it. This preserves the distinction between statistical representation and statistical intervention.

5.6.6 Algorithmic Performativity

Algorithmic systems intensify several mechanisms already present in legal, administrative, and statistical performativity. A computational representation can be generated rapidly, updated repeatedly, individualized at fine granularity, and connected directly to operational decisions. Scores, rankings, recommendations, classifications, forecasts, and generated outputs can therefore enter relational processes with short delays between representation and consequence.

Algorithmic performativity begins when computational outputs affect subsequent

action. A ranking can determine visibility; a recommendation can redirect attention; a risk score can trigger review; a scheduling system can reorganize temporal relations among workers, tasks, and managers; a classifier can determine which cases receive further human examination. Kellogg, Valentine, and Christin document how algorithmic systems in workplaces can participate in directing, evaluating, and disciplining work through computational mechanisms of control (Kellogg et al. 2020). The broader epistemic lesson is that algorithmic outputs can simultaneously represent a domain and intervene within it.

Several features make this form distinctive in degree even when its relational logic resembles earlier institutional technologies. First, computational systems can operate at high frequency and large scale. Second, their outputs can be personalized, producing different relational environments for different subjects. Third, automated systems can connect representation to action with little deliberative delay. Fourth, models can be updated using data partly generated after previous versions were deployed. Fifth, complex model architectures can make the operative path difficult for affected actors and sometimes difficult for institutional operators to reconstruct fully.

These features create recursive epistemic problems. A model predicts behavior; institutional action follows the prediction; subjects respond to the resulting environment; their response generates new data; and later models learn from data produced under the earlier intervention. The resulting dataset records a mixture of target behavior and system-induced behavior. Relational inquiry should therefore distinguish pre-deployment patterns, intervention pathways, behavioral responses, institutional adaptation, and later representational updates where evidence permits.

Algorithmic performativity also expands the importance of counterfactual evaluation. Observed outcomes after deployment cannot by themselves establish what would have occurred without the representational intervention. A low observed default rate among people granted credit, for example, does not reveal the outcomes of people who were denied access on the basis of a score. Similar selection problems arise in policing, employment, insurance, moderation, education, and other allocation contexts. The epistemic issue concerns missing relational trajectories created by the decision process itself.

The distinction in Claim 5.46 becomes especially important here. An algorithm can be operationally powerful because institutions rely on it extensively, while its target validity remains uncertain or uneven across contexts. Conversely, a well-validated model can have limited performative impact when humans routinely override its outputs or when the modeled decision has weak consequences. Evaluation therefore requires separate evidence for predictive or representational adequacy, institutional uptake, causal effects of deployment, and normative acceptability.

5.6.7 Recursive Representation

The preceding cases converge on a general epistemic structure: representation can enter the system it represents, contribute to subsequent relational change, and thereby alter the conditions from which later representations are produced. GRE calls this structure *recursive representation*. The term does not imply that the same representation repeats unchanged. Recursion can involve successive legal cate-

gories, updated administrative records, revised indicators, changing model versions, strategic responses, or institutional reinterpretations.

Definition 5.49 (Recursive representation)**.** *Recursive representation* is a process in which a representation contributes causally to subsequent relational conditions, and those altered conditions later become part of the evidential or practical basis for further representation.

Definition 5.49 adds time to the representational architecture developed in Section 5.5. The epistemic relation between representation and target can change after deployment because the target itself may develop partly through responses to previous representations. Evaluation at a later moment therefore cannot always assume that the represented system evolved independently of the representational practices used to know and govern it.

Recursive representation can produce several patterns. One is *stabilizing recursion*, in which a representation coordinates expectations and practices in ways that make the represented category or regularity more durable. Another is *destabilizing recursion*, in which actors respond strategically and reduce the representation's later predictive or classificatory usefulness. A third is *transformative recursion*, in which the representation redirects practices sufficiently that the original target changes form and requires a revised vocabulary or model. These patterns are analytical possibilities rather than exhaustive types.

The epistemic investigation of recursion therefore requires a genealogy of representation. Researchers may need to reconstruct when a representation was introduced, which institutions adopted it, how it was operationalized, which actors encountered its consequences, what opportunities for adaptation or contestation existed, how records were subsequently generated, and whether later measures reused the same categories. This historical reconstruction can prevent later observations from being treated as independent confirmation when they are partly products of earlier representational interventions.

Recursive representation also clarifies why knowledge infrastructures can become components of the realities they study. Statistical offices, registries, legal records, classification standards, ranking systems, and algorithmic platforms can initially emerge to observe, coordinate, or describe. Once their outputs influence action repeatedly, the infrastructure becomes part of the relational environment. Its categories can acquire persistence, causal efficacy, and institutional reach. The resulting relational reality may then include both the represented processes and the representational machinery through which those processes are governed and known.

This conclusion preserves ontological restraint. The causal incorporation of a representation establishes a claim about its relational efficacy within a specified system and interval. It does not establish the representation's ultimate ontological status, descriptive completeness, epistemic truth, or normative legitimacy. These dimensions require their own arguments and evidence. The distinction is particularly important for GRE because economic institutions routinely operate through prices, classifications, contracts, accounts, metrics, models, forecasts, and computational systems whose representational and causal roles are intertwined.

Section 5.6 therefore extends the epistemology of GRE from mediated access to

recursive mediation. Representations can preserve and distort relational knowledge, and some can also become causal participants in later relational generation. Their epistemic assessment consequently requires attention to the target they represent, the operational pathways through which they act, the relations they subsequently transform, and the traces produced after intervention. This result prepares Section 118, which turns to observation and partial access. Once representations can participate in producing the relations later observed, the position, scope, and limits of observation become even more consequential for relational knowledge.

5.7 Observation and Partial Access

Sections 5.4–5.6 established three progressively richer conditions of epistemic mediation: relations leave traces that acquire evidential roles, manifestations can be symbolized and represented through selective schemes, and some representations can enter practice and alter subsequent relational conditions. The present section examines a further constraint that cuts across all three processes: observation is ordinarily partial. Its role is to specify how access to relational reality varies with observer position, institutional capacity, distributed observation, hiddenness, concealment, and time. The objective is neither to reduce knowledge to perspective nor to treat partial access as generalized skepticism. It is to make the conditions of observation explicit enough that claims can be calibrated to what an observation regime could plausibly register. The section proceeds through seven components: partial observation, observer position, unequal epistemic access, distributed observation, hidden relations, strategic concealment, and temporal limits. The method is target-relative and relational. Observation is analyzed through the relation among an epistemic target, an observer or observing system, the channels through which traces become accessible, and the conditions that shape what remains outside those channels.

Scientific perspectivism provides one useful precedent for this orientation. Giere argues that scientific observation and representation are perspectival while remaining open to disciplined evaluation against selected aspects of the world (Giere 2006). Longino's contextual empiricism adds that evidential reasoning is socially organized and can be strengthened through critical interaction among differently situated inquirers (Longino 1990). GRE draws a narrower conclusion from these lineages: the position and capacities of an observer belong to the evidential conditions of a relational claim, yet perspectival mediation does not dissolve the distinction between better and worse warranted claims.

Definition 5.50 (Observational access)**.** *Observational access* is the target-relative capacity of an observer or observing system to register, retrieve, preserve, or otherwise obtain traces that can bear evidentially on a specified relational claim within a given interval and observational regime.

Definition 5.50 treats access as structured rather than binary. An observer may possess direct access to some traces, mediated access to others, and little access to further traces that remain outside the observation regime. Access can also change through instrumentation, institutional permission, record preservation, legal authority, cooperation from participants, technical interoperability, or historical reconstruction.

The epistemic question is therefore not simply whether a relation was observed. It concerns which aspects of the relation could become observable to which observer, through what channels, and under what conditions.

5.7.1 Partial Observation

Partial observation occurs when the accessible evidential field captures only a subset, projection, interval, manifestation, or trace structure relevant to the relational target. The partiality can arise because the target relation extends beyond the observer's spatial reach, persists longer than the period of observation, contains components that do not manifest through available instruments, or participates in neighboring relations that remain unrecorded. Partiality can also be produced institutionally when a registry, survey, platform, archive, or administrative procedure records selected categories while leaving other dimensions unregistered.

The term should be distinguished from simple error. An observation can be accurate with respect to what it registers while remaining incomplete with respect to the target relation. A transaction ledger may accurately record transfers while revealing little about the expectations, obligations, informal sanctions, or prior relations that gave the transfers their meaning. A labor dataset may accurately record wages and hours while only partially registering care responsibilities, informal work, bargaining relations, workplace authority, or dependencies outside the employing organization. A legal file may faithfully preserve formal acts while leaving much of the surrounding social relation outside the record. The problem is therefore one of evidential reach before it becomes one of incorrect measurement.

Partial observation is also distinct from underdetermination, although the two can interact. Partial access concerns the evidential field available to the observer. Underdetermination concerns the possibility that the available evidence remains compatible with multiple relational reconstructions. Expanding observation can reduce underdetermination when newly accessible traces discriminate among alternatives. It can also reveal additional complexity and thereby enlarge the set of plausible reconstructions. More observation therefore does not mechanically produce uniqueness, yet the structure of partial access remains indispensable for evaluating what conclusions the evidence can sustain.

Claim 5.51 (Target-relative partiality)**.** *An observation is partial only relative to an epistemic target and a specified claim. The same evidential field can provide extensive access for one target while providing limited access for another.*

Claim 5.51 prevents completeness from becoming an undefined ideal. A price series may be sufficient for a narrowly specified claim about recorded price variation and insufficient for a claim about the generative history of market power. A network trace may reveal interaction frequency while providing weaker access to the meanings, obligations, or asymmetries carried by those interactions. Observational adequacy should therefore be evaluated against the target relation and inference actually at stake.

Partial observation also has a recursive dimension after Section 5.6. Observation regimes can alter behavior, and those behavioral responses can change what later becomes observable. Once participants know which indicators are measured, which ac-

tions create records, or which traces trigger institutional responses, they may adapt to the observation regime. The evidential field then reflects both the target process and responses to being observed. Partiality is consequently capable of changing through the very practices designed to reduce it.

5.7.2 Observer Position

Observer position identifies the relational location from which traces become accessible and interpretable. Position can include physical location, organizational role, legal standing, technical permission, social membership, temporal location, disciplinary training, and participation in the relation being studied. These dimensions should not be collapsed into a single standpoint. They describe distinct conditions that can shape access to different portions of the evidential field.

An employee, a manager, a regulator, a customer, and an external researcher can encounter the same organization through different trace structures. The employee may observe day-to-day coordination and informal authority while lacking access to strategic records. The manager may possess aggregate reports while seeing less of informal adaptation. The regulator may obtain standardized disclosures without continuous access to internal practice. A customer may observe outcomes and interfaces while remaining outside the organization's production process. An external researcher may combine records across institutions while lacking the situated knowledge held by participants. These positions can generate complementary evidence and distinct blind spots.

Observer position also affects the interpretation of traces. A technically identical record can acquire different evidential significance when observers possess different contextual knowledge about how the record was generated. An entry in an administrative database may look like a direct indicator to an external analyst while practitioners know that it is routinely produced through local workarounds, discretionary coding, or delayed reporting. Conversely, participants deeply embedded in a practice can normalize regularities that become more visible through comparison across settings. Positional proximity and distance can therefore each generate epistemic capacities and limitations.

Giere's perspectivism is helpful here because it permits situated representation without making all perspectives epistemically interchangeable (Giere 2006). GRE likewise treats observer position as a condition to be reported and evaluated, rather than as an automatic source of privilege or disqualification. A positional claim gains warrant when the observer's location is relevant to the target, the access channel is specified, and the evidential contribution can be compared with other available traces.

Definition 5.52 (Observer-position profile)**.** An *observer-position profile* is a structured description of the locations, permissions, capacities, dependencies, and temporal conditions that shape an observer's access to evidence relevant to a specified relational target.

The profile in Definition 5.52 is an analytical device rather than a requirement for exhaustive self-description. Its purpose is to reveal the dimensions of position that materially affect an inference. For a platform study, technical access and data-retention policy may be decisive. For research on care relations, household

participation and temporal proximity may matter more. For historical reconstruction, archival survival and later access rules can dominate. The relevant positional dimensions should therefore be selected in relation to the claim rather than listed mechanically.

5.7.3 Unequal Epistemic Access

Observation is often distributed unequally. Actors can differ in access to records, instrumentation, language, expertise, computational resources, legal discovery, institutional archives, confidential communications, and opportunities to question participants. They can also differ in whether their own observations are preserved, recognized, and treated as credible by institutions. Unequal epistemic access therefore concerns both possession of traces and participation in the processes through which traces become accepted evidence.

These inequalities can follow existing relational asymmetries. An institution may possess detailed records about individuals who possess little reciprocal visibility into the institution's decision procedures. A platform can observe user behavior at fine granularity while users encounter only selected outputs of the platform's internal models. Employers may aggregate workplace data unavailable to workers; financial intermediaries may combine records unavailable to applicants; states can possess administrative information distributed across agencies while residents experience the resulting classifications without equivalent access to the underlying infrastructures. The epistemic relation is then asymmetric even before the resulting knowledge is used for action.

Unequal access can also arise within research communities. Expensive instruments, proprietary datasets, security classifications, language barriers, disciplinary specialization, and institutional affiliations can determine which investigators can inspect which evidence. Longino's account of socially organized criticism is relevant because the epistemic benefits of plural criticism depend partly on whether differently situated participants can actually enter the critical process and receive uptake (Longino 1990). Where access to evidence and channels of criticism are concentrated, apparent consensus can reflect a narrow observational field as well as strong evidential convergence.

Fricker's analysis of epistemic injustice provides a more specifically normative lineage concerning credibility, testimony, and interpretive participation (Fricker 2007). The present section uses that work cautiously. Unequal access is broader than epistemic injustice: differences in access can arise from specialization, confidentiality, temporal position, or technical constraints without already establishing an injustice. Conversely, some access inequalities can be produced or intensified through power and exclusion. Section 118 records the epistemic structure; the systematic normative treatment of epistemic justice is reserved for Section 129.

Claim 5.53 (Asymmetry of observational visibility)**.** *Relational systems can generate asymmetric observational visibility in which one participant or institution can inspect, aggregate, or preserve traces concerning another while reciprocal access remains substantially weaker.*

Claim 5.53 is important for GRE because observational asymmetry can become eco-

nomically consequential even before a later analysis of power or justice. Differential visibility can affect bargaining, prediction, screening, monitoring, coordination, and the ability to contest a representation. It can also shape the evidential archive available to future inquiry. Researchers should therefore record whose traces become legible to whom and whose interpretive resources enter the evidential process.

5.7.4 Distributed Observation

Partial access does not imply that observation must remain confined to the perspective of a single observer. Relational knowledge can be assembled through distributed observation: multiple persons, instruments, institutions, records, and computational systems can contribute different portions of the evidential field. The epistemic problem then shifts from the limits of one observer to the conditions under which heterogeneous observations can be combined without erasing their provenance or falsely treating them as independent.

Hutchins's study of navigation provides an influential precedent for analyzing cognitive accomplishment across persons, artifacts, procedures, and socially organized practice (Hutchins 1995). GRE does not identify distributed observation with distributed cognition. The narrower borrowing is structural: an epistemic accomplishment can depend on a system of differentiated observational roles whose contributions are coordinated through material and institutional arrangements.

Distributed observation can expand access in several ways. Different observers can occupy complementary positions. Instruments can register phenomena outside ordinary human perception. Administrative systems can preserve traces over long intervals. Historical archives can connect temporally separated observers. Computational systems can search volumes of records beyond unaided human capacity. Affected communities can contribute contextual knowledge missing from standardized datasets. Cross-disciplinary research can combine distinct techniques for eliciting, measuring, interpreting, and reconstructing evidence.

The combination process introduces its own risks. Observations can share a common source and therefore provide less independent corroboration than their number suggests. Several databases may reproduce the same upstream record. Multiple witnesses may rely on a shared narrative. Several models may be trained on overlapping datasets. Institutional reports may inherit a common classification scheme. Apparent triangulation can therefore be generated by replication of the same observational dependency.

Distributed observations can also be difficult to translate. Different observers may use categories that overlap only partially, operate at different temporal resolutions, or register different levels of a relational system. Integration then requires an explicit account of correspondence among the observational schemes. The goal is not necessarily to collapse them into a single dataset. In some cases, preserving several partially compatible representations can retain information that forced harmonization would destroy.

Proposition 5.54 (Provenance in distributed observation)**.** *The evidential value of distributed observation increases when the provenance, dependence structure, observational position, and transformation history of the contributing traces remain recov-*

erable during integration.

Proposition 5.54 connects distributed observation to the book's broader concern with future re-epistemization. Provenance allows later researchers to distinguish independent corroboration from repeated transmission, reconstruct disagreements, revise mappings among categories, and incorporate evidence that earlier syntheses excluded. Distributed observation is therefore strongest when integration preserves the conditions under which each contribution became observable.

5.7.5 Hidden Relations

Section 5.4 introduced hidden relations as relations whose relevant traces remain outside an observation regime because they are inaccessible, suppressed, displaced, masked, or routed beyond the observer's evidential field. The present subsection develops hiddenness from the standpoint of partial access. A relation can be hidden from one observer and accessible to another, hidden during one interval and later reconstructed, or visible through consequences while its internal organization remains inaccessible. Hiddenness is therefore relational to an observer-position profile and an observation regime.

This target-relative account avoids treating hiddenness as an intrinsic metaphysical property. A private agreement can be hidden from the public while fully known to its participants. An informal coordination practice can be hidden from an administrative database while directly experienced by workers. A computational dependency can be hidden from users while inspectable by engineers. A historical relation can be hidden during its operation and become partly accessible after archives open. The status of hiddenness can change without the underlying historical event changing.

Hidden relations often reveal themselves indirectly. A pattern of outcomes can be difficult to explain through visible relations alone. Repeated discrepancies among official categories, reported experience, and observed consequences can motivate inference toward an unobserved mechanism. Such inference requires restraint. The presence of unexplained residuals does not identify a unique hidden relation. It provides a reason to widen the compatibility set, seek discriminating traces, examine missing channels, and compare alternative reconstructions.

The distinction among latent, hidden, and merely unrecorded relations should also remain intact. A latent relation is analytically inferred from manifestations without requiring that actors intentionally obscure it. A hidden relation is inaccessible relative to an observation regime, regardless of whether the inaccessibility is deliberate. An unrecorded relation may have been openly visible at the time while leaving weak surviving traces. These conditions can overlap, yet they generate different evidential problems and call for different forms of reconstruction.

Hiddenness can also be institutionally produced without a deliberate decision to conceal. Organizational fragmentation can place mutually relevant records in separate units. Data protection can intentionally restrict access for legitimate reasons. Technical systems can store information in incompatible formats. Informal practice can remain outside reporting categories. Specialized language can make evidence practically inaccessible to outsiders. Treating all hiddenness as deception would therefore obscure the heterogeneous mechanisms through which relational

knowledge becomes unavailable.

5.7.6 Strategic Concealment

Strategic concealment is a narrower case in which an actor, organization, or coordinated group intentionally changes the visibility, accessibility, timing, or interpretability of traces in order to shape what another observer can know. The strategy can involve withholding information, compartmentalizing access, producing selective disclosure, delaying records, routing activity through less visible channels, manipulating categories, or generating misleading traces. The epistemic target is consequently affected by an adversarial or strategic relation between observer and observed.

Simmel's early sociology of secrecy treated differentiated access to knowledge as a constitutive feature of social relations rather than a marginal anomaly (Simmel 1906). GRE extends this insight into an epistemic specification: secrecy and concealment alter the observation relation itself. A researcher, regulator, contractual counterparty, competitor, or affected community may receive an evidential field partly shaped by the target actor's expectations about observation.

Strategic concealment complicates ordinary assumptions about missing data. Absence can result from nonexistence, failed detection, lack of preservation, restricted access, or successful concealment. The evidential meaning of non-observation therefore depends partly on whether the observation regime is robust against strategic behavior. Where actors benefit from remaining unseen, evidence of absence requires stronger knowledge of detection pathways and stronger reasons to believe that relevant traces could not easily have been displaced or suppressed.

Concealment can also be selective rather than comprehensive. An actor may disclose enough information to satisfy a formal requirement while obscuring the relation most relevant to the observer's target. A firm can provide aggregate figures that preserve confidentiality while also limiting inspection of internal distribution. A platform can publish policy descriptions while withholding model details. A political or commercial organization can release favorable records and leave unfavorable episodes difficult to reconstruct. These cases differ normatively and legally, yet they share an epistemic structure in which the observed evidential field has been strategically curated.

The response to strategic concealment should remain evidential rather than presumptive. Suspicion alone does not establish a hidden relation. Researchers can compare independent sources, inspect inconsistencies, analyze incentives for disclosure and concealment, study record-generation procedures, seek traces generated outside the control of the focal actor, and report remaining uncertainty. An adversarial observation setting raises the burden of reconstruction while preserving the requirement that claims remain supported by evidence.

Claim 5.55 (Strategic observability)**.** *When observed actors can anticipate an observation regime and possess meaningful capacity to alter the traces available to that regime, observability becomes partly strategic and should be modeled as a relational condition of evidence production.*

Claim 5.55 extends Section 5.6's account of performativity. Observation need not

merely record a pre-existing evidential field; the expectation of observation can influence which traces are generated, preserved, displayed, displaced, or concealed. The epistemology of GRE therefore requires attention to the interaction between observational design and strategic response.

5.7.7 Temporal Limits of Observation

Observation is temporally situated. An observer encounters a relation during an interval, through traces that have their own durations, delays, retention periods, and rates of decay. Some relations are slow and persistent relative to observation; others are episodic, rapidly changing, or visible only during transition. Temporal position therefore affects which aspects of a relational process can be observed and which must be reconstructed from surviving traces.

Several temporal limits are analytically distinct. First, an observation window can be shorter than the formation or transformation of the target relation. Short windows may then misclassify transient conditions as stable structures or stable structures as isolated events. Second, manifestations can lag behind relational change. An institutional reform can alter practice before aggregate indicators respond, while a financial or administrative record can continue reflecting earlier conditions after the relation has changed. Third, traces can decay or disappear. Informal communication, tacit coordination, and ephemeral digital interactions can leave uneven historical records. Fourth, later observation can benefit from archives and hindsight while losing access to meanings, expectations, and uncertainties that were available to contemporaneous participants.

Temporal access also interacts with recursive representation. A later observer may study a system after earlier classifications, measurements, and interventions have already reshaped it. Present traces then contain historical layers. Some features record earlier relations; some reflect adaptation to prior observation; some result from later reinterpretation or data migration. Reconstructing relational history therefore requires attention to when a trace was produced, when it was recorded, when it became accessible, and whether its meaning changed across those intervals.

The temporal limit of observation should not be answered by privileging either contemporaneous or retrospective knowledge in general. Contemporary observers may possess practical and contextual access unavailable later while lacking knowledge of long-run consequences. Later observers may compare broader trajectories and recover previously inaccessible archives while interpreting the past through categories that emerged afterward. Each temporal position produces characteristic capacities and blind spots.

Proposition 5.56 (Temporal indexing of observational warrant)**.** *A relational claim whose warrant depends materially on the timing, duration, preservation, or retrospective accessibility of evidence should state those temporal conditions as part of its observational scope.*

Proposition 5.56 is especially important for generative inquiry because causal and constitutive processes often unfold across multiple timescales. Evidence gathered at one moment can be adequate for a local state description while remaining weak for a claim about formation, persistence, transformation, or dissolution. Later sections

on relational identity, generative effects, and historical trajectories will develop these temporal problems further.

Section 5.7 therefore places observation inside the relational epistemology rather than outside it. Observation provides access through positions, institutions, instruments, records, and temporal windows whose capacities are uneven and sometimes strategically contested. Partiality can be reduced through distributed observation, provenance-preserving integration, and the widening of access channels, yet it cannot be assessed apart from a specified target and claim. The resulting epistemic discipline is constructive: researchers can identify what their observation regime reaches, where access becomes asymmetric or hidden, how strategic actors may shape visibility, and which temporal limits constrain inference. Section 119 extends this analysis from observer access to the selection of boundaries and scales through which relational systems become objects of knowledge.

5.8 Boundary and Scale in Relational Knowledge

Section 5.7 located observation within a structured relation among epistemic targets, observer positions, access channels, and temporal conditions. The present section addresses a logically subsequent problem: relational inquiry must also specify where an epistemic object begins and ends, and at what scale its organization is being described. Its role is to make boundary and scale selection explicit parts of epistemic warrant. The objective is to distinguish analytical delimitation from claims about the organization of relational reality, while showing how the two can inform one another. The section proceeds through boundary selection, internal and external relations, relational neighborhoods, scale dependence, cross-scale relations, open and permeable boundaries, and boundary uncertainty. The method is comparative and sensitivity-oriented. A relational claim is evaluated not only against available evidence, but also against the boundary and scale conditions under which the evidence has been assembled and the claim has been formulated.

The issue is especially important for GRE because economic objects are rarely isolated by a single natural perimeter. A firm can be analyzed through legal incorporation, ownership, contractual relations, production networks, workplace organization, financing, technological dependencies, ecological inputs, or household effects. A market can be delimited by product categories, geography, institutions, infrastructures, substitution patterns, or regulatory jurisdiction. A household can appear as a consumption unit, a care relation, a property arrangement, a site of labor reproduction, or a node in wider kinship and transfer networks. Each delimitation can be analytically useful, yet each reveals some relations and places others outside the immediate frame.

Systems and network traditions provide several precedents for taking this problem seriously without requiring a single universal ontology of systems. Simon's analysis of complex organization emphasizes hierarchical and near-decomposable structures whose useful description depends on the level at which subsystems and their interactions are examined (Simon 1962). Wellman's structural network perspective similarly directs attention toward patterned relations, clusters, boundaries, and positions

rather than treating social units as self-contained aggregates (Wellman 1983). Multiscale approaches make the dependence on scale even more explicit: Bar-Yam shows that organization and coordinated variation can differ across scales, so a description adequate at one scale can omit structure that becomes salient at another (Bar-Yam 2004). GRE draws from these lineages a limited epistemic conclusion. Boundary and scale are conditions of representation and inference whose adequacy must be assessed relative to the relational target, rather than assumed in advance.

Definition 5.57 (Epistemic boundary)**.** An *epistemic boundary* is a stated rule of inclusion and exclusion that delimits the entities, relations, events, traces, intervals, or environments treated as immediately constitutive of a specified object of inquiry.

Definition 5.57 concerns inquiry rather than ultimate ontology. An epistemic boundary can follow a legally instituted border, an organizational membership rule, a spatial perimeter, a temporal interval, a network criterion, or a researcher-defined analytical cutoff. Some such boundaries correspond closely to durable relational structures; others are provisional devices used to make inquiry tractable. Their epistemic status therefore depends on how they are justified and how sensitive the resulting claims are to alternative delimitations.

5.8.1 Boundary Selection

Boundary selection is the act of specifying which relations and conditions belong to the immediate object of inquiry and which are treated as part of its environment, background, or adjacent systems. Selection is unavoidable whenever the relational field exceeds what can be observed or represented in a single analysis. The epistemic problem is consequently less whether a boundary has been imposed than whether the chosen boundary is appropriate to the claim and whether its consequences for inference remain visible.

A boundary can be selected through several kinds of criteria. Institutional boundaries can follow formal membership, jurisdiction, ownership, or contractual responsibility. Spatial boundaries can follow physical proximity, administrative territory, ecological region, or infrastructural reach. Temporal boundaries can delimit episodes, policy periods, organizational lifecycles, or generational intervals. Relational boundaries can include actors connected through specified types or strengths of relation. Functional boundaries can follow participation in a production process, financial circuit, care arrangement, or knowledge system. These criteria can overlap without coinciding.

Boundary selection therefore already contains a theory of relevance. When an analysis defines a firm by corporate ownership, it gives one kind of relation priority. When it defines the same productive activity through supply-chain dependence, labor coordination, or financial exposure, different relations become constitutive of the object. The issue is not that one description is automatically more real. Each boundary supports different epistemic targets. Problems arise when conclusions obtained under one delimitation are generalized as though the omitted relations were irrelevant to the target claim.

This point is familiar in social–ecological inquiry. Ostrom's framework for social–ecological systems distinguishes connected resource systems, resource units, gover-

nance systems, users, interactions, and outcomes, thereby making the analyzed system depend on a configuration of linked components rather than a single institutional or ecological border (Ostrom 2009). GRE uses this precedent to emphasize diagnostic boundary construction: the research boundary should be chosen so that relations capable of materially affecting the target claim remain inspectable where feasible.

Claim 5.58 (Boundary-relative warrant)**.** *The warrant of a relational claim is partly conditional on the boundary within which evidence is assembled and relations are reconstructed when materially relevant relations cross, constitute, or alter that boundary.*

Claim 5.58 does not imply that every analysis must expand indefinitely. A narrowly bounded study can be rigorous when its target is correspondingly narrow and its exclusions are justified. The claim instead requires alignment between the reach of the conclusion and the reach of the inquiry. A workplace study can make strong claims about a specified organizational process while remaining cautious about effects that depend on household, regulatory, ecological, or transnational relations outside its evidential boundary.

Boundary selection can also be recursive. Once a boundary becomes institutionalized through law, accounting, statistics, or administration, it can affect the relations subsequently observed within it. A legal definition of an enterprise, a statistical labor-market region, or an administrative service area can organize reporting, eligibility, responsibility, and resource allocation. The analytical boundary then interacts with the performative mechanisms developed in Section 5.6. Epistemic inquiry should therefore distinguish a boundary selected for analysis from a boundary that has itself become relationally efficacious.

5.8.2 Internal and External Relations

Once an epistemic boundary is selected, relations can be described as internal or external relative to that boundary. An internal relation connects elements included within the immediate object of inquiry. An external relation connects an included element to an element, condition, or process treated as lying outside that object. These terms are boundary-relative classifications. They do not establish that an external relation is causally weak, ontologically secondary, or economically peripheral.

The distinction is important because many consequential processes are boundary-crossing. A firm's internal production arrangements can depend on external credit, regulation, energy infrastructures, intellectual-property regimes, platform access, household labor reproduction, and suppliers. A household's internal allocation can depend on wage relations, public services, property markets, kinship transfers, and legal status. A local market can be reorganized by financing, logistics, information, or regulatory decisions made elsewhere. Treating these relations as external for one analytical purpose can be entirely legitimate while still requiring them to be reintroduced when the target concerns formation, persistence, vulnerability, or transformation of the bounded object.

The internal–external distinction can also change with analytical purpose. An employment contract may be external to a study of household interaction and internal to a study of labor-market organization. A national regulation may be external to a firm-level process model and internal to an institutional analysis of the sector. The same

relation can therefore occupy different classificatory positions without contradiction when the epistemic target changes.

Simon's account of near-decomposability is useful for specifying when such boundaries can support tractable analysis (Simon 1962). A subsystem can sometimes be studied with relative autonomy when interactions within it are sufficiently stronger or faster than interactions with its environment over the relevant interval. GRE adopts this as a methodological possibility rather than a universal structural law. Near-decomposability is something to establish for the case at hand. Where boundary-crossing relations are strong, rapid, or constitutive, an analysis that treats them as background will have correspondingly narrower warrant.

Proposition 5.59 (Conditional analytical closure)**.** *A bounded relational object can be treated as provisionally closed for a specified claim when omitted boundary-crossing relations are unlikely to alter the inference materially over the relevant interval and scale, or when their effects are explicitly represented as external conditions.*

Proposition 5.59 gives closure an epistemic rather than ontological meaning. Closure is a controlled simplification. Its adequacy can be tested by widening the boundary, introducing external conditions, comparing cases with different environments, or examining whether residual patterns systematically track omitted relations. This treatment permits focused inquiry while retaining sensitivity to relational openness.

The distinction also disciplines causal language. If a bounded model explains an outcome through internal relations while a major external condition remains unexamined, the explanation should be stated at the level supported by the boundary. The model may identify an internal mechanism without establishing that the mechanism is sufficient across environments. Conversely, evidence that a process depends strongly on external relations can itself be a substantive result about the relational architecture of the object.

5.8.3 Relational Neighborhoods

Many relational inquiries do not require a complete system boundary at the outset. They begin from a focal entity, relation, event, or problem and reconstruct a *relational neighborhood*: the set of nearby relations judged relevant under a specified criterion of connection. Neighborhood reasoning is particularly useful when institutional borders are porous, when the target is locally situated within a much larger network, or when the relevant environment cannot be identified through spatial proximity alone.

A relational neighborhood can be defined through direct ties, repeated interaction, shared institutions, dependency, information flow, legal obligation, resource transfer, common infrastructure, or other target-relevant criteria. The meaning of "near" is therefore relational. Two geographically distant actors can belong to a close financial or informational neighborhood, while adjacent actors can remain weakly connected for the target relation. GRE consequently avoids assuming a common metric space for heterogeneous relations. Neighborhoods can be topological, institutional, temporal, semantic, contractual, or functional without being reducible to a single numerical distance.

Network analysis provides a useful precedent because it directs attention toward

patterned ties and positions rather than beginning from categorical aggregates (Wellman 1983). Yet a relational neighborhood in GRE can include conditions that are difficult to represent as pairwise links: legal regimes, infrastructures, shared classifications, historical dependencies, environmental constraints, or distributed fields. The neighborhood concept is therefore broader than a graph-theoretic ego network, although network measures can be appropriate in cases where the relevant relation admits that representation.

Neighborhood construction should also preserve the reason each relation is included. A researcher studying access to housing may include household income, landlord practices, credit screening, zoning, transport, employment location, family transfers, and public assistance because each bears differently on the target. Treating all of these as generic "connections" would lose evidential structure. The neighborhood should instead record relation type, direction where relevant, temporal status, evidential basis, and the pathway through which the relation can affect the claim.

Definition 5.60 (Relational neighborhood)**.** A *relational neighborhood* is a target-relative set of relations and conditions included around a focal epistemic object because their connection is judged materially relevant to describing, explaining, or reconstructing that object under a stated criterion.

Definition 5.60 keeps neighborhood construction open to revision. Initial inquiry may reveal relations whose importance was not known in advance. The neighborhood can then expand, contract, or change composition. This is especially important for exploratory research, historical reconstruction, and generative inquiry, where the relations responsible for an observed manifestation may initially be uncertain.

Neighborhoods can also overlap. A worker can simultaneously participate in workplace, household, credit, care, migration, professional, and platform neighborhoods. A firm can occupy production, finance, legal, innovation, and regional-development neighborhoods. Overlap can become epistemically important when a relation appearing weak in one neighborhood becomes consequential through another. This observation prepares the later treatment of higher-order relations and relational fields in this chapter.

5.8.4 Scale Dependence

Scale specifies the level of aggregation, spatial extent, temporal resolution, organizational depth, or relational granularity at which an object is observed and represented. A change of scale can alter which regularities become visible, which variations are averaged, which actors remain distinguishable, and which relations appear stable. Scale is therefore an epistemic condition of relational description rather than a neutral change in presentation.

Different kinds of scale should remain distinguishable. Spatial scale concerns extent and resolution in space. Temporal scale concerns observation interval and temporal granularity. Organizational scale concerns nested units such as teams, firms, sectors, jurisdictions, or transnational arrangements. Relational scale concerns the granularity at which interactions are represented, ranging from individual ties to clusters, networks, institutions, or distributed conditions. Statistical aggregation can combine these dimensions but should not be treated as equivalent to them.

Bar-Yam's multiscale analysis is relevant because it explicitly relates coordinated variation to the scale at which system behavior is described (Bar-Yam 2004). Simon's account of complex architecture similarly emphasizes nested levels and the analytical importance of identifying subsystems (Simon 1962). GRE uses these resources to support a modest principle: a relational pattern established at one scale does not automatically retain the same form, explanatory role, or evidential meaning at another.

For example, aggregate wage stability can coexist with substantial worker-level turnover and redistribution. A national increase in output can coexist with regional contraction. A firm-level productivity gain can coincide with greater unpaid work elsewhere in the relational system. A stable annual indicator can conceal rapid short-term volatility. A network that appears integrated at sector level can contain fragmented local clusters. None of these examples implies that the aggregate description is false. They show that aggregation changes the object represented and therefore changes the scope of the claim.

Claim 5.61 (Scale-indexed relational claims)**.** *When a relational regularity, dependency, or generative effect varies materially with spatial, temporal, organizational, or relational granularity, its epistemic statement should identify the scale at which the evidence supports the claim.*

Claim 5.61 is intended to limit unmarked scale transfer. A pattern observed among individuals should not be attributed to organizations without further evidence, and an aggregate regularity should not be assigned to constituent actors simply because they participate in the aggregate. Similar caution applies temporally: a short-run association may differ from a long-run trajectory because adaptation, institutional change, and delayed effects enter at different intervals.

Scale selection also affects evidential availability. Fine-grained data can reveal heterogeneous responses while creating privacy, sparsity, or interpretability problems. Aggregate data can reveal long-run structure while suppressing local variation. Historical archives can support institutional-scale reconstruction while leaving individual interaction weakly observed. High-frequency computational traces can provide detailed temporal access while covering only activities mediated by the relevant platform or instrument. There is consequently no universally privileged scale of observation. The relevant scale follows from the target, mechanism, and claim.

5.8.5 Cross-Scale Relations

Scale dependence becomes more demanding when processes at different scales interact. Cross-scale relations connect phenomena represented at different levels of aggregation, temporal duration, organizational depth, or relational granularity. Their epistemic importance lies in preventing scale-specific descriptions from being mistaken for self-contained explanations.

Cross-scale relations can operate in several directions. Local interactions can accumulate, coordinate, or diffuse into patterns visible at broader scales. Broader institutions can condition local possibilities through law, infrastructure, standards, prices, categories, or resource distributions. Slow processes can alter the environment within which faster processes unfold, while repeated fast interactions can gradually transform slower institutional arrangements. These descriptions should

be treated as candidate relational mechanisms whose presence requires evidence, rather than as a generic doctrine of upward or downward causation.

Complex-systems research provides useful examples of multilevel organization without resolving the epistemology for GRE. Levin's treatment of ecosystems as complex adaptive systems emphasizes localized interactions, historical dependence, self-organization, and multiple levels of dynamics (S. A. Levin 1998). Ostrom's social–ecological framework likewise studies connected components across ecological and institutional levels (Ostrom 2009). GRE draws on these works to emphasize that a scale can be analytically coherent while remaining dependent on processes represented elsewhere.

Cross-scale inference requires bridge evidence. If a household-level practice is proposed to contribute to a regional pattern, the analysis should identify the aggregation or transmission pathway. If a regulatory regime is proposed to alter individual behavior, evidence should connect the institutional rule to local incentives, constraints, interpretations, or enforcement. If a long-run structural change is proposed to emerge from repeated short-run interactions, the persistence and accumulation mechanisms should be specified. Merely observing compatible patterns at two scales provides weaker warrant than tracing the relations connecting them.

Proposition 5.62 (Cross-scale bridge requirement)**.** *A claim that attributes a relational or generative connection across scales gains warrant from evidence concerning the pathway that links the scale-specific processes, rather than from correspondence between scale-level patterns alone.*

Proposition 5.62 will become especially important in the later sections on generative relations and attribution of generative effects, where the chapter turns from relational knowledge toward knowledge of generation. For the present section, the point is epistemic: cross-scale interpretation requires an account of mediation between levels, including the possibility that intermediate relations modify, filter, amplify, or dissipate effects.

Cross-scale relations can also generate apparent contradictions that disappear once scale is specified. An institution can be stable at one organizational level while undergoing rapid change in local practices. A policy can increase aggregate access while intensifying exclusion in a subgroup. A network can become more connected globally while some neighborhoods become more isolated. GRE should preserve these differences rather than forcing them into a single scalar verdict. Divergence across scales can itself reveal the relational organization of the process.

5.8.6 Open and Permeable Boundaries

Many economic and social objects have boundaries that organize relations without fully containing them. GRE describes such boundaries as open or permeable when actors, resources, information, obligations, representations, risks, or generative effects can cross the analytical or institutional perimeter in ways relevant to the target. Permeability is therefore compatible with boundary significance. A boundary can structure access and responsibility while remaining traversed by important relations.

The distinction is useful for avoiding two opposite simplifications. One treats a for-

mally defined unit as though relations outside it were merely contextual. The other treats openness as though any delimitation were arbitrary. In practice, legal entities, jurisdictions, households, organizations, markets, and infrastructures often possess consequential boundaries precisely because crossing them is regulated, costly, asymmetric, or selective. The epistemic task is to identify what the boundary organizes and what kinds of relation pass through it.

Permeability can be typed. Resource permeability concerns flows of money, material, labor, energy, or goods. Informational permeability concerns communication, data, knowledge, and signaling. Institutional permeability concerns overlapping jurisdictions, shared standards, delegated authority, or external governance. Social permeability concerns mobility, membership, kinship, professional affiliation, or collective participation. Generative permeability concerns the transmission of capacities, constraints, opportunities, and downstream effects across a boundary. These forms can vary independently.

Open boundaries also matter for attribution. An outcome observed within a bounded unit can partly arise through incoming relations, and actions originating within the unit can generate effects elsewhere. A balance sheet, administrative dataset, or organizational performance indicator may record the internal manifestation while leaving the external transfer weakly represented. For GRE, this is particularly important when later chapters examine value conversion, return, extraction, externalization, and the distribution of generative conditions. The epistemology developed here precedes those normative and substantive analyses by asking whether the relevant boundary-crossing relations are visible at all.

Definition 5.63 (Boundary permeability)**.** *Boundary permeability* is the target-relative extent and manner in which relations, flows, constraints, representations, or effects traverse a specified boundary during the interval relevant to an epistemic claim.

Definition 5.63 does not require permeability to be measured by a single scalar quantity. In some inquiries it can be quantified through flows or network ties. In others it is better represented through legal pathways, institutional interfaces, qualitative process tracing, or historical reconstruction. The analytical representation should follow the type of boundary-crossing relation rather than forcing heterogeneous forms into premature commensurability.

Boundary permeability can itself change historically. Trade rules, migration regimes, data infrastructures, financial integration, technological standards, organizational restructuring, war, environmental disruption, or institutional reform can alter what crosses a boundary and under what conditions. The evidential meaning of a boundary should therefore be indexed to time. A perimeter that once supported relative analytical closure can become substantially more permeable, and a previously open interface can become restricted.

5.8.7 Boundary Uncertainty

Boundary uncertainty arises when the evidence and research purpose remain compatible with more than one plausible delimitation of the epistemic object, or when the significance of boundary-crossing relations remains incompletely known. It dif-

fers from ordinary observational uncertainty. An observer can possess extensive evidence while still face uncertainty about where the object should be delimited for the target claim.

Several sources of boundary uncertainty recur in relational inquiry. Institutional categories can overlap or conflict. Informal relations can extend beyond formal membership. Networks can lack a sharp cutoff. Historical processes can change the relevant perimeter during the period studied. Different relation types can imply different neighborhoods. A target can also be nested within several larger systems, each of which introduces potentially relevant conditions. These cases make boundary selection an object of inquiry rather than a preliminary housekeeping decision.

Boundary uncertainty should be represented rather than hidden behind a single convenient specification. One strategy is comparative delimitation: reconstruct the claim under several plausible boundaries and inspect which conclusions remain stable. Another is progressive expansion: begin from a focal neighborhood and widen the boundary until additional relations cease to change the target inference materially within the practical limits of the study. A third is layered representation: retain several overlapping boundaries corresponding to legal, organizational, spatial, financial, ecological, or social structures. A fourth is explicit residualization: identify relations known to cross the boundary while recording the limits of evidence concerning their effects.

Definition 5.64 (Boundary-sensitivity analysis)**.** *Boundary-sensitivity analysis* is the systematic comparison of a relational claim across two or more defensible boundary specifications in order to identify which components of the inference are robust, which are boundary-dependent, and which require additional evidence.

Boundary-sensitivity analysis in Definition 5.64 is a general epistemic practice rather than a single quantitative technique. It can be implemented statistically, computationally, historically, ethnographically, legally, or through mixed methods. Its value lies in exposing the dependence of a conclusion on delimitation choices that might otherwise remain implicit.

Boundary uncertainty also interacts with scale uncertainty. A researcher can be unsure both about where to draw the perimeter and about the granularity at which the relevant relations should be represented. Expanding the boundary can reveal a broader-scale structure; increasing resolution can reveal local heterogeneity; changing temporal extent can reveal formation or decay that was invisible in a shorter interval. These operations can alter one another. The appropriate response is therefore iterative: boundary and scale specifications should be revised together as evidence about the relational architecture develops.

The resulting epistemic stance is neither boundary skepticism nor boundary realism in a simple sense. Some boundaries are strongly instituted and causally consequential; others are provisional analytical constructions; many combine both features. Their status should be established from evidence about how relations are organized, how the boundary is produced and maintained, which processes cross it, and how conclusions change under alternative specifications. Ontological suspension remains intact because this procedure does not require a final claim about ultimate system boundaries.

Section 5.8 therefore extends the account of partial access by showing that observation always occurs within a delimited and scaled epistemic object. Boundary selection determines which relations enter immediate analysis; internal and external status remains relative to that selection; relational neighborhoods provide flexible local reconstructions; scale changes what patterns become visible; cross-scale claims require bridge evidence; open boundaries direct attention toward traversing relations; and boundary uncertainty calls for sensitivity analysis. These principles prepare Section 120, which turns from the delimitation of relational objects to their identity and persistence through time. Once boundaries and scales are made explicit, the chapter can ask more precisely under what conditions a changing relation should still be treated as the same relation, and when formation, transformation, or dissolution warrants a change of identity claim.

5.9 Identity and Persistence of Relations

Section 5.8 established that relational claims depend on explicit boundaries and scales. The present section addresses the temporal counterpart of that problem: once a relation has been delimited for inquiry, under what conditions may observations at different times be treated as observations of the same relation? Its role is to provide an epistemic account of relational identity and persistence that can accommodate formation, stabilization, transformation, and dissolution without reducing identity to surface similarity or requiring exact continuity of every constituent feature. The objective is to make persistence claims auditable by specifying which properties are treated as identity-bearing, which variations remain compatible with continuity, and which changes warrant a revised relational classification. The section proceeds through identity, persistence through change, formation, stabilization, transformation, dissolution, and historical continuity and discontinuity. The method is criterion-based and historically comparative. Identity is treated as a claim whose warrant depends on the target, scale, temporal interval, and evidential continuity relevant to the inquiry.

The problem is pervasive in economic and institutional analysis. An employment relation can persist while wages, supervisors, tasks, schedules, and contractual terms change. A credit relation can continue through refinancing, restructuring, partial repayment, and changes in collateral. A household relation can persist through changes in residence, income, caregiving arrangements, and membership. An organization can remain legally continuous while its personnel, technologies, ownership, and internal authority are substantially reorganized. Conversely, the continuation of a name, identifier, legal shell, or statistical category can conceal a transformation so extensive that treating the later configuration as epistemically identical to the earlier one becomes misleading for the target claim.

Relational sociology offers an important precedent for treating social objects through unfolding relations rather than through fixed substances. Emirbayer emphasizes processual and dynamic relations as an alternative to substance-centered explanations (Emirbayer 1997). White similarly develops identities and social formations through networks, control efforts, and emergent relational organization (White 2008). Temporal-network analysis makes a related point in formal terms: the

timing and duration of ties matter to what can be inferred from a network, because an aggregate network can conceal whether relations actually coexisted or followed one another (Holme and Saramäki 2012). GRE adopts a narrower epistemic conclusion from these traditions. A claim that a relation persists across time requires a defensible continuity criterion and evidence that the criterion remains satisfied over the interval at issue.

Definition 5.65 (Relational identity criterion)**.** A *relational identity criterion* is an explicit set of target-relative conditions under which relational configurations observed at different times are treated as instances or phases of the same relation for a specified inquiry.

Definition 5.65 makes identity operationally accountable without reducing it to a single universal property. Depending on the target, continuity may be carried by participating relata, institutional recognition, recurring obligations, organized patterns of interaction, causal dependencies, governance rules, shared history, functional roles, or processes that reproduce the relation. Several such features can jointly support identity, and their evidential importance can change with scale. The same historical sequence can therefore support continuity for one target and discontinuity for another without contradiction, provided that the respective identity criteria are stated.

5.9.1 Identity of a Relation

The identity of a relation concerns whether two temporally separated relational configurations should be treated as belonging to one continuing relational history. This is distinct from the identity of the entities participating in the relation. The participants can remain the same while the relation changes, and the relation can sometimes persist while some participants change. A firm can retain a contractual relation with a supplier after personnel turnover. An office can retain an authority relation after the officeholder changes. A household can preserve some relational organization through changes in membership. Conversely, two actors can remain physically or legally identical while trust, obligation, authority, dependence, or exchange between them is transformed.

Identity therefore requires specifying what is being tracked. For a legal inquiry, continuity of a recognized contract or corporate person may carry substantial weight. For an organizational inquiry, recurring authority and coordination patterns may matter more. For a historical inquiry, the continuity of a practice, inherited rule, or institutional lineage may be central. For a study of dependence, the relevant identity may lie in a continuing asymmetry of access or obligation even when the formal instrument through which it is realized changes. The identity criterion should follow the epistemic target rather than ordinary-language naming alone.

The ambiguity of identity language has long been recognized in the social sciences. Brubaker and Cooper show that the term “identity” can combine analytically different phenomena such as categorization, self-understanding, commonality, connectedness, and groupness (Brubaker and Cooper 2000). GRE applies the same discipline to relations. Claims of relational identity should be decomposed into the dimensions of continuity actually being asserted. A statement that “the same employment relation

continued" can refer to legal continuity, organizational role continuity, economic dependence, recurring interaction, or a combination of these. The evidential burden changes accordingly.

Claim 5.66 (Criterion-indexed relational identity)**.** *A relational identity claim is warranted only relative to a stated or recoverable identity criterion whose continuity is supported by evidence over the interval and scale relevant to the claim.*

Claim 5.66 prevents persistence from being inferred from labels alone. A continuing category can be evidence of institutional recognition, but it does not establish continuity of every relation carried under that category. Likewise, changes in terminology do not establish that the underlying relational organization has disappeared. Names, identifiers, and classifications belong to the evidential field and can themselves become causally important, yet their continuity and the continuity of the relation remain analytically distinguishable.

Identity criteria can also be plural. A relation can satisfy one criterion while failing another. A corporation can remain legally identical while its ownership and productive organization change; a long-standing exchange relation can remain economically continuous while its contractual form changes; a political or administrative relation can preserve formal authority while practical compliance weakens. The appropriate response is often a differentiated description rather than a forced binary decision. Researchers can report legal continuity together with organizational transformation, or interactional continuity together with a change in the distribution of power.

5.9.2 Persistence through Change

Persistence concerns the maintenance of sufficient relational continuity across change. It therefore differs from immobility. Relations can persist through variation in intensity, participants, media, rules, manifestations, and surrounding conditions when the identity-bearing organization relevant to the inquiry remains sufficiently continuous. Chapter 4 developed this idea ontologically through dynamic persistence. The present section translates it into an epistemic requirement: evidence of persistence should show how continuity is carried through the observed changes.

Several continuity carriers are common. Recurrent interaction can reproduce expectations and obligations. Legal or administrative recognition can maintain roles across changes in personnel. Records and memory can preserve commitments across interruptions. Infrastructure can sustain access and dependency despite changes in surface practice. Organizational routines can reproduce coordination through turnover. Financial balances, debts, credentials, property claims, or reputational histories can connect earlier and later states. None of these carriers is universally decisive, but each can provide evidence for a particular persistence claim.

Persistence can also be intermittent. Relations may tolerate gaps without losing identity when the system preserves expectations or mechanisms of resumption. A seasonal employment relation can recur after months of inactivity. A dormant credit line can remain a continuing relation despite periods without transactions. A diplomatic, kinship, or professional relation can persist through sparse interaction because status, memory, entitlement, or recognized possibility remains operative. Temporal-network representations are useful here because they distinguish the

existence of ties over time from their collapse into one static aggregate (Holme and Saramäki 2012). GRE extends that insight beyond pairwise ties by asking what is preserved during inactive intervals and what evidentially supports the claim of continued relational availability.

Definition 5.67 (Persistence profile)**.** A *persistence profile* is a structured account of the mechanisms, records, practices, recognitions, dependencies, and temporal recurrences through which a specified relation maintains identity-bearing continuity across an interval of change.

The persistence profile in Definition 5.67 helps distinguish several forms of continuity that can otherwise be conflated. A relation can persist because actors actively reproduce it, because an institution maintains it, because material or technical infrastructure carries it, because historical commitments remain enforceable, or because several of these mechanisms reinforce one another. A profile can also reveal fragility. If continuity depends on one record, one intermediary, or one recurring practice, the relation may be more vulnerable to interruption than its current stability suggests.

Persistence is also scale-sensitive. A supply relation can appear continuous at an annual scale while exhibiting repeated breakdowns at a weekly scale. A labor relation can persist institutionally while everyday supervisory relations change rapidly. A monetary institution can remain historically continuous while its technical settlement processes are replaced. The persistence claim should therefore specify the temporal and relational resolution at which continuity is being asserted. This follows directly from the scale discipline developed in Section 5.8.

5.9.3 Relation Formation

Relation formation concerns the transition from the absence of a specified relation, or from a looser precursor configuration, to a relational organization that satisfies the inquiry's entry criterion. The epistemic challenge lies in identifying when enough evidence exists to treat a relation as having formed. Formation rarely occurs through a single universal threshold. It can arise through a contract, repeated interaction, mutual recognition, technical connection, accumulated dependence, institutional designation, shared practice, or gradual convergence of several conditions.

A legal relation can have a relatively sharp formal beginning, such as the execution of an agreement or conferral of a status. An interpersonal relation may emerge gradually through repeated interaction and expectation. A market relation can form through recurring exchange and the development of mutual responsiveness. A dependency relation can arise incrementally as alternatives disappear or switching costs accumulate. A platform relation can begin with registration, yet economically consequential dependence may develop only after data, reputation, customers, or complementary investments accumulate. The beginning of the formal relation and the beginning of the substantively relevant relation can therefore differ.

Formation should consequently be analyzed through entry conditions tied to the target. An investigator interested in legal obligation may date formation to a recognized act. An investigator interested in practical dependence may require evidence that one party's feasible options or capacities have become materially conditioned by the other. An investigator interested in trust may require a pattern of expectation and

reliance extending beyond a single encounter. These criteria can identify different formation times while referring to one historical sequence.

Definition 5.68 (Relational entry condition)**.** A *relational entry condition* is the target-relative evidential threshold at which a developing configuration is treated as having formed the relation specified by the inquiry.

Definition 5.68 supports historical precision because it separates the earliest precursor from the point at which the relation becomes analytically operative. A negotiation can precede a contract; repeated encounters can precede trust; technical adoption can precede infrastructural dependence; shared classification can precede institutionalized membership. Formation can therefore be reconstructed as a process even when the inquiry uses a specific threshold for dating the relation.

Relational formation can also depend on recursive recognition. Participants may alter their conduct once they understand themselves to be in a relation. Institutions can classify a relationship and thereby create obligations or expectations that further stabilize it. This connects formation to the performative representation developed in Section 5.6. Recognition is neither necessary for every relational reality nor merely descriptive when it enters subsequent conduct. The evidential task is to establish which role recognition played in the specific formation process.

5.9.4 Stabilization

Stabilization concerns the processes through which a newly formed or previously variable relation acquires sufficient regularity, durability, and causal reliability to support stronger persistence claims. Stabilization can occur through repetition, institutionalization, mutual adaptation, infrastructure, law, routines, expectations, sanctions, learning, investments, classification, or accumulated history. It should be treated as a matter of degree and mechanism rather than as a universal stage through which every relation must pass.

Giddens's account of structuration provides one precedent for understanding how social practices can recursively reproduce rules and resources through continued enactment (Giddens 1984). GRE uses this insight cautiously. Reproduction can stabilize a relation when repeated practices make later continuation easier, more expected, more enforceable, or more materially embedded. The existence of repetition alone, however, does not establish the mechanism. Stability can also be maintained by legal coercion, technical lock-in, unequal dependence, organizational routine, shared meaning, or deliberate maintenance.

Stabilization should therefore be evidenced through the carriers that make continuation probable or resilient. Repeated successful coordination can increase confidence that a relation will recur. Complementary investments can raise the costs of exit. Records can preserve obligations across personnel turnover. Standardization can reduce ambiguity in interaction. Institutional recognition can make enforcement available. Shared narratives and categories can provide interpretive continuity. Infrastructure can make some interactions routine while making alternatives costly. Each mechanism leaves different traces and carries different implications for later transformation.

Claim 5.69 (Stabilization through reproduced conditions)**.** *Evidence for relational stabilization is strengthened when the conditions that support continuation are themselves shown to be reproduced, maintained, or renewed across time rather than inferred solely from repeated outcomes.*

Claim 5.69 distinguishes stabilization from mere recurrence. Two actors can transact repeatedly because external circumstances repeatedly bring them together without producing a durable relation between them. Conversely, a stable relation can persist through temporary inactivity when institutions, expectations, or obligations maintain the conditions for resumption. The relevant evidence therefore concerns both observed continuity and the mechanisms that sustain it.

Stabilization is normatively indeterminate. Trust, cooperation, care, exploitation, exclusion, hierarchy, monopoly, debt dependence, and discriminatory practice can all become stable. The epistemic task in the present chapter is to establish whether and how stabilization occurs. Evaluation of the desirability or justice of that stabilized relation requires separate normative analysis. Preserving this distinction is especially important because durable relations can become easier to observe precisely because institutions record and reproduce them, while unstable or marginalized relations may remain less legible.

5.9.5 Transformation

Transformation arises when change affects the identity-bearing organization of a relation sufficiently to require either a qualified continuity claim or a revised relational classification. The analytical difficulty lies between two errors. One error treats every change as evidence of a new relation. The other treats a continuing label or participant set as proof that the relation remains substantially unchanged. A defensible transformation claim compares the earlier and later configurations against the identity criterion, persistence profile, and scale of the inquiry.

Transformation can concern the relata, the structure connecting them, the distribution of capacities and obligations, the governing rules, the mechanisms of reproduction, the medium of interaction, or the relation's position within a wider field. Some changes modify only parameters within an established relation. Others alter the conditions through which the relation operates. A loan can be repriced while remaining the same debt relation; a restructuring can change priority, collateral, counterparties, or enforcement conditions enough to alter the relevant relational architecture. Employment can continue through a new schedule, while a transition from direct employment to platform-mediated contracting can alter authority, risk allocation, visibility, and access to protections.

Historical sociology provides useful resources for identifying consequential transformation. Sewell's analysis of historical events emphasizes that events can transform structures by reorganizing schemas, resources, and subsequent action (Sewell 1996). Pierson's account of path dependence emphasizes how timing, sequence, and self-reinforcing processes can make earlier developments consequential for later possibilities (Pierson 2000). GRE draws an epistemic implication from these approaches: transformation should be reconstructed through changes in the organization and reproduction of the relation, with attention to how earlier configurations condition the

later one.

Definition 5.70 (Relational transformation threshold)**.** A *relational transformation threshold* is the target-relative point at which accumulated or event-driven change alters one or more identity-bearing dimensions sufficiently that an unqualified persistence claim would obscure a materially relevant difference.

The threshold in Definition 5.70 need not be numerically sharp. Historical and qualitative inquiry can identify transformation through converging evidence that the relation now operates through different rules, capacities, dependencies, or reproduction mechanisms. Quantitative inquiry can specify thresholds where measurable structure changes. Legal or administrative inquiry can identify formal reconstitution. The appropriate threshold follows the target and evidence rather than a universal metric.

Transformation can preserve lineage. A relation may be historically continuous in the sense that the later configuration descends from and is causally shaped by the earlier one while differing enough to warrant a new subtype, phase, or category. This is particularly important for institutions. A monetary regime, organization, profession, or governance arrangement can transform repeatedly while preserving records, assets, memberships, obligations, or inherited constraints. Lineage and identity should therefore be reported separately when they diverge.

5.9.6 Dissolution

Dissolution concerns the point at which a relation ceases to satisfy the identity and persistence conditions relevant to the inquiry. Dissolution can be abrupt, gradual, formal, practical, partial, or contested. A contract can terminate on a legally specified date. A trust relation can erode through repeated breaches. A market connection can disappear as transactions and expectations cease. An organizational role can remain formally recorded while losing practical authority. A dependency can weaken as alternatives become available. These cases show that termination of one manifestation of a relation and dissolution of the relation itself can occur at different times.

The epistemic burden of dissolution resembles the problem of evidence of absence developed in Section 5.4. Non-observation after time t does not by itself establish that a relation has ended. Activity can become latent, hidden, intermittent, or inaccessible to the observation regime. A stronger dissolution claim requires evidence that the mechanisms, obligations, expectations, channels, or institutional conditions carrying the relation have ceased, become ineffective, or been replaced in ways that make continuation implausible under the stated criterion.

Formal termination can nevertheless be highly probative when the target relation is institutionally constituted by formal status. Dissolution of a corporation, revocation of a license, cancellation of a contract, or abolition of an office can change rights and obligations immediately. Even then, historical effects can remain. Debts, records, reputations, infrastructures, property distributions, learned routines, and legal precedents can survive the relation that generated them. The end of relational persistence therefore differs from the disappearance of all consequences.

Proposition 5.71 (Residual efficacy after dissolution)**.** *The dissolution of a relation*

does not imply the disappearance of effects generated during its persistence; later relational configurations can remain conditioned by residues of a relation whose own identity criteria are no longer satisfied.

Proposition 5.71 matters for historical explanation. Former institutions can continue to shape distributions, infrastructures, expectations, records, categories, and strategic positions. A relation can therefore cease to exist as a continuing relation while remaining causally relevant through its historical products. This distinction prevents retrospective disappearance: a dissolved relation can have been relationally real and economically consequential during the interval in which it persisted.

Dissolution can also be uneven across scales. A formal organization may dissolve while local networks formed within it continue. A legal relationship may end while social obligations persist. A production network may fragment while technical standards remain shared. An exchange relation may end between two firms while industry-level dependencies continue. Researchers should therefore specify which relational object has dissolved and which inherited relations remain operative.

5.9.7 Historical Continuity and Discontinuity

Historical continuity and discontinuity bring the preceding distinctions together. A longitudinal relational account should be able to state where a relation forms, what stabilizes it, which changes remain compatible with persistence, when transformation becomes analytically consequential, and under what conditions dissolution is inferred. These judgments depend on the identity criterion and scale of inquiry, yet they remain constrained by evidence. Historical reconstruction therefore requires more than chronological ordering. It requires a defensible account of what is continuing across the ordered observations.

Continuity can take several forms. There can be continuity of participants, legal recognition, institutional lineage, infrastructure, practice, causal dependence, memory, or generative conditions. Discontinuity can likewise affect some dimensions while leaving others intact. A revolution can transform formal authority while preserving administrative routines. A merger can terminate corporate identities while preserving production systems and employment relations. A technological transition can replace the medium of exchange while preserving creditor–debtor relations. An institutional reform can preserve names and offices while changing the distribution of decision authority. Historical interpretation should therefore identify the dimensions in which continuity and discontinuity occur.

This multidimensional approach also improves periodization. Historical periods are often constructed around events, reforms, crises, regime changes, or technological transitions. Such boundaries can be useful when they correspond to changes in the relations relevant to the inquiry. They become misleading when the period boundary is treated as if every relation changed simultaneously. Different relational processes can have different turning points, rates of change, and persistence mechanisms. A single chronology may therefore contain overlapping continuities and discontinuities.

Definition 5.72 (Relational continuity judgment)**.** A *relational continuity judgment* is an evidence-based assessment that specifies which identity-bearing dimensions of a

relation persist, transform, or dissolve across a stated historical interval and analytical scale.

Definition 5.72 replaces an undifferentiated same-or-different judgment with an auditable historical account. The judgment can conclude that a relation persists substantially, persists with transformation, divides into several relations, merges with another configuration, becomes dormant, or dissolves while leaving residual effects. These possibilities are analytically distinct and can be supported by different evidence.

Historical continuity can also be path-dependent. Earlier stabilization can alter later transition costs, available categories, institutional expectations, and distributions of capability. Pierson's treatment of increasing returns and path dependence highlights how sequences can become self-reinforcing under specified mechanisms (Pierson 2000). For GRE, this means that persistence is sometimes explained partly by the history of the relation itself. Continued existence can result from accumulated investments, learned coordination, legal precedent, reputational capital, sunk costs, institutional complementarities, or the narrowing of alternatives. A persistence claim should nevertheless distinguish such mechanisms from mere duration. Longevity is evidence of survival; explanation requires evidence about what reproduced the relation.

Discontinuity likewise requires historical specificity. Sewell's event-centered account shows how concentrated episodes can transform structures and later trajectories (Sewell 1996). Other transformations accumulate gradually without a single decisive event. The evidence should therefore be open to both event-driven and cumulative change. A discontinuity claim gains strength when earlier persistence mechanisms cease to operate, when new mechanisms become constitutive, or when the relation's causal capacities and obligations change enough that the previous identity criterion loses adequacy.

Section 5.9 therefore establishes relational identity as a temporally and epistemically disciplined claim. Identity depends on explicit criteria; persistence requires evidence of continuity carriers and reproduction mechanisms; formation requires target-relative entry conditions; stabilization concerns the reproduction of conditions supporting continuation; transformation marks materially relevant change in identity-bearing dimensions; dissolution concerns the failure of persistence conditions while allowing historical residues to remain effective; and historical continuity judgments specify which dimensions persist and which change. This framework prepares the following section's move from single relations through time to knowledge of relations among relations. Once the identity and persistence of individual relational objects can be stated with greater precision, higher-order relational configurations can be reconstructed without assuming that their constituent relations are timeless or internally homogeneous.

5.10 Higher-Order Relational Knowledge

Section 5.9 established criteria for judging the identity, persistence, transformation, and dissolution of individual relations through time. The present section extends

the epistemic problem from relations considered one at a time to configurations in which relations themselves become mutually dependent, collectively organized, nested, typed across several layers, or jointly constituted through interactions involving more than two relata. Its role is to specify what GRE may reasonably claim when the relevant object of knowledge is a relational configuration whose organization cannot be recovered by inspecting isolated dyads alone. The objective is to distinguish several forms of higher-order relational knowledge and to state the evidential requirements appropriate to each form. The section proceeds through relations among relations, collective relations, nested relations, higher-order relations, multilayer relations, hyperrelational configurations, and the limits of higher-order reconstruction. The method is reconstructive and representation-sensitive: higher-order claims are treated as inferential constructions constrained by observed traces, relational identities, boundary and scale choices, and the semantics of the representation through which the configuration becomes epistemically accessible.

Higher-order inquiry is economically important because many consequential arrangements are composed of several relations whose effects depend partly on one another. A household's credit relation may depend on employment income; employment may depend on an organizational authority structure; the organization may depend on financing, supply, and regulatory relations; and each of these may be conditioned by infrastructures that connect many actors at once. Studying each relation separately can identify important local mechanisms while leaving the architecture through which they become mutually reinforcing, substitutable, conflicting, or jointly vulnerable insufficiently reconstructed. Relational sociology and network analysis provide established resources for moving beyond atomized attributes toward patterned relations (Emirbayer 1997; Wellman 1983). GRE extends that epistemic orientation by asking what additional warrant is required when the object of inquiry is itself composed of several identified relations or relation types.

The resulting problem is partly representational. A configuration can be encoded as a set of pairwise ties, a membership structure, a multilayer network, a higher-order interaction, or another relational representation. These encodings illuminate different features and suppress others. A richer representation can therefore increase analytical capacity while also increasing assumptions, data requirements, and opportunities for misclassification. Higher-order knowledge should consequently be judged by correspondence between the target claim, the chosen relational representation, and the evidence available for reconstructing the relevant dependencies.

Definition 5.73 (Higher-order relational knowledge)**.** *Higher-order relational knowledge* is warranted knowledge about configurations in which the epistemic target concerns relations among relations, organized collectivities, nested relational structures, multiple relation types, or interactions whose relevant organization is not exhausted by independently described pairwise relations.

Definition 5.73 is intentionally broad. It does not imply that every economic phenomenon requires a higher-order representation. Pairwise relations remain appropriate when the target can be adequately reconstructed at that level. The definition instead identifies cases in which the evidential object includes organization among relations. The burden of inquiry then shifts from establishing that several relations exist to establishing how they are connected, coordinated, conditioned, or jointly con-

stituted.

5.10.1 Relations among Relations

Relations among relations arise when the existence, operation, strength, interpretation, or consequences of one relation depend materially on another relation. This dependence can be institutional, causal, informational, normative, temporal, or infrastructural. A collateral relation can condition a credit relation; an employment relation can condition eligibility for insurance; a legal relation can authorize an administrative relation; a supply relation can be activated only when a financing relation is maintained. The epistemic target is therefore a dependency between relational objects rather than a new attribute of one participant.

Knowledge of such dependencies requires the constituent relations to be identified with sufficient clarity before their interdependence is inferred. Section 5.9 matters directly here. If the identity or temporal continuity of one relation remains uncertain, a claim about its dependence on another relation inherits that uncertainty. The problem also inherits the boundary and scale conditions developed in Section 5.8: two relations may appear independent within a narrow boundary while sharing an external institutional condition at a wider scale.

A relation among relations should not be inferred merely because two relations share a participant. A worker may have an employment relation and a tenancy relation without the two being materially dependent. Conversely, a dependency can exist even when the relations do not share the same immediate relata. A lender's financing relation with a firm may alter the firm's employment relations with workers through covenant conditions, liquidity constraints, or restructuring decisions. Evidence for a relation among relations therefore concerns a mechanism or patterned dependency connecting relational processes, rather than simple co-occurrence.

Claim 5.74 (Non-aggregation of relational dependence)**.** *The observation of several relations within the same boundary does not by itself warrant a claim about relations among those relations. Higher-order dependence requires evidence that specifies how variation, persistence, activation, interpretation, or consequences in one relational object are connected to another.*

Claim 5.74 places an evidential threshold between relational inventory and relational architecture. Such evidence may come from institutional rules, temporal sequencing, intervention, comparative cases, organizational records, contractual conditions, recurring covariation supported by mechanism, or testimony from participants positioned within the relevant processes. Several forms of evidence can converge. The appropriate combination depends on whether the higher-order claim concerns causal dependence, legal dependence, functional coordination, symbolic coupling, or another specified relation between relations.

The distinction is especially important when relations can substitute for or compensate for one another. A household may respond to reduced wage income through borrowing, intra-household transfers, public benefits, asset sales, or informal support. A firm may replace one supplier, financing source, or distribution channel with another. In such cases, knowledge of the relations individually does not yet explain the resilience or fragility of the larger arrangement. The higher-order target con-

cerns the pattern of substitutability, complementarity, or mutual constraint among relations.

5.10.2 Collective Relations

Collective relations concern relations in which at least one relatum is an organized collectivity whose relational capacities cannot be reconstructed adequately by treating it as a mere list of individual members. Firms, households, associations, agencies, cooperatives, classes of officeholders, and other collectivities can act or be treated as relational participants through rules that organize membership, authority, representation, obligation, and continuity. The epistemic problem is to determine when a collective attribution is warranted and what features of the collectivity carry the relation.

The duality between persons and groups provides a useful precedent for this problem. Breiger shows that membership structures connect interpersonal and intergroup organization rather than reducing one level straightforwardly to the other (Breiger 1974). White's relational sociology similarly treats identities and social formations as emerging through patterned relations and control processes rather than as pre-given substances (White 2008). GRE adopts a narrower epistemic lesson: a collective relation should be reconstructed through evidence about the organization that enables the collectivity to enter, sustain, interpret, or modify the relation.

For example, a corporation may owe a debt even though the individuals working within it change. The relation is carried through legal personality, accounting systems, governance rules, authorized representatives, and organizational continuity. A household may participate in a mortgage relation through jointly organized income, ownership, legal responsibility, or caregiving arrangements. A labor union may bargain with an employer through procedures that authorize representatives to act on behalf of members. In each case, the relation involves individuals, yet the collective relational capacity depends on an organization of those individuals that must itself be evidenced.

Definition 5.75 (Collective relational attribution)**.** A *collective relational attribution* is an epistemic judgment that a specified collectivity may be treated as a relatum because identifiable organizational, legal, procedural, representational, or practical mechanisms enable the collectivity to enter and sustain the relation relevant to the inquiry.

Definition 5.75 guards against two opposite simplifications. The first treats collective entities as self-evident actors whose internal organization is irrelevant. The second reduces every collective relation to a sum of individual ties and thereby loses the mechanisms through which the collectivity persists, represents itself, and exercises relational capacities. A warranted account can move between these levels while specifying which evidence supports the collective attribution.

Collective relations also require attention to internal disagreement. A collective can enter a relation without all members sharing the same preferences, knowledge, or benefits. Organizational authorization, voting, hierarchy, delegation, legal representation, custom, or coercion may generate the effective collective action. The existence of the collective relation therefore does not establish internal consensus. GRE

should keep the external relation and the internal relations that constitute collective agency analytically separable, even when they are mutually consequential.

5.10.3 Nested Relations

Nested relations occur when a relation is organized within, enabled by, constrained by, or constitutive of a wider relation or relational arrangement. The nesting can be organizational, institutional, legal, spatial, temporal, or functional. A supervisory relation can be nested within an employment relation; an employment relation can be nested within an organizational arrangement; the organization can be nested within a supply regime, regulatory order, or ownership structure. Nesting therefore concerns relational containment or dependency across analytically distinguishable levels rather than mere physical inclusion.

The epistemic value of nesting lies in showing that local relations often inherit conditions from wider arrangements while retaining locally specific mechanisms. A supervisor's authority over an employee can depend on an employment contract and organizational office, yet the concrete exercise of authority can vary substantially by team, task, workplace, and historical moment. A transaction conducted within a platform can inherit platform rules, ranking systems, payment infrastructures, and dispute procedures while remaining a distinct exchange between participants. Knowledge at one level may therefore condition interpretation at another without determining every local outcome.

Nesting should be specified rather than assumed from organizational diagrams or administrative labels. Formal hierarchy provides one source of evidence, but practical relations can cross or circumvent formal nesting. Informal advice networks can connect units that are administratively separate. Contractors can be economically integrated into production while remaining legally external. Family, employment, ownership, and debt relations can overlap without forming a single neat hierarchy. The relevant question is which wider relation changes the conditions under which the nested relation exists or operates.

A useful reconstruction identifies at least three elements: the nested relational object, the wider relational object, and the mechanism connecting them. The mechanism can involve authorization, resource dependence, rule inheritance, infrastructural access, monitoring, sanction, identity, or another specified pathway. This structure helps prevent scale labels such as "micro," "meso," and "macro" from doing explanatory work by themselves. Nesting is established through the relation between levels, not simply by assigning them names.

Nested relations can also be recursive. A local relation can contribute to reproducing the wider arrangement that conditions it. Employment relations reproduce organizations through labor and coordination; organizations contribute to industries and institutional orders; those wider orders influence the terms under which employment is organized. Such recursion does not erase level distinctions. It makes the epistemic task more demanding because evidence must track both downward conditioning and upward contribution without presuming that one direction exhausts the relation.

5.10.4 Higher-Order Relations

The term *higher-order relation* can be used more narrowly than higher-order relational knowledge. It refers here to a relation whose relata include one or more relations or relational configurations. The objects connected by the higher-order relation are therefore themselves relationally constituted. Examples include a legal rule that subordinates one contractual relation to another, a governance arrangement that coordinates several organizational relations, or a dependency in which the continuation of one relational configuration conditions another.

Definition 5.76 (Higher-order relation)**.** A *higher-order relation* is a target-relative relation in which at least one relatum is itself an identified relation or relational configuration, and for which evidence supports the claimed connection among those relational objects.

Definition 5.76 distinguishes higher-order relations from ordinary pairwise ties between persons or organizations. The distinction concerns the level at which the epistemic target is specified. A bank can have a contractual relation with a firm; that is a first-order relation at the chosen level. A covenant linking continuation of that financing relation to specified debt ratios, ownership conditions, or other financing relations can create a higher-order dependency among relational arrangements. Similarly, a collective-bargaining framework can regulate relations between workers and employers while itself depending on legal recognition and organizational representation.

Higher-order claims can reveal architecture that disappears when all relational objects are flattened into one network of undifferentiated edges. White, Boorman, and Breiger's blockmodel work illustrates how multiple networks can be used to identify roles and positions from patterned relational structure rather than from isolated attributes (White et al. 1976). The broader epistemic lesson is that relational organization can be expressed through recurring configurations among ties and positions. GRE should nevertheless distinguish a formally detected pattern from the stronger claim that the pattern corresponds to a substantively meaningful higher-order relation. Interpretation requires domain knowledge and evidence about the mechanisms represented by the formal structure.

Higher-order relations can also carry asymmetries that are invisible at the first-order level. Two contractual relations may each appear bilateral while one is institutionally subordinate to the other. Several apparently independent exchange relations may be coordinated through a common platform rule. Separate organizational relations may be jointly conditioned by ownership or financing arrangements. The higher-order reconstruction becomes warranted when the evidence shows that the relations' terms, continuation, or consequences are linked through such an organizing mechanism.

5.10.5 Multilayer Relations

Multilayer relational analysis becomes useful when a system contains several distinguishable types of relations, contexts, or connectivity structures whose interaction matters to the target claim. Kivelä and colleagues synthesize a formal literature on

multilayer networks that includes multiplex relations, interconnected networks, and other settings in which nodes and links are organized across several layers (Kivelä et al. 2014). For GRE, the epistemic importance of this literature lies in making relation type and interlayer connection explicit rather than collapsing heterogeneous ties into a single undifferentiated network.

An economic configuration can contain ownership, employment, credit, supply, information, kinship, legal, and administrative relations among overlapping sets of actors. These relations can differ in direction, duration, institutional form, observability, and causal capacity. Aggregating them into one edge set can create false equivalence. Keeping every layer fully separate can produce the opposite problem by obscuring interdependence. Multilayer reconstruction therefore requires both layer-specific semantics and evidence about connections across layers.

Definition 5.77 (Multilayer relational reconstruction)**.** A *multilayer relational reconstruction* is an evidentially supported representation in which distinct relation types or relational contexts are modeled separately and the mappings or dependencies connecting those layers are specified according to the epistemic target.

The definition emphasizes semantics because a layer is an analytical representation, not an ontological domain established merely by being drawn separately. One layer may represent legal ties, another financial exposures, and another information flows. Their separation is justified when the distinctions matter to the target and are supported by the evidence. Interlayer connections then require their own interpretation. Shared actors can connect layers, but cross-layer dependence may also arise through rules, infrastructures, or institutions that connect otherwise different sets of relata.

Multilayer analysis can improve epistemic precision in several ways. It can identify actors whose prominence differs by relation type; distinguish redundancy within one layer from dependence across layers; reveal whether apparent resilience in one network depends on fragility in another; and examine whether a relation that seems peripheral in one domain becomes central because it connects layers. These possibilities are particularly relevant to GRE because value, resources, authority, information, and capabilities may circulate through different relational channels whose conversion interfaces matter economically.

The advantages also create new risks. Layer definitions can reify administrative categories, impose sharp distinctions on relations that are historically entangled, or multiply degrees of freedom beyond what the evidence supports. A multilayer model can appear richly realistic while remaining poorly identified. The number of layers should therefore follow the analytical need and evidential capacity rather than a presumption that more layers necessarily yield better knowledge.

5.10.6 Hyperrelational Configurations

Some interactions involve several relata jointly in ways that lose important information when decomposed into independent dyads. Contemporary higher-order network research formalizes this problem through hypergraphs, simplicial complexes, and related representations of interactions involving groups of three or more units (Battiston et al. 2020). GRE uses the broader term *hyperrelational configuration* for

epistemic targets in which the jointly constituted interaction matters to the economic relation being reconstructed.

A multilateral contract provides a simple illustration. If the obligations of three parties are defined jointly, replacing the arrangement with three bilateral contracts may misrepresent the conditions under which obligations arise. A consortium can allocate authority, contribution, and return through rules that operate at the level of the group. A clearing arrangement can connect several exposures through netting procedures whose consequences cannot be inferred by evaluating each gross bilateral exposure independently. A household decision can likewise involve joint obligations and dependencies that are altered when represented as separate pairwise ties.

Definition 5.78 (Hyperrelational configuration)**.** A *hyperrelational configuration* is a relational object in which three or more relata participate in a jointly constituted interaction and where decomposing that interaction into independent pairwise relations would omit information material to the target claim.

Definition 5.78 distinguishes hyperrelationality from higher-order relations in Definition 5.76. A higher-order relation relates at least one relational object to another object; a hyperrelational configuration concerns a joint interaction among several relata at the same specified analytical level. The two can coexist. A multilateral arrangement can itself become a relatum in a higher-order relation with a legal, financial, or administrative structure.

The epistemic threshold for hyperrelational reconstruction is correspondingly demanding. Evidence should establish that the joint participation is constitutive rather than merely simultaneous. Co-presence at an event or membership in the same organization does not by itself establish a hyperrelation. Relevant evidence can include joint rules, multilateral obligations, collective decision procedures, shared technological protocols, coordinated production processes, or outcomes that depend on the configuration of several participants together.

Pairwise decomposition can remain useful as an approximation when the omitted joint structure is weak relative to the target. The choice therefore remains target-relative. A bilateral exposure analysis can be appropriate for one question even when a multilateral representation is needed for another. GRE should treat the representational gain from hyperrelational modeling as an empirical and analytical question rather than as a general hierarchy in which higher-order formalisms automatically supersede simpler ones.

5.10.7 Limits of Higher-Order Reconstruction

Higher-order reconstruction increases what relational inquiry can represent, yet it also amplifies the epistemic limits developed throughout this chapter. Observation remains partial; relations can be hidden or strategically concealed; boundaries and scales remain consequential; relational identities can change through time; and representation can be performative. A higher-order model inherits these uncertainties from its constituent relations and adds uncertainty about how those relations are connected.

One limit is combinatorial. As the number of relation types, temporal states, nest-

ing levels, interlayer mappings, and multi-party interactions grows, the number of possible configurations expands rapidly. Richer representations can therefore outrun the capacity of available evidence to discriminate among plausible reconstructions. Computational tractability can alleviate some processing constraints, yet it does not create observations that were never available. A large model can enumerate possibilities while leaving the substantive configuration underdetermined.

A second limit concerns representation dependence. Pairwise networks, multilayer networks, hypergraphs, organizational charts, legal schemas, and qualitative relational maps each foreground different structures. Their outputs are therefore conditional on decisions about what counts as a relatum, what counts as a relation, which relation types remain distinct, how time is represented, and where boundaries are placed. Representation comparison becomes part of higher-order epistemic discipline. Robustness across several plausible encodings can strengthen confidence, while divergence can identify precisely where the conclusion depends on representational choice.

A third limit concerns inferential propagation. If evidence for one constituent relation is weak, higher-order claims relying on that relation should reflect the inherited uncertainty. Confidence should not increase simply because uncertain relations are assembled into an elaborate structure. The same principle applies to classification error. A misidentified legal relation, organizational boundary, or participant can alter several inferred dependencies at once. Provenance from Section 5.7 therefore becomes especially important when higher-order reconstructions integrate heterogeneous data sources.

Proposition 5.79 (Inherited uncertainty in higher-order reconstruction)**.** *When a higher-order relational claim depends on uncertain constituent relations or uncertain mappings among them, the warrant for the higher-order claim should remain conditional on those uncertainties and should identify which conclusions are sensitive to alternative admissible reconstructions.*

Proposition 5.79 does not require a single universal numerical uncertainty measure. Depending on the inquiry, uncertainty can be represented through alternative cases, confidence intervals, posterior distributions, sensitivity analyses, competing qualitative reconstructions, provenance grades, or explicit unresolved ambiguities. The common requirement is that complexity should not conceal fragility of inference.

A fourth limit concerns causal interpretation. Structural position, clustering, interlayer centrality, or membership in a higher-order motif can describe relational organization without by themselves establishing why an outcome occurred. Formal structure can generate hypotheses about mechanisms, exposure, coordination, or vulnerability. Causal claims require the additional evidential work appropriate to the mechanism and historical context. This restraint is especially important for GRE because later sections will distinguish relational knowledge from attribution of generative effects.

A fifth limit concerns ontological overreach. The success of a higher-order representation does not establish that economic reality is ultimately a network, hypergraph, multilayer system, or any other formal object. Under ontological suspension, these representations remain tools for disciplined access to relational organization.

Their value depends on explanatory, descriptive, predictive, comparative, or practical performance relative to specified targets and evidence.

Higher-order reconstruction therefore expands the epistemic vocabulary of GRE without establishing a universal representational hierarchy. Relations among relations identify dependencies among relational objects; collective relations concern organized collectivities with evidenced relational capacities; nested relations connect local and wider relational arrangements; higher-order relations take relations or relational configurations as relata; multilayer reconstruction preserves meaningful heterogeneity among relation types while specifying interlayer connections; and hyperrelational configurations capture jointly constituted interactions that materially exceed pairwise decomposition. Each construction requires evidence matched to its target and remains bounded by observation, history, scale, representation, and uncertainty.

Section 5.10 also marks a limit of configuration-based reconstruction. Even a richly specified set of pairwise, nested, multilayer, and hyperrelational relations can leave some distributed conditions insufficiently represented when effects depend on positions within a broader relational environment rather than on identifiable ties alone. The next section develops the epistemology of relational fields to examine that problem. Its task is to ask what kind of evidence can warrant claims about distributed relational conditions while preserving the same commitments to explicit boundaries, representation-sensitive inference, and ontological restraint established here.

5.11 Epistemology of Relational Fields

Section 5.11 extends the epistemology developed in Sections 5.7–5.10 from identifiable relations and higher-order configurations to distributed relational conditions. Its role is to clarify when the language of a *field* adds epistemic content beyond a dense collection of pairwise ties, a shared context, or an aggregate regularity. The section develops this problem in seven steps. It first distinguishes pairwise relations from distributed conditions, then specifies evidential requirements for field claims, reconstructive procedures, the relation between local position and distributed structure, overlapping fields, field boundaries, and limits of field attribution. The discussion treats field representations as target-relative analytical constructions under ontological suspension. Its method is therefore comparative and evidential: alternative representations are assessed by the differences they make to warranted description, explanation, and later generative attribution.

Field language already has several established meanings in the social sciences. Bourdieu and Wacquant formulate fields through relational positions, forms of capital, and structured struggles, while Martin analyzes field theory more generally through explanations in which regularities in action depend on positions relative to others (Bourdieu and Wacquant 1992; Martin 2003). Fligstein and McAdam develop strategic action fields as mesolevel social orders that can themselves be embedded in wider fields (Fligstein and McAdam 2012). GRE can learn from these traditions without identifying its own relational-field vocabulary with any one of them. The present task is narrower: to establish the epistemic conditions under which a distributed

relational environment becomes a warranted object of inquiry.

5.11.1 Pairwise Relations and Distributed Conditions

Pairwise relational analysis represents a system through identifiable relations between specified relata. This representation can be highly informative. Credit relations connect lenders and borrowers; employment relations connect workers and employers; supply relations connect firms; legal relations connect rights holders, duty bearers, offices, and institutions. Sections 5.4–5.10 have already developed the epistemic requirements for identifying such relations, locating them within boundaries and scales, tracing their persistence, and reconstructing higher-order configurations.

Some targets, however, depend materially on distributed conditions that are not adequately localized in any single pairwise relation. A firm's access to financing can depend on its position within a wider credit environment, prevailing classifications of risk, regulatory expectations, sectoral conventions, and the distribution of liquidity across institutions. A worker's bargaining possibilities can depend on labor-market tightness, occupational segmentation, legal recognition, organizational density, and expectations held by multiple actors who may never enter direct interaction with that worker. A price can be locally negotiated while the range of plausible negotiation is conditioned by distributed information, standards, infrastructures, institutional rules, and the positions occupied by other participants.

Network analysis already demonstrates why structural position can matter beyond individual attributes. Wellman's structural perspective emphasizes patterned relations, clusters, boundaries, dependency, and network position (Wellman 1983). Granovetter's analysis of embeddedness likewise shows that economic action is situated within ongoing structures of social relations (Granovetter 1985). A relational field extends the epistemic problem one step further when the target claim concerns a distributed condition whose effects depend on an actor's or relation's position within an organized environment and whose relevant organization cannot be exhausted by enumerating direct ties.

Definition 5.80 (Relational field)**.** A *relational field* is a target-relative reconstruction of a distributed relational condition in which the position, capacities, constraints, expectations, or possible transformations of relevant relata depend materially on an organized environment of relations, positions, rules, resources, classifications, or other relationally efficacious conditions whose joint significance exceeds the description of isolated pairwise ties.

Definition 5.80 makes three commitments. First, a field is target-relative. A configuration can be field-relevant for one question and adequately represented through local relations for another. Second, field attribution concerns distributed organization, not merely large size or high density. A network with many edges can remain fully tractable as a set of relations if the target depends primarily on those ties. Conversely, a relatively sparse configuration can exhibit field-like properties when positional differences, common institutional constraints, or distributed expectations materially condition local possibilities. Third, the definition remains compatible with ontological suspension. The field may be represented through physical, institutional, legal, symbolic, informational, organizational, or other coordinates without establish-

ing that one formal vocabulary captures the ultimate constitution of the economic world.

The distinction between a dense network and a relational field is therefore epistemic rather than cosmetic. Density describes one property of a network representation. A field claim adds the proposition that distributed organization is relevant to the target and that position within that organization changes what can occur locally. The additional burden of evidence follows from this stronger claim.

Distributed conditions can also operate through absence, scarcity, concentration, or patterned non-connection. A peripheral supplier can face limited alternatives because potential buyers are concentrated elsewhere in the field. A household can encounter credit constraints because institutions classify its location or income profile within a broader risk environment. A profession can reproduce opportunity differences through expectations and credential structures that are widely distributed across organizations. In these cases, the relevant condition is partly expressed through relations that are possible, foreclosed, weak, indirect, or institutionally mediated. Field reconstruction therefore concerns the organization of relational possibilities as well as observed ties.

5.11.2 Evidence for Fields

A field claim requires evidence that distributed organization contributes information that local relations or aggregate attributes leave unexplained. The evidential task is especially demanding because many patterns that appear field-like can also arise through compositional differences, common external causes, selection processes, institutional rules applied uniformly, or correlated responses to a shared event. Field language becomes analytically useful when the distributed relational organization can be identified with enough specificity to discriminate among these possibilities.

Several evidential forms can contribute to such warrant. Recurrent position-dependent differences provide one source. If actors occupying systematically different locations within a reconstructed relational environment encounter different constraints, opportunities, expectations, or response patterns, the evidence can support a field interpretation when relevant alternative explanations are addressed. Historical evidence provides another source by showing how positions, rules, resources, and classifications were assembled and reproduced. Organizational records, legal documents, transaction traces, network data, ethnography, interviews, administrative classifications, and computational reconstructions can each reveal parts of the distributed condition. The evidential strength comes from convergence among sources whose biases and access conditions differ, rather than from the quantity of traces alone.

Field evidence can also arise from patterned responses to changes that propagate through an environment. A regulatory revision may alter behavior differently across positions; a liquidity shock can have heterogeneous effects according to financing structures; a platform rule can reorganize opportunities across categories of participants; a new credential can shift the value of positions throughout an occupational domain. Such patterned variation can reveal distributed structure, although the stronger causal interpretation of propagation remains a later problem for the

chapter's subsequent treatment of generative relations and attribution.

Claim 5.81 (Evidential convergence for field attribution)**.** *Warrant for a relational-field claim is strengthened when heterogeneous evidence supports both the existence of a distributed relational organization and the target-relevant significance of positions or dependencies within that organization, while plausible aggregate and common-cause alternatives receive explicit examination.*

Claim 5.81 separates two evidential tasks. The first concerns reconstruction of the distributed organization itself. The second concerns the significance attributed to that organization for the target claim. A formally elegant map can satisfy the first task only partially and leave the second unresolved. Conversely, repeated local reports of constraint can establish an economically important phenomenon while leaving the wider field architecture underdetermined. Field epistemology becomes stronger when the two forms of evidence constrain one another.

The distinction between field effect and aggregate correlation is central. Suppose firms with a certain attribute exhibit similar outcomes. An aggregate account may explain the pattern through the attribute itself. A field account requires additional evidence that the outcome depends on relations, positions, distributed rules, or organized expectations surrounding those firms. Similarly, geographic clustering can reflect shared exposure to infrastructure or policy without establishing a relational field. Spatial proximity becomes field-relevant when the evidence shows that position within a distributed relational environment contributes to the pattern under investigation.

Field claims also benefit from negative and contrastive evidence. If a proposed field boundary predicts similar conditioning within a domain and weaker conditioning beyond it, observations that violate this pattern can reveal a misspecified boundary. If two positions treated as equivalent show systematically different possibilities, the positional reconstruction may require revision. If field language produces no observable or interpretive difference relative to a simpler representation, its epistemic contribution remains limited. A field concept earns analytical work by supporting distinctions that can be investigated.

5.11.3 Field Reconstruction

Field reconstruction is an inverse problem. Researchers encounter manifestations, traces, records, classifications, interactions, outcomes, and situated testimony, then infer a distributed organization that could have contributed to them. The non-invertibility developed in Section 5.2 therefore remains active. Several field reconstructions can be compatible with the same local observations, especially when relations are partially observed, boundaries are uncertain, or institutional categories already shape the traces from which the field is inferred.

A disciplined reconstruction begins with a specified target. The analyst identifies the phenomenon whose distributed conditioning is at issue, the relevant relata, candidate relations and institutional conditions, the temporal interval, and the boundary and scale assumptions inherited from Section 5.8. The reconstruction then asks which dimensions of position appear consequential for that target. These dimensions can include access to resources, legal status, organizational authority, dependence, in-

formation, reputation, credit, classification, spatial location, or other domain-specific conditions. Their selection should be justified by evidence and theory rather than imported from a preferred formal model.

Definition 5.82 (Field reconstruction)**.** A *field reconstruction* is an explicit, revisable representation of a target-relevant distributed relational environment that specifies the relevant relata, relations or conditioning structures, positional dimensions, boundaries, temporal scope, evidential sources, and uncertainties used to support claims about field organization.

Definition 5.82 places provenance at the center of the reconstruction. A field map assembled from administrative data can inherit institutional classifications. A map reconstructed from interviews can inherit unequal access, standpoint differences, strategic presentation, and memory limitations. Transaction data can privilege recorded exchanges over informal relations and unrealized possibilities. Computational network or embedding methods can detect patterned structure while depending strongly on data construction and representation choices. Section 5.5 therefore remains relevant: the reconstructed field is itself a representation whose relation to relational reality requires evaluation.

Field reconstruction can combine formal and interpretive methods. Blockmodeling, for example, identifies positions and roles from patterned relations across networks (White et al. 1976); field-theoretical traditions can emphasize structured positions, resources, struggles, and the logic of a domain (Bourdieu and Wacquant 1992; Martin 2003); strategic-action-field analysis can emphasize mesolevel orders and relations among fields (Fligstein and McAdam 2012). GRE can use these traditions as methodological resources while preserving distinctions among their objects and assumptions. Similar diagrams or terms across traditions do not establish theoretical identity.

Reconstruction should also compare plausible alternatives. One representation may organize a labor market primarily through firms and workers; another may foreground occupations, credentials, unions, legal categories, households, migration status, or platform infrastructures. Each can reveal relations hidden by the others. The appropriate comparison is target-relative: which representation preserves distinctions needed for the claim, which assumptions it introduces, which traces support it, and how sensitive the conclusion is to alternative admissible constructions.

Field reconstruction is therefore iterative. Local observations can suggest a wider distributed structure; the proposed field can then guide new observations; new evidence can alter positions, boundaries, relation types, or the field hypothesis itself. This recursion also creates the performative possibility developed in Section 5.6. Administrative, legal, statistical, or algorithmic field representations can be adopted by organizations and begin to alter the relational environment they describe. Provenance should consequently record when a representation remains primarily analytical and when it becomes part of the field's subsequent organization.

5.11.4 Local Position and Distributed Structure

Field epistemology links local observations to distributed structure through the concept of position. Position is not simply an intrinsic attribute attached to an actor. It

is a relational characterization of where an actor, organization, relation, or configuration stands with respect to relevant structures of dependence, access, authority, classification, distance, substitution, or other field dimensions. Martin's account of field theory highlights precisely this explanatory move: regularities are related to positions vis-a-vis others rather than reduced to isolated properties (Martin 2003).

Definition 5.83 (Field position)**.** A *field position* is a target-relative characterization of a relatum's location within a reconstructed distributed relational environment, defined by the dimensions of relation, dependence, access, resource distribution, classification, or institutional organization that are evidentially relevant to the inquiry.

The same local relation can therefore carry different implications at different field positions. A supplier contract can have one economic significance when alternative buyers are abundant and another when a dominant purchaser organizes access to the market. A debt contract can generate different vulnerabilities for borrowers occupying different income, collateral, legal, or refinancing positions. An employment relation can provide different bargaining possibilities depending on occupational demand, legal protections, union organization, household reserves, migration constraints, and available alternatives. Pairwise descriptions remain accurate at their own level while field position changes the conditions under which those relations operate.

Position also permits epistemic movement in the opposite direction. Local observations can become evidence for distributed structure when similar position-dependent patterns recur across cases. Testimony from participants located in several parts of a field can reveal differences in opportunity, expectation, or constraint. Transaction traces can show substitution patterns or dependencies. Institutional rules can explain why nominally similar actors occupy different practical positions. The inferential movement remains cautious because local evidence can support several field reconstructions. Distributed structure is inferred through patterned comparison, provenance, and alternative representations rather than read directly from a single local case.

Position should also be distinguished from rank. Some fields contain explicit hierarchies, yet positional structure can be multidimensional. An actor can have high legal authority and low informational access, strong reputation and weak liquidity, central connectivity and limited substitutability, or privileged classification in one institutional setting and constrained access in another. Compressing these dimensions into a single ranking can erase the particular mechanisms relevant to the target. Field reconstruction should preserve multidimensional positions whenever the evidence indicates that the dimensions operate differently.

A further complication arises because local action can modify distributed structure. Coordinated entry by firms, legal mobilization by workers, widespread adoption of a standard, changes in lending practice, or new classificatory technologies can alter the positions and dependencies that constituted the field. Position is therefore historically indexed. A field map should identify its temporal scope and remain open to structural change, consistent with the identity and persistence principles developed in Section 5.9.

5.11.5 Overlapping Fields

Economic actors frequently participate in several distributed relational environments at once. A university can occupy fields of higher education, research funding, labor, professional credentialing, real estate, public administration, and international mobility. A household can simultaneously participate in labor, housing, credit, care, education, welfare, kinship, and migration arrangements. A firm can occupy production, finance, regulation, technology, logistics, and professional domains whose boundaries and positional structures only partly coincide. Field overlap is therefore an ordinary epistemic problem rather than an exceptional complication.

Definition 5.84 (Field overlap)**.** *Field overlap* occurs when a relatum, relation, resource, classification, institution, or conditioning process participates materially in two or more distinguishable relational fields relevant to the inquiry, such that the fields' positions, rules, or trajectories can interact in the target phenomenon.

Overlap matters because an observation that appears anomalous within one field can become intelligible when another field is included. A firm may possess a peripheral position in a production network while occupying a privileged financial position. A worker may have scarce occupational skills while facing legal constraints on mobility. A household can appear income-secure while remaining vulnerable through housing, care, or debt relations. These examples do not require collapsing the fields into one larger undifferentiated structure. The epistemic gain comes from identifying where their conditions intersect.

Overlapping fields should also remain distinct from multilayer representation in Section 5.10. A multilayer model distinguishes types of relation or connectivity within a system. Field overlap concerns partially distinct distributed environments whose membership, boundaries, positional dimensions, and organizing processes can differ. A multilayer representation can be used to model overlapping fields, yet the formal representation and the substantive field claim remain separate epistemic objects.

Interactions among fields can take several forms. Conditions can reinforce one another when advantageous positions in finance facilitate entry into production or when professional recognition increases organizational authority. Conditions can conflict when a legally authorized practice encounters professional opposition or when financial incentives undermine another field's institutional norms. Resources, classifications, standards, and actors can travel across fields, although their meaning and efficacy can change during the transfer. Fligstein and McAdam's account of strategic action fields explicitly emphasizes embedding and inter-field relations, providing one established approach to such problems (Fligstein and McAdam 2012). GRE can use this as a comparative resource while retaining its own target-relative epistemic vocabulary.

Field overlap creates an attribution problem as well. An observed regularity may be incorrectly assigned to the most visible field when the operative conditioning is distributed across several. Research design should therefore track cross-field provenance where evidence suggests that positions or rules interact. Robustness can be tested by comparing reconstructions that separate, combine, or differently partition candidate fields. Divergent conclusions identify where field specification materially affects the epistemic result.

5.11.6 Field Boundaries

Field boundaries specify the domain within which distributed relational conditioning is reconstructed. The boundary problem developed generally in Section 5.8 becomes more demanding here because field claims frequently rely on interactions that cross organizational, legal, geographic, or classificatory borders. A field boundary therefore needs both an analytical rationale and evidence about the reach of the conditioning process relevant to the target.

Some boundaries are institutionally explicit. Licensing regimes, legal jurisdictions, organizational membership rules, trading venues, professional associations, platform access rules, or funding programs can create entry conditions and structured differences between participants and non-participants. Such boundaries can themselves possess relational reality when they persist and causally affect access, obligation, recognition, or opportunity. Other field boundaries are more permeable. Information, capital, standards, reputations, labor, and classifications can travel across nominal domains, making the effective relational field wider than the formal institution.

Definition 5.85 (Field-relevance boundary)**.** A *field-relevance boundary* is the provisional limit of a field reconstruction beyond which additional relata or relational conditions cease to make a material evidential difference to the specified target at the chosen scale and temporal interval, subject to revision when new evidence changes that assessment.

Definition 5.85 makes boundary selection an empirical and analytical judgment. The criterion concerns material relevance to the target, not mere formal membership. A supplier located outside a jurisdiction can remain field-relevant when its behavior changes local bargaining possibilities. A distant funding institution can shape research priorities through grant structures. An external regulatory standard can influence domestic production through certification requirements. Conversely, formal members can be peripheral to a particular target when their participation has little bearing on the distributed condition under investigation.

Boundary-sensitivity analysis is therefore especially important for fields. Researchers can compare nested or alternative boundaries and examine which positional claims, regularities, or inferred dependencies remain stable. If a result changes substantially when a plausible set of external actors or relations is included, the field claim should report that dependence. If several boundary specifications yield similar positional conclusions, confidence in the reconstruction can increase even though the boundary remains analytically constructed.

Temporal boundaries require comparable care. Fields can form, stabilize, transform, and dissolve. Institutional continuity can coexist with changes in position, resource distribution, or organizing rules. A reconstruction that pools several historical periods can therefore create an artificial field whose relations never coexisted in the represented form. The persistence criteria developed in Section 5.9 should be applied to the field itself: continuity claims need evidence about which organizing relations or mechanisms carry the distributed structure through time.

5.11.7 Limits of Field Attribution

Field language becomes epistemically weak when it functions as a residual label for whatever remains unexplained after local variables are considered. A field claim should add discriminating structure: it should identify a distributed organization, specify relevant positions or dependencies, delimit a provisional boundary, connect the reconstruction to evidence, and clarify what observations would favor alternative explanations. Without these elements, the term can remain metaphorically suggestive while contributing little to warranted knowledge.

A first limit concerns observational equivalence. Aggregate correlation, shared institutional exposure, network structure, common external causes, selection, and genuine field conditioning can produce similar manifestations. The inverse problem therefore persists at the level of fields. Evidence for a patterned outcome does not by itself identify which distributed mechanism produced it. Researchers should compare candidate reconstructions and identify which traces discriminate among them.

A second limit concerns scale. A pattern identified as field-level at one scale can decompose into several mechanisms at a finer scale or become one component of a wider field at a coarser scale. Scale dependence does not invalidate the field claim. It requires the claim to specify the level at which the distributed condition is reconstructed and the range over which the associated warrant is expected to travel.

A third limit concerns agency and heterogeneity. Field position conditions possibilities without mechanically determining action. Actors occupying similar positions can interpret, resist, exploit, or transform their conditions differently. Historical trajectories, identities, organizational capacities, resources, and cross-field affiliations can mediate responses. A field explanation therefore gains precision by identifying conditional tendencies or structured possibilities rather than converting position into deterministic prediction.

A fourth limit concerns formal representation. Network measures, spatial models, latent embeddings, correspondence analyses, agent-based models, and other computational tools can represent aspects of field structure. Their formal success remains distinct from substantive validation. The representation must preserve domain semantics, and its inferred positions or distances require evidential interpretation. Ontological suspension remains operative even when a field representation predicts effectively.

A fifth limit concerns causal and generative attribution. Establishing a field and locating positions within it does not yet establish that the field generated a particular capacity, relation, structure, constraint, or transformation. Field knowledge can identify the distributed conditions within which generative mechanisms operate, but the evidential burden for generative effect is stronger. The chapter's subsequent sections develop that distinction directly and address attribution among competing and distributed causes.

Proposition 5.86 (Minimum warrant for relational-field attribution)**.** *A relational-field attribution is epistemically warranted to the extent that the inquiry specifies a target-relevant distributed organization, provides evidence for meaningful positional or dependency structure, states the boundary and temporal scope of the reconstruction, examines plausible simpler or alternative explanations, and preserves uncertainty aris-*

ing from partial observation and representation choice.

Proposition 5.86 deliberately states a graded standard. Different inquiries can satisfy these requirements with different combinations of qualitative, historical, documentary, quantitative, network, spatial, legal, administrative, or computational evidence. The standard concerns explicitness and discriminating warrant rather than allegiance to a single method.

The epistemic value of field analysis can now be stated more precisely. Pairwise relations identify local connections; higher-order relational knowledge reconstructs configurations among relations; field analysis addresses distributed conditions in which position within an organized relational environment changes the interpretation of local relations, capacities, constraints, or possibilities. These representations can complement one another. Their usefulness depends on the target, evidence, boundary, scale, and historical interval of inquiry.

This distinction also establishes the transition to generativity. A field may be relationally real and epistemically well reconstructed while remaining only part of the background conditions for a later transformation. Conversely, a generative effect can depend on the interaction between a local relation and the field in which it operates. The next section therefore turns from the epistemology of distributed relational organization to the stronger problem of identifying *generative relations*: relations that participate in producing changes in capacities, relations, structures, constraints, possibilities, or the conditions of subsequent transformation.

5.12 Epistemology of Generative Relations

The preceding sections established how GRE can identify relations, reconstruct their persistence, move toward higher-order relational knowledge, and warrant claims about distributed relational fields. The present section introduces a stronger epistemic target: relations that participate in generating changes that become relevant to subsequent economic life. Its role is to specify what a generative claim means before the chapter turns to the more demanding problem of attributing generative effects among competing causes. The objective is therefore taxonomic and epistemic rather than fully causal. The discussion distinguishes generative effects from ordinary state change, then examines capacity generation, relation generation, structural generation, the generation of constraints and enabling conditions, the transformation of future possibilities, and changes in the conditions under which later transformation occurs. Throughout, the method is target-relative and temporally explicit: a claim of generation must identify what changes, for whom or for what configuration, over which interval, at which scale, and with what downstream relevance.

A relation can be relationally real without being generative with respect to the target under study. It can persist, structure interaction, and possess causal efficacy while leaving the relevant capacity, relation, structure, or option space materially unchanged during the interval of inquiry. Conversely, a relation can be generatively consequential even when its most important effects appear only after the initiating interaction has ended. GRE therefore treats generativity as a property of a relation-in-context relative to a specified effect, boundary, scale, and temporal horizon, rather

than as an intrinsic label attached permanently to a relation type.

Definition 5.87 (Generative relation)**.** A *generative relation* is a relation for which warranted inquiry supports the claim that participation in, exposure to, or operation through that relation contributes materially to the emergence, transformation, stabilization, suppression, or dissolution of a target capacity, relation, structure, constraint, possibility, or condition of subsequent transformation within a specified context and temporal horizon.

Definition 5.87 is deliberately relational and target-relative. Employment, credit, education, care, legal recognition, platform participation, research collaboration, or infrastructure access can be generative in one respect and comparatively inert in another. The definition also preserves directional openness. Generation can enlarge capacities and possibilities, but it can also stabilize dependence, produce constraints, suppress alternative relations, or narrow later option spaces. Epistemic identification of generativity therefore remains distinct from normative evaluation.

5.12.1 Relation and Generative Effect

Knowledge that a relation exists establishes an important part of the evidential basis for GRE, but existence alone does not establish what the relation generates. Two organizations can collaborate without the collaboration materially changing either organization's capabilities. A worker can hold a contract that structures payment and obligation without acquiring new skills or access through it. A legal status can be stable and causally relevant while producing little change in the target outcome during a particular interval. The epistemology of generative relations therefore begins by separating evidence for relational existence from evidence for a downstream generative effect.

A generative effect concerns a change that becomes part of the conditions of subsequent action, interaction, or transformation. Immediate outputs can be relevant evidence, yet they need not exhaust the effect. Training can produce an immediately observable certification while the more consequential effect lies in later competence or access. Collaboration can produce a publication while also generating shared routines, trust, instruments, or further collaborations. Infrastructure can provide current service while changing the set of activities that becomes feasible around it. The epistemic target is therefore temporally extended beyond the initiating relation and its first manifestation.

Granovetter's account of embedded economic action provides a useful precedent for treating ongoing relations as economically consequential rather than analytically incidental (Granovetter 1985). Powell, Koput, and Smith-Doerr similarly show that interorganizational collaboration can function as a locus of learning in biotechnology (Powell et al. 1996). These literatures do not by themselves establish the GRE category of a generative relation. They illustrate why the relation can be an explanatory object when later capacities and opportunities depend on relational participation.

Definition 5.88 (Generative effect)**.** A *generative effect* is a target-relevant change whose emergence or transformation is materially connected to a prior or ongoing relational process and whose significance extends to subsequent capacities, relations, structures, constraints, possibilities, or transformation conditions.

The phrase *materially connected* in Definition 5.88 states the epistemic burden without resolving the attribution problem in advance. Association, temporal succession, or narrative plausibility is insufficient on its own. The following section will examine the stronger evidential requirements involving mechanism, counterfactual dependence, multiple causation, distributed generation, delay, branching, and emergence. The present section specifies the objects among which such attribution must operate.

Generative effects can also be layered. A training relation can generate a capacity that later enables entry into a professional relation; the new relation can then alter organizational position; the changed position can affect later access to resources. Each step can be treated as a separate generative claim or as part of a longer generative trajectory. Epistemic clarity requires researchers to state which link is being claimed rather than treating an entire downstream history as the undifferentiated effect of one initiating relation.

5.12.2 State Change and Generative Change

A further distinction concerns change itself. Economic systems exhibit continual state change: prices move, balances fluctuate, persons relocate, inventories vary, organizations hire and release workers, and networks gain or lose connections. A change becomes generatively significant when it modifies the conditions from which later states can arise. The distinction is therefore temporal and structural rather than simply quantitative. A large change can be transient, while a small change can alter a pathway that later becomes consequential.

Consider a short-lived increase in income. If it changes current consumption and then leaves later capacities, relations, obligations, and access materially unchanged, the relevant claim may remain a state-change claim. If the same increase finances training, prevents the loss of housing, sustains a business through a liquidity shock, or permits entry into a relation that would otherwise have been inaccessible, its significance can become generative because subsequent conditions differ. The epistemic question concerns what persists or propagates from the change, not merely its magnitude at the moment of observation.

This distinction is compatible with established economic analyses of path dependence and increasing returns. Arthur's treatment of competing technologies shows how historically contingent events can become consequential when increasing-return mechanisms make later selection depend on earlier adoption (Arthur 1989). GRE uses such work as one lineage for thinking about how an apparently local change can become a condition of later development. It does not infer that every generative process is path dependent or governed by increasing returns.

Proposition 5.89 (Generative significance of change)**.** *Evidence of state change supports a claim of generative change only to the extent that the inquiry also identifies a warranted pathway through which the change alters subsequent capacities, relations, structures, constraints, possibilities, or conditions of transformation within the stated analytical boundary and temporal horizon.*

Proposition 5.89 prevents generativity from becoming a synonym for dynamism. It also separates generative analysis from a requirement that the generated consequence be permanent. A change can be generative over a finite interval if it modifies

subsequent conditions during that interval. Later reversal does not erase the historical effect; it changes the trajectory through which the effect should be reconstructed.

Generative change can occur through persistence, amplification, redirection, threshold crossing, or reconfiguration. These mechanisms have different evidential signatures. Persistence can be visible through durable capability or institutionalized routine. Amplification can appear through cumulative participation or increasing returns. Redirection can be inferred when later action follows a newly available pathway. Threshold crossing can be relevant when a previously unavailable relation becomes feasible. Reconfiguration can occur when the identities of components remain similar while their relational organization changes. The epistemic category should remain broad enough to accommodate these forms while requiring each empirical study to specify which form is supported.

5.12.3 Capacity Generation

Capacity generation concerns changes in what a subject, organization, collective, or relational configuration is able to do. It is one of the most direct ways in which a relation can alter later economic possibility. Capacities can be productive, epistemic, organizational, political, relational, adaptive, or infrastructural. Some can be attributed primarily to identifiable subjects; others remain distributed across teams, institutions, networks, or technical systems.

The capability approach provides an established conceptual resource because it distinguishes resources from substantive opportunities and directs attention to what persons are effectively able to do and to be (Sen 1999). GRE's epistemic problem is narrower and more processual: when does evidence support the claim that a relation participated in producing or transforming such an ability? A resource transfer and a capacity gain should not be treated as equivalent. The same nominal resource can produce different capacities when legal status, infrastructure, care obligations, prior knowledge, recognition, social support, or institutional access differ.

Capacity generation therefore requires at least a temporal comparison and a relational account of conversion. Evidence can include demonstrated performance, access to previously unavailable activities, durable competence, new organizational routines, successful coordination, changes in adaptive response, or the creation of shared infrastructure. Self-report can also be important, particularly for capacities that are not institutionally measured, although the evidential role of testimony must remain explicit. Where capacity is latent rather than exercised, inquiry should distinguish possession of an enabling condition from demonstrated use.

Some capacities are relational in their very operation. Trust, coordination, collective memory, professional recognition, bargaining power, and access through networks cannot be represented adequately as isolated possessions of one actor. Their generation may therefore require evidence at more than one level. A participant can acquire competence while a group simultaneously develops coordination capacity; an organization can learn through relations among units; a collaborative network can produce shared standards that later participants inherit. The higher-order epistemology developed in Section 5.10 becomes relevant whenever the generated capacity resides partly in a configuration rather than in a single relatum.

Capacity generation is also normatively open. A surveillance organization can acquire stronger monitoring capacity; a monopolistic platform can improve its ability to exclude rivals; a debt contract can increase purchasing capacity while also strengthening creditor leverage. GRE therefore records the generated capacity before evaluating its distribution or desirability. Later normative analysis can ask whose capacity increased, whose decreased, which dependencies were created, and how the generated capacity affects justice or power.

5.12.4 Relation Generation

Relations can generate further relations. A collaboration can produce trust that supports later collaboration; professional training can create mentorship and peer networks; infrastructure can connect previously separated actors; legal recognition can make contractual or organizational relations possible; a platform can create matching relations while simultaneously mediating their terms. Relation generation matters because the relational environment from which later economic action begins can itself be an outcome of earlier relations.

The epistemic burden is to distinguish a newly generated relation from a relation that was merely unobserved, latent, or already available. Temporal order provides part of the evidence but does not settle the issue. Researchers should examine whether the later relation became possible, probable, stabilized, or transformed through mechanisms associated with the earlier relation. Records of first contact, institutional eligibility, referral pathways, shared projects, communication histories, or changes in formal rights can be relevant traces. Where the later relation existed previously, the generative claim may concern strengthening, stabilization, or transformation rather than initial formation.

Interorganizational learning provides one empirical context in which relation generation can become visible. Collaboration can create knowledge and reputational effects that affect later alliance opportunities, while participation in a network can change access to additional partners (Powell et al. 1996). The epistemic lesson is not that networks automatically reproduce themselves. It is that later relational structure can be historically dependent on participation in earlier relational configurations.

Definition 5.90 (Relationally generated relation)**.** A *relationally generated relation* is a later relation whose formation, stabilization, weakening, or reconfiguration is supported by evidence linking that change materially to an earlier or ongoing relational process.

This definition also accommodates negative generation. A relation can generate exclusionary boundaries that suppress alternative ties. Exclusive contracts can make some supplier relations unavailable; professional closure can prevent entry relations; reputational mechanisms can discourage association; conflict can dissolve previously viable collaborations. The generative object is the transformation of the relational landscape, which can involve both formation and foreclosure.

Recursive representation from Section 5.6 provides an important special case. A representation can affect eligibility, ranking, recognition, or visibility and thereby generate later relations that produce new traces and representations. Relation generation is therefore one pathway through which epistemic infrastructures become

participants in the systems they describe.

5.12.5 Structural Generation

Structural generation concerns changes in relatively persistent patterns that organize multiple relations beyond a single dyad or episode. Examples include new organizational routines, durable divisions of authority, market architectures, standards, governance arrangements, infrastructures, classificatory regimes, or recurrent patterns of dependence. The concept therefore requires more than evidence that several individual relations changed at once. It requires evidence that the organization of relations acquired a degree of persistence and causal relevance at the scale specified by the inquiry.

Institutions provide a familiar reference point. North's account of institutions emphasizes rules and constraints that structure interaction and shape incentives (North 1990). GRE can treat institutional change as one form of structural generation when prior relations contribute to creating or transforming such organizing conditions. The category is wider than formal institutions, however. Informal routines, standards, technical architectures, and network structures can become sufficiently stable to condition later interaction even without codified rules.

Structural generation raises a scale problem. A relation can generate a local routine within one organization without transforming the wider institutional environment. Conversely, many local interactions can cumulatively contribute to a wider structural change. The claim should therefore specify the scale at which the generated structure is identified and the bridge evidence supporting movement across scales. Section 5.8 established this requirement generally; generative analysis makes it especially important because downstream structural claims can easily outrun the evidence available at the initiating scale.

Field reconstruction also becomes relevant. A newly generated structure can alter positions within a wider relational field without creating the field itself. A regulatory reform can change access to a profession; a platform rule can reorganize visibility among sellers; a standard can alter compatibility among firms. The epistemic claim can concern transformation of distributed position rather than replacement of the entire field. Researchers should therefore avoid treating every consequential structural modification as the birth of a wholly new system.

Structural generation can be identified through persistence, reproduction, and altered conditioning. A new rule or architecture becomes structurally consequential when later relations systematically encounter it as part of their environment. Evidence may include repeated administrative application, stable technical dependencies, recurrent organizational practices, patterned entry or exclusion, durable network reconfiguration, or sustained changes in the distribution of authority. The relevant test is whether the generated structure becomes an active condition of subsequent relations rather than remaining an isolated output.

5.12.6 Generation of Constraints and Conditions

Generativity includes the production of constraints as well as enabling conditions. A credit relation can create liquidity and repayment obligations. A technical standard can generate interoperability and exclude incompatible designs. A credential can create recognized access while making uncredentialed competence less legible. Infrastructure can lower some transaction costs while creating dependence on maintenance, ownership, or proprietary interfaces. These effects show why generativity cannot be equated with expansion, benefit, or freedom.

The epistemic task is to identify how a relation changes the conditions under which later action occurs. Constraints can concern legal permission, material resources, time, information, mobility, compatibility, obligation, visibility, bargaining position, or access to other relations. Enabling conditions can concern the same dimensions in the opposite direction, although a single change can enable one pathway while constraining another. The object of knowledge is therefore often a reorganization of conditional possibility rather than a simple increase or decrease in one variable.

North's institutional analysis is again relevant because institutions can both enable coordination and constrain behavior through structured rules and incentives (North 1990). Sen's emphasis on substantive opportunity likewise helps separate nominal resource possession from the social conditions under which resources become effective freedoms (Sen 1999). GRE uses these traditions to sharpen an epistemic question about generation: which prior relations produced the conditions that later actors encounter as permissions, resources, dependencies, obligations, or obstacles?

Constraints can themselves be generative. A standard can narrow permissible technical choices while enabling large-scale coordination within the remaining space. A budget ceiling can restrict current expenditure while inducing new organizational routines. A legal prohibition can suppress one practice and stimulate alternative organizational forms. Such cases make simple positive/negative coding inadequate. Inquiry should identify what is constrained, what becomes enabled, which actors experience each effect, and over what period.

The generation of conditions also includes maintenance. Some relations do not create a visibly novel capacity or institution; they reproduce the conditions under which an existing system can continue. Care relations sustain persons, maintenance work preserves infrastructure, administrative routines reproduce legal statuses, and ecological practices can maintain the material conditions of production. Epistemically, maintenance should not disappear merely because the observed state remains stable. Stability can itself be the generated consequence of ongoing relational work.

5.12.7 Transformation of Future Possibilities

Generative analysis reaches beyond realized outcomes to changes in the space of feasible or accessible futures. A relation can open, preserve, redirect, weight, or foreclose later possibilities without determining which possibility will be realized. Education can expand occupational and epistemic options; credit can make investment possible while narrowing later discretion through repayment; migration status can alter mobility and labor-market access; shared infrastructure can support activities

that were not specified when it was built. The epistemic object is a changed possibility structure, not a prediction of one future path.

This distinction is important because realized outcomes underdescribe generative significance. A research facility can expand the range of experiments that could be conducted even if only a fraction are eventually attempted. A legal right can create actionable options that remain unused. Redundant infrastructure can preserve alternatives that become valuable only under disruption. Conversely, an exclusive contract can remove feasible pathways even when the affected actor never attempts to use them. Evidence for transformed possibility therefore cannot rely exclusively on observed realized choices.

The capability literature again provides a useful precedent because it distinguishes achieved functionings from substantive opportunities (Sen 1999). For GRE, evidence of future possibility can include formal rights, eligibility, technical feasibility, available partners, resource access, documented opportunity sets, demonstrated substitutability, or credible pathways identified through historical and institutional reconstruction. Researchers should distinguish possibilities that are merely imaginable from those supported by a sufficiently specified relational and material pathway.

Definition 5.91 (Generative possibility transformation)**.** A *generative possibility transformation* is a warranted change in the set, accessibility, weighting, or durability of future pathways available to a specified subject or configuration that is materially connected to an earlier or ongoing relational process.

Possibility transformation is scale-relative and distribution-sensitive. The same institutional change can expand a firm's technological options while narrowing workers' mobility, or expand aggregate investment opportunities while concentrating access among already well-positioned actors. A system-level increase in the number of possible transactions does not establish that each participant's meaningful option space expanded. Epistemic claims should therefore state whose possibilities changed and at which scale.

Historical contingency remains central. Arthur's analysis of increasing returns illustrates one mechanism through which early events can reshape later technological possibilities and make some alternatives progressively harder to recover (Arthur 1989). Other domains can exhibit different mechanisms, including institutional learning, legal precedent, infrastructure dependence, ecological degradation, reputation, or cumulative capability. GRE therefore treats possibility transformation as a broad epistemic category whose mechanism must be established locally rather than assumed from path-dependence language alone.

5.12.8 Transformation of the Conditions of Transformation

The deepest generative claims concern changes in the conditions through which later change itself is produced. An intervention can alter outcomes while leaving the mechanisms of subsequent adjustment broadly intact. In other cases, it changes the institutional procedures, technical interfaces, learning capacities, classification systems, infrastructures, or selection environments through which later transformations occur. The epistemic target then moves from a generated state or option to a change in the generative conditions of future change.

Examples include platformization of a market, where matching and visibility become mediated by ranking and data infrastructures; legal reform that changes the categories through which later claims become recognizable; organizational learning that changes how future problems are solved; adoption of a common technical standard that reorganizes later innovation pathways; and machine-mediated decision systems that alter how subsequent classifications are produced. Espeland and Sauder's study of rankings demonstrates one concrete route through which public measures can reorganize organizational behavior and thereby recreate parts of the social environment they measure (Espeland and Sauder 2007). Such cases show why recursively performative representations can become relevant to generative epistemology.

A claim at this level should be stated carefully. Economic systems rarely possess a single fixed rule of change. The phrase *conditions of transformation* refers to the locally relevant mechanisms, procedures, infrastructures, capacities, and constraints through which change is generated in the studied domain. Different methods can represent these conditions differently. A legal analysis can reconstruct changing rights and procedures; organizational research can identify routines and learning; network analysis can track changing connection rules; computational work can model altered update mechanisms; historical inquiry can reconstruct how institutional sequences changed what later interventions could accomplish.

Definition 5.92 (Second-order generative change)**.** A *second-order generative change* is a transformation in the mechanisms, capacities, rules, infrastructures, or relational conditions through which subsequent generative changes are produced, selected, constrained, or propagated within the stated domain.

The term *second-order* in Definition 5.92 identifies an analytical level rather than a universal hierarchy. A change can be second-order relative to one target and ordinary structural change relative to another. The classification therefore depends on the research question and on evidence that later processes operate differently because the relevant transformation conditions have changed.

This level also sharpens the distinction between generativity and immediate effectiveness. An intervention can solve a present problem while weakening the capacities needed for later adaptation. Another can have modest immediate effects while building institutions, knowledge, trust, redundancy, or infrastructure that change how future problems are addressed. Generative epistemology therefore requires temporal horizons long enough to observe changes in the production of later change, while preserving uncertainty when those horizons exceed available evidence.

The eight subsections together establish a graded vocabulary for generative knowledge. Relations can generate immediate capacities, further relations, persistent structures, constraints and enabling conditions, altered possibility spaces, and changes in the conditions through which later transformation occurs. These objects can overlap, and one generative trajectory can move through several of them. Their analytical separation nevertheless matters because the evidential traces and temporal horizons differ. Evidence that a capacity was generated does not by itself establish structural transformation; evidence of structural change does not establish that the mechanisms of later change were transformed; evidence of expanded possibilities does not establish which possibilities will be realized.

The resulting epistemic discipline can be stated compactly. A generative claim should specify the initiating relation or relational configuration, the target change, the relevant boundary and scale, the temporal horizon, and the level of generative effect being asserted. It should also preserve the distinction between observed change and attributed generation. The present section has defined the possible objects of that attribution. The following section takes the next step by examining what evidence is required to warrant the claim that a particular relation, configuration, or field materially generated the effect in question.

5.13 Attribution of Generative Effects

Section 5.12 specified the objects of generative inquiry by distinguishing relational existence from claims about what a relation, configuration, or field helps to generate. The present section addresses the next epistemic problem: the attribution of those effects among competing, interacting, and temporally distributed conditions. Its role is to establish standards for moving from evidence that a generative change occurred to a warranted claim that some relation or relational configuration materially contributed to that change. The objective is neither to impose a single universal theory of causation nor to reduce generative inquiry to one identification technique. The section instead develops a plural evidential framework organized around association, mechanism, counterfactual dependence, multiple causation, distributed generation, delayed effects, branching pathways, and emergence. The method is comparative and target-relative. Each attribution claim should identify the effect, candidate contributors, relevant alternatives, boundary and scale, temporal horizon, and the evidential basis for assigning causal-generative responsibility.

Generative attribution is demanding because economic change is rarely produced by an isolated relation operating against a fixed background. Relations are embedded in infrastructures, institutions, fields, histories, material conditions, classifications, and other relations. The same observed effect can therefore be compatible with several causal accounts, while the same relation can contribute differently under different surrounding conditions. Mechanism-based explanation provides one established way to connect cause and effect by identifying the processes through which the connection is produced (Hedström and Ylikoski 2010). Counterfactual approaches provide another by asking how the target would vary under changes to a candidate cause or intervention (Woodward 2003; Gangl 2010). GRE draws on these traditions while preserving the additional problems created by relational dependence, historical sequence, heterogeneous scales, and distributed generation.

Definition 5.93 (Generative attribution)**.** A *generative attribution* is a warranted claim that a specified relation, relational configuration, or relational field materially contributed to the emergence, transformation, stabilization, suppression, or dissolution of a target generative effect within a stated boundary, scale, and temporal horizon.

Definition 5.93 leaves room for several forms of contribution. A relation can operate as a trigger, enabling condition, constraint, amplifier, mediator, channel, stabilizer, or component of a distributed configuration. The epistemic task is therefore

richer than assigning a binary label of cause or non-cause. Attribution should recover the form, scope, and degree of contribution that the available evidence can support.

5.13.1 Association and Generation

Association is often the first observable sign that a generative relation may be present. Participation in a training network can covary with later capability; access to finance can covary with organizational survival; legal recognition can covary with access to services; collaboration can covary with later innovation. Such patterns can direct inquiry toward plausible generative processes. Their evidential role is therefore important, especially when the relation under study is difficult to manipulate directly or when historical evidence is incomplete.

Association alone leaves several attribution problems unresolved. Selection into a relation can reflect pre-existing capacities. A shared institutional change can affect both the candidate relation and the later effect. The relation can be a manifestation of a deeper process rather than a contributor to the effect. Reverse influence can also occur when an emerging capability increases the probability of entering the relation subsequently treated as explanatory. These possibilities do not make association uninformative; they make its inferential role conditional on a broader reconstruction of temporal order, alternative explanations, and the processes linking the relation to the effect.

The distinction between association and generation should also remain sensitive to the object described in Section 5.12. A relation can be strongly associated with an outcome while weakly connected to the particular generative change under investigation. For example, membership in a professional network may correlate with income, while the relevant generative question concerns whether the network produces access to knowledge, legitimacy, referrals, or future collaborations. The attribution target should therefore be stated at the level at which the alleged generative contribution occurs.

Proposition 5.94 (Association as directional evidence)**.** *Evidence of association can support the direction of generative inquiry when temporal ordering, selection processes, plausible common conditions, and alternative relational explanations are examined explicitly. The strength of a generative attribution depends on the additional evidence that connects the association to a target-relevant contribution.*

Proposition 5.94 prevents two symmetrical errors. One error treats correlation as sufficient attribution. The other discards associative evidence whenever experimental identification is unavailable. GRE instead treats association as one evidential layer whose value depends on how it interacts with mechanism, counterfactual reasoning, temporal reconstruction, comparative cases, process tracing, quantitative identification, and other sources of warrant.

This layered view is especially important for historically situated relations. A relation may have existed only once, or under institutional conditions that cannot be reproduced. In such cases, attribution can still improve through triangulation across traces, comparison, sequence evidence, mechanism reconstruction, and carefully scoped counterfactual reasoning. The epistemic standard should reflect the attainable evidence while preserving uncertainty about rival accounts.

5.13.2 Mechanism

Mechanism evidence addresses how a candidate relation contributes to the target effect. A mechanism claim identifies a process or organized sequence through which relational participation changes capacities, incentives, expectations, resources, classifications, obligations, information, positions, constraints, or other conditions relevant to later states. Mechanism-based explanation has a long standing in the social sciences because it can connect observed regularities to the processes that generate them (Hedström and Ylikoski 2010). For GRE, mechanism evidence is particularly valuable when the generative effect concerns a transformation of relations or capabilities that cannot be understood adequately from end-state comparison alone.

A relation can support several mechanisms simultaneously. Credit can relax a liquidity constraint, alter bargaining power, create repayment obligations, and establish a history that affects later access. Legal recognition can change formal entitlement, administrative legibility, third-party expectations, and opportunities for collective organization. Collaboration can transmit knowledge, create trust, establish routines, and modify organizational reputation. A credible attribution therefore benefits from a mechanism profile rather than a single narrative link.

Definition 5.95 (Generative mechanism)**.** A *generative mechanism* is a reconstructable process through which a candidate relation or relational configuration contributes to a specified generative effect by altering one or more target-relevant conditions across time.

The requirement of reconstructability matters. A mechanism should be connected to traces, observations, interventions, institutional records, comparative sequences, behavioral evidence, or other forms of empirical support. A verbal sequence that merely redescribes the outcome offers limited additional warrant. Stronger mechanism evidence shows that intermediate changes occurred, that they were linked to the candidate relation, and that they plausibly carried part of the effect toward the target.

Mechanism evidence also has boundaries. Several mechanisms can produce observationally similar outcomes. A mechanism can operate without being sufficient for the effect. The same mechanism can generate different outcomes under different surrounding relations. Some components can remain latent or only indirectly observable. GRE therefore treats mechanism reconstruction as evidence for attribution rather than as automatic closure of the attribution problem.

The scale of mechanism should also match the scale of the claim. A macro-level institutional shift can depend on micro-level interactions, meso-level organizational routines, and field-level constraints. A complete account need not reproduce every lower-level event. It should, however, identify the cross-scale connections necessary for the claimed contribution. Section 5.8 established the need for bridge evidence when transporting relational claims across scales; generative attribution inherits the same requirement.

5.13.3 Counterfactual Dependence

Counterfactual reasoning asks how the target effect would differ under a relevant change to the candidate relation or its operation. Woodward's interventionist account treats such what-if-things-had-been-different questions as central to causal explanation and emphasizes invariant relations under interventions (Woodward 2003). In empirical social research, counterfactual frameworks likewise clarify causal identification by comparing observed outcomes with potential outcomes under alternative treatments or exposures (Gangl 2010). GRE adopts the epistemic discipline of this reasoning while extending the object of comparison from isolated treatments to relational and configurational conditions.

The relevant counterfactual is rarely a simple world in which one relation disappears while everything else remains fixed. Removing a relation can alter connected relations, classifications, expectations, resource flows, or institutional responses. A counterfactual concerning employment, credit, legal status, or network membership may therefore require a specification of what changes together with the focal relation and what is held approximately stable for analytical purposes. The credibility of the counterfactual depends on this relational specification.

Definition 5.96 (Relational counterfactual specification)**.** A *relational counterfactual specification* states the candidate relation or relational feature to be changed, the connected conditions permitted to vary with that change, the background conditions provisionally held stable, the target effect, and the temporal horizon over which the comparison is evaluated.

Definition 5.96 makes counterfactual reasoning compatible with the open and permeable systems analyzed in Sections 5.8–5.11. It also helps distinguish feasible alternatives from purely verbal ones. Historical and institutional constraints can make some counterfactuals comparatively informative and others remote from any plausible transformation pathway.

Counterfactual dependence can provide strong attributional evidence, yet absence of simple dependence does not always eliminate contribution. Redundant causes can each be sufficient under the observed conditions. An enabling relation may become visible only when another trigger occurs. Distributed systems can contain compensatory pathways that preserve the outcome after one component is removed. Generative attribution should therefore avoid treating a single binary counterfactual test as exhaustive.

Remark 5.97 (Counterfactual evidence and contribution)*.* Counterfactual evidence is strongest when the proposed intervention corresponds to a meaningful relational variation and when the resulting comparison preserves the dependencies necessary to interpret the target. Failure of one simple counterfactual test can reflect redundancy, substitution, compensation, or misspecified intervention boundaries rather than the absence of generative contribution.

5.13.4 Multiple Causation

Generative effects commonly arise from several contributors whose roles differ. One condition can enable a process, another can trigger it, a third can amplify it, and a

fourth can stabilize the resulting relation. Attribution in such cases should identify the contribution structure rather than search automatically for one privileged cause. This is especially important when institutional and economic outcomes depend on conjunctions of resources, permissions, capacities, infrastructures, and expectations.

Multiple causation can take several forms. Contributors can be jointly necessary within a local configuration. Several contributors can each be sufficient under the observed conditions. One contributor can substitute for another. A relation can increase the probability of an effect without determining it. A background condition can become causally salient only when another process changes. These forms have different implications for both explanation and intervention.

Definition 5.98 (Generative contribution profile)**.** A *generative contribution profile* records the evidenced role of a candidate relation within a multi-contributor process, including whether the relation functions primarily as an enabling condition, trigger, amplifier, mediator, constraint, substitute, stabilizer, or component of a jointly productive configuration.

The categories in Definition 5.98 are analytical roles rather than mutually exclusive ontological kinds. A single relation can occupy several roles over time. Credit can first enable investment, later constrain cash flow through repayment obligations, and eventually stabilize market access by building a recognized borrowing history. Contribution profiles therefore benefit from temporal indexing.

Multiple-cause analysis also changes the interpretation of negative evidence. If an effect persists after one relation is removed, the remaining pathways can indicate redundancy or substitution. If a relation produces little effect in one setting, a missing complement can explain the difference. Comparative inquiry should therefore examine configurations in which candidate contributors vary jointly and separately where the evidence permits.

For GRE, this configurational perspective is particularly compatible with the generative emphasis of Section 5.12. The aim is to understand how a target becomes possible, stabilized, redirected, or suppressed through interacting conditions. Attribution remains precise when the analysis specifies each candidate's supported role and avoids assigning the entire effect to the most visible contributor.

5.13.5 Distributed Generation

Some generative effects arise through distributed organization rather than through a compact set of readily isolable contributors. Knowledge production, market conventions, organizational routines, collective trust, infrastructural reliability, and field-level opportunities can depend on many interactions whose individual effects are modest while their combined organization is consequential. Section 5.11 established that field attribution requires evidence for distributed organization and positional significance. Generative attribution adds a further requirement: evidence that the distributed configuration contributes to the target transformation.

Complex adaptive systems provide useful precedents for understanding outcomes produced through localized interaction, historical dependence, and feedback across levels (S. A. Levin 1998; Arthur 1999). Adaptive-network research likewise examines

systems in which node states and network topology change through reciprocal feedback (Gross and Blasius 2008). GRE uses these literatures as analytical resources without assuming that economic relational fields obey one universal complexity model.

Distributed generation creates a localization problem. The effect can be attributable to the organization of the configuration even when no single relation reproduces the effect independently. Conversely, invoking "the system" can obscure concrete pathways if the distributed claim is left unspecified. Stronger attribution therefore identifies the organization that matters: connectivity, complementarity, feedback, positional differentiation, repeated interaction, shared infrastructure, or another target-relevant pattern.

Proposition 5.99 (Distributed generative attribution)**.** *A distributed generative attribution gains warrant when evidence supports both the existence of a relevant distributed organization and a pathway through which properties of that organization materially contribute to the target effect. Evidence concerning isolated components remains informative but need not exhaust the attribution when the effect depends on configurational properties.*

Proposition 5.99 preserves the distinction between distributed contribution and explanatory vagueness. It also permits mixed attributions. A focal actor or relation can have a distinctive role within a distributed process while the realized effect still depends on the surrounding field. Such cases should be represented through layered contribution profiles rather than forced into either purely individual or purely systemic explanation.

Distributed attribution also inherits the uncertainty of field reconstruction. Missing relations, changing boundaries, representation choices, and uneven observation can alter the inferred organization. The confidence attached to a distributed generative claim should therefore remain sensitive to the uncertainty established in Sections 5.7–5.11.

5.13.6 Delayed Effects

Generative effects can appear after substantial delay. A relation may first change a capacity, expectation, obligation, or infrastructure whose significance becomes visible only when later conditions activate it. Training undertaken years earlier can affect later occupational mobility; a legal classification can reshape future eligibility; an early technological choice can alter the costs of later switching; a trust relation can become consequential during a later crisis. Delay therefore weakens simple temporal proximity as a criterion of attribution.

Path-dependent analyses demonstrate how earlier events can acquire later significance when self-reinforcing processes make subsequent development sensitive to sequence (Arthur 1989; Pierson 2000). GRE extends this temporal sensitivity beyond lock-in. Delayed effects can also operate through stored capacity, institutional memory, accumulated obligations, latent options, slowly changing expectations, or deferred thresholds.

The main epistemic difficulty is separating delayed contribution from retrospective storytelling. As the time between candidate relation and observed effect

increases, the number of intervening conditions generally grows. Attribution should therefore identify the carriers through which the earlier relation remains relevant. These carriers can include skills, records, infrastructures, debts, organizational routines, legal statuses, durable classifications, network ties, or other persistent residues.

Definition 5.100 (Generative carrier)**.** A *generative carrier* is a persisting or transmitted condition through which the contribution of an earlier relation remains connected to a later target effect across a temporal interval.

Evidence for a carrier strengthens temporal attribution because it links the earlier relation to later conditions without assuming uninterrupted visible activity. The carrier itself can transform. A credential can become a reputation signal; a technical capability can become an organizational routine; a debt can become a constraint on later investment. The epistemic task is to reconstruct continuity of contribution through these transformations.

Temporal horizon also affects the sign and magnitude of attribution. A relation can generate a short-run capability while producing a longer-run constraint, or impose an immediate cost while creating later options. Generative attribution should therefore state the horizon over which the effect is assessed and, where relevant, separate short-, medium-, and long-run contribution profiles.

5.13.7 Branching Effects

A single relation can open several downstream pathways. Collaboration can generate knowledge, status, additional partners, conflict, dependence, and new organizational commitments. Access to infrastructure can enable several economic activities whose later trajectories diverge. A legal reform can alter rights, administrative practice, strategic behavior, and expectations simultaneously. Such branching makes it difficult to represent the generative effect as one linear chain.

Branching attribution begins by separating the opening of a pathway from the realization of a later outcome. A relation can make a trajectory feasible without determining which branch will later be taken. Subsequent decisions, shocks, complementary relations, and field conditions can select among the opened possibilities. Attributing the entire realized history to the initiating relation would therefore overstate its contribution.

Definition 5.101 (Generative branch)**.** A *generative branch* is a target-relevant downstream pathway made newly feasible, more probable, less probable, or structurally altered by a prior relational process, while later conditions continue to influence whether and how that pathway is realized.

Definition 5.101 connects attribution to the possibility transformations introduced in Section 5.12. The generative contribution can lie in changing the topology of feasible development rather than producing one fixed end state. Evidence for branching can therefore include newly available choices, altered transition probabilities, new organizational forms, emergent partnerships, institutional pathways, or the disappearance of previously available routes.

Branching also changes counterfactual reasoning. The relevant comparison may

concern the set of accessible trajectories rather than a single terminal outcome. A relation can be generatively important because it creates several possible futures even when the observed history ultimately follows only one. Conversely, a realized branch can depend heavily on later conditions that deserve separate attribution.

A useful practice is to decompose attribution across branch formation, branch selection, and branch stabilization. The initiating relation can be credited with opening or constraining pathways; later relations can be credited with selecting among them; still later processes can stabilize the chosen trajectory. This decomposition reduces retrospective compression of a long history into one causal statement.

5.13.8 Emergent Effects

Emergent effects are especially challenging because the target property can arise from interaction among many components without being attributable in the same form to any single component. Market conventions, collective expectations, organizational cultures, congestion, systemic fragility, and coordinated patterns of innovation can exhibit this structure. Complexity research offers well-established examples in which localized interactions generate system-level patterns whose dynamics depend on feedback, adaptation, and organization across levels (S. A. Levin 1998; Arthur 1999). These precedents support attention to emergent effects while leaving the empirical burden of each GRE application intact.

Emergence should not function as a substitute for causal reconstruction. A claim that an effect "emerged" can remain merely descriptive unless the inquiry identifies the interactions, constraints, feedbacks, thresholds, or organizational properties through which the higher-order pattern was produced. The epistemic advantage of an emergence claim lies in showing why the target cannot be attributed adequately to one component considered independently and why configurational organization matters to the realized effect.

Definition 5.102 (Emergent generative effect)**.** An *emergent generative effect* is a target-relevant change whose warranted explanation depends on organized interaction among multiple relations or components and whose explanatorily relevant properties are attributable to that interactional organization rather than to any single component considered independently.

Definition 5.102 remains compatible with ontological suspension. It is an epistemic and explanatory category. It does not require a metaphysical doctrine concerning irreducible levels of reality. The claim is narrower: for the specified target, boundary, and scale, the interactional organization carries explanatory content that is lost when components are analyzed independently.

Several kinds of evidence can support such attribution. Micro- or meso-level traces can show reciprocal adaptation or feedback. Comparative configurations can reveal that similar components produce different outcomes under different organizations. Simulation can test whether reconstructed interaction rules generate the qualitative pattern, while remaining a model-based source of evidence whose assumptions require scrutiny. Historical sequence can reveal how a distributed pattern stabilized. Field reconstruction can show positional dependencies that individual-level accounts omit. Convergence among these forms of evidence can strengthen the attribution

without converting any one method into a universal standard.

Proposition 5.103 (Minimum warrant for generative attribution)**.** *A generative attribution is comparatively well warranted when the inquiry specifies the target effect and temporal horizon, identifies the candidate relation or configuration and its proposed contribution, examines plausible alternative contributors, provides evidence for relevant mechanisms or dependencies, states the boundary and scale of the claim, and preserves uncertainty arising from multiple causation, distributed organization, delay, branching, or emergence where these are materially relevant.*

Proposition 5.103 summarizes the section without imposing a rigid checklist on every empirical design. Different research settings provide different evidential opportunities. Experimental or quasi-experimental identification can be strong in some cases; historical process evidence, comparative reconstruction, network or field analysis, simulation, legal and administrative records, or qualitative inquiry can be more informative in others. The epistemic requirement is that the form of evidence fit the structure of the attribution being made.

The resulting conception is deliberately graded. Generative attribution can be weakly supported, strongly supported, locally identified, historically plausible, mechanism-rich but counterfactually uncertain, or counterfactually well identified while mechanistically incomplete. These differences should remain visible in GRE rather than being compressed into a single binary label. The next section extends this temporal discipline from attribution at a bounded interval to the reconstruction of longer trajectories and historical knowledge, where relations and their generative effects accumulate, transform, disappear, and leave residues across time.

5.14 Trajectories and Historical Knowledge

Sections 5.12 and 5.13 established what counts as a generative effect and how a contribution to such an effect may be attributed within a specified temporal horizon. The present section extends that epistemic problem across longer historical sequences. Its role is to explain how GRE can know relations and generative processes when their significance depends on order, duration, inherited conditions, interrupted traces, and later reinterpretation. The objective is to distinguish several historical objects that are often compressed into a single narrative of "development": relational trajectories, generative trajectories, path-dependent sequences, genealogies of present configurations, historically situated evidence, constrained historical counterfactuals, and later re-epistemization. The method is reconstructive and sequence-sensitive. Historical claims should preserve temporal ordering, changes in meaning and category, evidence provenance, relevant alternatives, and the possibility that later knowledge revises how an earlier process is understood.

Historical knowledge matters to GRE because generative significance can be temporally displaced. A relation can appear inconsequential at one moment and become important after later complementarities arise. A constraint can disappear formally while continuing to shape capacities accumulated under it. A classification can be revised while leaving institutions built around the earlier classification intact. An intervention can alter a possibility structure whose consequences emerge only after

subsequent actors occupy it. The evidential object is therefore frequently a temporally extended configuration rather than an isolated state or event.

This historical orientation does not imply that every economic outcome is path dependent or that chronological narrative is sufficient explanation. Historical reconstruction becomes analytically valuable when order, duration, inherited conditions, or changing interpretive frameworks materially affect the claim. The task is to identify which parts of a sequence carry explanatory or epistemic significance and which are merely antecedent. GRE therefore treats historical depth as a source of possible warrant that must itself be justified.

5.14.1 Relational Trajectories

A relational trajectory records how a specified relation or relational configuration changes across time. The object may be a contractual relation, a collaboration, an authority relation, a household relation, a credit relation, a network position, an institutional linkage, or a wider relational configuration. What makes the object a trajectory is not simply the availability of observations at several dates. The observations must be connected by an explicit continuity judgment of the kind developed in Section 5.9, together with evidence about changes in participants, rules, intensity, meaning, position, or causal efficacy.

Definition 5.104 (Relational trajectory)**.** A *relational trajectory* is a temporally ordered reconstruction of the formation, persistence, transformation, interruption, or dissolution of a specified relation or relational configuration under an explicit criterion of continuity and a stated observational horizon.

Definition 5.104 makes trajectory reconstruction dependent on relational identity rather than on labels alone. An organization can retain the same name while its authority structure changes substantially. Two actors can remain formally connected while the practical content of their relation shifts from cooperation to dependence. A legal category can persist while administrative procedures alter the relations it produces. Conversely, a relation can retain substantial continuity through changes in personnel, representation, or institutional form. Historical reconstruction should therefore identify the dimensions across which continuity is claimed and the dimensions across which transformation occurs.

A trajectory is also boundary- and scale-dependent. A firm-level supplier relation can appear stable while the wider field in which it is embedded changes sharply; a national policy relation can look discontinuous while local routines preserve practical continuity. The boundary and scale principles established in Section 5.8 therefore remain active throughout historical analysis. A trajectory should state the observational unit, the temporal granularity, and the relations treated as relevant context. Changing these choices can alter where formation, transformation, and dissolution appear to occur.

Temporal granularity deserves particular attention. Annual observations can hide short-lived interruptions, bargaining episodes, or rapid reconfigurations. Fine-grained event data can make enduring structure difficult to see. Historical knowledge therefore requires a resolution appropriate to the target claim. Where several resolutions are plausible, researchers should examine whether the inferred trajectory

remains stable across them. A continuity judgment that exists only after aggressive temporal aggregation should be stated more cautiously than one supported across several resolutions.

Relational trajectories can also contain periods of latency. A relation may cease to produce visible manifestations while its obligations, expectations, reputational effects, or stored capacities continue. Section 5.9 introduced residual efficacy after dissolution; historical reconstruction extends this idea by asking whether later states still carry traces of an earlier relation. The absence of continuous visible interaction therefore does not by itself establish historical discontinuity.

Proposition 5.105 (Trajectory reconstruction and continuity)**.** *A relational trajectory is comparatively well supported when the inquiry states its identity criterion, temporal resolution, boundary and scale, documents relevant transformations and interruptions, and distinguishes continuity of the relation from continuity of its manifestations or representations.*

Proposition 5.105 prevents retrospective smoothing. Historical narratives often become cleaner than the processes they describe. Explicit continuity criteria preserve ruptures, ambiguities, and periods for which the evidence supports several reconstructions.

5.14.2 Generative Trajectories

A generative trajectory tracks a different object. It follows a sequence in which earlier relations or generative effects alter the conditions from which later relations, capacities, structures, constraints, or possibilities emerge. The trajectory can therefore include several different kinds of generative effect from Section 5.12. A training relation can generate capability; that capability can enable entry into a professional relation; the professional relation can create access to information and collaborators; the resulting position can later affect organizational authority. The continuity lies in a chain of historically connected contributions rather than in persistence of one relation.

Definition 5.106 (Generative trajectory)**.** A *generative trajectory* is a temporally ordered reconstruction in which earlier relations, configurations, or generative effects materially alter the conditions under which later target-relevant relations, capacities, structures, constraints, or possibility sets emerge or transform.

This definition separates generative trajectory from simple chronology. Event A occurring before event B is insufficient. The reconstruction should identify how conditions created or modified earlier remain connected to later developments. The generative carriers introduced in Section 5.13 are especially important here. Skills, routines, infrastructures, legal statuses, debts, classifications, expectations, reputations, organizational memory, and material assets can transmit earlier effects across intervals in which the initiating relation is no longer active.

Generative trajectories can branch. An earlier relation may open several pathways, only one of which becomes realized. Later relations can redirect, amplify, suppress, or reverse earlier contributions. Historical reconstruction should therefore avoid reading the realized sequence as if it were uniquely implied by its beginning. The

branching concept introduced in Section 5.13 becomes historical when the inquiry reconstructs both the path taken and evidence about alternatives that remained feasible at relevant moments.

A further complication is sign change across time. A relation that initially generates capacity can later create lock-in or dependence. An infrastructure that expands access can later become a bottleneck. A regulatory privilege can support early investment and later inhibit entry. A historical generative claim should therefore state the horizon over which its evaluative or causal description applies. Long-run significance cannot be inferred by extending a short-run effect indefinitely.

Generative trajectories may also contain second-order transformations. Section 5.12 defined these as changes in the conditions through which later transformation occurs. Historically, such changes are especially consequential because they alter subsequent rates, channels, or admissible forms of generation. A new accounting system can change what organizations can observe and govern; a new legal form can alter the kinds of relations that can be stabilized; a new communication infrastructure can change the speed and reach of association. These transformations can make later history difficult to compare directly with earlier periods because the process generating change has itself changed.

The epistemic burden therefore grows with trajectory length. Each link introduces possible alternative explanations, missing traces, changing categories, and boundary shifts. A long generative trajectory should not be treated as one undifferentiated causal claim. Stronger reconstructions identify which links are directly supported, which are mechanism-rich but uncertain, which remain conjectural, and where later developments cease to be attributable to the earlier process with useful precision.

5.14.3 Path Dependence

Path dependence concerns sequences in which earlier developments alter the relative feasibility, cost, probability, or stability of later alternatives. Economic and political scholarship has used the concept to explain cases in which increasing returns, complementarities, learning, coordination effects, institutional feedback, or quasi-irreversibility make sequence and timing consequential. David's analysis of QWERTY helped establish an economic-historical vocabulary for such mechanisms, while subsequent debate also illustrates why a path-dependence claim should not be inferred from persistence alone (David 1985). Pierson extends increasing-return reasoning to political development and emphasizes timing, sequence, and self-reinforcing processes under specified mechanisms (Pierson 2000).

For GRE, path dependence is best treated as a mechanism-sensitive historical claim. Persistence is not enough. An institution can persist because current conditions continue to favor it independently of its history. A practice can recur because actors repeatedly choose it under unchanged incentives. A technology can dominate because it remains technically superior. Path dependence requires evidence that the route taken has itself modified later conditions in a way that makes alternative routes differently accessible than they would have been under another plausible sequence.

Definition 5.107 (Relational path dependence)**.** A *relationally path-dependent process* is a historical process in which earlier relational developments materially modify

the conditions governing later relational possibilities, so that later outcomes depend partly on the sequence through which the system arrived at its current configuration.

This formulation makes path dependence compatible with several mechanisms. Repeated interaction can accumulate trust or distrust. Standards can create compatibility networks. Institutional rules can generate constituencies that defend them. Learning can make some capabilities cheaper to reproduce. Contracts can create obligations that narrow later choices. Reputational histories can alter access to future relations. The key epistemic task is to identify the carrier and feedback process through which history changes the later opportunity structure.

Path dependence should also be distinguished from historical contingency. A contingent event can redirect a trajectory without generating a self-reinforcing process. Conversely, a path-dependent sequence can begin from deliberate choice rather than chance. The concepts answer different questions: contingency concerns openness among possible events, whereas path dependence concerns how realized history changes subsequent possibilities.

The concept of lock-in requires further restraint. Some path-dependent processes narrow alternatives without making them practically irreversible. New technologies, coalitions, crises, legal changes, or shifts in complementary institutions can reopen pathways. GRE should therefore represent degrees of path dependence and the conditions under which reversal becomes feasible. Such a representation is more informative than treating history as deterministic once an early branch has been selected.

Proposition 5.108 (Path dependence and historical mechanism)**.** *A path-dependence claim gains warrant when the reconstruction identifies a sequence-sensitive mechanism through which earlier relational developments alter later transition conditions and when persistence can be distinguished from contemporaneous causes that would support the same configuration independently of the earlier path.*

Proposition 5.108 makes historical dependence empirically contestable. It invites comparison with alternative sequences, evidence about feedback and switching costs, and attention to moments when the process could plausibly have moved differently.

5.14.4 Genealogical Reconstruction

Genealogical reconstruction asks how a present relation, category, institution, practice, or field became historically possible. Its object differs from a trajectory defined around a stable identity criterion. Genealogy may begin with a present configuration and work backward through heterogeneous predecessors, category changes, institutional transformations, and episodes that do not form one continuous object. The purpose is to reconstruct formation rather than to presume a continuous essence that has merely changed its appearance.

This distinction is particularly important for economic categories. Terms such as unemployment, productivity, household, enterprise, market, creditworthiness, or risk can appear to name stable objects while their operational definitions, institutional settings, measurement practices, and practical consequences change historically. Hacking's work on historical ontology provides a relevant precedent for examining how concepts and objects become possible through historically situated styles

of reasoning, language, and classification (Hacking 2002). GRE draws a narrower epistemic lesson: present categories should not be projected backward without examining whether the relations they organize were constituted and rendered visible in comparable ways.

Definition 5.109 (Genealogical reconstruction)**.** A *genealogical reconstruction* is a historically situated account of the heterogeneous relations, practices, classifications, institutions, material conditions, and interpretive transformations through which a present target became possible, stabilized, or intelligible in its current form.

Genealogical reconstruction can reveal several kinds of discontinuity. The same word can designate different objects across periods. Different words can organize substantially related practices. An institution can inherit routines from predecessors while changing their justificatory language. A statistical category can create comparability where earlier records were organized around different administrative purposes. These discontinuities matter because historical evidence is interpreted through categories that may themselves be products of the history under investigation.

Genealogy also guards against teleology. Present arrangements should not be treated as the latent destination of earlier processes. Earlier actors faced possibility structures that included paths later abandoned, defeated, forgotten, or rendered illegible by subsequent classifications. Sewell's analysis of historical events emphasizes that consequential events can transform structures through linked changes in action, interpretation, schemas, and resources (Sewell 1996). Such transformations make later categories poor guides to what earlier actors could see or expect before the event occurred.

A GRE genealogy should therefore preserve superseded alternatives where evidence permits. Draft laws, failed standards, abandoned organizational forms, dissident classifications, unrealized plans, informal arrangements, and contested interpretations can be epistemically valuable because they reveal the field of possibilities within which the realized configuration emerged. Their historical importance does not depend on eventual success.

Genealogical reconstruction remains distinct from normative debunking. Showing that a category or institution has a history does not establish that it is false, illegitimate, or dispensable. Historical formation can be compatible with present usefulness or normative importance. The epistemic contribution is to make constitution, contingency, and inherited structure visible so that current claims are not mistaken for timeless descriptions.

5.14.5 Historical Evidence

Historical knowledge depends on traces that survive unevenly. Documents, administrative records, legal instruments, correspondence, artifacts, testimony, organizational data, statistics, media, physical infrastructure, and later recollections can each disclose parts of earlier relational configurations. Section 5.7 already established that observational access is partial and position-dependent; historical inquiry adds a preservation filter. What can be observed later depends on what earlier actors recorded, what institutions retained, what survived material loss, what became ac-

cessible, and what later researchers know how to interpret.

The survival of evidence is itself relationally structured. Powerful institutions often generate and preserve abundant records because administration requires documentation. Informal, stigmatized, precarious, clandestine, or rapidly changing relations may leave fewer durable traces. Strategic concealment can further distort the archive. Historical absence from records therefore requires the same caution that Section 5.4 applied to absence of traces more generally: non-observation becomes evidence of absence only when the inquiry has reason to expect that the relevant relation would have generated and preserved an accessible trace.

Historical evidence also changes meaning across contexts. A wage register can support claims about payment while leaving household dependence, bargaining, informal exchange, or care relations largely invisible. A contract can show formal obligation while underrepresenting coercion or practical non-enforcement. A statistical series can enable longitudinal comparison while embedding changing definitions. A retrospective interview can recover experience unavailable in administrative records while being shaped by later memory and interpretation. Evidence should therefore be evaluated relative to the target claim rather than through a fixed hierarchy of source types.

Provenance becomes especially important when historical traces are repeatedly copied, standardized, digitized, or summarized. A later dataset can contain values inherited from earlier administrative systems whose definitions changed across time. A secondary narrative can cite several accounts that ultimately derive from one original report. Digitization can improve access while severing contextual metadata. The provenance principle developed for distributed observation in Section 5.7 therefore extends naturally to historical reconstruction.

Proposition 5.110 (Historical evidential adequacy)**.** *Historical evidence is comparatively adequate for a relational claim when its provenance, production context, preservation conditions, category semantics, temporal coverage, and expected relation to the target are sufficiently explicit for alternative reconstructions and evidential gaps to be assessed.*

Proposition 5.110 does not demand complete archives. Many important historical questions cannot satisfy such a standard. It instead requires that evidential limitations remain part of the claim. A reconstruction can be strong despite missing evidence when surviving traces converge, rival interpretations are tested, and the pattern of missingness is itself historically understood. Conversely, a large archive can still produce weak knowledge if its categories or selection mechanisms remain opaque.

The next section will classify evidential forms for relational claims in greater detail. The present concern is narrower: historical evidence acquires epistemic force through an account of how traces were produced, preserved, transformed, and made available across time.

5.14.6 Historical Counterfactuals

Historical counterfactuals ask how a trajectory might have differed under a plausible alteration to an earlier relation, event, institution, or sequence. Their epistemic role is closely related to the counterfactual reasoning developed in Section 5.13, but historical application adds a demanding constraint: the alternative should be specified from the possibility structure available at the relevant historical moment rather than from later knowledge alone.

A counterfactual can be useful for testing whether an earlier development materially constrained later outcomes. If an institutional rule had differed, would the later relation still have been feasible? If a standard had failed to coordinate adoption, would the same network effects have emerged? If a legal recognition had occurred later, would the relevant organizational form have stabilized? These questions can reveal which links in a generative trajectory carry attributional weight.

Historical counterfactuals become weak when they alter too many connected conditions without specifying the consequences of those changes. Replacing one institution can change coalitions, expectations, resource flows, legal interpretation, and later opportunities. The relational counterfactual specification from Section 5.13 remains relevant: the inquiry should state what is changed, which connected conditions are permitted to change with it, what is provisionally held stable, and the horizon over which consequences are considered.

The criterion of historical plausibility is equally important. A later technology, category, or institutional design may provide an imaginable alternative while having been unavailable to actors at the time. Such a comparison can still serve a theoretical purpose, but it should not be confused with a historically grounded counterfactual. Stronger historical counterfactuals draw on alternatives that were materially, institutionally, or conceptually available, including unrealized proposals, neighboring cases, contested reforms, known technologies, or paths that were attempted and abandoned.

Definition 5.111 (Historically situated counterfactual)**.** A *historically situated counterfactual* is a counterfactual reconstruction whose altered condition and connected consequences are specified with reference to the relations, resources, institutions, knowledge, and feasible alternatives evidenced for the historical period under study.

Definition 5.111 does not require researchers to reproduce the subjective beliefs of every historical actor. The constraint is epistemic: alternatives should be disciplined by evidence about the period rather than by unrestricted retrospective imagination. Counterfactual uncertainty should increase as the imagined branch moves farther from historically evidenced possibilities or extends across longer downstream horizons.

Historical counterfactuals can also test path-dependence claims. If changing an early event while preserving plausible surrounding conditions yields little difference in the later reconstructed process, the alleged path dependence becomes weaker. If the altered sequence changes later transition conditions through a documented feedback mechanism, the claim gains support. Such reasoning remains conditional rather than demonstrative, especially where historical systems contain multiple interacting pathways.

5.14.7 Re-Epistemization through Historical Change

Historical change can alter not only the object of knowledge but also the conditions under which earlier evidence becomes intelligible. New records can be released; classifications can be revised; social practices can make previously invisible relations legible; later consequences can reveal the significance of earlier events; new methods can extract patterns from old data; and normative or conceptual developments can create questions that earlier inquiries did not ask. GRE uses the term *re-epistemization* for the disciplined reconstruction of an earlier epistemic object under such changed conditions.

Definition 5.112 (Historical re-epistemization)**.** *Historical re-epistemization* is the revisable reconstruction of an earlier relational or generative claim when later evidence, categories, methods, consequences, or interpretive conditions materially change what can be warranted about the earlier process.

Re-epistemization differs from simple correction. Sometimes later evidence shows that an earlier claim was wrong. In other cases the earlier claim was reasonable under the evidence then available but becomes too narrow after new traces or categories appear. A third possibility is that the object itself changes: a relation later acquires causal efficacy, legal recognition, or social meaning that it did not possess previously. Historical knowledge must therefore distinguish revision of evidence, revision of interpretation, and transformation of the target relation.

Hermeneutic traditions provide an important precedent for this temporal openness. Ricoeur emphasizes interpretation across distance and the interaction of explanation and understanding in the interpretation of text and action (Ricoeur 1991). GRE adapts a limited epistemic lesson: later interpretation can legitimately reopen earlier material without implying that interpretation is unconstrained. Re-epistemization remains answerable to preserved traces, provenance, historical context, rival interpretations, and the consequences of the distinctions introduced.

The emergence of new categories also requires care. Hacking's historical analysis of categories and styles of reasoning shows why later conceptual resources can reveal historically constituted objects while simultaneously changing the terms through which they are understood (Hacking 2002). A later category can illuminate relations that earlier records rendered poorly visible, yet it can also distort if projected backward as though actors and institutions already organized reality in the same way. Re-epistemization therefore requires a two-sided discipline: exploit the analytical resources of the present while preserving the historical semantics and possibility structures of the past.

Later outcomes can similarly alter retrospective significance. An early technical standard can look minor until network effects accumulate around it. A local legal classification can become historically consequential after administrative systems are built on it. A failed experiment can later become informative when a new theory identifies a mechanism that the original researchers could not articulate. Such retrospective significance does not mean that the later outcome was already contained in the earlier event. It means that historical knowledge can change when the downstream relations through which significance is assessed become visible.

Proposition 5.113 (Historical preservation)**.** *The future re-epistemization of a rela-*

tional or generative claim is strengthened when evidence, provenance, category definitions, alternative interpretations, model assumptions, uncertainty, and relevant negative or unresolved results are preserved in forms that allow later inquiry to reconstruct how the earlier claim was produced.

Proposition 5.113 connects historical epistemology to research design. Preservation is not merely archival housekeeping. It maintains future epistemic options. A dataset without category history, a model without assumptions, a summary without provenance, or a decision record without excluded alternatives can make later reinterpretation substantially harder even when the nominal evidence survives.

Historical re-epistemization also places a limit on claims of final closure. A well-supported historical account can be provisionally stable while remaining open to later evidence or reinterpretation. This revisability does not reduce every account to equal plausibility. Evidence can strongly favor one reconstruction, and some alternatives can be rejected. The point is narrower: the warrant of a historical claim remains indexed to the evidential and conceptual conditions under which it was assessed.

The seven subsections together establish history as an epistemic dimension of GRE rather than merely a background chronology. Relational trajectories track continuity and transformation; generative trajectories reconstruct historically connected contributions; path dependence identifies sequence-sensitive changes in later possibility; genealogy reconstructs the formation of present objects without assuming continuous essence; historical evidence is evaluated through production and preservation conditions; historical counterfactuals are constrained by period-specific possibility structures; and re-epistemization keeps historical knowledge open to disciplined reconstruction. The next section shifts from this temporal architecture to a systematic comparison of the evidential forms through which relational claims are supported.

5.15 Evidence for Relational Claims

Sections 5.1–5.14 have progressively specified the objects and epistemic conditions of relational inquiry: manifestation, trace, representation, observation, boundary, scale, persistence, higher-order configuration, fields, generative relations, causal-generative attribution, and historical trajectory. The present section turns from these conceptual conditions to the evidential materials through which relational claims are actually warranted. Its role is to distinguish major evidence forms without assigning any one of them universal priority. Its objective is to show what documentary, administrative, legal, behavioral, testimonial, ethnographic, network, longitudinal, and computationally inferred materials can establish about relations, together with the characteristic inferential limits attached to each. The structure follows these evidence forms in turn. The method is trace-sensitive and target-relative: each evidential source is evaluated by asking how it was produced, what relational property it can reveal, what conditions mediate its accessibility, and what forms of error or underdetermination remain.

The central premise is that evidence is not interchangeable simply because several sources refer to the same actors or event. A contract, a transaction record, an inter-

view, a fieldnote, a network edge, and a model-inferred tie can each concern the same apparent relation while recording different manifestations of it. A legal instrument may establish an authorized relation without showing how that relation is enacted in practice. Administrative data may record repeated interaction while omitting informal obligations. Testimony can disclose meanings or concealed dependencies that leave few institutional traces, while remaining situated and potentially contested. Computational inference can extend observation beyond manually coded relations while introducing model dependence. Evidential diversity therefore increases epistemic reach only when the relation between source, trace, and target claim remains explicit.

Definition 5.114 (Relational evidence)**.** *Relational evidence* is an observation, record, trace, testimony, representation, or warranted inference that bears on a specified claim concerning the existence, form, properties, persistence, transformation, boundary, position, or configuration of one or more relations.

Definition 5.114 makes evidence claim-relative. A payroll record can provide strong evidence of a formal employment relation during a specified interval while offering limited evidence about authority in day-to-day work. A sequence of messages can support a claim of repeated communication while leaving trust, obligation, or influence unresolved. A participant's account can support knowledge of experienced dependence while requiring additional evidence before the same account is used to establish the prevalence of that dependence across a population. The strength of evidence therefore depends partly on the distance between the trace that is available and the relational property being claimed.

This section accordingly resists a simple hierarchy in which quantitative evidence is treated as intrinsically stronger than qualitative evidence, institutional records as intrinsically more objective than testimony, or direct observation as automatically superior to inference. Each evidence form is generated within particular institutions, practices, categories, instruments, and access arrangements. Administrative and statistical data are especially powerful because they can provide large-scale and repeated observations, but their categories and collection systems also shape what becomes visible (Desrosières 1998; World Bank 2021). Qualitative and ethnographic evidence can recover relational meaning and practice that standardized records omit, while their scope and observer position must remain explicit. The epistemic problem is therefore one of evidential fit, combination, and calibrated inference.

5.15.1 Documentary Evidence

Documentary evidence includes letters, contracts, minutes, reports, correspondence, memoranda, organizational records, policy documents, archival files, diaries, technical specifications, media records, and other durable inscriptions produced within or around a relational process. Such documents can establish that actors communicated, recognized obligations, created categories, recorded decisions, asserted authority, coordinated activity, or represented a relation in a particular way. Their durability also makes them especially important for historical reconstruction, where direct observation is unavailable and relational trajectories must be recovered from surviving traces.

A document should nevertheless be treated as a produced object rather than a transparent window onto the relation. Documents have authors, audiences, genres, institutional purposes, preservation histories, and conditions of access. A memorandum may record the position that an organization was prepared to state formally rather than the full structure of disagreement that preceded it. Meeting minutes can establish that a decision was recorded while compressing uncertainty, dissent, or informal negotiation. A contract can preserve explicit obligations while leaving tacit expectations and practical dependence outside the written text. Ricoeur's hermeneutics of text is useful here because textual inscription creates a degree of distance between an act of writing, its immediate context, and later interpretation (Ricoeur 1991). For GRE, that distance is an epistemic condition to reconstruct rather than a defect that automatically disqualifies documentary evidence.

Documentary evidence is especially strong when the target claim concerns representation, formal acknowledgment, declared intention, authorized procedure, recorded sequence, or institutional memory. It becomes more inferential when used to establish relations that the document was not designed to record. The evidential task should therefore specify whether the document is being used as evidence of the represented relation, evidence of the practice that produced the document, evidence of the institutional categories available at the time, or evidence of a later archival selection process. These are different claims.

Preservation also creates selection. Surviving documents are rarely a neutral sample of past relational life. Powerful organizations often preserve records more systematically than marginal or informal actors. Routine success can be recorded differently from conflict, failure, or activity outside institutional reporting requirements. Section 5.14 treated provenance and preservation as conditions of historical re-epistemization. Documentary inquiry therefore benefits from recording archive provenance, gaps, destruction, access restrictions, and changes in filing or classification practice where these materially affect the relational reconstruction.

Proposition 5.115 (Document–relation distinction)**.** *A documentary source can warrant a relational claim only to the extent that the inquiry states how the document was produced, what aspect of the relation it records or represents, and what inferential steps connect the inscription to the target relational property.*

Proposition 5.115 prevents documentary existence from becoming automatic relational proof. A document can itself be relationally consequential, especially when it authorizes, classifies, obligates, or coordinates, while still remaining incomplete evidence about the wider relation in which it operates.

5.15.2 Administrative Evidence

Administrative evidence is produced through systems that register, classify, monitor, allocate, authorize, bill, tax, employ, enroll, license, inspect, or otherwise administer persons, organizations, resources, and transactions. Contemporary administrative systems can generate relational data at a scale and temporal resolution that would be difficult to obtain through direct observation. The expansion of administrative and private-sector data has materially increased the observability of many economic behaviors (Einav and J. Levin 2014), while public data systems increasingly combine ad-

ministrative, survey, citizen-generated, and machine-generated sources (World Bank 2021).

For relational inquiry, administrative records can reveal repeated transactions, institutional membership, transfers, claims, service use, organizational affiliation, co-location, authorization, sanction, or other patterned connections. Their major strength is often coverage and repetition. When identifiers are stable and collection procedures are known, administrative data can support large-scale reconstruction of relational neighborhoods, trajectories, and institutional positions.

Their major limitation is equally important: administrative systems observe through categories created for administrative purposes. A database records the relations that its schema permits and that its procedures require participants or officials to enter. Statistical and administrative classifications have histories of construction, coding, aggregation, and comparability rather than arising as neutral descriptions of social reality (Desrosières 1998). A household category, employment status, beneficiary identifier, ownership code, or provider relationship can therefore carry institutional assumptions into the evidence base.

Administrative evidence should consequently be evaluated along at least four dimensions: coverage, category validity, record-generation incentives, and linkage quality. Coverage asks who and what enters the system. Category validity asks whether administrative variables correspond sufficiently to the relational property under study. Record-generation incentives ask whether actors gain from accurate reporting, strategic reporting, or avoidance. Linkage quality asks whether records belonging to the same actor, organization, or relation can be connected reliably across sources and time. Failures in any of these dimensions can generate false absence, false continuity, or spurious connection.

Administrative silence is particularly ambiguous. A missing record can indicate that a relation did not exist, that it existed outside administrative jurisdiction, that it was exempt, informal, misclassified, unreported, technically lost, or deliberately concealed. The negative-evidence conditions developed in Section 5.4 therefore apply directly. Administrative nonobservation becomes stronger evidence of relational absence only when coverage, reporting, detection, and preservation conditions make the missing trace genuinely expected under the hypothesis that the relation existed.

5.15.3 Legal Evidence

Legal evidence is especially important when relational claims concern rights, duties, statuses, authority, jurisdiction, ownership, organizational personality, enforceability, or recognized procedures. Statutes, regulations, judicial decisions, contracts, charters, registries, licenses, and legally operative records can establish relations that have institutional force because relevant actors recognize and act through legal rules. Hart's analysis of legal systems through primary and secondary rules provides one established account of how recognized rules structure obligations and authoritative legal change (Hart 2012); Searle's account of institutional facts likewise emphasizes status functions, constitutive rules, and collectively recognized deontic powers (Searle 1995).

Legal evidence has a distinctive epistemic advantage: in some domains the legal

record does not merely describe an independently existing relation but helps constitute the formal relation itself. Incorporation documents and organizational law, for example, can create legally recognized entities and asset-partitioning relations that alter creditor and ownership claims (Hansmann and Kraakman 2000). A legal instrument can therefore be simultaneously evidence of a relation and part of the mechanism through which that relation is stabilized.

This constitutive role should not be extended beyond its evidential scope. Formal entitlement does not establish practical access. A statutory right does not demonstrate that administrative agencies implement it consistently. A contractual duty does not reveal the bargaining conditions under which the contract was accepted. Formal ownership does not by itself identify operational control. Legal evidence is therefore strongest for claims about legally recognized relations and weaker when transported without additional evidence into claims about enacted, experienced, or effective relations.

Legal interpretation introduces a further layer. Rules can contain open terms, conflicts, exceptions, jurisdictional boundaries, and historically changing precedents. The evidential task may therefore require identifying which legal source was authoritative for the time, place, actor, and issue under study. Where several interpretations were institutionally plausible, the reconstruction should preserve that contestability rather than reading a later settlement backward into an earlier period.

A useful distinction is thus between *formal relational validity* and *relational realization*. The first concerns whether a relation was legally recognized, authorized, prohibited, or constituted. The second concerns how that relation operated through practice, enforcement, compliance, evasion, negotiation, and institutional capacity. GRE often needs both because economic consequences can depend on the interaction between formal status and practical realization.

5.15.4 Behavioral Evidence

Behavioral evidence concerns actions and interaction patterns through which relations become manifest. Exchanges, transfers, communication, coordination, compliance, reciprocity, sanctions, referrals, mobility, repeated cooperation, avoidance, and other observable behaviors can provide evidence that actors are connected in ways that formal records do not fully capture. Behavioral approaches to collective action, for example, have examined how reciprocity, reputation, and trust are manifested through repeated interaction rather than inferred solely from abstract preference assumptions (Ostrom 1998).

The evidential strength of behavior lies in enacted relation. Repeated transfers can demonstrate a material connection even when participants never label it formally. Coordinated timing can reveal practical interdependence. Patterns of sanction can reveal authority or norm enforcement. Repeated referral can reveal brokerage or reliance. Behavioral traces can therefore help bridge the gap between formally represented relations and relations enacted in practice.

Behavior remains multiply interpretable. The same observed act can be compatible with several relational meanings. A transfer can represent payment, gift, repayment, obligation, coercion, care, strategic investment, or accounting adjust-

ment. Silence can indicate agreement, exclusion, indifference, deference, or lack of opportunity to respond. Frequent communication can reflect collaboration, monitoring, conflict, or procedural necessity. Behavioral evidence therefore warrants a relational claim most strongly when the mapping from action to relational property is supported by context, sequence, institutional knowledge, comparison, testimony, or other evidence.

Selection also matters. Actors choose whether to enter, continue, or leave relations, and their behavior within a relation may reflect capacities or constraints that preceded the observed interaction. Behavioral evidence can establish that an interaction occurred without by itself establishing why the actors were positioned to participate. This limitation becomes especially important when behavioral data are later used for generative attribution, which the next section addresses separately.

GRE should therefore distinguish *behavioral manifestation* from *relational interpretation*. The former identifies an observed action pattern. The latter identifies the relation for which that pattern is taken as evidence. The inferential bridge between them should remain open to revision when new contextual or comparative evidence becomes available.

5.15.5 Testimonial Evidence

Testimonial evidence includes interviews, oral histories, declarations, participant accounts, expert statements, complaints, witness reports, and other communicated accounts of relations or relational experience. It is indispensable when the relevant relation includes meanings, expectations, fear, trust, obligation, dependence, informal coordination, concealed practice, or other dimensions that may not produce adequate documentary or administrative traces. Participants can possess access to relational processes that external observers cannot recover from behavior alone.

Testimony should be evaluated neither as an unmediated report of reality nor as merely subjective material. A speaker occupies a position within the relation and therefore has both epistemic access and epistemic limits associated with that position. Participants can know tacit routines, informal expectations, coercive pressures, and historical context unavailable to an administrative database. They can also misremember, strategically represent, reinterpret retrospectively, or observe only one part of a distributed relation. Section 5.7 developed the idea of observer-position profiles; testimonial evidence is one setting in which such positionality is especially explicit.

Credibility itself is socially structured. Fricker's analysis of testimonial injustice shows how credibility can be unevenly allocated through identity and power relations, while hermeneutical disadvantage can affect the concepts available for making an experience intelligible (Fricker 2007). For GRE, this means that disagreement among testimonies cannot be resolved simply by assigning equal weight to all accounts or by privileging institutionally authoritative speakers. The inquiry should examine access, incentives, vulnerability, dependence, interpretive resources, corroboration, and the relational conditions under which testimony is produced and received.

Testimony can also be evidence about representation rather than only about the

represented relation. How actors name a relation, justify it, refuse a category, or contest an institutional description can reveal symbolic and classificatory structures that affect the relation itself. Divergent accounts may therefore constitute substantive evidence. A worker and a manager can describe the same arrangement differently because they occupy different positions, possess different information, or contest the normative meaning of the relation. The disagreement need not be reduced prematurely to a single corrected narrative.

Definition 5.116 (Testimonial position)**.** A *testimonial position* is the combination of relational location, access, dependence, incentives, interpretive resources, and exposure to consequences that conditions what a speaker can observe, experience, articulate, or strategically disclose about a target relation.

Definition 5.116 turns positionality into part of the evidence record. Testimonial triangulation then involves comparison across positions, not merely accumulation of speakers.

5.15.6 Ethnographic Evidence

Ethnographic evidence is produced through sustained situated engagement with practices, interactions, artifacts, environments, and participants. Its distinctive contribution to relational inquiry lies in recovering relations in operation: how formal rules are enacted, how actors coordinate without explicit articulation, how meanings are negotiated, how material arrangements organize interaction, and how routines distribute knowledge across persons and artifacts. Hutchins's study of navigation provides a well-known example of analysis in which cognitive work is reconstructed across people, procedures, instruments, and organizational arrangements rather than located within one individual (Hutchins 1995). GRE can draw on this evidential sensibility without treating its own relational categories as identical to distributed cognition.

Ethnographic evidence is particularly valuable when relational properties are tacit, situational, performative, or difficult to separate from context. An organizational chart can record formal authority, while observation may reveal who is actually consulted before decisions. A platform rule can specify an official workflow, while field engagement may reveal workarounds, informal assistance, or avoidance practices. A legal entitlement can exist formally, while situated observation reveals the interactional conditions that make claiming it easy, costly, humiliating, risky, or practically impossible.

The observer is part of the evidential situation. Access can depend on gatekeepers, rapport, timing, language, institutional permission, and the willingness of participants to permit observation. Presence can also alter behavior. Ethnographic evidence therefore requires explicit attention to observer position, field access, temporal coverage, note production, and transitions between observation and interpretation. Reflexivity here is an epistemic practice: it records conditions under which the evidence became available and the ways those conditions may have shaped what was observed.

Local richness does not automatically establish wider prevalence. Ethnographic evidence can strongly support a mechanism, practice, meaning, or relational form

within the observed setting while leaving its distribution across other settings uncertain. Generalization therefore requires an explicit bridge, such as comparative cases, purposive variation, theoretical sampling, administrative prevalence evidence, survey evidence, or other forms of cross-context support. The same caution applies in reverse: population-level regularities can establish distribution while missing the situated processes through which relations acquire practical meaning.

Ethnographic inquiry thus contributes a form of *context-preserving relational evidence*. Its epistemic strength lies less in escaping mediation than in documenting enough of the relational setting that actions, categories, artifacts, and accounts can be interpreted together.

5.15.7 Network and Relational Data

Network and relational data represent actors together with explicitly recorded connections among them. These connections can be directed or undirected, weighted or binary, multiplex, signed, temporal, observed, reported, or inferred. Network analysis developed precisely to study patterned relations rather than reducing social structure to aggregated individual attributes (Wellman 1983), while contemporary network science provides extensive tools for describing connectivity, clustering, centrality, degree structure, community organization, and dynamical processes on networks (Newman 2003).

For GRE, the main advantage of network data is explicit relational representation. A dyadic data structure makes it possible to ask whether actors occupy brokerage positions, whether relations cluster, whether some ties are reciprocal, whether paths connect otherwise separated groups, or whether relational patterns differ across layers. Such data are especially useful for the higher-order and field problems introduced in Sections 5.10 and 5.11.

A recorded edge is nevertheless only as meaningful as its operational definition. Co-authorship, communication, trade, co-location, friendship nomination, legal ownership, financial transfer, shared membership, and algorithmically inferred association are different relations. Combining them without preserving type can erase distinctions that matter for explanation. Conversely, treating every recorded edge as equivalent can make formal network precision conceal substantive ambiguity.

Boundary selection is another major source of uncertainty. Network measures can change when omitted actors, external ties, or missing relation types are restored. Sampling is therefore not merely an issue of sample size. Missing nodes and edges can alter the apparent position of observed actors and the architecture of the network itself. The boundary principles of Section 5.8 should be recorded directly in network-data construction: who could enter the network, what relations were detectable, over what period, through which data-generating procedure, and with what missingness.

Definition 5.117 (Relational data provenance)**.** *Relational data provenance* is the recoverable account of how nodes, relation types, edge values, time stamps, boundaries, missingness rules, and transformations were produced from underlying observations, records, reports, or inference procedures.

Provenance is especially important when relational data are repeatedly trans-

formed before analysis. Deduplication, entity resolution, thresholding, aggregation, projection from two-mode data, temporal binning, and privacy-preserving transformations can all change the represented relation. A reproducible relational analysis should therefore preserve these operations as part of the evidential record rather than treating the final adjacency structure as raw observation.

5.15.8 Longitudinal Evidence

Longitudinal evidence observes relational objects across more than one time point or records events with sufficient temporal information to reconstruct change. It is essential for claims about formation, persistence, transformation, dissolution, sequence, and trajectory. A cross-sectional network can show that two actors are connected at a given moment; longitudinal evidence can show whether the relation is newly formed, long-standing, intermittent, intensifying, weakening, or reconstituted after interruption.

Temporal network research demonstrates why timing and duration can alter the analysis of relational processes: the order of contacts can determine which paths are actually available and how processes propagate through a network (Holme and Saramäki 2012). GRE generalizes this temporal discipline beyond formal network models. The evidential question is whether observations preserve enough temporal resolution to support the identity and sequence claims being made.

Longitudinal evidence creates problems of comparability. Categories, measurement instruments, identifiers, organizational boundaries, and reporting rules can change across waves or periods. Apparent relational change can therefore arise from a changed observation regime. Conversely, harmonization can suppress historically meaningful category change by forcing later and earlier records into one coding scheme. Section 5.3 treated manifestation relations as historically variable; longitudinal inquiry must preserve this possibility rather than assuming that repeated variables have constant meaning.

Attrition and survivorship also matter. Relations that dissolve can disappear from later datasets, actors can leave panels, organizations can cease to report, and archives can become less complete farther into the past. Longitudinal evidence is strongest when entry, exit, censoring, missingness, and changing coverage are themselves documented. When these processes are related to the relational phenomenon under study, treating them as random missing data can bias the reconstructed trajectory.

A further distinction is needed between repeated observation and historical continuity. Multiple records bearing the same label do not establish that the same relation persisted. Continuity requires an identity criterion and evidence of the carriers through which the relation remained connected across time, as developed in Sections 5.9 and 5.14. Longitudinal evidence provides the temporal material for that judgment; it does not replace the judgment itself.

5.15.9 Computationally Inferred Evidence

Some economically important relations cannot be observed directly at the desired scale, speed, or granularity. They are reconstructed computationally from text, im-

ages, transactions, communication logs, sensor data, mobility traces, platform events, registries, or other high-dimensional observations. Computational methods can infer entity matches, latent affiliations, predicted ties, similarity relations, communities, roles, influence patterns, or probable interaction structures. Such inference can greatly expand epistemic access, especially where manual coding is infeasible.

Computational inference should be represented as an evidential layer rather than silently converted into observation. A predicted edge and an observed transaction are different epistemic objects even when both appear in the same graph. The distinction parallels Giere's pragmatic account of models as purposive representations of selected aspects of a target rather than identical copies of reality (Giere 2004). Computational simulation and modelling likewise mediate theory, data, approximation, and evidential judgment rather than eliminating those judgments (Winsberg 2010).

At least four components of computationally inferred evidence should remain recoverable. First, the input evidence should be documented, including its coverage and provenance. Second, the target relation should be operationally specified: the model must be trained or designed to infer something more precise than an unspecified notion of connection. Third, model assumptions and transformations should be visible, including thresholds, embeddings, priors, training labels, entity-resolution rules, or other procedures that materially affect the inferred relation. Fourth, validation should compare inferred relations with evidence that is sufficiently independent of the inference process where such evidence is available.

Error structure also matters more than aggregate predictive performance when the downstream object is relational. A small overall error rate can still distort centrality, community boundaries, brokerage positions, or the apparent isolation of a minority group if errors are concentrated systematically. Validation should therefore examine whether false positive and false negative relations vary by position, relation type, subgroup, time, or observation regime.

Computationally inferred relations can become recursive when institutions act on them. A fraud score, recommendation, risk classification, inferred social connection, or predicted affiliation can alter access, monitoring, visibility, or future interaction. Section 5.6 treated this as a performative-representation problem. The evidence file should therefore distinguish the period in which an inference was merely analytical from periods in which it entered the relational system and began to affect the very relations later used for validation.

Proposition 5.118 (Evidential fit for relational claims)**.** *A relational claim is comparatively well warranted when the evidence form is appropriate to the relational property being claimed, the trace-production process and access conditions are documented, characteristic sources of omission or distortion are examined, and materially different evidence forms converge or their disagreements are preserved and explained.*

Proposition 5.118 summarizes the section without requiring every inquiry to collect every evidence type. Some relations are documented densely but difficult to observe behaviorally; others are enacted repeatedly while remaining legally informal; still others become visible mainly through testimony, ethnography, network traces, or computational reconstruction. The appropriate evidential profile depends on the target relation and the strongest inferential gaps that remain.

The resulting stance is one of evidential pluralism under explicit provenance. Documentary, administrative, legal, behavioral, testimonial, ethnographic, network, longitudinal, and computational materials are partially complementary because they expose different manifestations and dimensions of relational reality. Their combination can strengthen reconstruction when differences among them remain visible rather than being collapsed into a single undifferentiated dataset. The next section applies the same discipline to a stronger epistemic target: evidence that a relation, configuration, or field generated a specified effect rather than merely existed or possessed a particular form.

5.16 Evidence for Generative Claims

Section 5.15 classified major evidential forms for establishing that relations exist, possess particular properties, persist, change, or compose into wider configurations. The present section addresses a stronger epistemic target. Its role is to specify what additional evidence is required when GRE claims that a relation, configuration, field, or trajectory contributed to generating a specified effect. Its objective is to differentiate evidence for immediate effects, downstream effects, capacity formation, relation formation, structural transformation, value propagation, recirculation, and generative foreclosure. The structure follows these generative targets in increasing temporal and structural depth. The method is attribution-sensitive: for each target, the analysis asks what change must be evidenced, what temporal and relational linkage must be reconstructed, what alternative explanations remain plausible, and what uncertainty should accompany the resulting claim.

The distinction between relational and generative evidence follows directly from Sections 5.12 and 5.13. Evidence that a relation existed establishes a candidate generative condition. Evidence that an outcome followed establishes temporal succession. A generative claim adds a further requirement: the inquiry must warrant the proposition that the candidate relation or relational configuration contributed to producing, enabling, suppressing, redirecting, or transforming the target effect. Mechanism evidence, counterfactual reasoning, temporal reconstruction, comparison, and heterogeneous traces can contribute to this warrant in different combinations (Woodward 2003; Hedström and Ylikoski 2010; Gangl 2010). The relevant combination depends on the generative object rather than on a universal methodological hierarchy.

Definition 5.119 (Generative evidence)**.** *Generative evidence* is evidence that bears on a specified claim that a relation, relational configuration, field, or historically connected process contributed to producing, enabling, constraining, redirecting, sustaining, or suppressing a target change under stated boundary, scale, and temporal conditions.

Definition 5.119 makes the target effect explicit. A record of collaboration can support a relational claim; evidence that the collaboration produced a new capability requires additional observations concerning capability before and after participation, the process through which learning or access occurred, and plausible competing sources of the change. A transfer can establish resource movement; a claim of recirculation requires evidence that some generated value returned to and altered

the conditions of further generation. A new institutional rule can establish formal change; a claim of structural transformation requires evidence that the rule reorganized recurring relations or possibilities at the relevant scale.

Generative evidence is therefore layered. At minimum, an inquiry normally requires evidence for the candidate relation or configuration, evidence for the target change, and evidence linking the two. Stronger claims can require additional layers: evidence of intermediate carriers, persistence across time, transformation at multiple scales, altered opportunity structures, or feedback into later generative conditions. These layers can be supplied by different source types. Administrative data may establish temporal patterns, testimony may reveal a mechanism, ethnography may identify changed practice, legal materials may establish altered authority, longitudinal network data may show relation formation, and computational models may test whether a specified mechanism is sufficient under explicit assumptions. Evidential pluralism becomes especially important as generative claims extend beyond immediate and directly observable effects.

5.16.1 Evidence of Immediate Effects

Immediate effects are changes that occur within a temporal interval sufficiently close to the candidate generative process for the inquiry to observe the initial response before extensive downstream mediation accumulates. Examples include a change in access following an eligibility decision, altered behavior following a new rule, a resource gain following a transfer, a coordination response following information exchange, or an initial skill improvement following instruction. The relevant meaning of *immediate* is empirical and process-relative. Minutes can be immediate in a market microstructure study, while months can be immediate in institutional or educational change.

Evidence of an immediate effect should normally establish four elements. First, the candidate generative condition must be identified with sufficient temporal resolution. Second, the target outcome must be measured or reconstructed before and after the relevant exposure or event, where the design permits such comparison. Third, the temporal order should place the candidate condition before the observed change. Fourth, plausible contemporaneous causes should be examined to the extent required by the strength of the attribution being made. Experimental, quasi-experimental, counterfactual, and mechanism-based strategies can each contribute to these elements under different research conditions (Woodward 2003; Gangl 2010; Hedström and Ylikoski 2010).

Temporal proximity is useful because it narrows the interval in which competing processes can intervene, yet proximity alone supplies limited causal information. A policy announcement can coincide with a behavioral response because both reflect a third process. A payment can precede increased activity when seasonal demand also rises at the same time. A newly recorded relation can appear shortly before an outcome because the relation itself became observable only after an administrative change. Evidence of immediate effects therefore benefits from combining temporal ordering with a specified mechanism, a credible comparison, intervention variation, or other evidence capable of discriminating among competing explanations.

Proposition 5.120 (Temporal proximity in generative evidence)**.** *Temporal proximity strengthens evidence concerning sequence and the timing of a response. Attribution of generation additionally requires evidence connecting the candidate relation or process to the target change and examining materially plausible contemporaneous alternatives.*

Proposition 5.120 also clarifies why immediate-effect evidence can be strong while remaining narrow. An intervention may have an identifiable first-order effect while its later consequences remain uncertain. Conversely, weak or absent immediate change does not settle whether delayed or mediated effects will emerge. Immediate evidence should therefore specify its temporal horizon and avoid silently extending a short-run result into a claim about a longer generative trajectory.

5.16.2 Evidence of Downstream Effects

Downstream effects occur after one or more mediating stages separate the candidate generative condition from the target outcome. An educational relation can alter competence, which later changes occupational access; an infrastructure investment can alter connectivity, which changes firm location and then local employment; a classification can affect eligibility, which changes resource access and later household behavior. The epistemic burden increases with each mediating stage because additional processes can enter the trajectory.

Evidence for downstream generation therefore requires more than observing a distant association between an earlier relation and a later outcome. The inquiry should reconstruct at least part of the intervening pathway. This can involve records of intermediate states, repeated observations, process-tracing evidence, institutional sequences, participant accounts, network changes, or other traces showing how the effect was carried through time. Mechanism-based explanation is especially useful here because it asks which processes connect earlier and later states rather than treating temporal distance as an unexplained gap (Hedström and Ylikoski 2010).

Definition 5.121 (Downstream evidential chain)**.** A *downstream evidential chain* is a temporally ordered set of evidentially supported intermediate states, relations, carriers, or mechanisms connecting a candidate generative condition to a later target effect.

The chain need not document every micro-event. Its adequacy depends on whether the omitted intervals contain plausible alternative pathways capable of changing the attribution. A long-term effect can be well supported when several independent traces establish the crucial transitions, while a densely recorded sequence can remain weak if its observations all derive from the same unvalidated administrative category or model. The quality of the chain therefore depends on both continuity and evidential independence.

Delayed effects also require attention to stored or latent carriers. Section 5.13 introduced the generative carrier for cases in which an effect is preserved through capabilities, records, infrastructure, expectations, obligations, or other intermediate conditions before becoming manifest. Evidence of downstream generation should identify such carriers where they are central to the explanation. A later outcome that appears after a long interval can then be linked to an earlier generative process through persistent relational or material conditions rather than through temporal

proximity alone.

A further difficulty concerns branching. The same initial condition can generate several pathways, and a downstream target may depend on only one branch. Evidence should therefore preserve branch-specific sequences where possible. Aggregating all later outcomes into a single average can conceal that one subgroup gained access through a generated relation while another encountered a new constraint. The evidential object is the historically realized generative pathway under the stated boundary and scale, together with credible alternatives relevant to the attribution.

5.16.3 Evidence of Capacity Formation

Capacity formation concerns changes in what an actor or collectivity can effectively do, sustain, access, coordinate, understand, create, or become within the relevant relational environment. The capability approach provides an established reason to distinguish resources from substantive opportunities and achieved functionings (Sen 1999). GRE extends this distinction toward an evidential question: what supports the claim that participation in a specified relation contributed to forming or transforming a capacity?

Evidence of capacity formation should identify a capacity with sufficient operational clarity to distinguish it from the inputs believed to support it. Training hours, funding, tools, credentials, or network membership can be enabling resources, while the target capacity may concern independent performance, coordination ability, access to institutions, problem-solving competence, bargaining ability, or the practical feasibility of undertaking a valued activity. Observing the input therefore provides evidence of exposure. Evidence of formation additionally requires traces of changed ability or changed effective opportunity.

Several evidential strategies can contribute. Repeated performance measures can show changed competence; independent task completion can show that a capability persists beyond the immediate instructional relation; new access to partners or institutions can reveal relational capacity; participant testimony can identify changes in confidence or practical feasibility; administrative or market records can show newly realized activities; and longitudinal observation can establish whether the capability persists, decays, or transfers across contexts. The strongest profile often combines demonstrated ability with evidence about the process through which the capacity was acquired.

Definition 5.122 (Capacity-formation evidence)**.** *Capacity-formation evidence* supports a claim that a specified relation or generative process contributed to a change in effective ability or opportunity by documenting the relevant pre-existing condition, the changed capacity, and a plausible pathway connecting relational participation to that change.

This definition leaves room for capacities that are collective or infrastructural. A research consortium can acquire a capacity for coordinated experimentation that no member possesses independently. A community can develop governance capacity through repeated participation and record keeping. A platform can create technical capacity for exchange while simultaneously concentrating control over access. Capacity evidence should therefore specify the bearer of the capacity and the relational

conditions required for its exercise.

Persistence also matters. A short-lived performance improvement and a durable capacity are different claims. The temporal window should match the intended conclusion. Where capacity depends continuously on a supporting relation, the inquiry should state that dependence rather than representing the capacity as fully internalized by the actor. This is especially important for economic capacities that rely on infrastructure, legal recognition, care, credit, data access, language, reputation, or membership in an institutional field.

5.16.4 Evidence of Relation Formation

Relation formation becomes a generative target when an earlier relation, configuration, or field contributes to creating a later relation. Examples include collaboration that creates later partnerships, membership that produces new professional ties, platform participation that creates buyer-seller relations, institutional recognition that enables contracting, or conflict that reorganizes alliances. Section 5.12 defined relationally generated relations; the present question concerns the evidence required to support that attribution.

The evidential burden has two parts. The inquiry must first establish that the later relation formed or changed in the relevant interval. It must then connect that formation to the prior relation. Longitudinal network data can establish temporal ordering, but the observed sequence can arise through selection: actors who were already likely to form the later relation may also have entered the earlier one. Mechanism evidence can help by showing how participation created information, trust, reputation, compatibility, access, obligation, or shared infrastructure that made the later relation possible or more likely.

Interorganizational research provides an illustrative precedent. Powell, Koput, and Smith-Doerr show how collaboration can operate as a locus of learning and how participation in interorganizational networks can shape later organizational opportunities (Powell et al. 1996). Such findings illustrate the kinds of traces that can support generative relation-formation claims: dated collaboration records, subsequent ties, partner histories, learning processes, reputational changes, and comparison with actors lacking similar prior participation. The specific GRE claim still requires target-relative reconstruction rather than assuming that network participation is generative in every setting.

Evidence is especially strong when the later relation would have been inaccessible, substantially less feasible, or materially different without the earlier generative condition. Formal authorization can provide one such bridge: a credential, legal status, or institutional membership may create eligibility for later relations. Informal processes can also be decisive: repeated interaction can create trust, shared language, recognition, or knowledge of available partners. These mechanisms leave different traces and therefore require different evidence forms.

Relation formation can also be negative. An earlier process can generate exclusionary ties, dependency, or relations of monitoring and control. The evidential standard should remain symmetrical with respect to desirability. Establishing that a relation was generated does not establish that it was beneficial, just, voluntary, or stable. Nor-

mative evaluation enters through separate criteria.

5.16.5 Evidence of Structural Transformation

Structural transformation concerns changes in relatively persistent arrangements that organize multiple subsequent relations. Relevant objects can include institutional rules, recurrent role structures, market architectures, organizational routines, technical standards, infrastructures, category systems, ownership arrangements, or patterned distributions of authority and access. Institutions are an established economic example because rules and constraints can organize interaction over time (North 1990). For GRE, the evidential question is whether a generative process altered such an organizing structure at the scale claimed.

Evidence of structural transformation should therefore extend beyond isolated local outcomes. A new rule can be documented legally, yet structural transformation requires evidence that the rule altered recurring relations or the conditions under which those relations form. A technological standard can be formally adopted, while evidence of structural transformation concerns its effects on compatibility, entry, coordination, or dependence across the relevant system. A reorganization can change an organizational chart while leaving actual authority patterns largely intact. Structural evidence consequently benefits from combining formal change with repeated behavioral, relational, or institutional traces.

Definition 5.123 (Structural-transformation evidence)**.** *Structural-transformation evidence* supports a claim that a generative process altered a persistent organizing condition of multiple relations by documenting the prior structure, the transformed structure, the mechanisms or sequence linking them, and recurring consequences at the boundary and scale specified by the inquiry.

Persistence is relevant because structural claims concern organizing conditions that continue to shape later interaction. The required duration varies by object. A market rule can transform trading immediately, while an educational classification may take years to alter institutional trajectories. Historical institutional research on increasing returns and path dependence shows how earlier arrangements can become progressively consequential when feedback alters the costs or feasibility of alternatives (Pierson 2000). Such work provides one evidential lineage for examining whether a change became structurally reproduced over time.

Structural transformation also requires boundary sensitivity. A change can be structural within one organization and local within an industry; structural within a national legal system and peripheral within a transnational production network. The claim should therefore state the population of relations organized by the transformed condition. Cross-scale claims require bridge evidence showing how the local transformation propagated into wider arrangements, following the scale discipline established in Section 5.8.

A useful evidential profile combines evidence of rule or architecture change, repeated relational consequences, persistence, and altered pathways for actors entering the structure later. This last component matters because a transformed structure often becomes most visible through how it conditions actors who did not participate in producing the original change.

5.16.6 Evidence of Value Propagation

Value propagation concerns the movement, transformation, recognition, or reproduction of a specified form of value across relations or sites. The term requires care because economic, cultural, social, symbolic, ecological, informational, and other forms of value need not share one metric. Throsby's distinction between economic and cultural value provides an established example of multidimensional valuation (Throsby 2001), while Appadurai's analysis of commodities emphasizes that value is organized through socially and politically structured trajectories of exchange (Appadurai 1986). GRE therefore treats value propagation as an evidential problem only after the relevant value form and its indicators have been specified.

Evidence of propagation requires more than repeated appearance of the same nominal quantity. A financial transfer can be traced through accounting records, but a claim that knowledge value propagated through a collaboration may require evidence that information was learned, reused, recombined, or made available to additional actors. Cultural value can persist while monetary price changes; reputational value can propagate through recognition networks without a direct transfer of assets. The evidential object is therefore the continuity or transformation of value-relevant effects across relational steps.

Definition 5.124 (Value-propagation evidence)**.** *Value-propagation evidence* supports a claim that a specified form of value or value-relevant capacity moved, transformed, or became effective across a sequence of relations by identifying the value form, the relational carriers or conversion interfaces, and the traces through which continuity or transformation can be reconstructed.

Conversion creates a major epistemic challenge. If financial support funds education and later competence contributes to scientific collaboration, the sequence contains several heterogeneous objects. Treating the entire sequence as propagation of one conserved quantity would erase the transformations that make the process economically and socially significant. Evidence should instead record where the value form changes, which actors or institutions perform the conversion, what is lost or created in conversion, and which indicators remain comparable across stages.

Propagation also differs from attribution of final benefit. Value can pass through an actor without remaining there; it can be amplified, diluted, redirected, captured, or transformed. A platform can propagate information while capturing monetary value; a community can generate cultural value that later acquires commercial value elsewhere; a public infrastructure can create access whose benefits disperse across many actors. The evidential design should preserve these directional and distributive differences rather than compressing them into one aggregate outcome.

This subsection remains epistemic rather than a completed theory of value. Its purpose is to state what evidence would be needed when later GRE chapters make substantive claims about heterogeneous value propagation. Those claims will require value-specific operationalization and cannot be inferred solely from the existence of a relational chain.

5.16.7 Evidence of Recirculation

Recirculation concerns a more specific temporal structure than propagation. Something generated through a relational process returns, directly or through mediated pathways, to replenish, maintain, repair, expand, or transform the conditions from which further generation can occur. The generative-justice literature provides an important precedent through its emphasis on unalienated circular value flows and the return of value toward the people and communities involved in its generation (Eglash 2016; Eglash et al. 2024). GRE uses this lineage while keeping its broader categories of heterogeneous value, capacity, relation, and generative condition analytically distinct.

Evidence of recirculation should identify at least four components: the generative configuration or condition from which the relevant value or capacity emerged; the generated object or benefit being traced; the pathway through which some portion returns; and evidence that the return affects the later generative condition. Repeated transfer alone establishes circulation. Recirculation, in the GRE sense used here, requires a return relation whose effects can be connected to renewed or transformed generative capacity.

Definition 5.125 (Recirculation evidence)**.** *Recirculation evidence* supports a claim that a generated resource, value form, capacity, or other consequential object returned through a specified relational pathway and contributed to maintaining, replenishing, repairing, expanding, or transforming the conditions of subsequent generation.

This definition allows recirculation to be partial and mediated. Revenue can return through taxation to public infrastructure; knowledge generated in research can return through teaching to a community of practice; cooperative surplus can finance shared equipment; reputational gains can attract new partners whose participation expands later capacity. In each case, the returning object may change form before it affects the generative condition. Evidence should preserve the conversion pathway rather than requiring literal return of an identical object.

The temporal horizon can be long. A generated surplus invested in training may affect productive capacity years later. Recirculation evidence therefore often combines accounting or transfer records with longitudinal evidence of changed capacity, infrastructure, membership, or relation formation. Where several cycles occur, the inquiry should distinguish a single return episode from a self-reinforcing recurrent process. A durable cycle claim requires evidence that the return repeatedly alters subsequent generation and that the cycle persists across more than one iteration.

Recirculation also has distributional structure. Value can return to one component of a generative system while leaving other contributors uncompensated or depleted. Evidence of recirculation therefore does not establish equitable return. The inquiry should identify which actors, infrastructures, ecosystems, or relations receive the return and which generative conditions remain unreplenished. This distinction will later matter for substantive analysis of extraction, capture, regeneration, and justice.

5.16.8 Evidence of Generative Foreclosure

Generative foreclosure occurs when a prior relation or generative process contributes to narrowing, disabling, making prohibitively costly, or otherwise suppressing future capacities, relations, trajectories, or transformation possibilities. The target is therefore an altered possibility structure rather than merely an unfavorable realized outcome. Evidence of foreclosure is demanding because unchosen possibilities leave weaker traces than realized events.

The first requirement is a historically credible account of the alternatives that were feasible before the relevant generative process. These alternatives should be grounded in contemporary resources, technologies, institutional rules, available partners, legal permissions, knowledge, or demonstrated practices. Section 5.14 established the same constraint for historical counterfactuals: later possibilities should not be projected backward into periods in which their enabling conditions were absent.

The second requirement is evidence of a mechanism through which the candidate process narrowed the option set. Increasing returns and lock-in provide one established family of mechanisms. Arthur shows how early contingent adoption under increasing returns can alter the later viability of competing technologies (Arthur 1989), while Pierson extends sequence-sensitive increasing-return reasoning to institutional development (Pierson 2000). GRE treats these as specific mechanisms rather than a complete theory of foreclosure. Other mechanisms can include legal exclusion, resource depletion, reputational penalties, loss of interoperability, concentrated ownership, dependency, destruction of infrastructure, accumulated switching costs, or suppression of alternative relation formation.

Definition 5.126 (Generative-foreclosure evidence)**.** *Generative-foreclosure evidence* supports a claim that a specified relation or generative process contributed to reducing a historically feasible set of future capacities, relations, trajectories, or transformation pathways by documenting the prior possibilities, the mechanism of narrowing, and the subsequent reduction in effective feasibility at the stated boundary, scale, and temporal horizon.

The third requirement is evidence that the narrowing affected effective feasibility. A formally available alternative can become practically inaccessible because costs, skills, infrastructure, recognition, financing, or partner availability have changed. Sen's distinction between resources and substantive opportunities is again useful here because nominal permission can coexist with severely reduced practical capability (Sen 1999). Evidence of foreclosure can therefore include rising switching costs, disappeared suppliers, loss of skills, withdrawn legal recognition, infrastructure incompatibility, shrinking partner sets, increased dependency, or repeated failure of alternatives that were previously feasible.

Reversibility should also be assessed. Some foreclosure is temporary and can be reversed through modest intervention; other forms become increasingly costly to undo as complementary investments, expectations, and institutions accumulate. The strength of the foreclosure claim should reflect this degree of persistence. A reversible local constraint and a historically entrenched reduction in system-level possibility are different generative objects.

Foreclosure remains analytically distinct from normative condemnation. Safety rules can intentionally eliminate hazardous options, environmental restrictions can close destructive extraction pathways, and compatibility standards can reduce certain forms of variation while enabling wider coordination. Evidence can establish which possibilities were narrowed, through what mechanism, for whom, and with what reversibility. Normative assessment requires additional criteria concerning the values, rights, harms, benefits, and distributional consequences involved.

Proposition 5.127 (Minimum evidential burden for generative claims)**.** *A generative claim is comparatively well warranted when the inquiry identifies the candidate generative relation or configuration, specifies and evidences the target change, reconstructs a plausible mechanism or dependency connecting candidate and target, examines materially relevant alternatives, and states the boundary, scale, temporal horizon, and uncertainty under which the attribution is made. Claims involving downstream mediation, structural transformation, recirculation, or foreclosure require additional evidence for the intermediate carriers, recurrent effects, return pathways, or altered possibility structures that define those generative objects.*

Proposition 5.127 summarizes the evidential difference between relation and generation. The burden does not demand one privileged research design. Immediate effects may sometimes be identified through intervention or quasi-experimental variation; downstream processes may require longitudinal reconstruction and mechanism evidence; capacity formation can require demonstrated ability and situated interpretation; relation formation can require temporal network and institutional evidence; structural transformation can require persistent cross-relational effects; value propagation and recirculation require traceable carriers and conversion pathways; foreclosure requires evidence about historically feasible alternatives and their later loss of effective accessibility.

The section therefore establishes a graded evidential architecture for GRE. Stronger claims require evidence that reaches farther into temporal sequence, mediation, structure, and possibility. Evidential pluralism remains compatible with demanding attribution because each evidence form is assigned a specific role in the generative reconstruction. The next section turns from the kinds of evidence that can support relational and generative claims to the uncertainty that remains after such evidence has been assembled, including uncertainty about relations, manifestations, generative effects, boundaries, scales, time, models, and competing explanations.

5.17 Uncertainty and Degrees of Epistemic Confidence

Sections 5.15 and 5.16 specified evidential forms for relational and generative claims. The present section addresses the epistemic remainder that persists after relevant evidence has been assembled. Its role is to organize uncertainty within GRE so that uncertainty is reported at the level where it arises rather than being compressed into a single undifferentiated judgment. Its objective is to distinguish relational, manifestational, generative, boundary, scale, temporal, and model uncertainty, and to specify how competing relational explanations affect degrees of epistemic confidence. The structure follows these sources of uncertainty from the target relation through the

observational and representational process to the explanatory model. The method is claim-relative and profile-based: confidence is assessed with respect to a specified proposition, boundary, scale, temporal horizon, evidence base, and inferential route.

Uncertainty enters relational inquiry through several routes. The relation itself can be incompletely identified; manifestations can underrepresent or distort it; generative contribution can remain only partially attributed; analytical boundaries can be contestable; scale changes can alter the pattern observed; temporal coverage can be insufficient; and alternative models can organize the same traces differently. Partial identification provides one useful precedent for disciplined restraint: Manski argues that researchers should distinguish what data identify from what follows only after stronger assumptions are imposed (Manski 2008). The broader philosophical problem of underdetermination similarly concerns cases in which available evidence remains compatible with more than one theoretical or explanatory account (Stanford 2023). GRE incorporates these concerns without reducing all uncertainty to statistical sampling error or to a single philosophical problem.

Definition 5.128 (Epistemic uncertainty in GRE)**.** *Epistemic uncertainty in GRE* is the residual openness concerning a specified relational or generative claim that remains after available evidence, assumptions, boundary and scale choices, temporal coverage, representational decisions, and competing explanations have been stated.

Definition 5.128 makes uncertainty conditional on an articulated inquiry. The same body of evidence can warrant high confidence in one proposition and limited confidence in another. Repeated administrative records can strongly support the persistence of a recorded eligibility status while providing weaker support for the lived relation between an institution and a household. Longitudinal network data can establish repeated interaction while leaving the meaning, authority, or generative significance of those ties uncertain. A credible quasi-experimental design can support a local causal effect while leaving the long-run trajectory, cross-scale consequences, or mechanism comparatively open.

For this reason, GRE treats epistemic confidence as a profile rather than presuming that every claim can be summarized by one scalar quantity. Quantified probabilities, confidence intervals, posterior distributions, sensitivity ranges, or partial-identification regions can be appropriate when the inferential design supports them. Other uncertainties are better expressed through bounded alternatives, competing reconstructions, graded qualitative judgments, or explicit statements of unresolved assumptions. Numerical expression gains epistemic force only when the quantity being represented and the assumptions generating it are themselves adequately specified.

Definition 5.129 (Epistemic confidence profile)**.** An *epistemic confidence profile* is a structured statement of the degree and location of warrant for a specified claim across the dimensions materially relevant to that claim, including where appropriate relational identification, manifestation, generative attribution, boundary, scale, temporal coverage, model dependence, and competing explanations.

The profile in Definition 5.129 prevents strength in one evidential dimension from silently compensating for weakness in another. A large dataset cannot by its size alone settle whether the recorded variable adequately manifests the target relation.

Rich qualitative material cannot by local depth alone establish prevalence across a wider population. Agreement among several models can strengthen confidence when the models rely on meaningfully different assumptions; agreement among near-identical specifications can provide less independent support. Confidence therefore concerns the architecture of warrant rather than the quantity of evidence in the abstract.

5.17.1 Relational Uncertainty

Relational uncertainty concerns what relation exists, between which relata, with what properties, and with what degree of persistence or efficacy. It begins at the level of the target itself. Two actors may exchange messages, share an administrative category, enter repeated transactions, or appear adjacent in network data while the substantive relation remains uncertain. The inquiry may know that some interaction occurred yet remain uncertain whether the relation is cooperative, hierarchical, contractual, fiduciary, coercive, symbolic, informational, or composed of several of these dimensions.

Relational uncertainty can arise from incomplete access, ambiguous traces, changing participant identities, heterogeneous interpretations, hidden intermediaries, or insufficient evidence about the persistence criteria discussed in Section 5.9. It can also arise when the relation is real but only partially stabilized. An emerging collaboration, contested legal status, unstable alliance, or newly forming market relation can possess causal efficacy before its properties become settled enough for a simple classification.

The epistemic task is therefore to disaggregate the relational claim. Confidence that interaction occurred can exceed confidence concerning its content. Confidence concerning legal obligation can exceed confidence concerning actual compliance. Confidence concerning repeated exchange can exceed confidence concerning trust. Confidence concerning organizational membership can exceed confidence concerning effective participation. Reporting these distinctions avoids treating the relation as epistemically all-or-nothing.

Remark 5.130 (Relational confidence and classificatory resolution)*.* Increasing classificatory precision can lower warranted confidence when the available evidence supports a broad relational category more strongly than a fine-grained subtype. GRE therefore permits a well-supported coarse relational claim to coexist with uncertainty about its more specific characterization.

Remark 5.130 is important for historical and comparative work. A surviving archive can support the existence of a dependency relation while leaving its precise informal obligations unclear. Administrative data can establish repeated service contact while providing limited information about interpersonal recognition or coercion. Computationally inferred communities can reveal clusters of interaction while leaving the substantive relation among their members open. Epistemic discipline sometimes requires reducing classificatory resolution rather than increasing it.

Relational uncertainty should also remain distinct from normative ambiguity. An inquiry can be highly confident that a relation is asymmetric while remaining uncertain about whether the asymmetry is justified under the relevant normative criteria.

Conversely, normative concerns can be substantial even when the exact relational structure remains uncertain. Chapter 5 concerns the epistemic architecture of the claim; later normative analysis can build upon that architecture without substituting moral evaluation for evidential warrant.

5.17.2 Manifestational Uncertainty

Manifestational uncertainty concerns the relation between relational reality and the manifestations through which it becomes accessible to inquiry. Section 5.2 established that manifestation is generally non-invertible, while Sections 5.3–5.5 distinguished manifestation relations, traces, symbolization, and representation. Even when the observed trace is measured accurately, uncertainty can remain about what relational state produced it.

A decline in recorded transactions can reflect weakening exchange, migration to an unrecorded channel, strategic concealment, administrative reclassification, or a change in the recording system. A stable legal category can coexist with changing practice. A survey response can reflect experience, strategic presentation, interpretive framing, or the available answer categories. A model-generated score can aggregate traces that correspond only indirectly to the relational target. The uncertainty therefore lies partly in the manifestation mapping rather than in measurement noise alone.

Manifestational uncertainty can be reduced when the inquiry possesses evidence about the production of the trace. Knowledge of administrative procedures clarifies how categories enter a database. Ethnographic observation can reveal how survey terms are interpreted. Technical documentation can show how platform events are logged. Legal analysis can distinguish formal status from implementation. Repeated measurement across different manifestation channels can reveal whether a relational inference is robust to the particular trace used.

Definition 5.131 (Manifestational uncertainty)**.** *Manifestational uncertainty* is uncertainty concerning how observed manifestations, traces, or representations correspond to the relational state or process targeted by an inquiry, including uncertainty about omission, distortion, selective visibility, translation, and changes in the manifestation process itself.

Definition 5.131 implies that data quality and relational correspondence are related but distinct questions. A dataset can be internally consistent and accurately recorded while providing a limited manifestation of the target relation. Conversely, a noisy set of heterogeneous traces can sometimes support a relational conclusion when their independent production pathways converge on the same underlying structure. The relevant question is how the evidence bears on the target through the specific manifestation relation.

Manifestational uncertainty also changes historically. When reporting rules, platform architectures, legal definitions, or cultural conventions change, the same observed category can acquire a different relation to the underlying process. Longitudinal research should therefore assess continuity in the manifestation relation itself. Apparent change in the target relation can otherwise be produced by a changing observational interface.

5.17.3 Generative Uncertainty

Generative uncertainty concerns whether, how, and to what degree a relation or configuration contributed to producing a target change. Sections 5.12, 5.13, and 5.16 established that generative claims are stronger than claims of relational existence. Even when a relation and an outcome are both well evidenced, uncertainty can remain concerning the contribution that connects them.

Several sources are common. The mechanism can be only partially observed. Multiple sufficient or enabling causes can coexist. A candidate relation can matter only in conjunction with complementary conditions. Counterfactual dependence can vary across units or contexts. Effects can be delayed, distributed, or mediated by several stages. A process can redirect the form of change without determining its occurrence. The same relation can generate different consequences under different surrounding configurations.

Generative confidence should therefore specify the object of attribution. Confidence that a program increased access can exceed confidence that the resulting access produced durable capability. Confidence that a classification altered eligibility can exceed confidence concerning its longer-term effect on household trajectories. Confidence that a network position supplied information can exceed confidence that information was decisive for a later innovation. Local causal identification does not automatically settle wider generative significance.

Interventionist and counterfactual approaches provide tools for distinguishing causal contribution under explicit assumptions (Woodward 2003; Gangl 2010), while mechanism-based inquiry can reconstruct the processes connecting earlier and later states (Hedström and Ylikoski 2010). GRE uses these resources selectively. Confidence can increase when distinct forms of evidence support the same generative attribution, especially when they constrain different plausible alternatives.

Proposition 5.132 (Layered confidence in generative claims)**.** *Confidence in a generative claim depends jointly on warrant for the candidate relation or configuration, warrant for the target change, and warrant for the linkage between them. High confidence in either the relation or the outcome cannot by itself compensate for weak evidence concerning the generative linkage.*

Proposition 5.132 also applies to stronger objects such as recirculation and foreclosure. A recirculation claim inherits uncertainty about the initial generation, the conversion or transfer pathway, the return path, and the effect of the returned value on later generative conditions. A foreclosure claim inherits uncertainty about prior feasible alternatives, the mechanism of narrowing, and the persistence of reduced effective accessibility. Generative uncertainty often accumulates across a chain, although independent evidence at later stages can sometimes narrow parts of that uncertainty.

5.17.4 Boundary Uncertainty

Boundary uncertainty concerns which actors, relations, institutions, environments, and processes should be included in the analytical object. Section 5.8 showed that analytical boundaries can be epistemic constructions while some boundaries are simul-

taneously relationally real and causally efficacious. Uncertainty arises when several plausible boundary specifications produce materially different interpretations of the same process.

Consider a firm-level productivity analysis. A narrow boundary can attribute performance to internal organization. A wider boundary can reveal dependence on suppliers, public infrastructure, family care, ecological inputs, regulatory systems, or knowledge produced elsewhere. Neither boundary becomes adequate simply by being wider. Expanding the boundary can introduce processes irrelevant to the target and reduce analytical tractability. The relevant question is which boundary captures the relations materially necessary for the claim being evaluated.

Boundary uncertainty can be explored through sensitivity analysis. The inquiry can reconstruct the claim under nested or alternative boundary specifications and identify which conclusions remain stable. If an attribution survives reasonable boundary changes, confidence in its portability increases. If the conclusion changes sharply when one neighboring relation is included, the analysis should report that dependency rather than hide it inside a preferred specification.

Definition 5.133 (Boundary-sensitive confidence)**.** *Boundary-sensitive confidence* is confidence in a relational or generative claim stated together with the range of plausible analytical boundaries across which the claim remains adequately warranted and the boundary changes under which its interpretation materially changes.

Boundary uncertainty can also be asymmetric. Excluded relations may matter more for some actors than for others. A household boundary that omits informal care can distort the position of caregivers more strongly than that of other members. A national boundary can obscure transnational production or financial relations for sectors whose operation depends heavily on them. Boundary sensitivity should therefore be evaluated with attention to heterogeneous positional effects rather than only to aggregate model fit.

The objective is conditional closure rather than exhaustive inclusion. An inquiry can legitimately delimit an object when the boundary is explicit, relevant external relations are examined, and the claim remains scoped to the resulting domain. Epistemic confidence weakens when a bounded result is silently generalized beyond the relations that made it possible.

5.17.5 Scale Uncertainty

Scale uncertainty concerns the level or resolution at which a relational pattern should be described and the extent to which a conclusion survives movement across scales. Section 5.8 established that relational claims can be scale-indexed. A regularity visible at an aggregate level can coexist with heterogeneous or contrary patterns at local levels, while a locally important relation can disappear when observations are aggregated.

Scale uncertainty therefore differs from boundary uncertainty. Boundary questions concern which elements are included; scale questions concern the level of organization or resolution at which their relations are represented. The two interact, but they can vary independently. The same bounded population can be studied at indi-

vidual, household, organizational, regional, or system level, and each representation can reveal different dependencies.

Confidence across scales requires bridge evidence. If an individual-level relation is used to explain an organizational pattern, the inquiry should specify how individual interactions aggregate, coordinate, or become institutionalized. If an aggregate relation is used to infer individual experience, the inquiry should establish the distributional or positional mechanism that carries the aggregate condition downward. A cross-scale inference gains strength when these bridge processes are directly evidenced rather than assumed.

Proposition 5.134 (Scale-indexed epistemic confidence)**.** *Epistemic confidence attaches first to a claim at the scale for which the evidence and inferential design provide warrant. Extension to another scale requires additional evidence concerning the relations that connect the two scales and the transformations introduced by aggregation or disaggregation.*

Proposition 5.134 protects against two common errors. The first is ecological extension, in which an aggregate pattern is attributed to individual relations without adequate bridge evidence. The second is atomistic extension, in which locally observed mechanisms are presumed to determine system-level outcomes despite coordination effects, institutional mediation, feedback, or compositional change. GRE's multiscale ambition therefore increases rather than reduces the need for scale-specific uncertainty statements.

Scale uncertainty can also be substantive. Some relations become causally efficacious only after sufficient aggregation or institutional stabilization; others are weakened by aggregation because their significance depends on local position or meaning. The appropriate epistemic response is to state which scale the evidence supports and which cross-scale claims remain provisional.

5.17.6 Temporal Uncertainty

Temporal uncertainty concerns when a relation begins, how long it persists, when an effect occurs, which historical interval is relevant, and whether an observed pattern can be transported across time. Sections 5.9 and 5.14 established that relational identity and historical trajectory require explicit continuity criteria. An inquiry can possess strong evidence about a relation at several time points while remaining uncertain about what occurred between them or whether the same generative mechanism persisted throughout the interval.

Temporal uncertainty is especially important when effects operate on different timescales. A policy can have a rapid administrative effect, a slower behavioral effect, and a much later institutional effect. A relational intervention can initially expand access while gradually creating dependency. An innovation can produce immediate efficiency gains while altering capability formation over a longer horizon. Confidence concerning one temporal window should therefore remain indexed to that window.

Historical evidence introduces additional asymmetry. Later periods can generate records that clarify earlier processes, yet later categories can also distort reconstruction when projected backward. Section 5.14 treated historical re-epistemization as

disciplined revision under later evidence. Temporal confidence should preserve both possibilities: later knowledge can strengthen an earlier reconstruction, and changing categories can make direct comparison more difficult.

Definition 5.135 (Temporal confidence horizon)**.** A *temporal confidence horizon* is the interval over which the available evidence and continuity assumptions provide adequate warrant for treating a relational or generative claim as applicable, together with the conditions that limit extension beyond that interval.

The temporal confidence horizon in Definition 5.135 can be short even when the underlying phenomenon is long-lived. Data availability, institutional change, altered measurement rules, or unobserved transitions can restrict the period for which a claim is warranted. Conversely, sparse records can sometimes support a longer continuity claim when independent historical evidence establishes stable mechanisms and persistent relational carriers.

Sequence also matters. Path-dependent processes can make the same intervention produce different outcomes depending on when it enters the trajectory. Pierson's analysis of increasing returns highlights how sequence and timing can shape institutional development (Pierson 2000). Temporal uncertainty therefore concerns more than duration; it also concerns historical ordering and the timing of relational entry into an evolving configuration.

5.17.7 Model Uncertainty

Model uncertainty concerns the dependence of an inference on the representational, statistical, computational, formal, or conceptual model through which evidence is organized. Every model selects variables, relations, functional forms, priors, categories, mechanisms, spatial or temporal resolutions, and criteria of relevance. These selections can materially affect the relational structure that appears in the analysis.

Model uncertainty includes specification uncertainty, parameter uncertainty, structural uncertainty, and uncertainty concerning the relation between the model and the target system. These forms should be distinguished. A model can have tightly estimated parameters while relying on a contested structural specification. Several models can fit observed data similarly while implying different relational mechanisms. A computational simulation can demonstrate that a mechanism is sufficient to produce a pattern under its assumptions while leaving open whether that mechanism generated the empirical case.

Partial-identification reasoning is especially useful when several assumptions remain plausible. Rather than selecting one strong assumption set merely to obtain a point estimate, an inquiry can report the range of conclusions consistent with weaker assumptions (Manski 2008). GRE generalizes the discipline behind this move: where the model does more inferential work than the evidence alone can support, the added assumptions should remain visible in the confidence statement.

Definition 5.136 (Model-dependent warrant)**.** *Model-dependent warrant* is epistemic support for a claim whose strength or content changes materially with the model class, specification, representational assumptions, or inferential constraints used to connect evidence to the target.

Model dependence does not make a claim unusable. It identifies where confidence resides. An inference can be highly robust within a well-justified model class and less secure across alternative classes. Sensitivity analysis, specification comparison, out-of-sample validation, qualitative cross-checking, mechanism evidence, and comparison with independently produced data can each reduce particular forms of model uncertainty. Their value depends on whether they probe genuinely different assumptions.

GRE should also distinguish model uncertainty from ontological uncertainty. Several models can remain empirically compatible because the evidence underdetermines the relational mechanism. This does not require a conclusion that the underlying relational reality itself is indeterminate. The epistemic claim is narrower: the current evidence and models do not yet warrant a unique reconstruction. Ontological suspension therefore remains compatible with strong comparative judgments among models when the evidence supports them.

5.17.8 Competing Relational Explanations

Competing relational explanations arise when two or more reconstructions remain materially compatible with the available manifestations and evidence while differing in the relations, mechanisms, boundaries, scales, or trajectories they posit. This problem appears throughout Chapter 5. The inverse problem of manifestation in Section 5.2 permits several relational realities to generate similar manifestations. Higher-order reconstruction in Section 5.10 can organize the same first-order ties into different structures. Field attribution in Section 5.11 can compete with aggregate or common-cause explanations. Generative attribution in Section 5.13 can remain open among several causal pathways.

The existence of competing explanations should therefore be represented as structured uncertainty rather than treated automatically as epistemic failure. Rival explanations can differ in their empirical commitments. New evidence can discriminate among them by targeting manifestations on which they diverge. A field explanation and a pairwise-network explanation may make different predictions about positional effects. A direct-causation account and a mediated account can imply different temporal sequences. A legal-institutional explanation and an informal-relational explanation can imply different responses to formal rule changes.

Definition 5.137 (Explanatory competition set)**.** An *explanatory competition set* is a stated collection of materially plausible relational or generative explanations that remain compatible with the current evidence at the relevant boundary, scale, and temporal horizon, together with the evidence that favors, weakens, or could discriminate among them.

The competition set in Definition 5.137 is narrower than an unrestricted list of imaginable alternatives. Plausible competitors should possess some evidential or theoretical basis and should address the same target claim. This discipline prevents manufactured uncertainty in which arbitrary possibilities are invoked merely because they cannot be logically excluded. Underdetermination matters when alternatives remain live under the actual evidence and reasonable background assumptions (Stanford 2023).

Competing explanations can also be partially complementary. An institutional rule can alter incentives while a social network shapes information diffusion and a cultural classification affects recognition. Inquiry should test whether the explanations truly compete for the same generative role or describe different parts of a composite process. Premature selection of a single explanation can be as misleading as premature synthesis. The appropriate reconstruction can retain several contributions while differentiating their domains and evidential status.

Proposition 5.138 (Profiled epistemic confidence)**.** *A relational or generative claim is epistemically stronger when confidence is stated at the level of the specific proposition and accompanied by the material uncertainties concerning relational identification, manifestation, generative attribution, boundary, scale, temporal horizon, model dependence, and competing explanations. Strength in one dimension should not silently erase unresolved uncertainty in another.*

Proposition 5.138 provides the organizing principle for degrees of epistemic confidence in GRE. Some inquiries can legitimately summarize particular uncertainties numerically. Others require intervals, sets of admissible explanations, sensitivity statements, or disciplined qualitative judgments. The common requirement is traceability: a reader should be able to identify which evidence supports the claim, which assumptions extend beyond that evidence, which dimensions remain open, and what additional observations could materially change the conclusion.

This profile-based approach also supports revisability. Confidence can increase when new evidence narrows the relation, manifestation mapping, boundary, scale, temporal sequence, or model class. It can decrease when new traces reveal omitted actors, changing classification rules, previously hidden pathways, or stronger competing explanations. Revision therefore becomes an expected epistemic operation rather than an exceptional admission of failure.

The next section turns from uncertainty within relational inquiry to the distribution of epistemic visibility, authority, and evidential capacity among differently positioned actors. Once uncertainty is recognized as structured and position-sensitive, questions arise concerning whose relations become visible, whose testimony receives uptake, whose classifications organize institutional reality, and whose capacities to produce evidence remain constrained. These questions provide the transition to epistemic justice in relational inquiry.

5.18 Epistemic Justice in Relational Inquiry

Section 5.17 treated uncertainty as structured across relational identification, manifestation, generative attribution, boundary, scale, time, and model choice. The present section adds a normative-epistemic dimension that becomes visible once those uncertainties are situated within unequal relations of observation, classification, testimony, documentation, and evidential production. Its role is to identify conditions under which the organization of inquiry can advantage some actors' capacities to make relations visible, intelligible, and evidentially consequential while constraining others. Its objective is to connect visibility, voice, classification, exclusion, institutional legibility, evidential capacity, representation, and generative

attribution without converting epistemic justice into a substitute for evidential warrant. The structure follows these sites of asymmetry in turn. The method is relational and process-sensitive: it asks how epistemic positions are produced, how they enter the evidential chain, and how inquiry can preserve contestability, provenance, and differentiated authority.

Fricker's account of testimonial and hermeneutical injustice provides an important philosophical precedent for analyzing credibility deficits and unequal participation in shared interpretive resources (Fricker 2007). GRE extends the problem into a wider architecture of relational inquiry. A participant can be disadvantaged before testimony is evaluated because the relevant relation leaves few institutionally recognized traces, because an administrative classification has already fixed the available categories, because access to data or instruments is concentrated, or because the actor lacks the resources required to convert situated experience into a form that travels within research and policy institutions. Longino's account of socially organized criticism is also relevant because epistemic robustness depends partly on whether criticism can enter a community and receive serious uptake (Longino 1990). These precedents motivate a concern with participation and contestability while leaving the specific GRE architecture open to domain-sensitive development.

Definition 5.139 (Epistemic justice in relational inquiry)**.** *Epistemic justice in relational inquiry* is the just organization of opportunities and capacities to become epistemically visible, contribute relevant testimony and interpretation, contest classifications and representations, produce or access evidence, and receive appropriately calibrated epistemic uptake concerning relations and generative processes in which actors are differently positioned.

Definition 5.139 separates justice from automatic deference. Situated actors can possess privileged access to particular manifestations, meanings, histories, or consequences while remaining uncertain about mechanisms outside their observational position. Institutional researchers can possess broad comparative data while lacking access to informal obligations or concealed dependencies. Technical systems can reveal regularities at scales inaccessible to unaided observation while inheriting the categories, missingness, and objectives embedded in their data-generating process. Epistemic justice therefore concerns the organization of access, authority, contestation, and evidential capacity together with disciplined calibration of what each source can support.

The section also remains narrower than a complete theory of social, political, or economic justice. Later GRE chapters can evaluate distribution, domination, exploitation, recognition, participation, and generative return more fully. Here the normative focus concerns the conditions under which relational knowledge is produced and attributed. A procedurally inclusive inquiry can still reach an empirically weak conclusion, and a well-identified empirical regularity can still emerge from an epistemically unjust process. GRE therefore keeps epistemic justice and evidential adequacy analytically distinct while examining the ways each can affect the other.

5.18.1 Visibility and Invisibility

Visibility is an epistemic condition through which a relation, actor, effect, or trace becomes available for observation, recording, comparison, or interpretation. Section 5.7 established that observational access is distributed unevenly across positions. Epistemic justice adds the question of how that distribution is organized and whose relations repeatedly enter the shared evidential field.

Institutional systems often privilege relations that generate standardized traces. Formal employment, registered ownership, taxable transactions, licensed activities, documented service use, and digitally mediated interaction can become comparatively visible because the relevant institutions already produce records. Informal care, tacit coordination, uncompensated maintenance, undocumented exchange, reputational dependence, ecological contribution, and many forms of exclusion can remain less visible because their traces are dispersed, privately held, weakly standardized, or absent from the categories through which administrative systems collect information. The resulting asymmetry can shape which relations appear empirically substantial and which appear marginal.

Visibility nevertheless requires a qualified normative treatment. Greater visibility can improve recognition, accountability, and evidential access, while intensified observation can also produce surveillance, exposure, strategic vulnerability, or new forms of classification. Strategic concealment in Section 5.7 already showed that opacity can be relationally produced. In some settings, limited visibility protects actors whose safety, autonomy, or bargaining position would be weakened by compulsory disclosure. Epistemic justice therefore concerns appropriate visibility relative to purpose, risk, consent, and relational position rather than maximal observability.

Claim 5.140 (Justice-sensitive visibility)**.** *A justice-sensitive account of epistemic visibility evaluates both access to relevant traces and the consequences of making those traces visible, including which actors gain interpretive or operational power from disclosure and which actors bear the resulting risks.*

Claim 5.140 matters for research design because the same data practice can increase knowledge while redistributing relational power. A survey that reveals hidden labor can support recognition and policy analysis; publication of highly granular records can expose vulnerable participants. A transparency requirement can make institutional decision rules contestable; disclosure of individual-level attributes can create new opportunities for profiling. The justice of visibility therefore belongs to the design of observation itself rather than appearing only after data have been collected.

In practical terms, GRE inquiry should record what is visible, through which infrastructure, to whom, and with what consequences. It should also identify relevant domains of invisibility and distinguish among absence of a relation, absence of a trace, lack of institutional recognition, and deliberate protection from observation. Such distinctions reduce the risk that institutional visibility becomes an implicit measure of relational importance.

5.18.2 Voice and Representational Authority

Voice concerns the capacity to contribute descriptions, interpretations, reasons, experiences, and contestations to the epistemic process. Representational authority concerns the degree to which those contributions can shape the categories and accounts through which a relation is understood. These are related but distinct. An actor may be invited to speak while the interpretive frame remains fixed elsewhere; another actor may possess formal authority to define a category despite limited situated access to the relation being classified.

Fricker's analysis of testimonial injustice is directly relevant where credibility is systematically discounted because of identity-mediated prejudice or other power-laden credibility practices (Fricker 2007). Within GRE, credibility assessment also interacts with relational position. A worker can have strong situated access to day-to-day authority relations while management possesses records of formal reporting lines. A patient can describe experienced dependence within a care relation while an institution possesses standardized clinical or administrative records. A platform user can observe recurrent consequences of ranking or moderation while the platform possesses aggregate behavioral data and internal system logs. These sources carry different epistemic strengths, and justice requires that the asymmetry among them be made explicit rather than resolved through institutional status alone.

Situated authority should remain bounded by the target of the claim. First-person or participant testimony can be especially strong regarding experienced treatment, local meaning, tacit practice, and consequences that remain weakly recorded. It does not automatically settle population prevalence, hidden mechanisms, or effects outside the participant's observational horizon. Institutional evidence can support broader comparison while remaining weak on lived interpretation or informal practice. Epistemic justice therefore supports differentiated authority: sources receive weight in relation to the forms of access they possess and the inferential distance between that access and the claim under consideration.

Definition 5.141 (Representational authority)**.** *Representational authority* is the institutionally or socially effective capacity of an actor, group, procedure, or system to shape how a relation or generative process is described, categorized, interpreted, and circulated within an epistemic domain.

Definition 5.141 directs attention beyond who speaks toward whose description becomes operational. A participant account can be heard and archived while a legal, administrative, statistical, or computational representation remains the version that allocates benefits, triggers investigation, determines eligibility, or structures later research. Section 5.6 showed that representations can become performative once they enter subsequent relational processes. Representational authority therefore has epistemic and generative consequences.

A justice-sensitive inquiry should preserve attribution and provenance so that different voices do not disappear into an anonymous synthesis. Where interpretations conflict, the disagreement can itself be evidentially informative. Recording who observed what, from which position, under which incentives and constraints, permits later readers to evaluate the relation between situated access and representational authority rather than treating a merged account as perspective-free.

5.18.3 Classification Power

Classification power concerns the capacity to establish categories that organize observation, comparison, eligibility, intervention, or subsequent interpretation. Sections 5.5 and 5.6 established that representation is selective and can become performative. Epistemic justice asks who participates in constructing those classifications, whose distinctions are preserved, and whose relations become difficult to express once a classificatory system stabilizes.

Statistical and administrative categories are historically produced rather than merely discovered. Desrosières shows how statistical reasoning depends on the construction of equivalences, coding practices, and institutions of comparability (Desrosières 1998). Hacking likewise emphasizes the historical emergence of categories and objects within styles of reasoning and classificatory practices (Hacking 2002). GRE draws a limited implication from these traditions: a classification can be epistemically useful and operationally necessary while still carrying assumptions about which differences matter, which entities can be compared, and which relations fit the available schema.

Classification power becomes justice-relevant when actors affected by a category have little capacity to contest its meaning, correct its application, or introduce distinctions that the schema suppresses. A household can be represented by an income band that is useful for aggregate analysis yet insensitive to unstable obligations or care burdens. A worker can be coded within an occupational category that obscures informal supervisory responsibility. A community can be represented through geographic or demographic units that fail to match the relational networks through which resources circulate. These examples concern mismatch and representational compression; they do not by themselves establish injustice. The normative question arises when the mismatch is consequential, systematically difficult to contest, and distributed through power-laden institutional arrangements.

Claim 5.142 (Classification power and epistemic consequence)**.** *When classifications govern observation, aggregation, or institutional response, power over their construction and revision can affect which relational distinctions acquire evidential visibility and which alternatives remain difficult to formulate within the dominant representational system.*

The claim is compatible with the practical necessity of classification. Research and administration require some reduction of complexity. Justice-sensitive classification therefore emphasizes revision mechanisms, explicit scope, documentation of category construction, preserved residual information where feasible, and channels through which affected or differently situated actors can challenge systematic mismatch. Espeland and Stevens' account of commensuration is relevant here because common metrics can reorganize attention and comparison while carrying political consequences (Espeland and Stevens 1998). The epistemic task is to preserve awareness of what a classification makes comparable and what relational differences it compresses.

5.18.4 Epistemic Exclusion

Epistemic exclusion occurs when actors or forms of knowledge are systematically prevented from entering, influencing, or contesting the processes through which relational claims are formed. Exclusion can operate through institutional membership, language, credentialing, technical access, proprietary data, security restrictions, meeting formats, publication channels, methodological conventions, or credibility practices. Its epistemic significance lies in the loss of observations, interpretations, objections, and alternatives that could materially alter the claim under examination.

This problem can occur without overt prohibition. A consultation may be formally open while requiring technical vocabulary, travel, digital access, unpaid time, or legal familiarity that distributes effective participation unevenly. A dataset can be publicly described while meaningful access requires computational resources or proprietary linkages. A research process can invite testimony while allocating interpretive decisions entirely to professional experts. In such cases, formal inclusion and effective epistemic participation diverge.

Longino's account of critical interaction helps clarify why this matters epistemically as well as normatively. The capacity of a community to expose background assumptions depends on the presence and uptake of criticism from differently positioned participants (Longino 1990). A homogeneous or access-restricted inquiry can therefore appear internally coherent partly because relevant objections never become operational within its critical process.

Definition 5.143 (Epistemic exclusion in relational inquiry)**.** *Epistemic exclusion in relational inquiry* is a patterned restriction on the effective capacity of relevant actors or knowledge-bearing positions to contribute evidence, interpretation, criticism, classification revision, or representational contestation concerning a relational or generative claim.

Definition 5.143 is deliberately process-focused. It does not imply that all viewpoints require equal evidential weight. A contribution can enter the inquiry and subsequently receive limited support because its evidence is weak, its scope is overstated, or stronger alternatives exist. Justice concerns the opportunity for relevant epistemic contribution and fair calibration of uptake; evidential evaluation still applies.

A useful diagnostic is to ask where in the epistemic chain exclusion operates: access to the phenomenon, recording of traces, preservation of records, admission to the dataset, category construction, interpretation, model specification, publication, institutional decision, or later revision. Different locations call for different remedies. Expanding testimony will have limited effect if the classification system cannot encode the relation described; opening a dataset will have limited effect if the relevant traces were never recorded.

5.18.5 Relations without Institutional Legibility

Institutional legibility concerns the extent to which a relation can be represented within the categories, records, procedures, and evidential formats recognized by an institution. Relational reality can exceed that legibility. Informal support networks, undocumented work, tacit obligations, community mediation, reciprocal care, eco-

logical dependence, reputational relations, and emergent coordination can exert substantial causal efficacy while remaining weakly represented in official records.

The epistemic problem is especially important because institutions often possess durable preservation systems. Once a relation enters administrative, legal, or statistical form, it becomes easier to retrieve, compare, cite, and incorporate into later decision making. Relations lacking such representation can leave fragmented traces that are costly to reconstruct. Over time, the archive can therefore make institutionally legible relations appear historically more substantial than relations whose manifestations were less systematically preserved.

Section 5.4 distinguished absence of evidence from evidence of absence, and Section 5.15 treated documentary and administrative materials as produced traces. Epistemic justice adds a distributional question: which actors and relations possess infrastructures that continually produce admissible traces? A relation can be socially important while generating little standardized evidence, particularly when the participants have weak access to documentation systems or when the relation falls outside the institution's operational categories.

Definition 5.144 (Institutional legibility of a relation)**.** The *institutional legibility of a relation* is the degree to which a relation can be recognized, encoded, preserved, retrieved, and acted upon through the categories and evidential procedures of a specified institution.

Institutional legibility is target- and institution-relative. The same care relation may be legible to a household, partially legible to a local organization, and weakly legible to a tax or employment system. A financial dependency can be visible to a lender while remaining obscure to a welfare agency. The same relation can also become differently legible over time as categories, reporting requirements, and data infrastructures change.

Justice-sensitive inquiry should therefore retain space for relations whose evidential form does not match the institution's preferred formats. This can involve qualitative reconstruction, community-held records, participant testimony, archival triangulation, or new measurement designs. Such inclusion still requires provenance and critical evaluation. Its purpose is to reduce the conflation of institutional readability with relational existence.

5.18.6 Unequal Capacity to Produce Evidence

Actors differ substantially in their capacity to produce evidence that travels across institutional settings. Governments, firms, universities, platforms, and large organizations can maintain databases, legal teams, standardized reporting systems, professional communication staff, archives, and computational infrastructure. Individuals, small organizations, informal groups, precarious workers, or dispersed communities may possess rich situated knowledge while lacking comparable means to preserve, aggregate, validate, or circulate it.

This asymmetry can influence the apparent evidential balance. Repeated standardized records often acquire institutional authority because they are searchable, comparable, and auditable. A diffuse set of experiences can remain epistemically weaker

in practice even when it concerns a consequential relation, because the experiences are costly to coordinate and translate into admissible form. The World Bank's treatment of modern data systems illustrates the growing institutional importance of administrative, survey, citizen-generated, and machine-generated data infrastructures (World Bank 2021). GRE emphasizes that access to such infrastructures is itself relationally distributed.

Evidence-production capacity includes more than data collection. It includes the ability to define variables, commission studies, retain experts, set reporting standards, choose temporal windows, maintain archives, control disclosure, and respond quickly when a dispute arises. It also includes the capacity to preserve uncertainty and provenance. An actor with extensive documentation can present a coherent historical record; another actor may rely on memory or fragmented traces partly because preservation resources were unavailable.

Claim 5.145 (Evidence-production asymmetry)**.** *Differences in resources, infrastructure, institutional standing, and access to recognized evidential formats can generate persistent asymmetries in whose relational claims are easiest to document, aggregate, circulate, and defend.*

The epistemic response should avoid compensatory romanticization. Scarce documentation does not make a claim true, just as abundant documentation does not make a representation complete. Justice-sensitive inquiry instead makes production conditions part of evidential assessment. It asks whether one side's documentary abundance reflects greater truth-tracking capacity, greater surveillance and archival capacity, or some combination of both. It also asks whether relevant counter-evidence was difficult to produce because access, preservation, or institutional recognition was unequally distributed.

Research design can partially address these asymmetries through data-access support, participatory documentation, translation, accessible reporting channels, preservation assistance, explicit recording of missingness mechanisms, and resources for independent analysis. The appropriate design depends on risk and context; some settings require strong privacy protections precisely because increased evidence production can expose vulnerable actors.

5.18.7 Justice in Relational Representation

Relational representation selects entities, relation types, directions, weights, boundaries, temporal windows, categories, and levels of aggregation. Section 5.5 treated those choices as epistemic mediation, and Section 5.6 showed that representations can subsequently shape relations. Justice in relational representation concerns how these choices distribute visibility, interpretive authority, contestability, and consequences among actors represented within or affected by the model.

A justice-sensitive representation should begin by making its standpoint and purpose explicit. A network built for fraud detection, a map built for community planning, a legal representation of obligation, and an ethnographic account of dependency can represent overlapping relations while selecting different features. Their differences can be legitimate when the analytical purpose is explicit. Problems arise when a purpose-specific representation travels into a new domain as though it were

a complete account of relational reality.

Representational justice therefore benefits from several practices. First, provenance should remain visible: readers should be able to reconstruct who generated the traces, who selected the categories, and what transformations were applied. Second, consequential category choices should be documented together with plausible alternatives. Third, affected or differently positioned actors should have channels to identify systematic mismatch and propose corrections. Fourth, uncertainty and missingness should remain attached to the representation rather than disappearing during aggregation. Fifth, when multiple representations capture materially different aspects of the same relation, preservation of plurality can be epistemically preferable to premature synthesis.

Proposition 5.146 (Justice-sensitive relational representation)**.** *A relational representation is comparatively more justice-sensitive when its purpose, provenance, categories, exclusions, uncertainty, and consequential uses are explicit; when materially affected or differently positioned actors possess meaningful opportunities for contestation; and when alternative representations with relevant evidential support can remain recoverable for comparison and revision.*

Proposition 5.146 does not establish the representation's empirical adequacy by itself. Contestable and well-documented models can still be wrong. The proposition concerns the epistemic conditions under which error, mismatch, and power-laden compression can become more visible and revisable. This aligns with the chapter's broader commitment to explicit mediation and revision rather than an ideal of perspective-free representation.

Young's critique of reducing justice to distribution is relevant to this process-centered orientation because participation, decision structures, domination, and cultural representation can themselves be justice-relevant (Young 1990). GRE does not import Young's framework wholesale. The narrower implication is that the justice of knowledge production cannot be assessed solely by distributing informational goods after representational structures have already been fixed.

5.18.8 Justice in Generative Attribution

Generative attribution assigns contribution to the relations, actors, infrastructures, institutions, environments, and prior processes that help produce capacities, structures, values, constraints, or later possibilities. Sections 5.12, 5.13, and 5.16 developed the epistemic burdens attached to such claims. Epistemic justice adds a further concern: contribution can be systematically misrecognized when some generative inputs are highly visible and others remain diffuse, backgrounded, informally organized, or weakly documented.

A familiar pattern is concentration of attribution at the most visible point of outcome realization. A product can be attributed primarily to the organization that markets it while prior public infrastructure, care work, maintenance, ecological conditions, upstream knowledge, standards, training, and collaborative networks remain less visible. An institutional success can be attributed to formal leadership while informal coordination and repair remain weakly documented. A research output can foreground named authors while technical, administrative, community, or data-

generating contributions are represented only partially. These examples differ substantively, yet they share an epistemic structure in which outcome visibility exceeds visibility of distributed generative conditions.

Justice-sensitive generative attribution therefore requires the contribution profile introduced in Section 5.13 to remain open to distributed and enabling contributions. It should distinguish direct production, enabling infrastructure, maintenance, reproduction of capacity, coordination, constraint removal, preservation, and downstream recirculation where these are evidenced. It should also preserve uncertainty where contribution cannot be disaggregated reliably. A broad attributional map can be more honest than a precise but unsupported allocation of shares.

Definition 5.147 (Justice-sensitive generative attribution)**.** *Justice-sensitive generative attribution* is the practice of attributing generative contribution in a manner that actively examines visibility asymmetries, evidential-capacity differences, classification effects, and background conditions that can systematically obscure or overstate particular contributors, while retaining the causal and evidential standards required for the underlying generative claim.

Definition 5.147 is intentionally epistemic before it becomes distributive. Establishing a contribution does not by itself determine compensation, ownership, recognition, liability, or return. Those normative questions require additional principles developed later in the book. The present requirement is that downstream evaluation begins from a contribution map whose omissions and asymmetries have been critically examined.

The same principle applies to blame and harmful generation. Highly visible actors can receive disproportionate causal attribution while background institutions, inherited structures, enabling infrastructures, or distributed incentives receive too little attention. Conversely, structural explanation can become so diffuse that identifiable agency disappears. Justice-sensitive attribution therefore preserves several levels simultaneously: actor contribution, relational configuration, enabling conditions, historical trajectory, and field-level structure where the evidence supports them. This layered account resists both individualized simplification and structure-only abstraction.

Proposition 5.148 (Epistemic-justice constraint on generative attribution)**.** *Where generative contributions are unevenly visible or unequally documentable, warranted attribution should examine whether evidential asymmetries systematically track power, institutional legibility, or access to preservation and representation; conclusions should preserve relevant distributed contributions and uncertainty before later normative claims about recognition, responsibility, return, or remedy are introduced.*

The epistemic-justice perspective developed in this section therefore modifies neither the requirement for evidence nor the chapter's commitment to uncertainty. It changes the questions asked about how evidence becomes available and authoritative. GRE inquiry should ask whose relations are visible, who can define categories, whose testimony receives uptake, which relations fit institutional formats, who can produce durable evidence, how representations remain contestable, and whose generative contributions are liable to disappear from the record. These questions strengthen relational inquiry by exposing systematic conditions under which evi-

dential fields themselves can be asymmetrically organized.

The next section turns to machine-mediated relational knowledge. Machine observation, algorithmic classification, computational inference, and AI-assisted reconstruction intensify many of the epistemic issues identified here because they can expand observational reach while concentrating classificatory and representational capacity in systems that operate at scales difficult for observed actors to inspect or contest. The transition therefore moves from epistemic justice in relational inquiry to the specific architecture of machine-mediated observation, inference, and representational power.

5.19 Machine-Mediated Relational Knowledge

Section 5.18 examined epistemic justice in relational inquiry by asking how visibility, voice, classification, evidential capacity, representation, and attribution are distributed among differently positioned actors. The present section narrows that problem to machine-mediated knowledge. Its role is to specify how computational systems enter the epistemic chain between relational reality, traces, representation, inference, and subsequent action. Its objective is to distinguish machine observation, algorithmic classification, computational inference, machine-generated representation, and AI-assisted reconstruction while identifying the epistemic asymmetries and contestability requirements that arise when these operations are concentrated in technical systems. The section proceeds from observation to classification and inference, then to representation and reconstruction, before examining asymmetry, representational power, and contestability. The method remains epistemically plural: computational output is treated as one mediated source of evidence whose warrant depends on provenance, target specification, model assumptions, boundary and scale, and the relation between machine-produced representations and other forms of evidence.

Machine mediation expands the range, speed, and granularity at which relational traces can be collected and organized. Administrative databases can connect records across institutions; platform logs can record interaction sequences at scales inaccessible to unaided observation; computer vision and remote sensing can generate repeated observations of physical or ecological environments; language models can summarize, classify, and recombine large documentary corpora; and network or statistical models can infer candidate relations that are only partially represented in the raw record. These capacities can materially improve inquiry. They also create additional layers at which categories, missingness, optimization objectives, architecture, training data, access privileges, and institutional purposes can shape what becomes visible as relational knowledge.

The distinction between machine mediation and machine authority is therefore fundamental. A computational system can assist observation or reconstruction without receiving final authority over the relational claim. Conversely, a machine-produced classification can become operationally authoritative even when its epistemic basis remains uncertain, especially when institutions embed it in eligibility, ranking, allocation, monitoring, or enforcement. Section 5.6 developed this

possibility through performative representation. Machine-mediated epistemology must therefore evaluate both whether a system tracks a target relation adequately and how its outputs enter subsequent relations.

Definition 5.149 (Machine-mediated relational knowledge)**.** *Machine-mediated relational knowledge* is relational knowledge whose evidential access, classification, inference, representation, reconstruction, or circulation depends materially on computational systems, such that the system's data-generating conditions, categories, transformations, model assumptions, and operational uses become part of the epistemic conditions of the claim.

Definition 5.149 is deliberately broader than machine learning. A rule-based administrative system, a database query, a sensor network, a statistical model, a graph algorithm, and a generative model can all mediate relational knowledge in different ways. The relevant question is not whether a system is called "AI," but where computational operations enter the evidential chain and how those operations affect what can be warranted.

5.19.1 Machine Observation

Machine observation concerns computationally mediated acquisition of traces that bear on a relational target. The term includes automated sensors, transaction logs, administrative data pipelines, digital interaction records, remote sensing, platform telemetry, and other systems in which observation is produced through technical infrastructure rather than through unaided human perception alone. The World Bank's account of contemporary data systems, for example, explicitly includes administrative, survey, citizen-generated, and machine-generated data within wider data infrastructures (World Bank 2021). For GRE, the epistemic importance of machine observation lies in the way these infrastructures extend observational reach while also fixing particular units, events, intervals, and recording rules.

Section 5.7 treated observation as position-dependent and partial. Machine observation does not remove that condition. It relocates observer position into an engineered observation regime. A platform can observe clicks, messages, transactions, or mobility traces because its architecture has defined which events are recorded and at what resolution. A sensor can repeatedly measure a physical variable while remaining insensitive to relations that do not manifest through its detection channel. An administrative system can observe registered interactions while missing informal obligations or unreported exchange. Machine observation can therefore be extensive and still relationally selective.

Definition 5.150 (Machine observation regime)**.** A *machine observation regime* is the organized combination of instruments, event definitions, sampling rules, recording intervals, data schemas, access conditions, and preprocessing operations through which computational infrastructure converts selected manifestations into machine-readable traces.

The definition makes several sources of uncertainty explicit. First, event ontology matters: the system determines what counts as an interaction, transaction, encounter, exposure, or response. Second, temporal resolution matters: repeated observations at one interval may obscure dynamics occurring at another. Third, miss-

ingness matters: a system can record only actors, locations, devices, or activities that enter its observational infrastructure. Fourth, preprocessing matters: filtering, deduplication, imputation, aggregation, and identity resolution can alter the trace before analysis begins. Fifth, access matters: the institution controlling the infrastructure may observe a relation at a level of granularity unavailable to the people whose behavior generates the traces.

Machine observation should therefore be documented as a trace-production process. A relational claim based on logs or sensor data should identify what the infrastructure was capable of recording, what it systematically excluded, how identities or events were linked, what transformations occurred before analysis, and how the observational window relates to the target relation. Large volume does not remove the need for this account. A very large set of selectively generated traces can support precise estimates of the wrong relational object.

5.19.2 Algorithmic Classification

Machine observation becomes analytically consequential when traces are assigned to categories. Algorithmic classification maps observed or derived features into labels, scores, clusters, rankings, risk classes, similarity groups, or other operational distinctions. The epistemic issue is continuous with the chapter's earlier treatment of statistical and administrative representation. Desrosières shows historically how statistical categories and comparability depend on conventions of classification and coding (Desrosières 1998), while Hacking emphasizes the historical interaction between classificatory practices and the objects or persons classified (Hacking 2002). Algorithmic systems intensify this problem because classification can occur repeatedly, automatically, and at scale.

A classification is not yet a relation. A label such as "high risk," "similar," "coordinated," "fraudulent," "influential," or "vulnerable" may be used to infer a relational position, but the connection between category and relation requires separate warrant. Two actors placed in the same cluster may share measured features without interacting. A recommendation system may classify users as behaviorally similar while remaining agnostic about whether any socially meaningful relation exists between them. A fraud-detection model may flag transactions as related through a learned pattern while the substantive mechanism remains uncertain.

Algorithmic classification also introduces threshold dependence. A continuous score can become a discrete category through an operational cutoff, and that cutoff can affect which relations appear present or consequential. When categories subsequently control access, review, surveillance, or opportunity, classification becomes performative in the sense developed in Section 5.6. The epistemic and performative questions should remain separate: whether a classification is well supported is one issue; what institutional consequences follow from assigning it is another.

Proposition 5.151 (Classification dependence of machine-mediated relational claims)**.** *Where a relational claim depends materially on algorithmic categories, the warrant for that claim depends partly on the evidential adequacy of the category definition, feature construction, threshold or grouping rule, and portability of the classification to the population, period, and relational target under study.*

Proposition 5.151 does not imply that every classification requires a single uniquely correct category system. Several classifications can be useful for different research purposes. The requirement is that the category's purpose and scope remain explicit and that a purpose-specific classification is not silently treated as a complete description of relational reality.

5.19.3 Computationally Inferred Relations

Computational inference moves beyond recorded traces or predefined categories by estimating relations that are incompletely observed. Link-prediction models, latent-variable models, embedding methods, clustering procedures, probabilistic graphical models, sequence models, and related techniques can identify candidate connections, dependencies, similarities, or relational structures. Section 5.15 already distinguished computationally inferred evidence from directly observed relations. The present subsection clarifies the epistemic status of the inferred relation itself.

Definition 5.152 (Computational relational inference)**.** *Computational relational inference* is the model-mediated estimation of a relation, relational property, or relational configuration from observed traces and specified assumptions when the target relation is not completely recorded in the evidential input.

The inferential distance between data and target can vary considerably. Inferring that two registered accounts exchanged messages may require relatively little modeling when the underlying logs are reliable. Inferring that two actors coordinate strategically, share an obligation, occupy analogous institutional positions, or participate in the same latent community requires additional assumptions about how the observed traces map onto the substantive relation. Section 5.2 described this as an inverse problem of manifestation: multiple relational realities can generate similar observed patterns.

Manski's work on identification is relevant because it separates what data identify from conclusions that become available only after stronger assumptions are added (Manski 2008). GRE applies the same discipline to computational relation inference. Model performance on a prediction task does not by itself establish that the inferred latent object corresponds to the substantive relation named by the researcher. A representation can predict interaction successfully while organizing that interaction through dimensions that differ from the researcher's interpretive vocabulary.

For this reason, computationally inferred relations should carry explicit provenance about training or estimation data, target construction, validation conditions, model class, relevant assumptions, error structure, and sensitivity to alternative specifications. External or qualitative evidence can be especially important when the substantive meaning of an inferred relation exceeds what was directly encoded in the training target. The goal is not to subordinate computational inference to human interpretation, but to prevent predictive success from becoming an unexamined bridge between trace and relation.

5.19.4 Machine-Generated Representations

Computational systems increasingly generate representations rather than only classify existing inputs. They produce summaries, captions, labels, rankings, graph layouts, synthetic descriptions, extracted entities, reconstructed timelines, and natural-language accounts of relational configurations. Generative models can further reorganize large corpora into compact representations that appear coherent and immediately usable. These capabilities increase the speed with which relational material can be explored, but they also increase the distance between the original trace and the representation presented to the investigator.

Section 5.5 treated representation as selective mediation. Machine generation adds a transformation process whose output can contain compression, interpolation, omission, normalization, or unsupported completion. Bender and colleagues' discussion of large language models is relevant because fluent linguistic output does not by itself establish grounded understanding or factual adequacy (Bender et al. 2021). Within GRE, the corresponding point is narrower: linguistic or graphical coherence does not establish that the represented relations are evidentially warranted.

Definition 5.153 (Machine-generated representation)**.** A *machine-generated relational representation* is a computationally produced description, visualization, categorization, summary, or structured encoding of relations whose form is generated through model operations rather than being a direct transcription of the underlying evidential record.

Such representations can be epistemically useful when they reduce search cost, reveal patterns, generate candidate comparisons, or make complex relational structures inspectable. Their use nevertheless requires preservation of the path back to source material. A generated summary of correspondence should permit retrieval of the documents that support each consequential relational claim. A generated network description should remain linked to the records and inference rules through which edges were created. A machine-produced historical narrative should distinguish sourced events from model-generated connective language.

The need for source recoverability grows with generative compression. When hundreds or thousands of traces are compressed into a concise narrative, the representation can become easier to circulate than the evidence that produced it. Repetition then gives the generated representation an appearance of stability even when its evidential basis is mixed. GRE therefore treats machine-generated representations as revisable analytical artifacts whose claims should remain decomposable into traceable evidential units where consequences are substantial.

5.19.5 AI-Assisted Relational Reconstruction

AI-assisted relational reconstruction uses computational systems to help assemble partial traces into a candidate account of relations, trajectories, fields, or generative processes. Relevant tasks include entity resolution across archives, extraction of relation mentions from documents, coding of qualitative materials, identification of temporal sequences, comparison of alternative classifications, detection of anomalous patterns, and generation of candidate hypotheses for human examination. These ap-

plications can expand the feasible scope of relational inquiry while also creating new forms of dependency on model behavior.

The epistemic unit should be the reconstruction workflow rather than the model output in isolation. A robust workflow specifies which tasks are delegated to the system, which outputs are independently checked, how disagreements are handled, how evidence is linked to reconstructed relations, and where human interpretation enters. Longino's account of socially organized criticism is useful here because epistemic robustness depends partly on opportunities for critical interaction and uptake of objections (Longino 1990). AI assistance can widen the space of candidate interpretations, yet it can also narrow that space when one model's categories or summaries become the default entry point to the evidence.

Proposition 5.154 (AI-assisted reconstruction)**.** *AI assistance strengthens relational reconstruction when it expands evidential search, comparison, or pattern detection while preserving source provenance, alternative interpretations, uncertainty, and independent routes of criticism; its epistemic contribution weakens when generated representations become difficult to trace back to the evidence or when model outputs silently replace the inferential steps they were intended to assist.*

The proposition supports a division of epistemic labor rather than a general hierarchy between human and machine judgment. Machines may be superior at repeated comparison across large corpora; situated participants may possess forms of access that the corpus does not record; domain experts may identify institutional distinctions that a general model merges; computational models may reveal regularities that established theory overlooked. GRE therefore evaluates contributions task by task and preserves disagreement as evidence about where reconstruction remains unsettled.

AI assistance also changes the economics of hypothesis generation. When candidate relations and explanations can be generated cheaply, the bottleneck shifts toward validation, source checking, discrimination among alternatives, and preservation of negative results. Abundant candidate explanations should therefore increase, rather than relax, the importance of explicit evidential burden. Machine-assisted inquiry becomes epistemically stronger when it makes comparison easier without making acceptance automatic.

5.19.6 Epistemic Asymmetry between Observer and Observed

Machine-mediated inquiry can create unusually large differences between what an observing institution knows about a relation and what observed actors can know about the observing process. A platform can aggregate behavioral histories across millions of interactions while an individual sees only a local interface. An employer can use computational systems to direct, evaluate, and discipline work at scale, a phenomenon documented in the literature on algorithmic management (Kellogg et al. 2020). A lender, insurer, government agency, or marketplace can combine records from multiple sources while the person classified may not know which variables, historical records, proxies, or model transformations contributed to the result.

Burrell's analysis of machine-learning opacity distinguishes secrecy, technical-literacy barriers, and opacity arising from model characteristics and scale (Burrell

2016). This distinction is useful because epistemic asymmetry can arise for different reasons and therefore require different remedies. Contractual secrecy may require disclosure or independent audit. Technical complexity may require explanation, expertise, or tooling. Scale-related opacity may require sampling, monitoring, or structured documentation rather than an expectation that every individual inspect every model operation.

Definition 5.155 (Machine-mediated epistemic asymmetry)**.** *Machine-mediated epistemic asymmetry* is a relational difference in access to the observations, categories, model operations, aggregate patterns, or revision mechanisms through which computational systems produce consequential knowledge about actors or relations.

This asymmetry has several dimensions. *Observational asymmetry* concerns access to traces. *classificatory asymmetry* concerns knowledge of the categories and thresholds applied. *inferential asymmetry* concerns access to the models and assumptions connecting traces to conclusions. *temporal asymmetry* arises when institutions preserve long histories while observed actors cannot reconstruct the same record. *revision asymmetry* concerns who can correct data, categories, or outputs once an error or mismatch is identified.

Asymmetry is not automatically unjust or epistemically defective. Epidemiological surveillance, fraud detection, infrastructure monitoring, or scientific instrumentation can require specialized access. The relevant question is how asymmetry interacts with consequence, error, vulnerability, and opportunities for challenge. Where outputs materially affect actors' opportunities or standing, the burden for provenance and contestability becomes correspondingly stronger.

5.19.7 AI and the Power to Define Relational Reality

The phrase "define relational reality" requires restraint. Computational systems do not acquire ontological authority merely because they classify at scale. The stronger and more defensible claim is that institutions can grant machine-produced representations *operational authority*: the categories, scores, clusters, or inferred relations become inputs to decisions that reorganize subsequent interaction. Section 5.6 showed how representation can become performative, while Section 5.18 showed that classification and representational authority can be distributed unequally.

Historical work on classification and statistical reasoning helps clarify the structure. Desrosières demonstrates that categories and measures are institutionally produced rather than transparent windows onto a preformatted social world (Desrosières 1998). Hacking likewise examines how classificatory practices can participate in the historical constitution of objects of knowledge (Hacking 2002). Machine systems can accelerate and routinize this process because classification is embedded directly in operational infrastructures.

A recommendation system can alter which social or commercial relations become likely to form. A ranking system can change organizational attention. An automated risk score can redirect scrutiny. Algorithmic management can restructure the temporal and informational relation between workers and supervisors (Kellogg et al. 2020). In such cases, the machine-produced representation participates in the generation of the relational reality later observed. The epistemic danger is recursive confirmation:

a classification changes behavior or opportunity, and the resulting trace is then interpreted as further evidence that the original classification captured an underlying stable relation.

Proposition 5.156 (Operational authority of machine representation)**.** *When a machine-produced representation is embedded in consequential allocation, ranking, monitoring, recommendation, or enforcement, its epistemic role cannot be assessed solely by predictive performance; inquiry should also examine how the representation changes the relations that later generate evidence about its apparent validity.*

This proposition does not imply that performative effects invalidate a model. Some systems are intentionally designed to alter outcomes, as in early-warning or safety systems. The requirement is temporal and relational clarity. Researchers should distinguish evidence collected before deployment, effects produced through deployment, adaptation by affected actors, and later data generated within the altered environment. Otherwise, the system can appear to discover a relation that it has partly stabilized or produced.

5.19.8 Contestability of Machine-Mediated Knowledge

Contestability concerns the practical capacity to question, inspect, test, correct, or replace a machine-mediated relational claim. It extends beyond explanation in the narrow sense. A system can provide an intelligible local explanation while leaving the underlying data, category, target definition, institutional purpose, or appeal process fixed. Conversely, complete publication of source code may provide little meaningful contestability to an affected actor if the relevant training data, operational thresholds, or institutional consequences remain inaccessible.

Kroll and colleagues argue that consequential automated systems require accountability mechanisms capable of verifying compliance with relevant standards rather than relying on ordinary assumptions developed for human decision makers (Kroll et al. 2017). Dataset documentation offers a complementary infrastructure: Gebru and colleagues propose recording dataset motivation, composition, collection processes, and recommended uses so that downstream users can evaluate provenance and limitations (Gebru et al. 2021). GRE draws a broader epistemic lesson from these approaches. Contestability should be attached to the whole relational-knowledge pipeline rather than to the final model output alone.

Definition 5.157 (Contestability of machine-mediated relational knowledge)**.** The *contestability of machine-mediated relational knowledge* is the degree to which relevant actors can identify the target claim, recover its evidential and computational provenance, understand the consequential categories and assumptions at an appropriate level, introduce counter-evidence or alternative interpretations, obtain review of material error or mismatch, and preserve the result of that challenge for subsequent revision.

Contestability is therefore layered. *Data contestability* concerns whether records can be inspected and corrected where appropriate. *category contestability* concerns whether the relation between operational labels and substantive concepts can be challenged. *model contestability* concerns assumptions, validation, uncertainty, and sensitivity to alternatives. *decision contestability* concerns how outputs enter conse-

quential action. *historical contestability* concerns whether earlier versions, disputes, and corrections remain preserved so that later re-epistemization is possible.

Proposition 5.158 (Contestability architecture)**.** *For consequential machine-mediated relational claims, a minimally adequate contestability architecture should preserve enough provenance to reconstruct how the claim was produced, specify the target and relevant categories, expose material uncertainty and known limitations, provide a route for qualified counter-evidence or review, and record substantive corrections or unresolved disputes for future revision.*

Proposition 5.158 is intentionally compatible with differentiated access. Privacy, security, trade secrecy, or protection of vulnerable actors can limit complete disclosure. Contestability can therefore involve trusted independent review, secure audit, controlled data access, or representative challenge rather than universal publication of every technical artifact. The epistemic standard concerns the existence of credible routes through which consequential claims can be tested and revised.

Machine-mediated relational knowledge thus intensifies themes developed throughout Chapter 5 without replacing them. Observation remains partial; classification remains historically and institutionally situated; inferred relations remain model-dependent; representations remain mediated; generative attribution remains burdened by mechanism and alternatives; and epistemic justice remains concerned with unequal capacities for visibility, voice, evidence, and correction. Computational systems can expand the reach of inquiry while simultaneously concentrating the infrastructure through which relational reality becomes visible and actionable. GRE therefore treats machine mediation as an epistemic architecture requiring explicit provenance, calibrated confidence, and contestability rather than as an independent source of authority.

The next section turns from machine mediation to revisability. Once relational knowledge is understood as partial, mediated, historically situated, and increasingly produced through human-machine infrastructures, the ability to update relational maps, categories, interpretations, and attributions becomes a constitutive requirement of epistemic adequacy rather than a secondary procedure applied only after error has been discovered.

5.20 Revisability of Relational Knowledge

This section establishes revisability as a constitutive property of relational knowledge in GRE. Its role is to specify how warranted claims can remain usable while the observed relations, manifestation processes, categories, evidential bases, and conditions of inquiry continue to change. The objective is therefore methodological in an epistemic sense: to distinguish several sources of revision and to identify the documentary and interpretive conditions under which revision can be disciplined rather than improvised. The section proceeds through provisional relational maps, updating through new evidence, revision after intervention, historical revision, category revision, reflexive observation, and preservation of alternative interpretations. The discussion treats revision as traceable change in a claim, representation, or attribution under stated reasons and preserved provenance. This orientation is compatible

with traditions that expose scientific claims to criticism and correction (Popper 2002; Longino 1990), while GRE gives the requirement a specifically relational and historical form.

Definition 5.159 (Revisability of relational knowledge)**.** The *revisability of relational knowledge* is the organized capacity to modify, qualify, extend, contract, replace, or retire a relational or generative claim when changes in evidence, intervention, historical conditions, categories, observer relations, or competing interpretations materially alter its warrant, while preserving enough provenance to reconstruct why the earlier and later formulations differed.

Definition 5.159 separates revisability from epistemic instability. A claim can be strongly warranted at a specified time, scale, boundary, and evidential state while remaining revisable under materially changed conditions. Revisability therefore concerns the architecture of knowledge maintenance rather than a presumption that every conclusion is equally fragile. It also differs from routine textual editing. The relevant change is epistemically consequential: the object, representation, evidential basis, inferential relation, or confidence profile has changed sufficiently that the knowledge claim should change with it.

5.20.1 Provisional Relational Maps

Relational inquiry commonly produces maps of actors, relations, fields, boundaries, flows, dependencies, generative pathways, or historical trajectories. Such maps can be indispensable analytical objects while remaining provisional. Provisionality follows from the conditions developed throughout this chapter: observation is partial, boundaries and scales are selected, relation identity is criterion-dependent, higher-order structures are reconstructed, field claims require distributed evidence, and generative attributions carry additional inferential burdens. A relational map should therefore be understood as a warranted representation under stated conditions rather than as a completed inventory of the relevant relational world.

Definition 5.160 (Provisional relational map)**.** A *provisional relational map* is an explicitly bounded and time-indexed representation of identified relations, positions, fields, trajectories, or generative linkages whose evidential basis, representational choices, uncertainty, and conditions of revision are sufficiently documented for later reassessment.

Provisionality has at least four dimensions. *Observational provisionality* concerns incomplete or unequal access to traces. *representational provisionality* concerns the possibility that another formal, linguistic, legal, statistical, or computational representation preserves different aspects of the same target. *historical provisionality* concerns transformation of the relations themselves. *inferential provisionality* concerns the possibility that new evidence changes the relative warrant of competing explanations. These dimensions can vary independently. A network representation, for example, may remain an adequate summary of recorded interactions while later evidence changes the interpretation of what those interactions mean.

A provisional map should therefore carry metadata about its epistemic conditions. At minimum, the map should identify its target, observational window, boundary, scale, relation criteria, principal evidence types, major representation choices, and

known uncertainties. When generative links are included, the map should also distinguish observed association from stronger mechanism-sensitive attribution. This practice allows a map to be used operationally without allowing its graphic or computational completeness to imply stronger warrant than its evidential basis supports.

Proposition 5.161 (Provisional warrant)**.** *A relational representation may support action, comparison, or further inquiry while remaining provisional, provided that the conditions under which its claims are warranted and the conditions under which they should be reconsidered remain explicit.*

Proposition 5.161 matters because a demand for unrevisable certainty would make most relational inquiry unusable, whereas a refusal to stabilize any working representation would prevent cumulative investigation. GRE therefore permits temporary stabilization under documented conditions. The epistemic task is to make the stabilization inspectable and corrigible.

5.20.2 Updating through New Evidence

New evidence can alter relational knowledge in several ways. It may increase confidence in an existing relation, weaken an earlier identification, reveal a previously hidden participant, extend the temporal duration of a relation, narrow its scope, expose an alternative mechanism, or motivate replacement of the earlier interpretation. Updating is consequently broader than adding observations to an unchanged model. The update can affect the data, the representation, the category system, the causal interpretation, or the confidence profile introduced in Section 5.17.

The relevance of evidence is itself mediated by background assumptions, categories, and standards of criticism, a point emphasized in Longino's account of scientific objectivity and critical interaction (Longino 1990). GRE therefore treats updating as an argued relation between an earlier claim state and a later evidential state. The investigator should identify what changed and why the new material bears on the target claim. A newly available administrative record may change confidence in a formal relation without resolving its enacted intensity. New ethnographic evidence may revise interpretation of an interaction while leaving its recorded frequency unchanged. A newly reconstructed historical source may reopen a genealogy without directly altering contemporary observational evidence.

Definition 5.162 (Traceable epistemic update)**.** A *traceable epistemic update* is a documented revision that identifies the prior claim, the new or reinterpreted evidence, the inferential reason for revision, the dimensions of the claim affected, and the resulting change in confidence, scope, representation, or attribution.

The definition supports a versioned understanding of relational knowledge. Earlier formulations need not disappear when they are superseded. Their retention can show which evidence was available at the time, which assumptions governed interpretation, and where later revision entered. This matters especially when a later claim appears obvious only because intervening evidence has changed the epistemic environment.

Updating also requires proportionate response. Minor evidence should rarely trigger wholesale theoretical replacement when a narrower qualification is sufficient.

Conversely, a large volume of confirmatory observations should not protect a claim when new evidence undermines the relation criterion, identifies a systematic observation failure, or reveals that the apparent pattern was produced by the measurement regime itself. The magnitude of revision should therefore correspond to the part of the epistemic architecture that the new evidence actually affects.

Proposition 5.163 (Dimension-matched revision)**.** *When new evidence alters only a specified dimension of a relational claim, revision should ordinarily be concentrated on that dimension unless the dependence structure of the argument shows that wider conclusions also lose warrant.*

This proposition preserves both responsiveness and continuity. It also makes disagreement more diagnosable: researchers can dispute the evidence, the relation between evidence and target, the affected dimension, or the wider dependencies without treating every update as a judgment on the entire research programme.

5.20.3 Revision after Intervention

Intervention creates a distinctive revision problem because the inquiry may change the relational system whose earlier representation it sought to describe. Policy reform, organizational restructuring, legal recognition, platform redesign, resource redistribution, experimental treatment, public disclosure, or governance intervention can alter participants, incentives, opportunities, classifications, and manifestation processes. Evidence gathered after intervention may therefore concern a transformed relational configuration rather than a cleaner observation of the earlier one.

Interventionist accounts of causal explanation use controlled changes and counterfactual contrasts to clarify causal dependence (Woodward 2003). GRE adopts the value of intervention-sensitive reasoning while adding a historical-relational caution: an intervention can become part of the subsequent relational reality. The epistemic task is then twofold. Inquiry may learn about the earlier system from how it responded, while also needing to reconstruct the new system produced through that response.

Definition 5.164 (Intervention-sensitive revision)**.** *Intervention-sensitive revision* is the reassessment of relational knowledge that distinguishes evidence about a pre-intervention configuration from relations, manifestations, or generative pathways produced, suppressed, or reorganized through the intervention itself.

This distinction is especially important when interventions are adaptive. Actors can learn from monitoring, reorganize around a new rule, create substitutes for a constrained pathway, or redirect activity into less visible channels. A short-run post-intervention change can therefore differ from the later stabilized configuration. The relevant temporal horizon should remain explicit, and the revision record should identify which parts of the earlier map persisted, which transformed, and which newly emerged.

Intervention can also expose relations that were previously difficult to observe. Removing a constraint may reveal latent coordination capacity; altering an institutional interface may expose dependencies that had been absorbed by routine practice; changing access conditions may make hidden relations observable. Such evi-

dence can legitimately revise the earlier account, but the reasoning should separate discovery from creation. The intervention may have revealed a pre-existing relation, created a new relation, or done both in different respects.

Proposition 5.165 (Post-intervention relational reassessment)**.** *When an intervention materially changes the conditions under which relations are formed, manifested, or observed, post-intervention evidence should be interpreted through an explicit reassessment of relation identity, manifestation rules, boundary conditions, and temporal horizon before it is used to update claims about the pre-intervention system.*

Proposition 5.165 limits a common inferential shortcut: treating later observations as if they belonged automatically to the same relational object. It also prepares the methodological discussion of intervention in later Parts, where research and application praxis require designs capable of learning from transformation without erasing the distinction between observation and intervention-produced change.

5.20.4 Historical Revision

Historical revision arises when later evidence, later consequences, changed categories, or a transformed interpretive context alters what can be warranted about an earlier relational configuration. Section 5.14 described historical re-epistemization as a disciplined reconstruction of earlier knowledge under later conditions. The present subsection places that process within the broader architecture of revisability.

Historical revision can proceed from newly recovered sources, improved provenance, reinterpretation of previously known records, changed knowledge of surrounding institutions, or recognition that an earlier category concealed distinctions relevant to the historical actors or relations. Hacking's historical ontology emphasizes that concepts and objects of knowledge can acquire historically specific conditions of possibility (Hacking 2002); Ricoeur's hermeneutics likewise treats interpretation as mediated through distance, text, and changing horizons of understanding (Ricoeur 1991). For GRE, these traditions support a practical requirement: later reconstruction should preserve the difference between revision of present knowledge about the past and transformation of the past itself.

Definition 5.166 (Historical epistemic revision)**.** *Historical epistemic revision* is a documented change in the warranted interpretation, classification, boundary, trajectory, or generative attribution of an earlier relational configuration produced by later evidence or later analytical resources, while preserving the temporal location and evidential conditions of the earlier claim.

The preservation clause is essential. An earlier claim may have been reasonable given the records then available even if later evidence substantially revises it. Conversely, a historically influential interpretation can remain important as an object of study after its descriptive warrant has weakened, because institutions or actors may have acted on it. Revision should therefore distinguish at least three objects: the past relational configuration, the earlier representation of that configuration, and the historical effects produced by that representation.

Later consequences also alter salience. An event that appeared minor at the time

can become analytically significant because it entered a long generative trajectory. This later significance does not establish that the event already contained its later outcome or that contemporaries could have known the trajectory. Historical revision should therefore preserve the chapter's earlier distinction between retrospective significance and retrospective determinism.

Versioned historical knowledge is especially important where records are incomplete or politically uneven. Superseded interpretations, disputed classifications, alternative chronologies, and unresolved evidential gaps should remain visible when they materially affect later reconstruction. Such preservation allows future inquiry to distinguish a settled finding from an interpretation that became dominant because competing records disappeared.

5.20.5 Revision of Categories

Relations become knowable through categories: actor types, institutional statuses, transaction classes, legal forms, network edge definitions, risk groups, occupational codes, value categories, and many other classificatory devices. Categories enable comparison and cumulative research, yet they can become misaligned with the relational system. Category revision is therefore a distinct epistemic operation rather than a special case of adding more data.

Historical studies of statistics show that comparability depends on conventions of classification and coding (Desrosières 1998). Hacking likewise examines the historical interaction between classificatory practices and the objects classified (Hacking 2002). Sections 5.5, 5.6, and 5.19 have already shown that categories can mediate and sometimes alter relational reality. A category that once produced useful analytical compression may later obscure differentiation, become strategically gamed, exclude emergent subjects, or acquire performative consequences that change what the category measures.

Definition 5.167 (Relational category revision)**.** *Relational category revision* is the explicit modification of a classificatory scheme used to identify, compare, or represent relational objects when evidence indicates that the existing categories materially distort, omit, overmerge, or misalign with the target relations or their historical transformation.

Category revision can involve splitting an overly broad category, merging distinctions that have ceased to matter for the target, adding a previously unrepresented relational form, changing membership criteria, altering temporal or spatial resolution, or replacing a category whose operational meaning has drifted. These changes affect comparability. A revised category can improve current fit while making historical series less directly comparable. The revision record should therefore retain category definitions and mapping rules between versions where such mappings are defensible.

Category failure should be diagnosed with target-specific evidence. Low predictive performance may indicate category inadequacy in one setting, while ethnographic mismatch, systematic testimonial disagreement, institutional change, high within-category heterogeneity, or emergent strategic behavior may reveal other forms of failure. None supplies a universal threshold. The relevant question is whether the

category continues to preserve distinctions required by the relational claim for which it is used.

Proposition 5.168 (Category-revision discipline)**.** *When a relational category is revised, the revision should document the target problem, the evidence of mismatch, the semantic change, the consequences for comparability, and any effects that the old and new categories may themselves have on subsequent relational behavior.*

This proposition prevents category revision from becoming an invisible preprocessing step. It also allows later inquiry to determine whether an observed change reflects transformation in the relational world, transformation in the classification scheme, or an interaction between the two.

5.20.6 Reflexive Observation

Observation can become reflexive when the process of observing, measuring, publishing, ranking, classifying, or explaining enters the relations under observation and changes their subsequent development. Section 5.6 treated performative representation, and Section 5.19 analyzed machine-mediated recursive classification. Reflexive observation places these phenomena inside the revision process: once an inquiry becomes consequential to its object, later evidence cannot be interpreted as if the observational relation remained external and unchanged.

Research on rankings documents how public measures can alter expectations and organizational behavior through reactivity (Espeland and Sauder 2007). MacKenzie similarly shows how financial models can become incorporated into market practice and participate in reshaping the processes they represent (MacKenzie 2006). These cases differ in mechanism, yet both illustrate a general epistemic possibility relevant to GRE: the observer, representation, or measurement infrastructure can become a participant in the relational configuration.

Definition 5.169 (Reflexive observation)**.** *Reflexive observation* occurs when an observational, classificatory, representational, or explanatory practice becomes known, anticipated, or operationally consequential within the target system and thereby contributes to changes in the relations or manifestations subsequently observed.

Reflexive observation is more specific than ordinary measurement error. A noisy instrument can distort a reading without changing the underlying relation. Reflexivity requires a pathway through which the inquiry or its representation enters the relational process. That pathway can operate through anticipation, strategic adaptation, stigma, prestige, resource allocation, compliance, resistance, imitation, learning, or redesign of institutional routines.

Revision under reflexivity requires temporal segmentation. The investigator should distinguish observations produced before the inquiry became consequential, the period in which actors learned or responded to it, and the later configuration that incorporates those responses. Where possible, the analysis should also compare differently exposed actors or settings. Such strategies cannot fully restore an external observer position, but they can make the observer relation itself part of the evidential account.

Proposition 5.170 (Reflexive monitoring requirement)**.** *When there is credible evi-*

dence that an inquiry, measure, classification, or published representation has become consequential to the target system, subsequent relational claims should include the observer–system relation among the candidate mechanisms shaping the observed configuration.

The proposition also applies to GRE itself. A relational map circulated among institutions, a generative-foreclosure diagnosis used in policy, or an AI-assisted classification adopted operationally can alter the object that subsequent GRE research encounters. Reflexivity therefore links epistemology to research ethics and governance without collapsing those domains into one another.

5.20.7 Preservation of Alternative Interpretations

Revisability depends on more than the ability to overwrite an earlier conclusion. Future revision requires access to the evidential and interpretive alternatives that made earlier judgment non-trivial. If rival explanations, negative findings, disputed categories, uncertainty ranges, or minority interpretations disappear from the research record, later inquiry may inherit an artificially narrowed possibility space. Preservation of alternatives is therefore part of epistemic infrastructure.

Longino's account of objectivity emphasizes the importance of effective criticism and plural perspectives in the production of scientific knowledge (Longino 1990). GRE translates that insight into a preservation requirement. Alternative interpretations need not receive equal weight, and implausible possibilities need not be retained indefinitely as live explanations. The relevant alternatives are those that were materially plausible given the evidence, represented consequential disagreements about category or mechanism, or preserve information needed to understand why a dominant interpretation prevailed.

Definition 5.171 (Alternative-interpretation record)**.** An *alternative-interpretation record* is a preserved account of a materially plausible competing relational or generative interpretation, including its evidential basis, assumptions, boundary and scale, principal objections, current epistemic status, and conditions under which it could regain or lose warrant.

This record can include rejected hypotheses, unresolved anomalies, competing relation criteria, alternative historical periodizations, different boundary specifications, or interpretations supported by evidence that later became inaccessible. Preservation is particularly valuable when disagreement tracks unequal access to records or representational authority. An interpretation can be weakly institutionalized without being evidentially empty, and future evidence can change its status.

Alternative preservation should also record why an interpretation was set aside. A superseded model that failed because its mechanism contradicted evidence is different from one that lost favor because data were unavailable, categories changed, or research priorities shifted. This distinction allows later investigators to avoid rediscovering abandoned paths without understanding the reasons for abandonment.

Proposition 5.172 (Preservation condition for revisability)**.** *Where competing interpretations are materially relevant to a relational or generative claim, a revisable knowl-*

edge system should preserve enough information about serious alternatives and their evidential status to permit later reassessment without reconstructing the earlier controversy solely from the interpretation that became dominant.

The requirement remains proportional. Routine exploratory alternatives need not all become permanent archival objects. Preservation becomes more important when the claim is consequential, uncertainty remains substantial, categories are historically unstable, evidence is difficult to reproduce, or alternative interpretations are linked to differently positioned observers whose access may later disappear.

Revisability therefore completes the chapter's movement from mediated access to disciplined epistemic maintenance. GRE treats relational knowledge as capable of strong warrant while remaining open to revision through new evidence, intervention, historical transformation, category change, reflexive observation, and preserved alternatives. The resulting epistemic stance avoids both premature closure and unrestricted indeterminacy. Claims are stabilized enough to support inquiry and action, yet their conditions of warrant, histories of change, and routes of correction remain visible. The next section consolidates this architecture by stating the principal epistemic commitments that GRE carries forward into methodology.

5.21 Epistemic Commitments of GRE

This section consolidates the epistemic architecture developed across this chapter into a set of commitments that can guide later research design without collapsing epistemology into method. Its role is synthetic: the preceding sections examined manifestation, trace, representation, observation, boundary, scale, relational identity, higher-order structure, fields, generative attribution, historical reconstruction, evidence, uncertainty, epistemic justice, machine mediation, and revisability as distinct problems. The present section states what GRE commits itself to after those problems are taken together. The objective is to make those commitments sufficiently explicit that later empirical, historical, interpretive, formal, and computational work can be assessed against them. The discussion proceeds through partial knowledge, explicit representation, explicit boundary and scale, explicit uncertainty, mechanism-sensitive attribution, evidential pluralism, historical sensitivity, revisability, and epistemic humility. The method is reconstructive rather than additive: each commitment summarizes an epistemic discipline already developed in the chapter and identifies the constraint it places on subsequent inquiry.

Definition 5.173 (Epistemic commitment of GRE)**.** An *epistemic commitment of GRE* is a standing discipline governing how relational and generative claims are formulated, warranted, delimited, represented, challenged, and revised under conditions of mediated access to relational reality.

Definition 5.173 distinguishes an epistemic commitment from a preferred technique. A commitment such as explicit uncertainty can be satisfied through different research methods; conversely, the use of a sophisticated method does not by itself establish that the commitment has been satisfied. This distinction prepares the transition developed in the next section: epistemology specifies what a warranted claim requires, whereas methodology specifies how inquiry can be organized to meet those

requirements.

5.21.1 Partial Knowledge

GRE treats partiality as a normal condition of relational knowledge rather than as an exceptional defect. The argument follows from the architecture already established in this chapter. Manifestation does not transparently disclose relational reality; inverse inference is generally non-unique; traces depend on production and preservation; observation is position-dependent and incomplete; boundaries and scales delimit what enters the analytical field; higher-order structures and relational fields are reconstructed from partial evidence; and generative attribution adds further inferential burdens. A claim can therefore be warranted without being exhaustive.

Partial knowledge has several forms. *Observational partiality* concerns incomplete access to manifestations and traces. *representational partiality* concerns the selective preservation of some target properties over others. *relational partiality* concerns incomplete identification of relevant relations, participants, positions, or higher-order configurations. *historical partiality* concerns uneven preservation of past evidence and changing categories of interpretation. *generative partiality* concerns incomplete knowledge of mechanisms, mediating conditions, distributed contributors, delayed effects, or unrealized possibilities. These forms can coexist while differing in degree.

Definition 5.174 (Bounded epistemic warrant)**.** *Bounded epistemic warrant* is support for a claim whose target, evidential basis, boundary, scale, temporal horizon, representation, and principal uncertainties are stated with enough precision that the claim can be used without implying knowledge beyond those conditions.

Bounded warrant permits GRE to make substantive claims while preserving the difference between local adequacy and epistemic completeness. A reconstruction of a labor relation, for example, can be well supported within a specified institution and period even when informal dependencies outside the observed boundary remain incompletely known. A field model can be useful for a defined target while leaving some relations latent. A generative attribution can identify a strongly supported contribution without exhausting every contributing condition.

Partiality therefore changes the grammar of strong claims. Strength comes from fit between evidence and target, explicit scope, discrimination among alternatives, and preserved uncertainty. It does not require a declaration that all relevant relations have been observed or that every competing explanation has been eliminated. This commitment protects GRE from converting the breadth of its relational vocabulary into an assumption of total relational visibility.

Proposition 5.175 (Partial knowledge and substantive inquiry)**.** *Partial knowledge can support substantive relational and generative claims when the limits of access are characterized and the claimed warrant remains proportionate to the evidence available within those limits.*

Proposition 5.175 also places a burden on claims of absence. As Section 5.4 established, non-observation becomes evidence of absence only under sufficiently specified conditions of observability. Partial knowledge therefore does not merely counsel modest wording; it changes how positive, negative, and comparative claims are

warranted.

5.21.2 Explicit Representation

The second commitment concerns the visibility of representation. Section 5.5 distinguished relation, trace, symbolization, and representation, while Section 5.6 showed that representations can enter subsequent relational processes. GRE therefore treats representations as analytically consequential choices rather than transparent containers for already given reality.

An explicit representation identifies what is represented, which properties are preserved, which are compressed or omitted, what categories and symbols are used, and what inferential work the representation is expected to perform. The requirement applies to prose categories as much as to formal models. Terms such as "dependency," "trust," "capital," "value," "field," or "constraint" already organize observation and comparison; a network diagram, regression specification, legal category, archival code, ethnographic typology, or machine-generated embedding adds further representational commitments.

Definition 5.176 (Representation declaration)**.** A *representation declaration* is an explicit account of the target, representational form, principal selection or compression choices, relation between represented features and the underlying claim, and known conditions under which the representation can become misleading.

The purpose of a representation declaration is not to demand exhaustive philosophical commentary for every variable or diagram. Its function is proportional disclosure. A highly consequential classification requires more explanation than a conventional formatting choice. A representation that materially affects relational identification, comparison, causal attribution, or operational decisions requires enough documentation for readers to understand what the representation contributes to the inference.

Explicitness is especially important when formal precision exceeds epistemic precision. A numerical score can be reported to several decimal places while the mapping from the score to the relational target remains contestable. An algorithm can produce stable clusters while the substantive relation represented by those clusters remains uncertain. A legal category can be formally definite while incompletely describing enacted relations. GRE therefore distinguishes precision of representation from adequacy of representation.

The commitment also includes contestability. When a representation materially shapes what can be seen, classified, compared, or acted upon, affected interpretations should remain examinable against alternative representational choices where feasible. This follows from Sections 5.18 and 5.19: representational authority can be unequally distributed, and machine-generated representations can acquire operational power beyond their evidential warrant. Explicit representation creates the documentary basis on which such authority can be evaluated.

5.21.3 Explicit Boundary and Scale

Relational claims depend on what is included in the analytical field and at what level or resolution relations are reconstructed. Section 5.8 showed that boundaries are neither purely arbitrary analytical conveniences nor automatically given by the object. Some boundaries are institutionally, legally, materially, or organizationally consequential; others are research selections; many combine both properties. Scale similarly affects which relations, variations, and generative processes become visible.

GRE therefore requires boundary and scale to become part of the claim rather than remaining hidden in the research setup. A statement about a firm, household, platform, market, neighborhood, national economy, supply network, or historical period tacitly establishes inclusion and exclusion rules. The interpretation of a relation can change when external dependencies are included, when a local process is examined across a wider field, or when a long-run trajectory is reconstructed from observations that appeared stable at a shorter horizon.

Definition 5.177 (Scope specification)**.** A *scope specification* identifies the boundary, scale, temporal window, relevant level of aggregation or resolution, and principal cross-boundary or cross-scale dependencies under which a relational or generative claim is asserted.

Scope specification serves at least three epistemic functions. First, it prevents local findings from acquiring an unearned universal range. Second, it makes cross-study disagreement more diagnosable: two studies may reach different conclusions because they study different relational neighborhoods or temporal scales rather than because one is methodologically defective. Third, it reveals when the research boundary excludes a mechanism necessary to explain the observed outcome.

Explicit scope does not imply that a single correct scale exists. Some relations are most intelligible at one level; others are produced through interactions across levels. Cross-scale claims therefore require evidence for the bridge by which local and distributed processes are connected. The commitment is to expose the scale logic of the argument and to avoid treating a convenient unit of observation as an ontologically privileged unit of explanation.

Proposition 5.178 (Scope-indexed warrant)**.** *The warrant of a relational claim is indexed to the boundary, scale, and temporal horizon under which the relevant evidence and inferential relations hold; portability beyond that scope requires additional justification.*

5.21.4 Explicit Uncertainty

The fourth commitment follows from Section 5.17. GRE treats uncertainty as structured information about the state of an inquiry. Uncertainty can concern relational existence, manifestation, generative attribution, boundary choice, scale, temporal persistence, model specification, or the relative support of competing explanations. Compressing these dimensions into a single confidence statement can obscure where the argument is strong and where it remains vulnerable.

An uncertainty statement should therefore identify the dimension to which uncertainty belongs. A relation may be well evidenced while its mechanism remains

uncertain. A mechanism may be plausible while the magnitude or temporal reach of its effect remains weakly identified. A historical trajectory may be strongly reconstructed over one interval while continuity across an archival gap remains uncertain. A computational model may predict reliably while its relational interpretation remains contested. These are different epistemic states and should be reported differently.

Definition 5.179 (Uncertainty disclosure)**.** An *uncertainty disclosure* identifies the principal dimensions of a claim whose warrant remains incomplete, contested, model-dependent, boundary-sensitive, scale-sensitive, temporally limited, or dependent on unresolved alternatives, together with the evidence that could materially change that assessment where such evidence can be specified.

Explicit uncertainty supports comparison and revision. It allows later evidence to address the uncertain part of a claim without requiring wholesale reassessment of everything already supported. It also reduces the risk that technical sophistication masks unresolved inferential assumptions. A simulation, causal model, or machine-learning system can quantify one source of uncertainty while leaving classification, representation, boundary, or historical uncertainty largely outside the formal calculation.

GRE consequently favors profiled confidence over rhetorical certainty. This orientation permits strong localized conclusions where the evidence supports them and visible restraint where the evidential architecture remains incomplete. Uncertainty is therefore neither a disclaimer appended to an otherwise finished argument nor a reason to suspend inquiry indefinitely. It is part of the content of the claim.

5.21.5 Mechanism-Sensitive Attribution

Generative claims create a stronger epistemic burden than claims that a relation exists or covaries with an outcome. Sections 5.12 and 5.13 distinguished generative effects from ordinary state differences and developed a plural architecture for attribution involving mechanisms, counterfactual dependence, multiple causation, distributed generation, delayed effects, branching pathways, and emergence. GRE therefore commits to mechanism-sensitive attribution without making one mechanism template a universal criterion.

Mechanism sensitivity asks how the attributed contribution is carried, enabled, mediated, reproduced, or transformed through the relevant relations. In some cases the mechanism can be specified through organizational rules, legal obligations, material flows, incentives, communication pathways, or institutional procedures. In other cases the contribution is distributed across a configuration, making a single linear mechanism an inadequate description. The epistemic requirement is to identify the structure of dependence that makes the generative claim stronger than observed association.

Proposition 5.180 (Mechanism-sensitive generative attribution)**.** *A generative attribution gains warrant when evidence identifies a credible pathway or dependency structure linking the candidate relation or configuration to the target effect, while relevant alternative explanations, boundary conditions, temporal ordering, and distributed contributions are examined in forms appropriate to the case.*

This proposition deliberately allows different combinations of evidence. Interventionist evidence can be powerful where meaningful interventions are possible. Historical sequence can identify enabling conditions or branching processes that cannot be experimentally recreated. Ethnographic or documentary evidence can reveal mechanisms hidden from aggregate data. Longitudinal or computational analysis can identify temporal dependencies or distributed patterns requiring further interpretation. The commitment therefore links mechanism sensitivity to evidential pluralism rather than to methodological monism.

Mechanism-sensitive attribution also requires restraint in normative interpretation. A relation can generate an effect without that effect being desirable, just, efficient, or valuable. Conversely, a desirable outcome does not establish the mechanism that produced it. GRE keeps causal-generative attribution distinct from normative evaluation so that later analyses of value, power, justice, capture, return, and governance can build on rather than substitute for the epistemic argument.

5.21.6 Evidential Pluralism

Sections 5.15 and 5.16 established that relational and generative claims can draw on documentary, administrative, legal, behavioral, testimonial, ethnographic, network, longitudinal, historical, formal, and computational evidence. These evidence forms differ in what they record, how they are produced, whose position they encode, what they systematically omit, and how directly they bear on the target. GRE therefore commits to evidential pluralism in the sense of target-relative complementarity rather than indiscriminate accumulation.

Definition 5.181 (Evidential pluralism in GRE)**.** *Evidential pluralism in GRE* is the disciplined use and comparison of heterogeneous evidence forms according to the relational or generative property each can support, their trace-production conditions, characteristic omissions or distortions, and the way convergence or disagreement among them affects the target claim.

Pluralism does not imply that every research project should use every method or that every evidence type receives equal weight. A legal document can strongly evidence formal obligation while weakly evidencing enacted intensity. Behavioral data can reveal patterned interaction while underdetermining meaning. Testimony can provide access to experience or interpretation unavailable in administrative records while remaining situated and potentially contested. Network data can reveal recorded ties while depending on how edges were defined and observed. Computational inference can extend analytical reach while adding model and category dependence.

The epistemic task is therefore to match evidence to claim. Heterogeneous evidence becomes especially valuable when distinct trace-production processes converge on the same relational proposition or when disagreement reveals that apparently identical measures refer to different dimensions of the relation. Evidential pluralism also protects against systematic blindness produced by a single archive, administrative regime, platform, expert vocabulary, or machine classification system.

This commitment has a justice dimension without collapsing evidential standards into representational inclusion. Section 5.18 showed that actors differ in their ca-

pacity to create durable records, institutional categories, expert interpretations, and machine-readable traces. Evidential pluralism can widen the space of epistemic participation, while warrant still depends on what each source can support and how conflicts among sources are adjudicated.

5.21.7 Historical Sensitivity

GRE treats relations, categories, manifestation processes, evidential infrastructures, and standards of interpretation as historically situated. Section 5.14 developed relational trajectories, generative trajectories, path dependence, genealogical reconstruction, historically constrained counterfactuals, and historical re-epistemization. Historical sensitivity therefore concerns more than adding chronological background to a contemporary analysis.

A historically sensitive relational claim asks whether the relation itself persisted, whether its participants or constitutive rules changed, whether the same manifestation carried the same significance at different times, whether evidence was preserved under comparable conditions, and whether present categories distort earlier forms. A historically sensitive generative claim additionally asks whether the mechanism, opportunity structure, and feasible alternatives changed across the trajectory.

Definition 5.182 (Historical index of a relational claim)**.** The *historical index of a relational claim* specifies the period, trajectory, category regime, evidential conditions, and relevant path-dependent or transformative processes under which the claim is warranted.

Historical sensitivity also limits retrospective determinism. Later consequences can change the significance attributed to earlier events without proving that those consequences were already inevitable or fully contained in the earlier configuration. Historical counterfactuals should therefore be constrained by possibilities evidenced for the period rather than by alternatives that became available only later.

This commitment has implications for concepts used throughout GRE. Terms such as capital, market, household, labor, ownership, value, organization, expertise, and technology may preserve partial continuity across periods while their relational constitution changes. The framework should therefore remain capable of tracing continuity and transformation together. Historical sensitivity prevents a stable label from being mistaken for an unchanged relation.

5.21.8 Revisability

The eighth commitment synthesizes Section 5.20. GRE treats relational knowledge as revisable because new evidence can emerge, interventions can transform the object, historical conditions can change, categories can fail, observation can become reflexive, and previously weak alternatives can acquire stronger support. Revisability is consequently part of responsible stabilization rather than its opposite.

A revisable claim preserves enough provenance for later investigators to reconstruct how its warrant was established. This includes the evidence available at the time, category definitions, boundary and scale choices, major representational decisions, uncertainty profile, competing interpretations, and reasons for selecting the

working conclusion. Versioning is therefore epistemic infrastructure. When a claim changes, the change should be traceable to the dimension that changed.

Definition 5.183 (Revision architecture)**.** A *revision architecture* is the set of documentary, procedural, and interpretive practices through which a relational or generative claim can be reassessed, updated, qualified, replaced, or retired while preserving the provenance of earlier formulations and the reasons for change.

Revisability includes contestability. A claim that cannot be meaningfully challenged because its data, categories, model assumptions, representational choices, or inferential path are inaccessible has a weaker revision architecture even when its current performance appears strong. This point is particularly important for machine-mediated inquiry, where analytical capability can expand faster than human capacity to reconstruct every internal operation. Contestability can therefore be supported through provenance, documentation, comparative testing, alternative representations, appeal procedures, or other mechanisms appropriate to the domain, without requiring that every technical process be reducible to a simple human-readable explanation.

Revisability also supports cumulative inquiry. Earlier claims can remain useful even when later work narrows their scope or revises their categories. Preservation of serious alternative interpretations allows future researchers to distinguish evidence that genuinely resolved a disagreement from conditions that merely made one interpretation institutionally dominant. GRE therefore treats the history of its own knowledge claims as part of the material needed for future research.

5.21.9 Epistemic Humility

The final commitment concerns the relation between theoretical ambition and epistemic limitation. GRE is intentionally ambitious in analytical scope: it seeks to study heterogeneous relations, distributed fields, generative processes, historical trajectories, multiple forms of value, power over relational and conversion structures, and transformations of future possibilities. Such breadth can create a temptation to treat the relational vocabulary as if it offered a privileged view from which the system can be comprehensively known. The epistemology developed in this chapter rejects that inference.

Definition 5.184 (Epistemic humility in GRE)**.** *Epistemic humility in GRE* is the disciplined refusal to infer epistemic mastery from theoretical scope, formal sophistication, computational capacity, evidential volume, institutional authority, or temporary explanatory success, together with the positive practice of stating what is known, how it is known, where its warrant ends, and what could revise it.

Epistemic humility differs from generalized skepticism. It permits strong claims where evidence, scope, mechanism, and alternatives support them. It also permits action under incomplete knowledge. Its function is to prevent a successful analytical framework from erasing the mediations through which its own claims are produced. Ontological suspension remains relevant here: GRE can investigate relational reality rigorously without converting analytical usefulness into a final metaphysical settlement.

Humility also has an institutional dimension. Analysts, experts, organizations, and computational systems can occupy positions that make their representations unusually consequential. The resulting authority does not automatically track epistemic adequacy. Sections 5.18 and 5.19 therefore make contestability, provenance, unequal evidence-production capacity, and representational authority part of the epistemic architecture. Humility requires institutional arrangements capable of receiving correction, especially from positions whose evidence is weakly represented by dominant recording systems.

The commitments developed in this section can now be stated together.

Proposition 5.185 (Minimum epistemic commitments of GRE)**.** *A GRE inquiry that advances relational or generative knowledge should ordinarily make visible, in forms proportionate to the claim and research context:*

1. *the partial character and evidential reach of the knowledge claim;*
2. *the principal representational choices through which the target is rendered;*
3. *the boundary, scale, and temporal scope under which the claim is asserted;*
4. *the principal dimensions of uncertainty and live competing explanations;*
5. *the mechanism or dependency structure supporting stronger generative attribution where such attribution is made;*
6. *the relation between heterogeneous evidence forms and the target they support;*
7. *the historical conditions under which relations, categories, evidence, and mechanisms are interpreted;*
8. *the provenance and contestability required for later revision; and*
9. *the limits beyond which the inquiry does not claim epistemic mastery.*

Proposition 5.185 is intentionally methodological only in the broad sense of disciplining inquiry. It does not select a research technique. The same commitment can be satisfied differently in archival research, ethnography, survey analysis, network analysis, causal inference, formal modeling, computational simulation, or mixed research designs. The proposition therefore completes the epistemic synthesis while leaving the design problem open.

GRE can remain ambitious under these commitments because ambition concerns the range and depth of questions that inquiry is prepared to pursue, whereas epistemic mastery concerns an unwarranted claim to complete, final, or position-independent knowledge. The framework can investigate distributed generativity, historical transformation, heterogeneous value, and complex relational fields while continuing to expose its boundaries, mediations, uncertainties, and revision conditions. This combination of analytical reach and disciplined limitation provides the immediate basis for the transition from epistemology to methodology developed in the next section.

5.22 From Epistemology to Methodology

This section closes the epistemic argument of this chapter by translating the chapter's commitments into requirements for subsequent research design. Its role is tran-

sitional: the preceding sections established what must be made explicit before GRE can claim warranted knowledge of relations, fields, trajectories, and generative effects; the next Part must determine how inquiry can be organized so that those epistemic requirements are practically addressed. The objective here is therefore neither to prescribe a universal research procedure nor to introduce a new methodological canon. It is to identify the bridge between epistemic warrant and research practice. The discussion proceeds from the difference between knowing relations and studying relations, to epistemic requirements for design, claim-sensitive method selection, the additional burden associated with generative claims, and the transition toward relational methodology. The method is architectural: each subsection converts an epistemic commitment already developed in this chapter into a design question that later methodological chapters can answer with domain-appropriate techniques.

Definition 5.186 (Epistemic design translation)**.** An *epistemic design translation* is the process of converting a condition of warranted knowledge into an explicit requirement for research design, evidence production, analysis, documentation, or revision.

Definition 5.186 establishes the limited function of this section. Epistemology identifies what would make a claim defensible; methodology organizes inquiry so that evidence and analysis capable of supporting, qualifying, or revising that claim can be produced. The relation is therefore constraining without being mechanically deductive. A commitment to explicit boundary and scale does not determine one technique, yet it does require the design to identify the relevant inclusion rules, levels of analysis, and conditions of cross-scale inference. A commitment to revisability does not select one empirical method, yet it does require provenance, versioning, preserved alternatives, and procedures through which later evidence can alter earlier claims.

5.22.1 Knowing Relations and Studying Relations

Knowledge of a relation and the practical study of that relation belong to different analytical levels. The first concerns warrant: what supports the claim that a relation exists, persists, changes, or contributes generatively to a target outcome. The second concerns research organization: how observations are obtained, how evidence is produced or recovered, how participants and archives are accessed, how representations are constructed, how comparison is performed, and how alternative explanations are evaluated. The chapter has concentrated on the first level while repeatedly exposing its dependence on the second.

The distinction matters because epistemic adequacy cannot be inferred directly from the label of a method. An interview may provide strong evidence concerning lived dependency, weak evidence concerning population prevalence, and indirect evidence concerning institutional structure. A network dataset may represent a recorded interaction pattern with considerable precision while leaving the substantive meaning of an edge uncertain. An archival series can support reconstruction of institutional categories and historical sequences while preserving systematic silences. A computational model can clarify consistency, sensitivity, or possible dynamics without independently establishing that its represented relations correspond to the empirical world. Method names therefore provide limited information until the target claim and evidential pathway are specified.

Conversely, the same epistemic target can often be approached through different research practices. A relation of dependence may be reconstructed through contractual records, administrative data, longitudinal behavior, testimony, ethnography, historical comparison, or combinations of these materials. Each route reveals some aspects of the target and obscures others. The methodological problem is consequently one of fit between a claim, the traces through which that claim may become accessible, and the procedures capable of recovering and interpreting those traces.

Definition 5.187 (Relational study design)**.** A *relational study design* is an organized set of procedures for identifying, observing, reconstructing, comparing, representing, and revising claims about specified relations under explicit conditions of access, boundary, scale, temporality, and uncertainty.

The definition treats research design as more than a sequence of techniques. It includes the conditions through which a relation becomes researchable. Access arrangements, category construction, sampling rules, temporal windows, field boundaries, recording systems, legal classifications, machine infrastructures, and researcher position can all affect what becomes visible. Sections 5.7, 5.8, 5.18, and 5.19 established that such conditions can shape both evidence and the object represented by that evidence. Studying relations therefore requires methodological attention to the production conditions of knowledge itself.

The distinction between knowing and studying also protects GRE from a common shortcut: moving directly from an epistemic ideal to a preferred technique. A commitment to evidential pluralism, for example, does not imply that every project should use mixed methods. It means that no evidential form receives unconditional authority and that the selection of evidence should be justified relative to the claim. A narrowly designed study can be epistemically strong when its claim is correspondingly narrow and its evidential fit is clear. A methodologically elaborate project can remain epistemically weak when the relation between evidence and target is poorly specified.

Proposition 5.188 (Claim–study distinction)**.** *The epistemic strength of a relational claim depends on the fit between the target, the evidence generated or recovered by the study, and the inferential pathway connecting them; it cannot be determined from the nominal sophistication or plurality of methods alone.*

Proposition 5.188 provides the first bridge into methodology. The next methodological chapters must therefore ask how research practices produce evidence of different kinds, which claims those practices can support, and how their characteristic blind spots can be made visible.

5.22.2 Epistemic Requirements for Research Design

The epistemic commitments consolidated in Section 5.21 become design requirements when inquiry begins to specify an object, field site, archive, dataset, model, comparison, or intervention. These requirements do not form a universal checklist whose every item must receive equal attention. Their relevance and burden vary with the strength and consequence of the intended claim. They nevertheless provide a common architecture for asking whether a design can generate evidence proportionate to its epistemic ambitions.

Partial knowledge becomes a requirement to characterize access conditions and likely blind spots. A design should identify what can be observed directly, what must be inferred, what remains latent or hidden, and which absences are interpretable. Explicit representation becomes a requirement to document how relations are encoded in concepts, categories, variables, graphs, narratives, legal forms, or computational objects. Boundary and scale commitments become requirements to state the domain of inclusion and the level at which claims are expected to hold. Uncertainty becomes a requirement to preserve dimensions of doubt rather than compress them prematurely into a single confidence statement.

Mechanism-sensitive attribution becomes a requirement to collect or reconstruct evidence capable of discriminating among plausible generative pathways when stronger causal or generative claims are intended. Evidential pluralism becomes a requirement to justify why a particular evidence form is suitable for the target and, where consequential uncertainty remains, whether complementary evidence could materially improve discrimination. Historical sensitivity becomes a requirement to reconstruct the categories, opportunity structures, institutions, and trace-production systems relevant to the period rather than projecting contemporary classifications backward without qualification. Revisability becomes a requirement for provenance, versioning, preserved assumptions, and explicit triggers for revision. Epistemic humility becomes a requirement to state the limits of portability, generalization, and authority.

These translations can be summarized through the notion of an epistemic design requirement.

Definition 5.189 (Epistemic design requirement)**.** An *epistemic design requirement* is a research-design condition introduced because failure to satisfy it would materially weaken the warrant, scope control, interpretability, contestability, or revisability of the intended claim.

The definition makes proportionality central. A study of a narrowly bounded documentary relation may require relatively modest procedures for cross-scale inference, while a claim concerning distributed generative transformation across institutions requires considerably stronger boundary, temporal, and mechanism design. The burden should therefore rise with inferential depth, scope, and consequence.

Research design also involves prioritization. Some epistemic problems can be reduced by obtaining more observations or recovering missing records. Others arise from category ambiguity, strategic concealment, historical discontinuity, observer effects, or underdetermination among relational explanations. Additional data can sometimes leave these problems intact. The appropriate response may require interpretive reconstruction, comparative design, historical analysis, participant engagement, category revision, sensitivity analysis, or preservation of competing explanations. Methodology therefore begins by diagnosing the type of epistemic limitation before selecting the procedure intended to address it.

Proposition 5.190 (Design proportionality)**.** *The methodological burden of a GRE study should be proportionate to the inferential distance, scope, temporal reach, and practical consequence of the claims it intends to support.*

Proposition 5.190 prevents two symmetrical distortions. One is methodological

minimalism applied to claims whose generative, historical, or cross-scale scope exceeds the evidence produced by the design. The other is unnecessary methodological expansion in studies whose claims are deliberately local and modest. GRE methodology should be demanding where the claim requires it and economical where additional complexity would not materially improve warrant.

The design stage should therefore make explicit at least four elements: the intended epistemic target; the principal evidence pathway; the major conditions under which that pathway can fail; and the procedures through which those failures will be detected, bounded, or preserved as uncertainty. Later chapters can operationalize these elements differently across qualitative, historical, quantitative, formal, computational, and mixed research practices.

5.22.3 Relational Identification and Method Selection

Method selection follows from the structure of the relational claim rather than from allegiance to a disciplinary technique. The first methodological question is therefore not which method GRE prefers, but what kind of relation the study seeks to identify and which properties of that relation matter for the research problem. A relation may be legal, material, behavioral, symbolic, institutional, affective, informational, ecological, spatial, computational, or composite. Its evidential traces can differ accordingly.

Relational identification usually contains several separable tasks. The study may need to identify the relevant relata; determine whether the relation is direct, mediated, nested, collective, multilayer, or field-like; specify the temporal criterion under which the relation is treated as persistent; reconstruct its boundary and scale; characterize its directionality or symmetry; and determine whether observed manifestations are sufficient to distinguish it from plausible alternatives. The appropriate methods depend on which of these tasks carry the main uncertainty.

A study concerned with formal legal relations may require close analysis of legal texts, institutional procedure, and enacted practice because formal validity and relational realization can diverge. A study concerned with informal care or dependency may require testimony, observation, and contextual interpretation because administrative traces can remain sparse. A study concerned with network structure may require relational data and explicit edge semantics, while a study concerned with historical persistence may require longitudinal or archival reconstruction. A study concerned with a relational field may require evidence that local positions derive meaning or constraint from distributed organization rather than merely from pairwise density.

Definition 5.191 (Claim–method fit)**.** *Claim–method fit* is the degree to which a research procedure can generate, recover, or interpret evidence that bears directly on the properties required to identify and delimit the intended relational claim.

Claim–method fit is therefore property-specific. A method can fit one component of a claim while remaining weak for another. Longitudinal administrative data can support persistence and sequence, yet offer limited access to unrecorded meaning. Ethnographic observation can clarify relational enactment and category mismatch, yet require additional design for population-level prevalence. Formal models can ex-

pose structural consequences of assumptions while requiring independent evidence for empirical correspondence. Method selection should make such asymmetries explicit rather than allowing the prestige or familiarity of a method to substitute for evidential fit.

This orientation also clarifies the role of methodological pluralism. Pluralism does not require the accumulation of methods for its own sake. It permits the research design to combine methods when distinct properties of the claim require different forms of access. Complementarity is strongest when each method addresses a known weakness in another evidential pathway or when heterogeneous evidence provides independent support for a relational reconstruction. Redundancy without additional discrimination can increase workload without materially increasing warrant.

A further implication concerns sequencing. Method selection can be iterative. Early qualitative or historical inquiry can reveal categories that later support structured measurement; computational exploration can identify patterns requiring interpretive reconstruction; formal analysis can expose assumptions whose empirical plausibility must then be examined; surprising field observations can trigger revision of a sampling frame or relational boundary. GRE therefore permits research designs in which identification and method selection co-evolve as evidence clarifies the object under study.

Proposition 5.192 (Relational method selection)**.** *Method selection in relational inquiry should be justified by the properties required to identify, delimit, compare, or reconstruct the target relation, together with the characteristic access conditions and failure modes of the proposed evidential pathway.*

Proposition 5.192 prepares the more detailed relational methodologies developed later. Those methodologies can organize concrete procedures around relational identification without treating one technique as the defining method of GRE.

5.22.4 Generative Claims and Methodological Burden

Generative claims place a heavier methodological burden on inquiry because they extend beyond relational identification toward claims about contribution to emergence, transformation, persistence, suppression, capacity formation, structural change, or alteration of future possibilities. Sections 5.12, 5.13, and 5.16 established that generativity must be specified relative to a target and supported through evidence connecting a relation or configuration to the claimed effect.

The methodological burden has several layers. First, the underlying relation must be identified with adequate warrant. Second, the target change must itself be evidenced. Third, the design must support an inferential pathway linking the relation to that change. Fourth, materially relevant alternatives, enabling conditions, mediators, and distributed contributors must be considered at a level proportionate to the strength of the attribution. Fifth, delayed and branching effects require temporal design capable of tracing carriers across stages rather than relying exclusively on immediate association.

These layers mean that a generative study may require different forms of evidence at different points in the argument. The existence of a relation may be documented

through contracts or network data; its mechanism may require process evidence; its downstream effect may require longitudinal observation; its historical conditions may require archival reconstruction; its distributed contribution may require comparative or configurational analysis; its transformation of future possibilities may require reconstruction of feasible alternatives rather than observation of realized outcomes alone. No single evidential form receives automatic priority across these tasks.

Definition 5.193 (Generative methodological burden)**.** The *generative methodological burden* is the additional design and evidential work required to move from a warranted claim that a relation or configuration exists to a warranted claim that it contributed to a specified generative effect under stated boundary, scale, temporal, and uncertainty conditions.

The burden is graded. A modest claim that a relation plausibly enabled a capacity can require less evidential discrimination than a claim that the same relation transformed an institutional structure or altered the conditions through which later transformation occurred. The vocabulary of attribution should track this difference. Terms such as association, contribution, mediation, enabling, constraint, co-generation, and stronger generative attribution can express different levels of warranted commitment.

Generative inquiry also increases the importance of negative and unrealized evidence. Foreclosure concerns possibilities that became less accessible; path dependence concerns alternatives whose feasibility changed through sequence; capacity formation concerns what actors or systems became able to do; second-order generative change concerns altered conditions of later transformation. Research design therefore cannot rely only on directly realized outcomes. It may need historical comparison, counterfactual discipline, institutional analysis, process tracing, or formal representation of feasible states, with the evidential status of each construction kept explicit.

The methodological problem is especially demanding where generation is distributed. An outcome can depend on background infrastructure, maintenance, tacit coordination, legal conditions, ecological supports, technical systems, and contributions whose traces are unequally preserved. Section 5.18 showed that unequal evidence-production capacity can distort generative attribution. A methodology adequate to distributed generation should therefore examine whether evidential visibility is itself patterned by power, institutional legibility, or recording infrastructure.

Proposition 5.194 (Escalating burden of generative inference)**.** *As a claim moves from relational identification toward stronger claims about downstream, distributed, historical, structural, or second-order generative effects, the methodological burden ordinarily increases because additional mediating conditions, alternative pathways, temporal carriers, and boundary assumptions become relevant to warrant.*

Proposition 5.194 supplies the principal reason for maintaining a distinction between methodologies of relational inquiry and methodologies of generative relational inquiry. The two remain connected: generative inquiry presupposes relational identification. Their methodological burdens differ because the latter adds a further

inferential layer concerning transformation through time.

5.22.5 Transition to Relational Methodology

The epistemic work of this chapter establishes the conditions under which GRE can move responsibly from manifestation and trace toward claims about relations and generative processes. The next Part must convert those conditions into research praxis and concrete methodological architectures. The transition therefore begins with a change in question. The chapter has asked what warrants a relational or generative claim. Subsequent chapters ask how inquiry should be organized when researchers must produce, recover, interpret, compare, formalize, and revise the evidence needed for such warrant.

The first consequence is that methodology must remain relationally reflexive. Research is conducted through relations: between researchers and participants, analysts and institutions, observers and instruments, archives and classification systems, computational systems and datasets, funders and research agendas, disciplines and objects of study. These relations can shape access, categories, recording, interpretation, and the practical effects of published representations. The epistemic concerns developed in Sections 5.6, 5.7, 5.18, 5.19, and 5.20 therefore become problems of research praxis as well as abstract epistemology.

The second consequence is methodological pluralism with explicit division of labor. Historical and interpretive inquiry can recover categories, meanings, trajectories, and institutional transformations that sparse contemporary datasets cannot preserve. Qualitative inquiry can examine enacted relations, observer position, category mismatch, and weakly institutionalized experience. Quantitative inquiry can estimate distributions, comparisons, temporal patterns, and conditional associations where measurement is appropriate. Formal and computational inquiry can clarify structural implications, generate counterfactual scenarios, test sensitivity, and represent complex relational configurations. Their value depends on the target and their relation to evidence; none receives automatic jurisdiction over the others.

The third consequence is that methodology must preserve the distinction between relational and generative questions. Relational methodology concerns how relations are identified, reconstructed, represented, compared, and situated within boundaries and fields. Generative relational methodology adds the study of how such relations contribute to the production or transformation of capacities, relations, structures, constraints, values, trajectories, and future possibilities. Integrated designs can combine the two, yet their inferential steps should remain visible so that evidence for relational existence is not mistaken for evidence of generative effect.

The fourth consequence is that research design itself becomes revisable. If categories change, access conditions shift, interventions transform the field, new evidence appears, or machine-mediated observation alters what can be seen, then the design may require modification. A methodology aligned with Section 5.20 therefore includes procedures for documenting such revision rather than treating the initial research plan as epistemically privileged simply because it came first.

These consequences can be consolidated into one transition principle.

Proposition 5.195 (Epistemology-to-methodology transition)**.** *GRE methodology should organize research practices so that the evidential, representational, historical, relational, generative, justice-sensitive, and revisability requirements established in this chapter become explicit design problems rather than implicit assumptions of analysis.*

Proposition 5.195 marks the endpoint of the chapter's argument. Ontological suspension in the preceding chapter prevented analytical representations from being mistaken for final ontology. The present chapter has added a corresponding epistemic discipline: manifestations, traces, representations, observations, models, and historical records provide mediated and partial access whose warrant depends on boundary, scale, evidence, attribution, uncertainty, justice, provenance, and revisability. The methodological chapters that follow can now proceed without requiring epistemic certainty and without treating technical procedure as a substitute for epistemic justification.

The resulting research programme begins from a demanding but workable position. GRE may study complex relational systems under incomplete knowledge; it may combine heterogeneous evidence; it may use historical, interpretive, quantitative, formal, and computational resources; and it may advance generative explanations where the evidential burden is met. At the same time, each design remains answerable to the limits of its access and representation. Methodology therefore becomes the practical organization of disciplined inquiry under the epistemic conditions established here.

Programme Charter

Standards Programme Charter

Governance Working Draft

Draft version 0.1

22 September 2026

WORKING DRAFT FOR REVIEW

This document is not adopted. Its requirement language expresses proposals for review and rehearsal. Preparation of this text does not establish programme governance, approve a formal standards project, or certify substantive truth, legal validity, or institutional legitimacy.

Publication class, scope, dependencies and unresolved decisions are stated in the document. No ISO, IEC or IEEE affiliation or endorsement is claimed.

Contents

1 Purpose, status, and application 2

2 Mission and public purpose 2

3 Scope and boundaries 3

4 Publication authority and work sequence 3

5 Participation and fair consideration 4

6 Governance functions and accountable appointments 4

7 Decision procedure and governance launch 5

8 Resources, records, and external relations 6

9 Founding procedure and decision eligibility 6

10 Evidence for adoption and continuing review 7

11 Informative sources and proposed choices 8

1 Purpose, status, and application

Responsible editor: `UNASSIGNED`. Canonical source: `governance/standards_programme_charter.tex`. Intended readers are founding participants, programme administrators, reviewers and affected people.

This Charter proposes the mission, authority, participation model, and accountability of the Generativity Standards Program. It is a governance publication, not a technical Standard. Its requirements are proposed conditions for operating the programme after recorded adoption. No office, membership, delegation, institutional partnership, or publication authority is created by this draft.

CH-001 The programme shall identify this document as a Governance Working Draft until a founding adoption record identifies the adopting persons, their actual authority over programme resources and publications, the edition adopted, its effective date, and the scope of that authority.

CH-002 An adoption record shall distinguish the programme's own publication authority from any claim to represent a profession, institution, community, jurisdiction, or international constituency. Each representation claim shall identify its actual mandate and limits.

Informative note. The proposed launch model is open individual participation with appointed, accountable decision functions. It does not presume national delegation, institutional membership, international recognition, accreditation, or a legally incorporated body. The older Markdown charter remains a historical outline.

2 Mission and public purpose

The programme develops epistemic and practical infrastructure for warranted recognition, assessment and revision of factual claims, and preservation of consequential generative trajectories. Its motivation is symbolic crisis: instability among representations, their referents, institutional classifications, and practical trust. The purpose includes the conditions under which people can examine grounds, challenge interpretations, revise action, and preserve or reopen future possibilities.

Generativity records can concern what happened, how it became knowable, and how categories and decisions affected later relations. Preserving an output alone can omit contributions, alternatives, constraints, losses, and changes in capacity. More records, stronger authentication, and institutional acceptance do not themselves establish truth, justice, or beneficial generativity.

CH-003 Each proposed programme work item shall identify the recognition or practical problem it addresses, its intended beneficiaries and affected interests, its anticipated contribution to the mission, and the evidence by which that contribution will be evaluated.

CH-004 Programme evaluations shall distinguish demonstrated improvements in recording, interpretation, contestation, or practical response from broader claims about restored trust, justice, or future generative capacity. A broader claim shall identify its evidence and limitations.

CH-005 The programme shall examine its own classification, recording, decision, and publication practices as potential sources of exclusion, dependency, and concentrated authority. Findings and corrective decisions shall enter the programme's maintained issue record.

3 Scope and boundaries

The portfolio covers recording, preservation, exchange, presentation, assessment, contestation, revision, and accountable institutional use of generativity-related records. It includes conceptual work, practical procedures, technical implementation, and distinct policy inquiry.

CH-006 Programme publications shall distinguish metamodel, record ontology, epistemic representation, normative assessment, jurisprudential status, institutional governance, political economy, and technical implementation wherever a requirement or claim depends on more than one of these layers.

CH-007 The programme shall preserve the distinction between theoretical GR concepts and scoped operational requirements. Intentional narrowing, operationalization, or departure shall identify its foundation sources, alternatives, rationale, and recorded architectural decision.

CH-008 Programme publications and public claims shall not present technical conformance, authentic provenance, a programme decision, or a recorded institutional finding as sufficient proof of factual truth, ethical legitimacy, legal validity, or international endorsement.

CH-009 The programme shall identify jurisdictional and institutional authority separately whenever a proposal concerns legal duties, rights, admissibility, liability, or public power. Unresolved applicability shall remain explicit.

Informative note. The six candidate record classes are operational recording concepts. This Charter neither declares them exhaustive constituents of reality nor selects a compulsory mathematical semantics or software platform. Legal and policy research can proceed without pretending that programme publications enact law.

4 Publication authority and work sequence

CH-010 Each publication shall declare its class, maturity, version, responsible editor, and decision authority. Specifications, adopted Standards, policy proposals, governance documents, Technical Reports, and manuals shall retain their distinct authority.

CH-011 The programme shall reserve the designation adopted Standard for an edition approved under its operative development procedure. A draft, schema, prototype, protocol, or technically normative Specification shall not acquire that designation through technical completion alone.

CH-012 Standards-track work shall begin with a stated normative problem, scope, terminology, intended requirements, conformance subjects, and relevant constraints. A dependent Specification work item shall identify the reusable technical need that motivates it. Draft requirements and Specifications may co-evolve through pilots and review.

CH-013 A policy proposal shall identify its intended institution or class of institutions, mandate assumptions, institutional alternatives, expected effects, safeguards, and evaluation approach. Its recommendations shall not amend technical conformance requirements outside the standards-development procedure.

CH-014 Formal work-item approval shall depend on the governance launch conditions in this Charter and Directives Part 1. Preliminary source research, draft preparation, synthetic examples, and technical exploration shall retain their preliminary status while those conditions remain unmet.

5 Participation and fair consideration

CH-015 The programme shall provide a documented route for interested individuals to contribute proposals and comments and to receive reasoned dispositions. Employment, institutional sponsorship, a proprietary tool account, payment, or travel shall not be a prerequisite for submitting a relevant comment.

CH-016 The participant register shall distinguish participation in an individual capacity from authorized institutional representation. It shall record relevant affiliations, interests, assigned roles, and any limits on a representation mandate, subject to justified protection of sensitive information.

CH-017 For each work item, the coordinator shall identify affected interests, reviewer competence needed, known participation gaps, outreach undertaken, and feasible measures for language, disability, time-zone, connectivity, and resource barriers. Unfilled gaps shall remain visible in progression decisions.

CH-018 The programme shall provide an asynchronous contribution route and a human-readable account of proposed substantive changes. A contribution requiring assistance with format shall be assessed for its substance after proportionate assistance or an accessible alternative has been offered.

CH-019 Funding, institutional affiliation, authorship volume, technical access, or control of repository credentials shall not by itself confer decision rights or priority in comment disposition. The decision authority shall assess whether concentrated interests or unpaid-work burdens materially limit fair consideration.

CH-020 Any restriction on participation shall state the conduct or process reason, its scope, duration or review trigger, responsible decision maker, and available challenge route. Restrictions shall not be imposed solely because a participant disputes a proposal or authoritative interpretation.

Informative note. Participation does not imply agreement, authorship, ownership, or authority to speak for others. Consultation with one participant does not establish consent of an entire community. Funded support and declared expertise can improve participation; their influence remains inspectable.

6 Governance functions and accountable appointments

The following functions constitute the proposed minimum organization. They are functions to staff, not assertions that bodies already exist.

Founding authority — UNASSIGNED. Records the basis on which the launch package is adopted and establishes bounded appointments.

Programme decision authority — UNASSIGNED. Authorizes scoped work, assesses progression and adoption evidence, appoints accountable officers, and maintains the programme mandate.

Coordinator and records custodian — UNASSIGNED. Maintains notices, role and work registers, decision evidence, protected access arrangements, and continuity information.

Technical committee convenor — UNASSIGNED. Coordinates work and multidisciplinary review within the committee mandate.

Editors and work-item leads — UNASSIGNED. Prepare drafts, trace requirements, and resolve comments under recorded decisions.

Neutral procedural reviewer — UNASSIGNED. Reviews challenged procedure without participation in the disputed decision or a material conflict.

Ethics contact and alternate — UNASSIGNED. Receive protected reports and arrange conflict-sensitive consideration under the ethics policy.

Maintenance owner — UNASSIGNED. Coordinates review, corrections, revisions, withdrawal, and continuity for assigned publications.

For coordination with Directives Part 1, the programme decision authority is the governance authority; the coordinator and records custodian performs the Secretariat function; and the neutral procedural reviewer performs the independent appeal-review function. A review chair is an explicitly assigned function for a particular review, not an additional standing body. The appointment record identifies the responsible release owner and maintenance owner.

CH-021 An appointment shall identify the person, appointing authority, accepted mandate, decision limits, relevant interests, start date, term or review date, alternate or vacancy arrangement, and removal or replacement procedure. An office shall not be treated as staffed until acceptance is recorded.

CH-022 The programme decision authority shall publish reasons for appointments, renewals, and removals at a level compatible with necessary protection. A challenged appointment or removal shall have access to neutral procedural review under Directives Part 1.

CH-023 Where one person holds multiple functions, each decision record shall identify the capacity exercised and any resulting conflict. A person shall not conduct the neutral review of their own challenged decision.

CH-024 The programme shall not delegate a decision to an automated system. AI-assisted drafting, summarization, analysis, or validation shall retain an accountable human role responsible for checking the resulting material and recording consequential use.

CH-025 The programme shall not exercise a delegated function while its required responsible role is vacant or recused without an authorized substitute. Unaffected preliminary work may continue with its status declared.

7 Decision procedure and governance launch

Directives Part 1 specifies stages, notice and review periods, comment handling, consensus assessment, decision evidence, appeals, and maintenance. Directives Part 2 specifies drafting and publication structure. This Charter defines their mandate and does not duplicate numerical rules.

CH-026 Each consequential progression, adoption, mandate, or appointment decision shall identify the operative procedure, authority, evidence considered, interests and recusals, alternatives, material objections, reasons, consequences, and review route.

CH-027 A claim of consensus shall include evidence that relevant concerns were considered and that remaining substantial objections received reasoned treatment. Silence, elapsed time, a vote total, or lack of a funded alternative shall not alone establish consensus.

CH-028 Before formal work-item initiation, the governance launch record shall identify the adopted Charter and Directives, committee mandate, ethics and contribution arrangements, public-review route, maintenance and records arrangements, accepted appointments, and an available neutral procedural review route. It shall include the results and dispositions of a governance rehearsal.

CH-029 If neutral review is unavailable for a consequential contested decision, the programme shall defer that disputed progression or adoption decision and record the capacity gap. The programme shall continue research and drafting that do not depend on the contested authority.

CH-030 An amendment to governance shall follow the change and review procedure in Directives Part 1, state its effective date and transition arrangements, and preserve the prior edition. A procedure shall not be changed retrospectively solely to validate a disputed decision.

8 Resources, records, and external relations

CH-031 The programme shall maintain an inspectable record of material funding, in-kind support, decision-related conditions, and control of essential infrastructure. Restricted details shall have a stated reason for restriction and an accountable reviewer.

CH-032 A funding or hosting arrangement shall not authorize a sponsor to suppress relevant criticism, require adoption of its preferred technical solution, or bypass review. Material changes in support shall trigger a capacity and continuity assessment.

CH-033 The records custodian shall maintain access to publication status, version history, work scopes, decision reasons, comment dispositions, and correction notices. Protection or deletion of underlying sensitive records shall retain a non-sensitive account of the action and its authority where permitted.

CH-034 An external liaison, pilot, endorsement, submission, or agreement shall identify who is authorized to act, its purpose and limits, and any external institution's actual assent. Participation in the programme shall not be represented as institutional endorsement.

CH-035 The programme decision authority shall review mission performance, participation gaps, concentrated influence, conflicts, unresolved appeals, review capacity, and maintenance resources at least annually with the programme account required by Directives Part 1 and after a material institutional change. The review shall record remedial actions, owners, and follow-up.

9 Founding procedure and decision eligibility

The founding instrument records an explicit commitment by persons with actual authority over identified programme resources or publication functions. It does not derive authority from a draft claiming to be already adopted. The following procedure is the proposed condition for declaring the programme launched.

CH-036 Before founding adoption, the prospective founding signatories shall identify their actual capacities and proposed commitments, publish the exact governance package within cleared rights, identify proposed appointments and decision-eligibility criteria, and announce a founding review that applies the public-review, comment-disposition, reply, and material-change periods in draft Directives Part 1 as explicit conditions of that founding process.

CH-037 The founding signatories shall execute an adoption instrument only after review dispositions, a governance rehearsal, accepted minimum appointments, and independent assessment of the founding process are recorded. The instrument shall identify each signatory's express agreement, scope of commitment, dissent, outstanding limits, and the exact texts adopted. A person or institution shall not be bound or represented by a signature that lacks actual authority.

CH-038 The founding instrument shall identify the first programme decision authority, its delegated limits, appointment and succession route, and review date. Founding adoption shall not itself approve GR/NWIP-001 or any technical Standard. Subsequent formal adoption and maintenance decisions shall use the applicable ballot and review rules of operative Directives Part 1, distinguishing substantive maintenance from editorial correction and confirmation.

CH-039 Before constituting a decision roster, the programme decision authority shall publish the proposed decision scope, nominations route, closing date, competence or affected-perspective criteria, expected review commitment, and conflict rules. Eligible individuals shall have an accepted bounded role, disclosed relevant interests, agreed applicable conduct terms, and a recorded capacity for the particular decision. Institutional representation shall require an identified mandate.

CH-040 Selection to or exclusion from a decision roster shall have recorded reasons against the announced criteria and an available procedural challenge. The authority shall assess concentrated interests and missing perspectives before fixing the roster. A roster shall not change during a ballot except through the correction and restart rules of Directives Part 1.

CH-041 An appointment renewal or proposed removal shall receive a recorded grounds statement and an opportunity for the affected person and relevant participants to respond before a final decision. A non-conflicted authority shall decide the matter within its mandate and provide access to neutral procedural review. Urgent temporary protective measures shall follow the ethics policy and emergency procedure, with a stated review point.

Informative note. The founding instrument uses express agreement by the actual signatories because it establishes their own programme commitments. Later technical adoption uses the separately proposed ballot rules. The requirement for review and available independent capacity prevents the initial signature from being represented as an already completed standards process.

10 Evidence for adoption and continuing review

The adoption dossier provides a clause-to-evidence index. For CH-001–CH-002, CH-021–CH-030, and CH-036–CH-041, evidence includes the founding instrument, accepted role register, decision records, rehearsal record, and neutral-review arrangement. For CH-015–CH-020 and CH-031–CH-035, it includes tested contribution routes, participation and funding records, protection rules, maintenance arrangements, and documented gaps. Mission and scope clauses are checked against an actual proposed work item and its intended claims.

Informative note. A paper declaration of independence or accessibility is insufficient evidence that a reviewer is available or a route works. Rehearsal can expose these defects without asserting that an external institution has participated. Adoption establishes local governance authority only within the recorded mandate.

11 Informative sources and proposed choices

Source and interpretation. Programme Brief, version 0.2; comprehensive development plan, version 0.1; cross-domain programme; foundation traceability map, particularly FT-01 and FT-06. Local paths: `PROGRAMME_BRIEF.md` and `docs/planning/`. These explain the mission and candidate operational direction.

Source and interpretation. Foundation manuscripts: FM-001, `GRE_Chapter_01.pdf`, section 1.14.2–1.14.5, pp. 79–83; FM-003, `GRE_Chapter_03.pdf`, section 3.12, pp. 129–132; FM-005, `GRE_Chapter_05_Complete_First_Draft.pdf`, section 5.18, pp. 150–153. Files are in `foundation_manuscripts/`. These ground the orientation to representational instability, revisable action, and unequal evidential capacities; they do not enact these governance clauses.

Source and interpretation. WTO, Principles for the Development of International Standards, Guides and Recommendations, official presentation of the 2000 TBT Committee decision, consulted 2026-09-22: https://www.wto.org/english/tratop_e/tbt_e/principles_standards_tbt_e.htm. Its treatment of transparency, participation, impartial consideration, relevance, coherence, and resource barriers informs process design. Local requirements and organization are programme proposals, not a claim of WTO recognition.

The selected draft direction uses individual contribution and bounded appointments, with separation of authoring, decision authority, and neutral review. Alternatives include institutional membership or a hybrid representative model. The launch choice reduces administrative assumptions while leaving representation and concentrated influence visible. Transition to a different membership model needs a recorded Charter revision; it does not occur through informal growth.

OPEN. Founding authority, organizational form, actual appointments, neutral reviewer capacity, operating resources, and public/protected contact routes remain OPEN. The text supplies reviewable rules; it does not fill those roles.

OPEN. The scope of public distribution rights and the operative contribution terms remain OPEN under the Ethics, Conflict-of-Interest, and Contribution Rights Policy. Drafting and internal review remain possible within actual permissions.

Procedures for Development and Maintenance

Governance Working Draft

Draft version 0.1

22 September 2026

WORKING DRAFT FOR REVIEW

This document is not adopted. Its requirement language expresses proposals for review and rehearsal. Preparation of this text does not establish programme governance, approve a formal standards project, or certify substantive truth, legal validity, or institutional legitimacy.

Publication class, scope, dependencies and unresolved decisions are stated in the document. No ISO, IEC or IEEE affiliation or endorsement is claimed.

1 Status, scope, and authority

This document proposes an executable development procedure for the Generativity Standards Program. Its clauses govern the programme only after explicit governance adoption. It is a **PROVISIONAL Governance Working Draft**, not an adopted Standard, an approved project, or evidence that a committee exists. Its numbered requirements are proposed requirements. A rehearsal can test them without making them operative.

Responsible editor: `UNASSIGNED`. Canonical source: `governance/directives_part_1.tex`. Intended readers are founding participants, procedural administrators, editors, reviewers, affected people, and prospective implementers of the development procedure. The assessed subject is a particular project-development or maintenance procedure and its records, not the substantive truth of a resulting Standard.

The procedure supports inspectable, revisable recognition and practical action by preserving grounds, alternatives, objections, decisions, and subsequent changes in standards development itself. It does not determine the truth of recorded claims, settle GR theory by vote, or confer external legal authority.

D1-001 The programme shall apply the adopted Charter for decision authority and appointments, these Directives for development procedure, Directives Part 2 for drafting, and the adopted Ethics, Conflict-of-Interest, and Contribution Rights Policy for conduct, conflicts, and rights. A conflict between these instruments shall be referred to the governance authority and resolved before a dependent decision proceeds.

D1-002 Every procedural decision shall identify its accountable decision maker, operative authority and procedure versions, input document versions, grounds, outcome, date, and review or appeal route. Drafting, a repository merge, an ADR, or successful compilation shall not constitute governance adoption or Standard approval.

D1-003 An organizational function without an appointed holder and recorded mandate shall remain `UNASSIGNED`. Formal project initiation and adoption shall remain pending while required authority or an independent appeal route is unavailable. Preliminary research, drafting, and synthetic rehearsals may continue with explicit status labels.

2 Terms used in this procedure

Governance authority The body or bounded transitional authority constituted by the adopted Charter; its mandate determines which decisions it can take.

Technical committee An actually constituted committee with a bounded project mandate; not a label that itself establishes authority.

Substantive change A change that could alter scope, meaning, duties, permissions, conformance outcomes, interoperability, protection, or practical consequences.

Substantive objection A reasoned concern about technical adequacy, evidence, scope, procedure, rights, participation, harm, or feasibility relevant to the proposed decision.

Consensus assessment A documented assessment of participation, consideration of concerns, remaining disagreement, and grounds for progression. It is distinct from a ballot tally.

Eligible participant A person assigned decision rights under the Charter and recorded for the specific decision; authorship, payment, or attendance alone does not confer those rights.

Calendar day A day counted using the closing time and time zone stated in the notice. A notice states an exact closing timestamp.

3 Founding, responsibilities, and participation

D1-004 Before formal standards-project approval, the founding adoption record shall identify the founding basis, adopted governance texts and versions, participants and capacities, decision method, dissent, transitional limits, review date, and replacement route. Governance adoption shall follow the founding procedure recorded under the Charter, rather than assume that these draft Directives have already authorized themselves.

D1-005 The governance authority shall assign oversight, project progression, public-review administration, release, maintenance, conflict handling, and independent appeal functions. The assignment register shall identify holders, terms, delegated limits, substitutes, and contact routes. Combined roles shall be disclosed; an interested decision maker shall not determine their own procedural appeal.

D1-006 The Secretariat shall maintain an accessible work programme and participation route. A project notice shall identify the problem, scope, current status, available documents, contribution terms, comment routes, decision roles, and intended review dates. Public comment shall not require voting membership or endorsement of the proposal.

D1-007 The review chair shall document outreach to affected interests and relevant expertise, participation barriers, affiliations relevant to dominance, and remaining gaps. The chair shall provide an asynchronous contribution route and record requested accessibility or language accommodations and the response. Lack of response shall not be recorded as consent.

D1-008 Before a formal decision, the chair shall confirm current conflict declarations and apply the adopted recusal procedure. The record shall identify recusals and their effect on eligibility and quorum without disclosing protected details unnecessarily. If conflicts prevent a valid decision or impartial review, progression shall be deferred.

Informative note. Participant eligibility and appointment belong to the Charter; conduct and contribution permissions belong to the Ethics, Conflict-of-Interest, and Contribution Rights Policy. These Directives do not grant membership, impose a license, or establish a legal entity.

4 Project initiation and scope control

D1-009 A New Work Item Proposal shall identify purpose, intended users and affected people, publication class, bounded deliverables, exclusions, proposed conformance subjects, alternatives to new standardization, source basis, dependencies, review expertise, pilot evidence, resource needs, and prospective maintenance responsibility.

D1-010 The proposal shall explain how the work addresses warranted recognition or generative trajectory and identify epistemic assumptions, ethical impacts, legal and institutional boundaries, public-policy implications, accessibility, protection needs, and distribution of recording and implementation burdens. A claimed institutional mandate shall identify its source and limits.

D1-011 The technical committee shall begin with the normative problem and assessment needs. A dependent Specification proposal shall identify the draft requirements requiring reusable

technical infrastructure, the implementation alternatives, and intended tests. A protocol proposal shall additionally identify actors, interactions, states, transitions, outcomes, failure handling, and authority boundaries.

D1-012 The authorized project decision maker shall record accept, revise, defer, or reject, with reasons, scope, assigned responsibilities, dependencies, and review milestones. A coordinated proposal shall retain a separate bounded scope and progression record for each deliverable. A technical dependency shall not acquire Standard status through inclusion in a proposal.

D1-013 A proposed expansion beyond approved scope shall receive impact review and an explicit scope decision before dependent progression. A Specification intended for promotion to a Standard shall enter an explicit standards-track proposal and the applicable review stages; technical stability alone shall not authorize promotion.

5 Stages and progression evidence

The following codes are the programme's local lifecycle. They retain the repository's grouping of review, revision, and withdrawal under stage 90. Specifications have separately declared maturity; stage 60 is reserved here for adopted Standards.

Stage	Local status	Evidence for progression
00	Preliminary	Need, preliminary sources, alternatives, and draft NWIP; no project authority presumed.
10	Proposal	Approved bounded scope, capacity, assignments, dependencies, and review plan.
20	Working Draft	Candidate clauses, source and decision traceability, assessment methods, and example or pilot design.
30	Committee Draft	Integrated requirements, review findings and dispositions, pilot evidence and limitations, proposed public-review package.
40	Public Review Draft	Versioned notice, accessible draft, comments and responses, material-change review, and remaining objections.
50	Final Approval Draft	Frozen approval package, consensus assessment, valid ballot, procedural checks, and appeal handling.
60	Published Standard	Recorded adoption and release authorization, verified publication package, maintenance owner and next review date.
90	Review / revision / withdrawal	Issue and impact evidence; recorded confirmation, correction, amendment, revision, supersession, or withdrawal.

D1-014 Each progression decision shall state the current and proposed stage, evaluate the relevant evidence, identify remaining limitations, and record approval, return for revision, deferral, or closure. A stage label shall not substitute for the decision record. No Standard shall skip public review or final approval by claiming that a prototype or pilot already establishes acceptance.

D1-015 The editor shall retain versioned drafts, a requirement-to-source and assessment map, an issue register, and substantive decision records identifying alternatives, selected direction, rationale, and affected artifacts. GR interpretation shall use relevant foundation manuscripts

and preserve unresolved source differences; operational narrowing affecting architecture shall have an ADR.

D1-016 At committee review, named reviewers shall evaluate epistemic adequacy, practical usability, ethical and distributional effects, accessibility, preservation and protection, legal/institutional boundaries, and technical feasibility within declared competence. Missing expertise or evidence shall be reported and resolved, or the scope narrowed, before unsupported requirements advance.

D1-017 Pilot reports shall identify the tested versions, cases and negative cases, methods, participants' roles, failures, burdens, limitations, and resulting changes. Synthetic or author-operated tests shall be labelled accordingly. External institutional participation, access authority, independent validation, and legal validity shall not be inferred from a synthetic rehearsal.

6 Public review and comment disposition

D1-018 Before opening public review, the chair shall freeze a uniquely identified draft and publish its scope, class, maturity, change summary, dependencies, known limitations, review questions, exact opening and closing times, submission routes, and intended treatment of commenter information. Required supporting material shall be accessible to reviewers under workable terms.

D1-019 Public review shall remain open for at least 60 calendar days. The chair shall record outreach, access interruptions, and accommodation needs; a material access failure shall receive an extension sufficient to restore meaningful opportunity, with reasons and revised closing time published.

D1-020 The Secretariat shall accept comments in an accessible free-text route as well as any structured template. It shall assign a stable identifier, record the affected version or topic, requested change if supplied, receipt date, and disclosure preference, and acknowledge receipt within seven calendar days. A comment shall not be rejected solely for lacking technical drafting expertise.

D1-021 The Secretariat shall offer a protected route for justified confidential submissions and explain its access limits. The chair shall arrange competent consideration and publish a safe summary of the issue and disposition where possible. If essential grounds cannot be exposed sufficiently for fair review, the chair shall record the limitation and defer or narrow the affected decision.

D1-022 The responsible review group shall give every in-scope comment a disposition of accepted, accepted with modification, not accepted, or deferred, with reasons and links to affected clauses or issues. Out-of-scope and duplicate comments shall retain identifiers and a reason or linked disposition. Deferral shall identify an owner, next action, and why the unresolved issue does not invalidate proposed progression.

D1-023 The chair shall target initial dispositions within 30 calendar days after review closes. If that target cannot be met, the chair shall publish reasons, interim status, and a new target before it expires. A target extension shall not deem comments resolved. Commenters shall receive disposition notice and at least 30 calendar days to reply before final approval.

D1-024 The chair shall assess each reply and record remaining disagreement. Late comments shall be logged with reasons for current-cycle consideration or later referral; a newly identified

material safety, rights, or validity defect shall receive assessment before adoption regardless of receipt date.

D1-025 A substantive post-review change shall undergo public re-review for at least 30 calendar days, showing the changed text, reasons, effects, and affected dependencies. The chair shall notify previous commenters and newly affected interests. A change that substantially alters the purpose, affected constituency, or conformance subject shall receive renewed scope approval and a full 60-day review.

D1-026 Re-review shall permit comments on changed material and its consequences for unchanged clauses. Further substantive changes shall repeat the applicable review. Editorial changes shall be logged with a reason why meaning and conformance remain unchanged.

7 Consensus, ballots, and final approval

D1-027 Before recommending progression, the chair shall produce a consensus assessment identifying participation and gaps, objections, attempts at resolution, evidence and alternatives considered, remaining dissent, and reasons for the recommendation. Numerical approval shall not establish substantive truth or by itself dispose of an objection.

D1-028 A sustained substantive objection shall receive reasoned consideration and an opportunity for reply. It shall not automatically confer a veto. Unresolved defects in mandatory procedure, decision authority, rights to participate, or required evidence shall prevent progression until remedied. Other remaining disagreement shall be visible in the approval package and assessed by the authorized decision maker.

D1-029 For adoption, substantive maintenance decisions, and other decisions assigned a formal ballot by the Charter, the Secretariat shall circulate a frozen package and proposed resolution for at least 30 calendar days. It shall state eligible participants, recusals, closing time, threshold calculation, ballot options, and challenge route. Ballots shall be approve, disapprove, or abstain; nonresponse shall be recorded separately.

D1-030 The eligible non-recused roster shall be fixed before ballot opening. Each eligible person shall have one ballot in their declared capacity; proxies and duplicate capacities shall not count. Eligibility corrections or later recusals shall be recorded. A change materially affecting the electorate, quorum, or result shall require a new ballot; membership shall not be manipulated to obtain a desired outcome.

D1-031 Let N be the number of eligible non-recused participants, R valid returned ballots including abstentions, Y approvals, and D disapprovals. A ballot shall meet quorum only if $R \geq \lceil 2N/3 \rceil$. Approval shall also require at least three substantive ballots, $Y + D \geq 3$, and $Y \geq \lceil 2(Y + D)/3 \rceil$. Abstentions shall count for returned-ballot quorum but not the substantive-ballot minimum or approval denominator; nonresponses shall count for neither.

D1-032 The result shall include the frozen roster count, recusals, returned ballots, approvals, disapprovals, abstentions, nonresponses, calculation, minority grounds, and decision. Failure of quorum or threshold shall return the matter for further work or deferral, without deemed approval. A substantive change during ballot shall return to the applicable review stage.

D1-033 Final approval shall require a procedurally valid ballot, reasoned consensus assessment, completed dispositions and reply periods, resolved blocking findings, compatible normative dependencies, rights clearance, maintenance assignment, and an authorized adoption record.

The Secretariat shall publish accessible decision notice, notify participants and commenters, and record when the appeal period starts. Release shall await that period and resolution of any appeal affecting adoption or publication.

OPEN. All numerical values in this draft are local proposals requiring author and participant review before governance adoption. They are not ISO/IEEE rules. A valid three-person ballot does not itself demonstrate stakeholder breadth or independent review capacity; Annex A identifies these participation-risk choices for explicit review.

8 Procedural appeals and separate complaint routes

D1-034 A participant, commenter, or person directly affected by a programme decision may lodge a procedural appeal identifying the decision, alleged procedural failure, available evidence, and requested remedy. Membership or payment shall not be a condition. The ordinary filing period shall be 30 calendar days after accessible notice of the decision; lack of effective notice or newly discovered concealed procedural failure shall permit a reasoned extension by the independent reviewer.

D1-035 The Secretariat shall acknowledge an appeal within seven calendar days and refer it to an appointed reviewer independent of the disputed decision. The reviewer shall disclose relevant involvement and interests, consider conflict objections, and record independence. The decision's author, a materially interested participant, or a person deciding a related complaint about their own conduct shall not determine the appeal.

D1-036 The reviewer shall state scope, admissibility reasons, record access arrangements, and timetable; provide the appellant and responsible decision maker a meaningful opportunity to reply; and issue a reasoned determination. An initial determination shall be targeted within 30 calendar days of receipt, with reasoned extensions and updated dates notified before expiry. No response or elapsed time shall constitute rejection.

D1-037 An appeal concerning adoption, public-review exclusion, or authority shall pause the affected publication decision. Other appeals shall receive a recorded decision on whether a stay is necessary to prevent prejudice. If no independent reviewer is available, consequential contested progression shall remain pending while unaffected work continues.

D1-038 The reviewer may uphold the process, require disclosure or correction of records, set aside a procedurally defective decision, or remit the matter for renewed participation, review, or ballot. The reviewer shall not substitute a ruling on factual truth, external legal entitlement, or technical merit for procedural review. The accountable body shall record implementation of the remedy before renewed progression.

D1-039 Technical reconsideration, conduct complaints, record-specific access or correction requests, and external legal remedies shall have distinguishable routes. Misrouted submissions shall receive assisted referral rather than silent rejection. Protected conduct handling shall follow the adopted ethics policy; disagreement alone shall not be treated as misconduct. Internal review shall not be presented as replacing external rights or remedies.

9 Publication and release integrity

D1-040 The release owner shall verify that the exact publication package implements the approved text and decision. The package shall identify edition, date, class, maturity, adoption authority, conformance scope, dependencies, licenses or permissions, known limitations, maintenance contact, next review date, and superseded publications where applicable.

D1-041 The release manifest shall identify authoritative source files, rendered publications, schemas or fixtures where included, their versions and integrity checks, build instructions and tool versions, and the approval record. A reviewer other than the final editor shall compare the rendered output with the approved source for omitted, altered, or unreadable requirements and record the result.

D1-042 The release owner shall resolve source/build discrepancies before release. Source corrections affecting meaning shall return to substantive review; a rebuild shall not silently change an adopted requirement. Public notices shall distinguish an adopted Standard, a Specification, an informative publication, and a policy recommendation and shall not claim ungranted endorsement or certification.

10 Maintenance, review, and withdrawal

D1-043 Every release shall have an assigned maintenance owner, issue intake route, and next review date. The default review interval shall be two years, shortened by a recorded risk-based decision. Loss of ownership, serious defects, changed dependencies, inaccessible implementation rights, or evidence of material exclusion or harm shall trigger earlier review. An overdue review shall be publicly marked and escalated; silence shall not confirm continued suitability.

D1-044 The maintenance owner shall log reported issues, classify their effect, identify affected versions and dependencies, and publish disposition or investigation status. A correction request shall not be rejected merely because the reported behavior matches the current text.

D1-045 A corrigendum shall correct an error without introducing a new obligation, altering intended meaning, or changing a valid conformance outcome. It shall identify the affected text, corrected text, justification, reviewer, and authorization. If semantic effect is uncertain, the change shall use the amendment or revision route. Historical publications shall remain identifiable rather than silently overwritten.

D1-046 An amendment shall make a bounded substantive change to a named edition; a revision shall issue a consolidated new edition. Both shall receive scope approval, assessment of dependent artifacts and users, appropriate pilots, committee and public review, and final approval under these Directives. An incompatible change shall include migration, coexistence, and deprecation information without claiming lossless conversion absent evidence.

D1-047 Periodic review shall invite evidence from users and affected parties and record confirmation, correction, amendment, revision, supersession, or withdrawal with reasons. Confirmation shall require a maintenance report and an authorized decision; it shall not erase known limitations.

D1-048 Proposed withdrawal or supersession shall receive a public notice of reasons, dependencies, transition consequences, and alternatives for at least 60 calendar days, followed by comment disposition, reply, and formal approval. Withdrawn editions shall remain identifiable

with status and date; withdrawal shall not retroactively change what a past conformance claim asserted. Necessary protection of underlying records shall follow D1-052, D1-053, and EIP-039.

11 Emergency safeguards and continuity

D1-049 An authorized governance or release holder may issue a time-limited warning or suspend programme distribution or programme recommendations for new use where a documented serious protection, rights, or integrity risk requires immediate action. The action shall state evidence, scope, authority, duration, contact, affected users, and safe public reasons. It shall remain within programme authority and shall not create or amend normative requirements or purport to invalidate external legal decisions.

D1-050 Emergency action shall receive independent review within seven calendar days and expire within 30 calendar days unless the governance authority records a justified extension, next review date, and remedy plan. Unavailable independent capacity shall not authorize emergency adoption. Permanent amendment or withdrawal shall follow the ordinary procedure; protective handling of unlawfully or improperly disclosed material remains governed by the applicable policy and context.

D1-051 A vacant role shall trigger recorded reassignment within the Charter's mandate or deferral of dependent decisions. A temporary substitute shall meet the same conflict and independence conditions. Emergency procedure shall not be used to avoid consultation because ordinary development is late or under-resourced.

12 Records, transparency, and external liaison

D1-052 The Secretariat shall preserve linked proposal, draft, comment, disposition, decision, ballot-result, appeal-outcome, release, and maintenance records. Public readers shall be able to follow the grounds and changes of a decision without mandatory access to private correspondence. Record corrections shall retain the prior account and correction relationship where lawful and appropriate.

D1-053 A records schedule shall state purpose, custodian, access category, retention period or trigger, restriction review, and authorized disposition for each record category. Public publication history and safe decision reasons shall be retained durably; sensitive submissions and personal data shall not be retained indefinitely by default. A restriction or deletion shall preserve a safe explanation when permitted, without revealing protected existence or identity.

D1-054 The governance authority shall publish an annual account of active work, decisions, unresolved objections, participation gaps, funding influence, overdue maintenance, and procedural incidents at a level that protects affected people. The account shall distinguish claimed representation from evidenced participation.

D1-055 External liaison shall have an explicit mandate identifying purpose, authorized speaker, commitments permitted, and reporting duties. A policy proposal shall identify its intended institution and review route and remain recommendatory. Liaison, use of external sources, and informal participation shall not imply affiliation, institutional endorsement, or adoption of another body's procedures.

12.1 Publication routes outside Standard adoption

D1-056 Before external release of a Specification or informative publication, the responsible authority shall approve a work-item review plan identifying publication class, maturity criteria, release authority, reviewers and needed competence, public-comment arrangements and period with rationale, objection disposition, appeal route, maintenance responsibility and rights clearance. The release record shall identify fulfillment and remaining limitations. Drafting alone shall not constitute that approval.

D1-057 A Specification release containing technical conformance requirements shall use the technical review, public review, disposition, ballot and appeal rules in this Part, while retaining Specification status and its declared maturity. Its release shall not use stage 60 or imply Standard adoption. Promotion shall require an explicit Standard work-item and adoption decision with review of changed scope, requirements and prior evidence.

D1-058 A Policy or Institutional Proposal shall receive a separate mandate-specific release decision identifying its intended addressee, institutional and affected-interest review, public-comment opportunity, considered alternatives and unresolved objections. Its review plan shall preserve a reasoned disposition and the procedural appeal route in this Part. An informative report or manual shall likewise identify its review and release decision without claiming technical Standard conformance authority.

A Proposed defaults and alternatives (informative)

These choices make the draft exercisable; they remain **PROVISIONAL** until explicit governance adoption. A future change to operative thresholds or minimum periods needs governance amendment and does not apply retrospectively to an open ballot or review.

Proposed default	Purpose	Alternative and evidence needed
60-day public review; 30-day material re-review	Allow asynchronous participation while enabling bounded iteration.	Longer multilingual review or shorter narrow review; test notice reach, access, and actual response burden. Shortening minima needs prior governance amendment.
30-day disposition target and reply period; seven-day acknowledgement	Make receipt and delay visible while preserving substantive consideration.	Different service targets; test volunteer capacity and accessibility needs. A target is not an automatic closure rule.
30-day ballot and appeal periods	Give participants time to read a fixed package and challenge process.	Longer periods for complex work; test availability and remedy effectiveness.
Two-thirds returned-ballot quorum; three substantive votes; two-thirds approval	Prevent adoption based on one affirmative vote and abstentions; require substantial expressed support.	Larger minimum electorate or stakeholder balance conditions. Three voters do not demonstrate constituency breadth; assess actual participation and available competence.

Proposed default	Purpose	Alternative and evidence needed
Two-year maintenance review	Require periodic attention without continuous reballoting.	Annual or longer scope-specific review; evaluate dependency change, harms, issue volume, and maintenance resources.
Seven-day emergency review; 30-day expiry	Limit exceptional authority and expose delays.	Shorter periods for urgent privacy incidents; test reviewer availability and restoration of ordinary review.

B Governance rehearsal evidence (informative)

A useful rehearsal records actors as fictional or unassigned, uses identified draft versions, and leaves a complete decision trail. It is not actual public review, proof of representativeness, or governance adoption.

Assessment uses an evidence register with a row for each applicable D1 identifier, the procedure or decision assessed, required record location, reviewer, result (fulfilled, not fulfilled, not assessed, or not applicable), and unresolved action. A not-applicable result identifies the absent trigger. Document inspection assesses notices, disclosures, reasons, and manifests; arithmetic recalculation assesses ballot results; observed exercises assess intake, recusal, reply, appeal, and restoration behavior. Independent procedural review assesses contested fairness and authority. Missing records or unperformed procedures are not counted as fulfillment.

1. Process a bounded NWIP through accept, revise, and defer alternatives. Identify an infrastructure need without presuming a Specification or Standard already exists.
2. Receive an accessible free-text comment, a protected submission, and a sustained minority objection. Show acknowledgement, reasoned disposition, reply, and safe publication.
3. Re-review a material change and demonstrate why a change of constituency restarts full review. Preserve unsuccessful alternatives and source uncertainty.
4. Recalculate a ballot after recusal: with five eligible people, four returns meet quorum; two approvals, one disapproval, and one abstention satisfy the approval threshold. Repeat with two returns and show deferral.
5. Test three returns consisting of one approval and two abstentions. Record failure of the three-substantive-vote minimum even though returned-ballot quorum can be met.
6. Appeal exclusion from review; document independent appointment, conflict challenge, stay, reply, remedy, and renewed decision. Repeat with no independent reviewer and show pending progression.
7. Compare approved source and rendered output, detect an omitted requirement, and prevent release. Distinguish typographic correction from a changed conformance result.
8. Simulate maintenance, incompatible revision, withdrawal, an urgent warning, and role vacancy. Demonstrate that an emergency cannot adopt a Standard.

The rehearsal report records failures, required staffing, elapsed effort, participation and confidentiality barriers, revised clauses, and remaining questions before the founding participants assess readiness.

C Source and tailoring record (informative)

The programme's Brief and comprehensive plan supply the mission and local lifecycle. The comparative planning study supplies the alternatives examined. This draft proposes its own procedures and values; it does not claim ISO, IEEE, or WTO conformity, accreditation, or international representativeness.

Source and interpretation. ISO, *International harmonized stage codes*, official webpage checked 22 September 2026, https://www.iso.org/stage-codes.html. The source distinguishes publication, review, and withdrawal; this programme retains its existing local stage 90 grouping. No ISO substage deadlines or voting rules are imported.

Source and interpretation. IEEE SA, *Standards Board Operations Manual*, clause 5, official webpage checked 22 September 2026, https://standards.ieee.org/about/policies/opman/sect5/. Its separation of project supervision, review, and appeals informs comparison. The programme's staffing, deadlines, eligibility, and remedies above are new local proposals, not statements of IEEE requirements.

Source and interpretation. WTO, *Principles for the Development of International Standards, Guides and Recommendations*, official presentation of the 2000 TBT Committee decision, checked 22 September 2026, https://www.wto.org/english/tratop_e/tbt_e/principles_standards_tbt_e.htm. Its process principles inform scrutiny of transparency, participation, relevance, and coherence; no determination of legal status under the TBT Agreement is made.

OPEN. The comparative study records an access gap for the full ISO/IEC Directives Part 1:2026 and Part 2 amendment text. This draft makes no clause-level claim about those unverified texts. Founding authority, actual appointments, contribution terms, neutral review availability, and numerical defaults need explicit resolution before governance adoption.

10 Assessment of a publication package **6**

11 Informative source basis and drafting decisions **7**

1 Scope and standing

Responsible editor: `UNASSIGNED`. Canonical source: `governance/directives_part_2.tex`. Intended readers are publication editors, reviewers and implementers preparing assessment artifacts.

This draft defines proposed rules for preparing, reviewing and maintaining programme publications and their associated machine-readable artifacts. Its conformance subject is a publication package: the declared source document, rendered edition, references, associated artifacts and assessment material. A package can be reviewed against this draft without claiming adopted-Standard status.

The rules become operative only through a recorded governance adoption under the Charter and Directives Part 1. The present exercise is a drafting rehearsal. Requirements use *shall*; recommendations use *should*; permissions use *may*; *can* describes possibility or capability. An unresolved choice is not concealed inside an operative requirement.

D2-001 A publication shall identify its code or other identifier, title, publication class, maturity status, version, responsible editor or unassigned responsibility, and source location near its beginning.

D2-002 A draft shall state that it is not adopted and shall distinguish authoring progress from formally authorized project status. A publication shall not imply ISO, IEC, IEEE or governmental authority without a documented basis.

Informative note. The source files in this initial package are preparatory Working Drafts. The repository's existing numbers remain project-family identifiers; creating a PDF does not advance a document to stage 60.

2 Publication architecture and authority

2.1 Classes and intended readers

D2-003 An editor shall assign one principal publication class and state its intended readers, use and authority. A Standard, Specification, Technical Report, Manual, governance document and Policy or Institutional Proposal shall not be treated as interchangeable classes.

D2-004 A protocol description shall identify its containing publication class. Protocol behavior shall be distinguished from the institutional authority and procedure under which that behavior is used.

D2-005 A Policy or Institutional Proposal shall distinguish factual background, interpretation, objectives, options, mandate, implementation implications and unresolved questions. It shall not create technical conformance obligations through an unapproved policy recommendation.

2.2 Document components

A Standards-track or Specification draft normally contains a foreword or standing statement, scope, normative references if any, terminology, requirements, conformance, informative examples, source rationale, and known open issues. The extent depends on the actual subject; empty headings are not evidence of completeness.

D2-006 The scope shall identify the subject of conformance, intended use, relevant environment and exclusions. A claim of conformance shall be assessable within that stated boundary.

D2-007 Normative and informative material shall be distinguishable at clause, annex or artifact level. Notes, examples and informative annexes shall not introduce additional requirements.

D2-008 Every table, figure, annex and associated artifact shall have a stated role and, where interpretation depends on it, a stated authority status. A normative requirement represented in a diagram shall also have an identifiable textual formulation.

3 Requirements and recommendations

3.1 Form of a provision

D2-009 A requirement shall identify the responsible actor or object, the applicable condition, the required behavior or property, and an outcome or evidence by which fulfillment can be assessed.

D2-010 A requirement shall use a stable identifier independent of its displayed section number. An identifier shall not be reassigned to a different obligation after circulation; a withdrawn identifier shall remain traceable.

D2-011 A requirement shall not combine independent obligations whose applicability or assessment differs so materially that one result would conceal another. Related obligations can be grouped when their joint assessment is explicit.

D2-012 Terms such as adequate, appropriate, trustworthy or significant shall have a scoped criterion, declared decision responsibility or assessment procedure when they determine conformance. A broad aspiration alone shall not be presented as a testable requirement.

D2-013 A permission shall not override a requirement implicitly. Exceptions shall identify the affected obligation, conditions, authority, required record and any limitation on the resulting conformance claim.

D2-014 The editor shall distinguish mandatory conditions, recommendations, permissions and capability statements consistently. A recommendation's non-fulfillment shall not be reported as failure of a requirement.

3.2 Conditions, absence and proportionality

D2-015 A conditional requirement shall state its trigger and how applicability is determined. A result of not applicable shall include its reason; it shall not substitute for unavailable evidence or an unperformed assessment.

D2-016 When complete information is not realistically available, a recording requirement shall specify whether a justified unknown, limitation or restricted disclosure satisfies the obligation. It shall not require invented content to complete a mandatory field.

Informative note. A requirement can demand a declaration of uncertainty without demanding a resolved historical fact. Proportionality concerns the recording obligation; it does not make unsupported substantive claims better supported.

4 Terminology, sources and GR interpretation

D2-017 An operational definition shall state its scope and shall not imply that it exhausts a broader philosophical concept. A definition imported or adapted from a source shall identify that source, edition and the nature of the adaptation.

D2-018 For a substantive GR definition, the editor shall record the relevant foundation passage, alternatives, unresolved differences and the rationale for operational use. A material narrowing or departure shall have an Architecture Decision Record before the definition is stabilized for adoption.

D2-019 An operational definition of Entity, State, Event, Process, Relation or Property shall address admissibility, identity, temporal behavior, allowed relations, required and optional information, examples, counterexamples and unresolved edge cases. A declaration that an item remains provisional shall identify the missing decisions.

D2-020 The editor shall not equate a formal state with an archival State, a mechanism with a Process, or formal change with an Event without an explicit argument and scoped decision. The six record roles shall not be presented as exhaustive constituents of reality.

D2-021 A draft shall distinguish occurrence claims, observations, evidence assessments, interpretations, normative evaluations, legal assertions and institutional determinations wherever conflation would strengthen a claim beyond its grounds or authority.

D2-022 An external reference used to support a normative or scholarly claim shall be verified against an identified primary source. Inaccessible text, uncertain edition, incomplete review and unverified compatibility shall be identified rather than reconstructed as fact.

5 References and dependencies

D2-023 A normative reference shall identify the exact document and edition required to apply a requirement, the part relied on and a means of obtaining it. Informative motivation shall be listed separately from normative dependencies.

D2-024 A draft depending on another draft shall identify the dependency's version and status and the consequences of a change. It shall not imply the dependency has already been adopted.

D2-025 Before approval for publication, the editor shall produce a dependency review identifying incompatible versions, unavailable dependencies, circular requirements and licensing or access constraints material to implementation.

D2-026 A claim of equivalence, compatibility or interoperability with another model shall identify its direction, scope, tested cases, unsupported distinctions and known loss. Matching terminology alone shall not justify that claim.

Informative note. Core documents can co-evolve without circular authority: vocabulary supplies terms; recording and epistemic documents supply complementary requirements; a package declaration pins both drafts for an experimental assessment.

6 Conformance clauses and profiles

D2-027 The conformance clause shall distinguish the assessed subject, publication edition, profile, applicable requirements, assessment method, assessor and result. It shall distinguish a record, producer, protocol participant, presentation, archive and organizational procedure when their obligations differ.

D2-028 Each requirement shall have at least one stated assessment method and evidence expectation. Structural checks, protocol tests, human interpretation and procedural review shall have separately identifiable results.

D2-029 A conformance report shall distinguish fulfilled, not fulfilled, not assessed and not applicable results. A missing assessment shall not be counted as fulfillment.

D2-030 A profile shall state its parent requirements, additions, permitted restrictions, exclusions and intended users. It shall not silently weaken a parent requirement while claiming unqualified parent conformance.

D2-031 A draft shall state the limits of its conformance claims, including the distinction between record structure and factual truth, between source authentication and evidential warrant, and between technical conformance and legal or ethical judgment.

D2-032 An automated check shall identify the constraints it actually assesses. A passing automated result shall not be presented as evidence of a human or institutional action that the check did not observe.

7 Protocol and machine-readable artifacts

D2-033 A protocol Specification shall define its participants, inputs, preconditions, state transitions, observable outputs, effects, refusal and failure cases, recovery behavior, version assumptions and authorization boundaries.

D2-034 An artifact package shall identify the relationship between its prose requirements and its schemas, examples, vocabularies, test fixtures and executable components. Conflicts shall have a documented resolution rule that does not silently amend an approved requirement.

D2-035 Examples intended to be valid shall identify the supported profile and expected result. Negative examples shall identify the intended defect. Synthetic evidence shall be labelled as synthetic.

D2-036 A schema, API or encoding choice shall be traceable to a stated requirement or interoperability need. Implementation convenience alone shall not be described as a philosophical necessity or universal institutional rule.

D2-037 Executable validation or rendering shall not silently retrieve unpinned remote resources, disclose protected input or substitute a current external vocabulary for the edition declared in the package. Any required external processing shall be explicit.

8 Presentation, accessibility and legal context

D2-038 A publication shall use headings, table labels, link text and readable typography that expose its structure. Essential meaning shall not depend solely on color, visual position or a diagram.

D2-039 An editor shall provide a usable source or alternative reading representation and identify known accessibility limitations of the rendered document. Successful PDF compilation alone shall not establish accessibility conformance.

D2-040 A legal or institutional assertion used in a requirement shall identify the context, asserted source of authority and scope. A proposed model rule or policy option shall be labelled as such rather than described as generally applicable law.

D2-041 The editor shall record cross-domain review findings relevant to scope, including epistemic, ethical, legal, institutional, political-economy, archival, security and accessibility questions. Unavailable competence or unresolved material objections shall remain visible in progression records.

9 Versioning and publication production

D2-042 Each circulated edition shall identify its canonical source and rendered artifacts. Changes to proposed requirements shall be traceable through the change record, with superseded reasoning retained subject to justified access and retention rules.

D2-043 A release candidate shall be built from the declared source revision, with build instructions, required tooling and an artifact manifest sufficient to reproduce and compare its substantive content.

D2-044 The release check shall detect broken internal references, duplicate requirement identifiers, missing glyphs, visibly clipped material, mismatched status labels and disagreement between declared source and generated artifact. Unresolved defects shall be reported with their effect on use.

D2-045 An editorial correction shall not silently change the substance of a requirement. A substantive change to an adopted normative edition shall use the amendment or revision procedure in Directives Part 1, including affected-artifact and compatibility review. A draft change shall follow the change-control and re-review rules applicable to its current stage. Changes to a released Specification shall follow its declared maintenance procedure and promotion shall require a separate decision.

Informative note. Byte-identical PDF reproduction is not assumed: timestamps and compiler versions can change bytes. The initial build manifest records source and PDF hashes, compiler results and review warnings so each reviewed artifact is identifiable.

10 Assessment of a publication package

The editor prepares an assessment register with one row for each applicable D2 requirement: identifier, evidence location, result, reviewer and unresolved action. Examples of evidence

include the source front matter, dependency inventory, requirement-to-case matrix, source-to-definition map, compilation report and page inspection.

A review against this draft is described as an experimental drafting assessment. It is not ISO/IEEE conformance, accreditation, accessibility certification or adoption of a programme Standard.

11 Informative source basis and drafting decisions

The programme's AGENTS instructions, publication taxonomy, source manifest, comprehensive plan and accepted ADR-0002 provide the local basis. The proposed publication-source architecture and bounded technical drafting are recorded in ADR-0004.

Source and interpretation. ISO's public house-style and foreword guidance were consulted for distinctions among requirements, recommendations, permissions, possibilities and conformity assessment: https://www.iso.org/ISO-house-style.html and https://www.iso.org/foreword-supplementary-information.html. IEEE's public Operations Manual clause 6 was consulted for the distinction among normative and informative materials: https://standards.ieee.org/about/policies/opman/sect6/. Checked 22 September 2026. These sources inform independently written programme proposals; their procedures are not adopted by citation.

The initial production choice is canonical TeX source beside existing project documents, a shared presentation preamble and LuaLaTeX rendering through an explicit manifest. Markdown remains navigation and historical context. Alternative authoring systems remain possible after a recorded maintenance decision.

OPEN. The licence terms, founding adoption, actual editor appointments, minimum accessibility target and final profile terminology remain to be decided. This draft does not grant publication rights to third-party material.

OPEN. Full ISO/IEC Part 1:2026 and Part 2:2021 with its 2026 amendment were not available in the earlier comparison. No clause-level conformity with those editions is asserted here.

Governance Working Draft

Draft version 0.1

22 September 2026

WORKING DRAFT FOR REVIEW

This document is not adopted. Its requirement language expresses proposals for review and rehearsal. Preparation of this text does not establish programme governance, approve a formal standards project, or certify substantive truth, legal validity, or institutional legitimacy.

Publication class, scope, dependencies and unresolved decisions are stated in the document. No ISO, IEC or IEEE affiliation or endorsement is claimed.

5 Conceptual sources and operational decisions 3

6 Multidisciplinary review 4

7 Pilots, assessment, and failure evidence 5

8 Progression, maintenance, and accountability 5

9 Review evidence and informative sources 6

1 Status and committee mandate

Responsible editor: `UNASSIGNED`. Canonical source: `governance/technical_committee_charter.tex`. Intended readers are committee participants, editors, domain reviewers and the programme decision authority.

This draft defines the proposed remit, responsibilities, and evidence obligations of GR/TC 1. It is a governance document; it does not constitute the committee, approve a work item, or adopt a technical Standard. The programme Charter and Directives supply decision authority and procedure.

TC-001 The committee shall become active only through a recorded mandate under the adopted programme Charter. The mandate shall identify its convenor, responsible decision authority, participating capacities, accepted work items, review resources, and mandate review date.

TC-002 The committee shall develop coordinated recording and practical procedures that support warranted, contestable, revisable recognition and preservation of consequential generative trajectories. Each accepted work item shall state its contribution to this purpose and the limits of its expected effects.

TC-003 Committee work shall distinguish changes in the situation under inquiry, changes in evidence and judgment, and changes in categories or methods of recognition. A technical representation connecting these histories shall preserve their distinguishable meaning.

2 Scope and exclusions

The proposed scope includes source-grounded vocabulary, recording requirements, epistemic representation, evidence and interpretation, contestation, revision, accountable institutional use, information models, exchange, presentation, preservation, access, and conformance assessment.

TC-004 The committee shall retain the distinctions between theoretical metamodel, operational record ontology, epistemic representation, normative assessment, jurisprudential status, institutional governance, political economy, and implementation when defining scopes or allocating work.

TC-005 The committee shall not claim authority to certify substantive historical truth, resolve a complete metaphysics, determine legal rights across jurisdictions, endorse a political choice on technical grounds alone, or mandate unrestricted disclosure of recorded material.

TC-006 The committee shall preserve existing publication identifiers when refining scopes. A proposal to change a publication's class, merge or divide its scope, or introduce a new identifier shall record the reason, dependencies, alternatives, and authorizing decision before the change is treated as operative.

Informative note. Protocols describe actors, interactions, states, transitions, outcomes, and failures within a Specification or adopted Standard. Protocol is not a separate publication-authority class. The committee can investigate category-theoretic semantics in Technical Reports without making them a user-facing ontology.

3 Work-item authorization and coordination

TC-007 A work-item proposal shall identify purpose, scope and exclusions, conformance subjects, affected interests, foundation sources and tensions, existing alternatives, related publications, anticipated Specifications, reviewer competence, practical evidence, and maintenance ownership.

TC-008 The committee shall record work-item dependencies and allocate requirements to their responsible publication before producing a normative technical binding. A shared requirement shall have one authoritative location, with versioned references from dependent work.

TC-009 Editors shall begin with the normative or procedural need and create a Specification proposal when reusable infrastructure is required to satisfy or assess it. A prototype shall not silently determine a theoretical definition or institutional obligation.

TC-010 A proposed substantive scope expansion shall return to the responsible decision authority with its consequences for participation, sources, dependencies, review, and resources. Work outside the authorized scope shall remain exploratory pending a decision.

Informative note. GR/NWIP-001, Generativity Recording and Presentation Infrastructure, is the candidate first coordinated work item. Its current draft does not itself authorize formal committee drafting. Preliminary drafts and synthetic exercises provide evidence for that decision.

4 Functions, work groups, and capacity

The proposed committee convenor, editors, domain reviewers, affected-participant contacts, implementation reviewers, and maintenance owners are **UNASSIGNED**. A single coordinated group can initially perform several tasks, subject to declared competence and conflicts. The six working groups named in the historical outline remain possible allocations; their names do not establish active bodies.

TC-011 For each active deliverable, the committee shall record an accepted editor or lead, a maintenance contact, required review competence, available reviewers, and unfilled roles. Multiple roles held by one person shall be declared.

TC-012 A new working group shall have a bounded scope, actual willing participants, an accountable lead, dependencies, intended outputs, and review or closure conditions. Its formation shall not imply autonomous adoption authority.

TC-013 A reviewer shall identify the domain and scope of their assessment, relevant competence or situated knowledge, interests, material limitations, and whether they contributed to the material reviewed. A self-review shall not be labelled independent.

TC-014 Where required expertise or affected perspectives are unavailable, the committee shall record the gap and its material effect on progression. It shall narrow claims, seek additional review, or defer the affected decision when the gap prevents a justified assessment.

5 Conceptual sources and operational decisions

TC-015 Before introducing or materially changing a GR definition, notation, ontology class, or compatibility claim, the responsible editor shall examine the relevant foundation manuscripts

and record exact source locations, terminology, scope, historical differences, and the proposed operational translation.

TC-016 The committee shall preserve unresolved foundation differences rather than harmonizing them silently. A material operational narrowing or departure shall be recorded through an architectural decision with alternatives, rationale, affected publications, and remaining uncertainty.

TC-017 A candidate record-class definition shall identify its definition, admissibility conditions, identity criterion, temporal behavior, permitted relations, required and optional metadata, examples, counterexamples, and unresolved edge cases, or explicitly identify which elements remain under development.

TC-018 An external compatibility or reuse proposal shall identify the exact source and edition, verified relevant provisions, mapping assumptions, exclusions, and evidence needed to support the claimed relationship. Similar terminology shall not alone establish equivalence.

6 Multidisciplinary review

TC-019 At work-item scoping, before a real pilot, and before publication progression, the committee shall maintain a review dossier covering applicable epistemic, ethical, jurisprudential, institutional, political-economic, archival, privacy/security, accessibility, and technical questions. Each domain shall have findings or an explicit justified statement of non-applicability or unassessed scope.

TC-020 The review dossier shall identify evidence, reviewers and their capacities, affected perspectives, conflicts, alternative designs, findings, dispositions, owners of corrective action, and residual limitations. A metadata field or completed checklist shall not by itself count as domain assessment.

The following review questions guide implementation of TC-019. They are informative prompts, not additional undeclared conformance requirements.

Epistemic. Can a reader distinguish a trace, observation, claim, inference, counterevidence, institutional finding, and a changed method? Are uncertainty and absent or restricted evidence intelligible?

Ethical. Who is exposed or excluded, who bears recording and contestation work, which values conflict, and what refusal, correction, or repair is feasible?

Jurisprudential. Which forum, rule, authority, and procedural status are asserted? Is the text descriptive analysis, a model rule, a policy option, or an implemented institutional procedure?

Institutional and policy. Who can decide, give reasons, reconsider, implement a remedy, and monitor consequences? Which mandate and policy alternatives remain open?

Political economy. Who controls evidence, categories, infrastructure, access, and migration? How do costs, contributions, dependency, and benefits differ among participants?

Archival and protection. What is preserved, omitted, restricted, revised, transferred, or destroyed? Can a later user understand an authorized historical view without exposing protected material?

Technical and human use. Can independent users implement the required behavior and understand the presentation? Are failures, conflicts, unsupported features, accessibility, and feasible human alternatives addressed?

TC-021 A legal or institutional profile shall state its jurisdiction or forum, target action, relevant sources and status, claimed authority, temporal scope, unresolved conflicts, and reviewing competence. Generic technical conformance shall not replace assessment of actual applicability.

TC-022 A policy proposal arising from committee work shall follow the separate policy-publication route and compare plausible institutional options, including existing infrastructure or deferral when relevant. The committee shall not present participation in technical review as assent to a policy recommendation.

7 Pilots, assessment, and failure evidence

TC-023 Before a pilot begins, its record shall identify the case and baseline, questions and success criteria, participants and actual authority, material and access permissions, resource burden, anticipated harms, challenge and correction routes, stop conditions, and responsible reviewers. Synthetic cases shall be labelled synthetic.

TC-024 The initial coordinated demonstration shall exercise a claim and its grounds, a consequential relation or contribution, an alternative or challenge, a reasoned response, a historical revision, a protected or unavailable record, and a presentation that makes their distinct status understandable.

TC-025 Pilot findings shall report failed tasks, missing or conflicting evidence, excluded participants, unmet assumptions, and burdens alongside successful behavior. The committee shall trace each material finding to a requirement change, retained decision with reasons, further inquiry, or scope limitation.

TC-026 A conformance proposal shall identify the assessed subject, edition, profile, applicable requirements, methods, evidence, unresolved findings, and limits of the resulting claim. Syntax checks, semantic interoperability, procedural compliance, usability, and substantive warrant shall receive distinguishable results.

TC-027 The committee shall substantiate an interoperability claim with independent implementation or exchange evidence appropriate to the claim. A single internally consistent prototype shall be reported as such.

8 Progression, maintenance, and accountability

TC-028 For each requested progression decision, the convenor shall assemble the current draft, requirement and source trace, comment dispositions, unresolved objections, multidisciplinary findings, pilot or other assessment evidence, rights-clearance status, and maintenance proposal. The programme decision authority shall apply Directives Part 1.

TC-029 The committee shall retain a link from a corrected or superseded requirement to the prior text, reason, decision, affected dependencies, and migration consequence. Historical decisions shall remain distinguishable from the current authoritative edition.

TC-030 The committee shall submit scope, participation, resource, and outstanding-risk information at its mandate review and when material conditions change. An inactive or unstaffed work item shall receive an explicit status and continuity disposition.

9 Review evidence and informative sources

Committee readiness is assessed against accepted appointments, a scoped work item, a requirements/dependency register, a source trace, a review dossier, and a rehearsal record. Technical publication readiness remains a separate decision. A reviewer can select a material requirement and follow it from the problem and source through alternatives, draft, assessment, comments, and disposition.

Source and interpretation. Programme Charter and Directives Parts 1 and 2, companion Governance Working Drafts, version 0.1. These are proposed internal dependencies pending coordinated adoption. Their adopted edition identifiers must be fixed in the committee mandate.

Source and interpretation. Local planning basis: `docs/planning/comprehensive_development_plan.md`, `docs/planning/cross_domain_programme.md`, `docs/planning/protocol_specification_plan.md`, and `docs/planning/foundation_traceability.md`. The committee responsibilities are new operational proposals derived from that programme plan.

Source and interpretation. Foundation orientation: FM-001, Chapter 1, section 1.14, pp. 79–83; FM-003, Chapter 3, section 3.12, pp. 129–132; FM-005, Chapter 5, section 5.18, pp. 150–153. Exact files and version uncertainties are recorded in `foundation_manuscripts/MANIFEST.md`. Operational obligations in this Charter do not purport to exhaust the manuscripts' theoretical concepts.

The draft selects one coordinated committee with declared review functions. Alternatives include immediate formation of six standing groups or independent domain committees. The selected direction keeps shared dependencies visible and avoids claiming staffing or independence that has not been demonstrated. Additional groups remain available when actual work and capacity justify them.

OPEN. Committee constitution, membership register, reviewers, formal work-item approval, and live pilot partners remain OPEN. The first case can be rehearsed using synthetic material and appropriately shareable programme history without implying external consent.

OPEN. Property/Attribute terminology, Chapter 3 version precedence, and the relationship between fixed-carrier formalism and broader emergence remain OPEN source questions. The committee mandate does not resolve them.

WORKING DRAFT FOR REVIEW

This document is not adopted. Its requirement language expresses proposals for review and rehearsal. Preparation of this text does not establish programme governance, approve a formal standards project, or certify substantive truth, legal validity, or institutional legitimacy.

Publication class, scope, dependencies and unresolved decisions are stated in the document. No ISO, IEC or IEEE affiliation or endorsement is claimed.

10 Informative sources and rationale 7

1 Purpose, status, and distinct responsibilities

Responsible editor: UNASSIGNED. Canonical source: governance/ethics_ip_policy.tex. Intended readers are contributors, affected people, ethics and rights reviewers, and programme administrators.

This governance draft addresses conduct in programme development, conflicts affecting decisions, impacts of the infrastructure being developed, and the rights needed to receive, revise, preserve, and publish contributions. These are connected responsibilities with different review questions. Ethical acceptability, evidential adequacy, and permission to reuse material are not interchangeable.

No copyright transfer, licence, patent undertaking, contract, or institutional legal mandate is created by this draft. Operative contribution and publication terms require a recorded choice, authority to offer them, and acceptance where required. Programme-internal conduct remedies do not determine legal liability or replace external remedies.

EIP-001 The programme shall identify the adopted edition, effective scope, responsible ethics contact and alternate, protected reporting route, decision authority, and neutral-review route before treating this policy as operational. Until then it shall retain Governance Working Draft status.

EIP-002 The programme shall assess conduct, conflicts, substantive impacts, and contribution rights through distinguishable findings. A favorable finding in one area shall not be represented as clearance in another.

2 Respectful participation and evidential integrity

EIP-003 Participants acting in programme roles shall not engage in harassment, threats, retaliation, discriminatory exclusion, or coercive disclosure of protected information. Critical disagreement about sources, methods, policy, and requirements shall remain eligible for reasoned consideration.

EIP-004 A participant presenting a factual or source-based claim shall distinguish observation, quotation, interpretation, inference, and proposal where that distinction affects review. Known material errors, fabricated evidence, or falsely attributed sources shall not be retained as support after discovery without correction or explicit disputed status.

EIP-005 Editors shall preserve attribution of material contributions and competing positions within actual permissions and protection needs. Authorship, acknowledgement, evidential reliability, ownership, and decision authority shall remain distinct.

EIP-006 A participant using AI assistance for a material draft, analysis, evidence synthesis, or disposition proposal shall identify the consequential assistance and the responsible human reviewer in the development record. The reviewer shall verify material sources and conclusions before relying on them.

EIP-007 Participants shall not submit protected, confidential, or third-party material to a tool or service without an established basis for that disclosure. Uncertainty about such a basis shall be resolved before the disclosure.

Informative note. The AI-use record can be proportionate: task, material sources, consequential transformations, and human checking can be sufficient without preserving every prompt or exposing protected inputs. AI use alone does not establish either error or authorship entitlement.

3 Interests, influence, and recusal

EIP-008 Before accepting a decision or review role and when relevant circumstances change, a participant shall disclose interests that could materially affect, or reasonably call into question, their impartial performance of that role. The disclosure shall include relevant financial, employment, funding, authorship, institutional, personal, and infrastructural-control interests.

EIP-009 The responsible coordinator shall record a conflict assessment, its author, the affected decision, the disclosed interest, protection limits, and the selected management action. Disclosure alone shall not be treated as resolving a conflict.

EIP-010 A person shall not determine the disposition of a complaint against themselves, act as neutral reviewer of their own decision, or independently assess a rights clearance in which they have an unresolved material interest. The alternate route shall be used.

EIP-011 Conflict management shall identify whether disclosure with oversight, separation of roles, partial recusal, replacement, or deferral is required. A recusal shall identify the decision scope and substitute authority without suppressing relevant technical evidence from the recused contributor.

EIP-012 The decision authority shall examine material concentration of funding, affiliation, available unpaid labor, infrastructure access, and agenda control when assessing fair consideration. If the concentration impairs review, it shall record corrective measures and reassess progression.

Informative note. Expertise and experience often arise through involvement. The aim is bounded, inspectable authority and conflict-sensitive review, not automatic exclusion of knowledgeable contributors. A public summary can state the conflict category and management action while protected details remain with a neutral reviewer.

4 Protected reports and fair treatment

EIP-013 The programme shall provide a reporting route to an ethics contact and an alternate independent of a reported person. Its notice shall explain receipt handling, who can access material, limits on confidentiality, possible outcomes, record retention, and the procedural-review route.

EIP-014 A report shall receive acknowledgement, triage, status communication, and a reasoned disposition. The acknowledgement and initial-determination targets, including notified extensions, in D1-035 and D1-036 shall apply to report handling without converting the report into a procedural appeal. Triage shall distinguish immediate protection needs, conduct issues, procedural appeals, substantive technical objections, and record-specific correction or access requests.

EIP-015 A report shall not be rejected solely because its author requests protected handling or lacks a formal role. The reviewer shall record whether limited identity or unavailable evidence constrains investigation and what fair assessment remains possible.

EIP-016 Before an adverse conduct finding, the responsible reviewer shall provide the affected person a sufficient account of the concern and an opportunity to respond, using redaction or a protected intermediary when necessary. Where protection prevents a fair determination, that limitation shall remain explicit.

EIP-017 A temporary protective measure shall identify the immediate risk, authority, limited scope, review point, and route to challenge. It shall be distinguished from a concluded misconduct finding.

EIP-018 A final conduct disposition shall identify the applicable rule, assessed evidence and limits, conflicts and recusals, finding, reasons, proportionate remedy, responsible implementer, and review route. Available programme remedies include correction, facilitated participation, role reassignment, limited access, suspension, or removal under the Charter.

EIP-019 The programme shall monitor agreed remedies and potential retaliation and shall publish a non-sensitive account sufficient to inspect procedural handling. Confidential material shall not be published merely to demonstrate transparency.

EIP-020 If a fair, sufficiently independent review cannot be provided, the programme shall record that limitation, preserve appropriate protections, and defer the affected consequential determination. It shall not represent inability to investigate as proof that a report is false or established.

5 Impacts of proposed standards and pilots

EIP-021 Each work item shall assess whose experiences become visible, who can challenge classifications, who bears recording and review burdens, and who gains control or access through the proposed infrastructure. Assessment shall consider relevant alternatives, evidence, and residual uncertainty.

EIP-022 An impact assessment shall distinguish observed effects, predicted effects, value commitments, and institutional choices. It shall identify material tradeoffs involving recognition, privacy, autonomy, unequal participation, maintenance labor, ecological conditions, and future capacities where relevant to the use case.

EIP-023 Before a real pilot or consequential expansion, the responsible authority shall record its purpose, actual participants and mandate, permitted material, accessible notice and challenge routes, protection measures, monitoring, stop conditions, and capacity to implement correction or repair.

EIP-024 A proposal involving contribution or generativity return shall distinguish descriptive attribution, normative evaluation, and any proposed allocation of benefits or responsibilities. It shall not infer a monetary amount, entitlement, or contractual obligation solely from a generativity record.

EIP-025 A material unresolved ethical or participation finding shall receive a recorded disposition before the affected publication or pilot decision. Completion of a form shall not alone establish that an impact is acceptable or a remedy effective.

6 Contribution intake and rights register

Contribution intake means receiving material for a specified purpose. Publication, redistribution, modification, retention, software implementation, and use of personal information can require different authority. A rights register makes those distinctions visible; it does not establish that an asserted permission is legally effective.

EIP-026 For contributed material proposed for incorporation or distribution, the rights register shall identify the artifact and version, contributor and stated capacity, claimed rights holder, source, intended uses, asserted permission or licence, restrictions, third-party components, evidence of authority, and unresolved questions.

EIP-027 A contribution record shall distinguish permission to examine material from permission to incorporate, edit, redistribute, sublicense, or publish it. Repository access, submission of comments, acknowledgement, or the absence of a licence notice shall not alone be treated as permission for those further uses.

EIP-028 The programme shall keep terms for prose, schemas, software, examples, datasets, and foundation manuscripts separately identifiable. A licence applying to one artifact class shall not be presumed to cover the others.

EIP-029 Foundation manuscripts and third-party sources shall retain their recorded source terms. Incorporating a source in the foundation manifest, citing it, extracting concepts from it, or placing it in the repository shall not be represented as relicensing the source.

EIP-030 Before public distribution of an artifact, the designated rights reviewer shall record that the intended distribution and included material are covered by identified permissions or another reviewed basis. Unclear rights shall block the affected distribution, while drafting and review within established permissions may continue.

EIP-031 Where an intended use exceeds available permission, the editor shall obtain suitable permission, replace or remove the material, narrow the use, or retain the affected artifact as restricted. The disposition shall preserve the source and reason without exposing restricted content.

EIP-032 A change in contribution or publication terms shall identify the artifacts and versions affected, authority for the change, contributor acceptance needed, and transition treatment. A new licence shall not be represented as retrospectively covering existing contributions without an established basis.

7 Selecting terms without presumed commitments

The following options identify distinct review questions. They are not an operative licence offer.

Document prose. Compare access to adopted text, quotation, redistribution, translation, derivative versions, attribution, and protection against misleading modified editions.

Schemas and code. Compare implementation, modification, distribution, dependency compatibility, notices, patent-related provisions, and long-term maintenance under the actual selected terms.

Examples and datasets. Examine source rights separately from privacy, confidentiality, consent, representational authority, cultural restrictions, and permitted reuse. Synthetic labels do not excuse copying protected source material.

Foundation corpus. Preserve manuscript-specific authority, authorship, and version history; choose any future distribution arrangements explicitly with the relevant rights holder.

EIP-033 Before offering contribution terms or choosing publication licences, the programme shall record its organizational and jurisdictional context, intended rights and obligations, artifact classes, alternatives, implementation consequences, and review by a person competent for the relevant rights questions.

EIP-034 The programme shall make operative contribution terms available before requesting assent to them and shall retain the accepted version and scope. A record of assent shall not assert that the contributor holds rights that remain unverified.

8 Patent and essential-rights concerns

This draft selects disclosure and issue handling as interim governance controls. It adopts no royalty policy, mandatory patent licence, representation of patent validity, or external standards body's assurance mechanism.

EIP-035 A participant aware of a potentially material rights obstacle to implementing a proposed requirement shall report the known concern and its basis to the designated rights contact. The report shall distinguish actual knowledge, an asserted claim, and unresolved inference; it shall not be presented as a legal determination.

EIP-036 The programme shall record a material implementation-rights concern, affected requirements, available public information, review competence needed, feasible alternatives, and its disposition before approving an implementation claim that depends on the concern.

EIP-037 No programme participant shall make a licensing promise, patent assurance, rights waiver, or financial commitment on behalf of another person or institution without documented authority. A declaration under another organization's process shall not be represented as a programme agreement without review of its actual scope.

EIP-038 Where implementation rights remain materially unresolved, the responsible decision authority shall narrow the claim, select a reviewed alternative, or defer the affected normative adoption. An empty concerns register shall not be described as proof that implementation is free of third-party rights.

9 Records, review, and evidence

EIP-039 Ethics, conflict, and rights records shall identify an accountable custodian, access rules, retention or review basis, correction route, and treatment of protected information. Public decision evidence shall avoid unnecessary disclosure while making authority, procedure, and unresolved limits inspectable.

EIP-040 The programme shall review this policy with the governance review cycle and after a material complaint, rights dispute, change of legal or organizational context, or change in

publication arrangements. A revision shall preserve the prior edition and unresolved cases' transition treatment.

The adoption dossier includes tested public and protected contact routes, accepted ethics/alternate/rights roles, conflict and contribution-register examples, a synthetic recusal and complaint exercise, a rights-clearance exercise, and a report of remaining gaps. A useful rehearsal includes a contributor who disputes a draft, an editor funded by an affected implementer, and a manuscript available for reading but lacking established redistribution permission. The exercise checks separate dispositions for the objection, the conflict, and the proposed source use.

10 Informative sources and rationale

Source and interpretation. Foundation orientation: FM-005, `GRE_Chapter_05_Complete_First_Draft.pdf`, section 5.18, pp. 150–153, distinguishes opportunities for epistemic visibility and contestation from evidential adequacy and examines risks of intensified visibility. FM-001, `GRE_Chapter_01.pdf`, section 1.14, pp. 79–83, connects verification infrastructure to practical reliance and concentrated power. These theoretical sources inform questions; the policy clauses are programme proposals.

Source and interpretation. Local basis: `docs/planning/cross_domain_programme.md`, sections 3.4–3.7; `docs/planning/standards_development_comparison.md`, sections 3 and 8. These planning texts preserve unresolved contribution-policy and organizational choices.

Source and interpretation. IEEE SA Standards Board Operations Manual, official online clause 6, consulted 2026-09-22: `https://standards.ieee.org/about/policies/opman/sect6/`. Its separate treatment of contributions, patent matters, and open-source artifacts informs the separation of rights questions here. No IEEE contribution agreement, assurance, or platform policy is adopted by this draft. The comparative study records the available 2026 PDF edition; the online clause is cited only for the stated comparison.

Source and interpretation. ISO Standards and Patents, official resource page, consulted 2026-09-22: `https://www.iso.org/iso-standards-and-patents.html`. The page links common patent-policy resources and declaration mechanisms. The programme uses this as a comparison source, not as evidence of permission to implement a particular technology or as an adopted patent policy.

The draft selects granular contribution and clearance records over a presumed repository-wide licence. The alternatives are adoption of specified terms by artifact class or individually negotiated permissions; a future choice can combine them. Granularity permits useful drafting now while exposing exactly which public distribution or implementation claims still need a decision.

OPEN. Operative contribution agreement, publication licences, patent policy, organizational/legal context, qualified rights review, named ethics contact and alternate, and protected reporting infrastructure remain OPEN. This text creates none of those commitments by implication.

OPEN. Jurisdiction-specific duties, external remedies, and legal validity of a permission or retention decision require context-specific primary sources and qualified review. The draft defines programme process requirements without determining those questions.

Foundations and Vocabulary

Standards-track Working Draft

Draft version 0.1

22 September 2026

WORKING DRAFT FOR REVIEW

This document is not adopted. Its requirement language expresses proposals for review and rehearsal. Preparation of this text does not establish programme governance, approve a formal standards project, or certify substantive truth, legal validity, or institutional legitimacy.

Publication class, scope, dependencies and unresolved decisions are stated in the document. No ISO, IEC or IEEE affiliation or endorsement is claimed.

Responsible editor: Unassigned.
Canonical source: `standards/GR-100-foundations-vocabulary/GR-100.tex`

Maturity: PREPARATORY; PROVISIONAL. This is an authoring draft for examination of proposed requirements. It is not an adopted Standard, a formally initiated standards project, or evidence of approval of GR/NWIP-001. Formal initiation depends on the governance launch decisions. The word "shall" expresses a candidate requirement within this draft, without conferring programme adoption or legal authority.

9 Open issues and next evidence **12**

1 Purpose and scope

This document supplies a bounded operational vocabulary for recording and examining claims about generative histories. It addresses a practical problem: a record can accurately preserve an assertion while the assertion is mistaken, an authentic document can contain an unsupported inference, and a later correction can conceal the historical consequences of an earlier judgment. Inspectable practice requires distinctions among what is claimed to have happened, how it became accessible, what was recorded, what was inferred, and how the account was used.

The scope includes vocabulary use, the separation of levels of description, identity and temporal distinctions, and a candidate description of six record roles. It does not define truth, a complete metaphysics, a universal theory of evidence, legal validity, a universal generativity score, or a machine-readable schema. Domain methods can provide stronger criteria within a declared scope.

GR-110 develops trajectory recording requirements. GR-200 develops the epistemic record package. GR-120 and associated Specifications are intended to resolve technical representation after requirements and cases expose a reusable need. GR-210 is intended to address assessment and contestation procedures. References to these publications identify coordinated draft work; none is an adopted normative dependency.

2 Reading conventions and conformance subject

Sections 3–5 contain operational definitions and candidate vocabulary-use requirements. Section 6 contains informative examples. Sections 7–9 contain candidate assessment methods, informative source traces, and unresolved issues. “Shall” denotes a requirement, “should” a recommendation, “may” permission, and “can” capability or possibility. Notes, examples, source descriptions, and open issues do not add requirements.

The conformance subject is a *declared vocabulary application*: a named and versioned document, record package, profile, or implementation description that uses the terms in this draft. Vocabulary assessment checks what the subject claims and distinguishes. It does not establish that its account of a target is true, that a system implements every future family member, or that an institution has acted legitimately.

V100-001 A vocabulary application shall identify this document and version, its own boundary and version, the terms it uses, and any local extensions or narrower domain meanings. It shall describe departures explicitly and shall not claim unqualified GR-100 vocabulary conformity for a conflicting use of a defined term.

An application can use only a subset of the vocabulary. Using the term “Event,” for example, does not require adding an Entity, Process, or Property record solely to fill a catalogue. A field’s spelling alone does not establish its semantic role.

3 Operational vocabulary

3.1 Reality, manifestation, and representation

Target. That about which a claim is made. A target can be a situation, participant, occurrence, relation, condition, possibility, record, or another claim. Its identification can remain partial

or contested. A target reference is an act of reference; it does not establish existence or identity.

Manifestation. For recording purposes, an identified way in which a difference becomes available to encounter, registration, measurement, expression, or classification under specified conditions. This is a limited operational use informed by FM-004; it does not exhaust that manuscript's account of manifestation.

Representation. A description or arrangement of signs used to describe, classify, model, or otherwise stand for a target. Representations can themselves become targets of inquiry and participants in later action.

Record. An identified retained representation, together with the context needed to interpret its declared recording purpose. A record can contain several claims, and several records can concern one target. Retention need not mean public disclosure or indefinite preservation.

Record package. A declared collection of records and contextual references presented together for a specified purpose and version. A package can contain protected components and a restricted or public view. A view's limitations are part of its declared scope.

The foundation's ontological, relational, and manifestational registers concern different analytical questions. They are not exclusive categories of objects or a mandatory temporal sequence. A practice can operate before its recognition, and a classification can subsequently change the practice. This document does not require every target to receive a philosophical register label.

V100-002 A vocabulary application shall distinguish a represented target, an identified manifestation or trace, a retained record, and a claim wherever it uses those roles. It shall not treat a record identifier, representation, or manifestation as establishing the existence, complete nature, or identity of its target solely by being recorded.

3.2 Claim, observation, inference, and judgment

Claim. An attributed assertion with identifiable content and target, expressed under a stated scope. The assertion can concern an occurrence, a possibility, an interpretation, a value judgment, or institutional or legal status. Recording it does not endorse it. Several parties can assert the same content with different grounds.

Attribution. A recorded association between a claim or activity and the person, institution, system, or source represented as originating or performing it. Attribution can be pseudonymous, unknown, disputed, or mediated through another source.

Observation. A situated activity of attending to or registering a manifestation through a stated method. An observation report is a claim about that activity or its result; "direct" does not mean free of mediation or interpretation.

Inference. A step that relates identified premises or material to a conclusion under a stated method or reasoning. An inferred claim has a different epistemic role from the claim that its premises were recorded.

Interpretation. An attributed assignment of meaning, classification, or significance within a stated context. Interpretation can participate in observation and inference; these terms do not partition human or machine activities into exclusive kinds.

Judgment. An attributed assessment or determination made using identified grounds and criteria. A judgment can assess evidential warrant, ethical acceptability, legal status, or institutional action. These functions carry different bases of authority.

Assessment. A recorded examination of a specified question using identified criteria and material, with a result and limitations. In GR-200 an evidence assessment concerns a claim-relative evidential role. A syntax check concerns a different assessment target.

Uncertainty. Specified unresolved limitations or alternatives affecting a claim's content, identification, observation, method, interpretation, timing, boundary, or warrant. An uncertainty description is itself attributed and scoped. A numerical quantity is one possible representation, not a mandatory universal measure.

V100-003 A vocabulary application shall distinguish assertion, observation report, inference, interpretation, and assessment where those functions occur. Where one item performs several functions, it shall identify the functions and their scopes rather than infer one function's warrant from another.

3.3 Trace, evidence, and provenance

Trace. Material, behavior, testimony, inscription, or another manifestation identified as a remainder or consequence relevant to a target inquiry. The proposed connection to its generative conditions is a claim with its own grounds; calling an item a trace does not establish the proposed origin.

Evidence. A role assigned to identified material in assessing a specified claim, with an account of relevance, reliability, and alternative explanation. The material can support, challenge, limit, or fail to discriminate the claim. Evidence is not an intrinsic status permanently attached to a file or person.

Evidential warrant. The grounds offered for accepting, qualifying, or rejecting a specified claim under stated methods, assumptions, and scope. This draft records those grounds without imposing one universal sufficiency rule.

Provenance. A recorded account of origins, attribution, derivation, custody, or transformations of an identified item. Provenance can be incomplete or disputed. Provenance of a claim's expression differs from evidence for the claim's content.

Authenticity assessment. An assessment of whether an item is what it is represented to be, within a specified question and method. Authenticity of an utterance or document does not establish truth of its substantive claims.

Missingness. A stated condition in which information sought for a recording purpose is absent or unavailable. Not observed, not recorded, lost, withheld, unknown, inapplicable, and disputed describe different conditions and are not interchangeable with a zero, false value, or non-occurrence claim.

V100-004 A vocabulary application shall represent an evidential role relative to an identified claim. It shall keep provenance or authenticity results, evidential assessments, technical conformance, institutional acceptance, and normative or legal judgments distinguishable. It shall not describe success in one of these assessments as success in another without a separately stated argument.

3.4 Identity, time, and history

Record reference. A designation sufficient to distinguish a record or a particular version within a declared context. A reference scheme does not itself determine the identity of the represented target.

Identity criterion. A stated basis for treating two appearances or descriptions as concerning the same target within an inquiry. Identity claims can be contested and criterion-dependent. Similar behavior, equal content, shared names, and common descendants do not alone establish target identity.

Lineage. A directed account of derivation, succession, or continuation. Lineage can branch or merge. Its use does not automatically assert that predecessors and successors are one identical target.

Target time. The time or interval a claim concerns, including an explicitly unknown or uncertain temporal location.

Observation time. The time at which an observation or acquisition is represented as occurring. It can differ from target time and recording time.

Recording time. The time at which a record or identified version was made or entered into a recording context. It does not automatically date the target occurrence.

Assessment time. The time of a stated assessment or judgment, distinct from the time to which that judgment applies.

Descriptive regime. The declared categories, definitions, methods, scales, or boundary choices used to describe a target within an inquiry. This is an operational term; it does not require a fixed family of regimes or a particular mathematical construction.

Revision. An identified change to a representation, claim, assessment, or descriptive regime, with its relationship to an earlier formulation and the stated reason. Revision of an account of the past does not itself change the past occurrence.

Trajectory. A scoped account linking conditions, occurrences, continuations, alternatives, and consequences over a declared temporal or ordering frame. A reconstructed trajectory can remain partial and contested; it need not be a single fully ordered sequence.

V100-005 A vocabulary application shall distinguish record reference, target identity, and lineage. A stated identification of targets across appearances shall identify its criterion and the scope in which it is used. Unresolved identity shall remain expressible without forced merger.

V100-006 A vocabulary application shall distinguish target, observation, recording, and assessment times wherever it uses them. It shall preserve uncertainty about time or order rather than derive occurrence order solely from record entry order.

V100-007 An application that represents revision shall distinguish change in the target situation, change in evidence or assessment, and change in the descriptive regime. It shall allow more than one reason to apply and shall not silently replace the earlier formulation with a later one. Where earlier content cannot be retained or disclosed, it shall identify the resulting limit on historical reconstruction.

These are three linked histories rather than three mutually exclusive event types. Publication of a revised classification can change a target situation as well as its description. A later assertion that the earlier situation differed is an epistemic revision; it does not backdate the physical act of correction.

3.5 Generativity and practical consequences

Generativity-related claim. In this operational vocabulary, a claim about how relations, conditions, or activity generate, sustain, transform, restrict, or destroy subsequent states,

capacities, relations, distinctions, or possibilities. This defines the programme's recording subject; it is not a comprehensive definition of GR generativity.

Generative condition. A condition claimed to enable, constrain, or shape a specified trajectory or possibility. Its role needs attribution and grounds; contemporaneous presence alone does not establish contribution.

Possibility claim. A scoped claim that a continuation was or is available, feasible, blocked, lost, or conjectured under identified conditions. An unchosen proposal differs from an evidenced feasible alternative, and each differs from a later imagined counterfactual.

Contribution. An attributed participation or influence in a specified trajectory or outcome. Contribution, credit, causal responsibility, entitlement, and legal liability remain distinct questions.

Practical uptake. An identified use of a representation or judgment in action, classification, allocation, or institutional decision. Its consequences can become new recording targets.

Generativity return. A research and recording topic concerning claimed return pathways through which generated effects alter conditions of further generation. Its operational measurement, evaluative meaning, and any allocation rule remain **OPEN**; no universal quantity or entitlement is defined here.

V100-008 An application using generativity-related terms shall identify the claimed change or continuation, affected target or participants, relevant conditions, and scope. It shall distinguish a generative attribution from a value judgment and shall not infer beneficialness, entitlement, or legitimacy from the term "generative" alone.

4 Six candidate operational record roles

4.1 Status and shared use rule

These role descriptions are standards-specific proposals, informed by FM-007 and earlier programme vocabulary. They describe how a target is represented for an inquiry. They neither exhaust reality nor require exclusive schema classes. The term Property is retained from the programme; FM-007 uses Attribute. No equivalence between them is asserted.

In the descriptions below, *minimum metadata* means the information required when the role is applied under V100-009. An explicit unknown or restriction with reason can satisfy the obligation to state an unavailable contextual value; it does not satisfy an independent requirement to establish a factual claim. Common metadata means record reference and version, role, described target, recording responsibility and time, and links to the relevant claims and their epistemic context. Referenced context can be shared across a package without duplication.

V100-009 An application of a six-role description shall identify the applied role, its admissibility and identity criteria, the common metadata, and the role's minimum metadata below. It shall disclose unresolved boundaries and use the temporal meaning associated with the role. Missing information shall retain its stated reason rather than be converted to a substantive negative claim.

V100-010 An application shall allow a target to be described through more than one applicable record role without treating role overlap as evidence of inconsistency. A restriction in an application profile shall state its recording purpose and information limits. A Relation whose own identity, state, properties, or history matters to the declared inquiry shall remain independently referenceable.

4.2 Entity

Definition and admissibility. A record role for a focal subject tracked across appearances under a declared continuity criterion. Admissible when the inquiry needs cross-context or cross-time reference; use does not require an unchanging substance.

Identity. The stated reidentification criterion and evidence determine the claim of continuity. A database key identifies a record, not automatically the represented subject. A disputed criterion can remain unresolved.

Temporal behavior. Properties, membership, and relations can change while continuity is asserted. Formation, dissolution, replacement, or uncertain duration can be recorded separately.

Relations to other roles. Participation in Events and Processes; possession of described States or Properties; participation in Relations; lineage links to other Entity descriptions. These are candidate meaningful links, not an exhaustive edge schema.

Minimum metadata. Focal subject and appearances in scope; continuity criterion; temporal scope; attributed identity judgment or unresolved status.

Optional metadata. Names, identifiers assigned by other systems, formation history, known predecessors and successors.

Example and counterexample. An association tracked across a change of premises under a stated organizational continuity criterion. Two unrelated associations sharing a name are not thereby one Entity.

OPEN edge. A split into two successors can preserve lineage while leaving continuity with the predecessor disputed.

4.3 State

Definition and admissibility. A record role for a scoped description of conditions of a target at a stated time or interval. Admissible when the question concerns those conditions rather than an exhaustive inventory of reality.

Identity. Same target, temporal scope, and descriptive regime identify the intended condition description; record versions and conflicting accounts remain distinct. Equality of observed values alone does not establish equality of target conditions.

Temporal behavior. A condition can persist over an interval or be known only at an observation time. Persistence between observations requires a claim. Predictive sufficiency is relative to specified questions and continuations.

Relations to other roles. Conditions of Entities or Relations; preconditions and results of Events; intermediate descriptions in Processes; values articulated through Properties.

Minimum metadata. Target; time or interval; description boundary and regime; conditions described; observation or inferential basis.

Optional metadata. Supported queries, omitted conditions, comparison horizon, warranted persistence interval.

Example and counterexample. A committee's recorded membership on a given date. A timestamped snapshot alone does not establish every member's continuing participation throughout a month.

OPEN edge. A reduced state adequate for a current report can omit historical memory needed for a later operation.

4.4 Event

Definition and admissibility. A record role for an individuated happening or attempted happening under a declared occurrence criterion. Hypothetical, planned, or reconstructed events remain admissible as explicitly qualified targets of claims.

Identity. An occurrence criterion distinguishes event tokens; a description can refer to one event in several records. Repetition of the same operation or outcome does not merge occurrences.

Temporal behavior. Duration, boundaries, sequence, or overlap can be exact, interval-based, partial, or unknown. Failure or interruption does not imply non-occurrence of an attempt.

Relations to other roles. Participants represented as Entities or Relations; changes between States; steps of Processes; Properties of the occurrence.

Minimum metadata. Proposed happening; occurrence and individuation criteria; claimed actuality or modality, such as occurred, attempted, planned, hypothetical, or unresolved; separate epistemic basis, such as reported, observed, or retrospectively inferred; temporal scope; participating targets where known. A retrospectively inferred event can be claimed to have actually occurred.

Optional metadata. Place, before/after conditions, attempted purpose, completion status, links to repeated occurrences.

Example and counterexample. Two separately evidenced permission issuances with the same final status. A formula for the effect of an issuance does not establish that either occurred.

OPEN edge. Different temporal resolutions can treat one prolonged happening as an Event, Process, or several Events; the segmentation rationale matters.

4.5 Process

Definition and admissibility. A record role for activity linked by a declared ordering and criterion of unity. Admissible for goal-directed, recurrent, interrupted, branching, or otherwise connected activity; achievement of an intended endpoint is not required.

Identity. The stated grouping and boundary criterion individuates the process. Equal endpoints or equal modeled composite effects do not establish the same process history.

Temporal behavior. Ordering can be partial; duration and completion can be uncertain. Alternative possible paths remain distinct from the reconstructed actual path.

Relations to other roles. Comprises or links Events and intermediate States; involves Entities and Relations; has scoped Properties; connects to dependent Processes.

Minimum metadata. Unity and boundary criterion; activity in scope; supported ordering; claimed actuality or modality, distinguished from its observational or reconstructive basis; time scope and completion/continuation status.

Optional metadata. Intended purpose, branches, interruptions, excluded steps, retained intermediate conditions.

Example and counterexample. A proposal–revision–authorization sequence with a recorded failed earlier attempt. A factorization of an outcome into mathematically possible operations is not evidence of that history.

OPEN edge. Overlapping practices can belong to several processes; no universal segmentation rule is proposed.

4.6 Relation

Definition and admissibility. A record role for an identified connection, arrangement, or dependence among specified targets or conditions within a stated context. Admissible when its incidence, formation, continuity, or effects are relevant. Potential efficacy requires a further claim.

Identity. A stated criterion distinguishes a continuing arrangement from a renewed or separate one. Equal participants and equal current effects do not alone establish the same relation.

Temporal behavior. Formation, persistence, dormancy, change of terms, and ending are separately attributable. A relation can change while participants remain identified.

Relations to other roles. Participants can be targets described by any relevant role, including other Relations; Events can form or change it; Processes describe its history; States and Properties describe its conditions.

Minimum metadata. Relation reference; participant or condition references with roles; context; relation criterion and temporal scope; stated identity basis.

Optional metadata. Formation history, dependency claims, terms, changing states, prospective effect comparisons.

Example and counterexample. Two separately identified agreements between the same parties, each with its own renewal history. Co-occurrence in a table alone does not establish cooperation, trust, or dependence.

OPEN edge. Uncertain or changing participants can prevent a complete incidence description without eliminating the recorded relation claim.

4.7 Property

Definition and admissibility. Provisionally, a record role for an attributed characteristic or value of a specified subject under a stated definition, time, and context. Admissible when the meaning and subject of the attribution are explicit. This operational use does not resolve the broader Property/Attribute relationship.

Identity. A property assertion is distinguished by subject, characteristic definition, contextual and temporal scope, attribution, and version. A type of characteristic differs from a particular assignment of its value.

Temporal behavior. A value can change with the subject; a later correction can instead revise knowledge of an earlier value. The two histories remain distinguishable.

Relations to other roles. Describes a target represented through any role; measurement or classification can be linked to an Event or Process; multiple conflicting assignments can concern one subject.

Minimum metadata. Subject; characteristic definition; value or explicit missingness state; time and context; method or attribution; scale and unit when used.

Optional metadata. Measurement uncertainty, valid domain, derivation, calibration reference, alternatives.

Example and counterexample. A reported resource quantity for an organization at a specified time. A numbered nominal category is not a measurement permitting arithmetic solely because its code is numeric.

OPEN edge. FM-007's Attribute has explicit domain, interpretation, scale, and definedness conditions. Equivalence to Property, separation, or renaming needs source comparison and a recorded decision.

5 Boundaries between layers

V100-011 A vocabulary application shall distinguish operational record roles from metamodel concepts. It shall not identify a formal carrier state with a record State, a mechanism with a Process, or formal change with an Event without an explicit scoped mapping and argument.

V100-012 A vocabulary application shall keep descriptive, epistemic, evaluative, legal, institutional, and technical assertions distinguishable by their stated question and grounds. It shall not represent technical conformance as automatically creating factual truth, rights, duties, liability, admissibility, jurisdiction, or institutional authority.

The same dossier can connect these assertions. For example, an institutional decision can cite an evidential assessment and an asserted rule, while each remains separately attributable and open to the appropriate form of review. This is separation of questions and authority, not a requirement for independent databases.

6 Worked distinction tests (informative)

1. A clerk records that a request arrived late. A timestamp proves that a record was entered at a time; whether the request itself arrived late requires identifying the timing source, applicable deadline, and inference. The record, target event, and deadline assessment remain distinguishable.
2. A later witness report changes the assessment of the arrival time. That is a revision of the account. A later extension of the deadline changes a governing condition. A new definition of "arrival" changes the descriptive or institutional rule. One dossier can contain all three histories without conflating them.
3. Two administrations reuse an office name. An application follows their records under the same catalogue heading while recording replacement and disputed institutional continuity. Shared cataloguing does not decide Entity identity.
4. A new procedure reduces review time and makes some participants unable to contest an error. A generativity record can preserve both the increased processing capacity and the restricted capacity for correction; an ethical judgment states its own affected parties and criteria.

7 Candidate conformance evidence

Each row identifies a review method, not an already executed test. An assessor examines the declared subject and reports pass, fail, or not applicable for each requirement, with an evidence

locator. Not applicable requires an absent trigger, not an inconvenient result. A review cannot establish the correctness of an external fact merely from compliant vocabulary.

Requirement	Evidence and discriminating check
V100-001	Declaration names version, boundary, terms, extensions. Compare a local "fact" label against its stated meaning; detect an undisclosed conflicting use.
V100-002	Trace a target, manifestation, record, and claim in the subject. An authentic but incorrect report remains representable.
V100-003	Inspect a summary combining observation and inference. Recover which content was registered and which was inferred, by whom.
V100-004	Inspect one material item used differently for two claims. A successful authenticity check does not become a truth result.
V100-005	Inspect a merger, split, or disputed identification. Recover identity criterion and directed lineage without an automatic merger of targets.
V100-006	Inspect a late-entered report. Target time, observation time, recording time, and review time remain distinguishable or explicitly unknown.
V100-007	Compare target change, corrected report, and changed category. Prior meaning and reasons remain recoverable to the declared retention/access extent.
V100-008	Inspect a generative attribution. Scope and affected targets are present; description of expanded capacity is separate from its evaluation.
V100-009	For each applied role, locate admissibility, identity, temporal meaning, and required metadata; inspect a missing value's explicit reason.
V100-010	Inspect a relation with changing terms and an event analyzed as a process. Relevant identity/history and overlapping views remain expressible.
V100-011	Inspect any metamodel mapping. Identify additional premises; absence of a mapping means the conditional check is not applicable.
V100-012	Compare event report, institutional determination, legal assertion, ethical judgment, and technical check. Their distinct grounds remain visible.

8 Foundation trace and drafting rationale (informative)

Page numbers below are one-based pages in the supplied PDFs. FM identifiers are those in `foundation_manuscripts/MANIFEST.md`. The definitions here are operational proposals rather than quotations or claims that the manuscripts prescribe this recording model.

Source	Preserved distinction and draft application
FM-004, §4.2, pp. 11–14; §4.6, pp. 43–45	Registers answer different questions; manifestation is broader than representation, and recognition need not precede relational reality. Basis for V100-002; no exclusive philosophical register schema.
FM-005, §5.4, pp. 28–31	Trace, target relation, and evidence differ; evidential force is target-relative. Basis for V100-003/004 and GR-200 evidence-role requirements.

Source	Preserved distinction and draft application
FM-005, §5.17, pp. 141–142	Uncertainty concerns several dimensions and need not have one scalar measure. Basis for the uncertainty definition and GR-200.
FM-005, §5.20, pp. 168–174	New evidence, intervention, historical revision, and category revision differ. Basis for V100-006/007; three linked histories are an operational organizing proposal.
FM-007, p. 2; §7, pp. 26–29; §8, pp. 32–33	Roles overlap; identity criterion, lineage, participant incidence, and relation continuity require distinct information. Basis for V100-005/009/010 and Entity/Relation proposals.
FM-007, §9, pp. 37–38, 43; §12, pp. 56–57	Occurrence differs from effect; histories differ from endpoints and possible factorizations. Basis for Event/Process proposals.
FM-007, §10, pp. 43–44; §11, pp. 52–53, 56	Attribute domain/scale and State sufficiency are scoped. Basis for Property/State proposals, with Property/Attribute unresolved.
FM-003, §3.10.9, p. 115; §3.13, pp. 141–142	Generativity has no fixed normative sign; effects vary across subjects and time. Basis for V100-008, without a universal measure. Both Chapter 3 variants remain independently preserved.

The main alternatives were a complete philosophical definition, an exclusive six-class schema, or a limited operational vocabulary. This draft selects the third provisionally because initial cases need distinguishable claims and histories before a technical model can be justified. A programme decision record accompanies this drafting choice; adoption and technical realization remain separate decisions.

9 Open issues and next evidence

- **OPEN — Property/Attribute.** Compare FM-007 with sustained programme usage and test conflicting value assignments, undefined values, and nominal scales before deciding equivalence, separation, or a terminology change.
- **OPEN — Claim representation.** Compare independently identified claims, attributed assertions within records, and hybrids using disagreement, revision, restricted access, and round-trip examples. This draft requires distinguishability, not a seventh ontology class.
- **OPEN — Role overlap and profiles.** Test overlapping Event/Process and Entity/Relation descriptions. No exclusive schema typing or full cross-role relation vocabulary has been adopted.
- **OPEN — Identity.** Domain-specific criteria and disputed linkage need examples beyond names and administrative identifiers; branching continuity does not have a universal resolution.
- **OPEN — Generativity and return.** Test possibility, foreclosure, contribution, and return pathways without presuming a universal metric or a normative entitlement.
- **OPEN — Source chronology.** Chapter 3 editorial precedence remains unresolved. This draft cites particular passages without declaring one variant authoritative over the other.

1 Scope and standing

Responsible editor: `UNASSIGNED`. Canonical source: `standards/GR-110-recording-requirements/GR-110.tex`. Intended readers are recording practitioners, record custodians, affected participants and assessors.

This document proposes requirements for a bounded generativity record package and for the practice that produces and maintains it. A package is an identified collection assembled for a stated inquiry or practical purpose, with an inventory, scope, responsible recording practice, attributed claims and a history relevant to that purpose.

The objective is to preserve enough information to examine what is represented, how it became known, how judgments changed and how earlier relations contributed to later capacities, constraints or possibilities. Completeness of reality, exhaustive personal surveillance and a uniquely recoverable history are outside scope.

This is preparatory authoring, not a formally initiated or adopted Standard. Proposed requirements are available for synthetic assessment while programme governance is developed. Full GR-120/130/140/150/160/400 documents and a common technical schema are not prerequisites for this draft's manual assessment.

2 Draft dependencies and terminology

For the bounded assessment in this edition, GR-100 Working Draft 0.1 supplies operational terms and GR-200 Working Draft 0.1 supplies the epistemic requirements invoked below. Both dependencies are drafts, not adopted Standards. A change to either dependency requires review of affected results.

A *material claim* in this document is an assertion relied on to explain a consequential relation, generative effect, decision, classification, assessment or revision within the declared purpose. The package's selection rationale identifies such reliance. Importance is purpose-relative; the label does not establish truth.

A *recording practice* comprises the responsible people or organization, methods and custody arrangements used to assemble and maintain a package. Technical capture can be one component. A *generative account* is an attributed account of how conditions or relations enabled, maintained, transformed or constrained subsequent capacities, relations or possibilities. It remains subject to evidential assessment.

3 Purpose, boundary and responsible practice

R110-001 A package shall identify its purpose, intended users, subject matter, boundary, relevant time horizon, recording practice and package version.

R110-002 The recording practice shall state the selection criteria for included material and identify known omissions material to the purpose, including unavailable perspectives, uncollected information and limits of reconstruction.

R110-003 The package shall distinguish an inventory of retained records from an assertion that the underlying history is complete. The existence of a record shall not be used as proof of its represented content.

R110-004 The recording practice shall assign responsibility for capture, assessment, custody, access decisions and correction, recording combined roles and relevant conflicts. An automated component shall not substitute for an unassigned responsibility.

4 Epistemic and identity requirements

R110-005 The package shall identify its material claims and assessments as a bounded epistemic record package assessed against GR-200 Working Draft 0.1, including that draft's package-level obligations. It shall identify the assessed claim set, dependency versions, applicable requirements, evidence, exceptions and results; a claim-level check alone shall not establish fulfillment of the package dependency.

R110-006 Each retained record and version shall be distinguishable within the package, and a reference shall identify its intended target sufficiently for the declared use. A record identifier shall not itself establish identity of the represented person, event or relation.

R110-007 A continuity or identity judgment material to the trajectory shall identify its criterion, responsible source, supporting grounds and known dispute. Merger, succession and common labels shall not silently be treated as identity.

R110-008 The package shall distinguish the represented occurrence or validity time from observation, recording and later assessment times when their difference is relevant. Uncertain intervals and unsupported ordering shall remain explicit.

R110-009 Represented observations, actions, relations, states and properties shall retain the information needed to distinguish their operational roles. A relation with a material history, status or properties of its own shall be identifiable as a recordable subject.

Informative note. These provisions do not mandate a database type hierarchy. A source, a claim about it and an assessment can be represented in different technical forms if the distinctions survive the declared uses. Property remains programme terminology pending the Attribute/Property decision.

5 Recording generative trajectories

5.1 Conditions, contributions and consequences

R110-010 For each generative account, the package shall identify the target capacity, relation, constraint, distinction or possibility; the relevant actors or configuration; the comparison or earlier condition; and the temporal and contextual scope.

R110-011 The account shall state how the proposed enabling, maintaining, transforming or constraining contribution connects earlier conditions to the target, with grounds, method and limitations. Temporal precedence or a diagram edge alone shall not be presented as establishing that connection.

R110-012 An account shall distinguish the asserted occurrence or modality of an effect, such as realized, intended, possible, unrealized or disputed, from its epistemic basis, such as observed, reported, inferred or reconstructed. A realized past effect can be retrospectively inferred. The recording practice shall not manufacture an observed outcome where follow-up evidence is absent.

R110-013 Material participants and contributions shall be attributed with their basis and uncertainty. The recording practice shall provide a means to record disputed, collective, indirect or unknown contribution without forcing attribution to one actor.

R110-014 When an enabling encounter, decision or judgment is material to the account, the package shall identify its represented role, relevant conditions and the claim connecting it to subsequent developments.

5.2 Alternatives, changes in distinctions and loss

R110-015 A recorded alternative shall state whether it was considered at the time, inferred retrospectively, modeled or merely proposed, and identify the grounds for any claim of feasibility. Recorded alternatives shall not be presented as exhaustive or equally feasible without supporting grounds.

R110-016 A material change in categories, available distinctions or methods shall identify the earlier and later formulation, the reason for change and its effect on interpretation. A new description shall not automatically be represented as a newly existing underlying object.

R110-017 Known maintenance, depletion, restriction, exclusion or loss material to the declared generative account shall be recorded alongside creation or expansion, or have an explicit collection or protection limitation under R110-002 and R110-026. The account shall distinguish descriptive effects from their evaluation for particular people or values.

R110-018 Where generativity return is assessed or proposed, the package shall identify the asserted concept, intended recipients, scope, grounds and evaluative basis. Where it is not assessed, that limitation shall be stated without inventing a quantity or entitlement.

Informative note. A stable laboratory collaboration can maintain capabilities despite little immediate output. A successful output can coexist with the loss of a contributor's access. Neither observation alone establishes whether the arrangement was just.

6 Decisions, practical uptake and revision

R110-019 When a represented claim or classification informs a decision within scope, the package shall identify the claim version relied on, the decision, the asserted decision authority, its stated grounds and known subsequent response.

R110-020 A revision shall identify its actor or responsible source, time, target, reason and affected records, distinguishing a change in the represented situation, evidence or interpretation, and descriptive regime. More than one reason can apply.

R110-021 The recording practice shall preserve the intelligible relationship between earlier and later accounts, subject to stated retention and access rules. It shall not retrospectively present earlier actors as possessing evidence or categories first available later.

R110-022 A correction shall identify dependent records or presentations known to the practice, actions taken to correct them and any limits on propagation. The practice shall not assert that uncontrolled external copies were corrected or deleted without evidence.

R110-023 The practice shall provide a declared route for questions, contested attribution and correction requests, identify the responsible recipient and maintain permitted request/disposition records. Availability of the route shall not imply a legal entitlement or a promise of agreement.

Informative note. GR-210 Working Draft 0.1 supplies a complementary procedure for receiving, examining and disposing of such cases. It is not made a blanket dependency of every record package: a claim about a GR-210 procedure needs its own assessment.

7 Protection, custody and absence

R110-024 The recording practice shall declare the purpose and authority basis for collecting, retaining, accessing and disclosing material within the package, including the applicable policy or institutional context and unresolved constraints. It shall limit collected detail to that justified by the declared purpose.

R110-025 Access and retention decisions shall distinguish content, metadata, derived views and audit traces. Preservation of history shall not automatically require public disclosure or indefinite retention of sensitive material.

R110-026 Where material is unavailable, the package shall distinguish known non-collection, loss, destruction, restriction and an unknown reason to the extent that doing so is supported and permitted. It shall not disclose a protected fact merely to label an absence.

R110-027 A transfer, migration or custody change performed by the practice shall identify the source and destination versions or custodians, its authority, relevant transformation and known information loss. Unsupported finer distinctions shall not be invented during conversion.

R110-028 An authorized correction, restriction, retention or disposal action shall have a scoped disposition and an accountable executor. The practice shall record permitted evidence of its result and known limitations without retaining prohibited content solely to prove deletion.

8 Presentation and reviewability

R110-029 A presentation supplied as part of the assessed practice shall identify its source package/version and disclose material selection, reconstruction, uncertainty, disagreement and restriction within the permitted audience. It shall distinguish an attributed claim, an assessment and an institutional determination.

R110-030 A public or reduced view shall not imply that it contains the entire retained package. A validation or provenance result shall state what was checked and shall not be presented as certification of substantive truth or normative legitimacy.

R110-031 The practice shall provide enough accessible explanation for intended users to locate the grounds of a material claim and the relevant review route. A practical assessment shall record observed comprehension barriers and the alternatives or limitations offered.

9 Conformance and experimental assessment

9.1 Separate subjects

Two subjects are distinguished: the *package* and the *recording practice*. Package assessment examines the retained representation. Practice assessment additionally examines responsibility, selection, protection, action and user-facing behavior. A practice claim identifies at least one package or scenario through which behavior was examined.

This edition defines no reduced package profile. A package-only assessment reports a documentary subset and its limits; it is a partial assessment, not overall fulfillment of GR-110. An obligation to perform an action remains not assessed when only its documentation was examined. Not applicable is reserved for an absent stated trigger, not a change of assessment subject. Practice assessment covers every applicable requirement, with recording and behavioral components distinguished where a clause contains both.

R110-032 A report shall identify the assessed subject, versions of this draft and its dependencies, purpose/profile, applicable requirements, assessor, method, evidence, results and unresolved limitations. Package-only results shall not be presented as assessment of unobserved practice.

R110-033 The report shall distinguish fulfilled, not fulfilled, not assessed and not applicable results for each requirement, with reasons for exclusions. A failed or unassessed applicable requirement shall prevent an unqualified claim that the declared scope satisfies this draft.

R110-034 The report shall distinguish structural or documentary checks from tests of understanding, evidential warrant and institutional performance. It shall not infer truth, complete historical recovery, beneficial generativity or legal validity from structural fulfillment.

The following methods are informative assessment guidance, not additional requirements.

Requirements	Assessment method	Evidence or counterexample
R110-001–004	Inspect declared scope, inventory and responsibilities	An omitted participant or unassigned custodian is visible rather than invented.
R110-005–009	Review claim set, identity and temporal distinctions	Two reports of one event remain two reports; an uncertain date remains uncertain.
R110-010–014	Trace a generative account to its grounds	A proposed enabling relation has an attributed explanation; an unobserved effect is not labelled observed.
R110-015–018	Compare alternatives and evaluative scope	A rejected branch differs from a retrospective possibility; restriction of one group remains visible.
R110-019–023	Replay decision, revision and challenge records	A prior decision retains its earlier grounds; subsequent correction reaches declared dependents.
R110-024–028	Inspect policy and exercise protected lifecycle actions	Authorized views differ; disposal evidence does not reproduce removed sensitive content.
R110-029–031	Reader tasks and view comparison	A reader distinguishes allegation, assessment, decision and omission.

Requirements	Assessment method	Evidence or counterexample
R110-032–034	Inspect report completeness and limitations	A syntax-only result cannot be reported as complete practice assessment.

10 Informative example and source rationale

The accompanying synthetic funding-decision case is in `examples/p1-contested-decision.md`. It includes an inference from missing calibration metadata, contrary testimony, a restricted log, a change in evidential assessment, a separate change in classification, and uncertain downstream effects. It is a design fixture, not an empirical pilot.

Source and interpretation. FM-001, GRE Chapter 1, section 1.14, PDF pp. 78–83, distinguishes authenticity, provenance, representational adequacy and practical trust. FM-005, GRE Chapter 5, sections 5.4 and 5.14, pp. 28–36 and 113–122, distinguishes trace from claim-relative evidence and relational from generative trajectories. Sections 5.18–5.20, pp. 150–176, inform situated evidence, contestation and revision.

Source and interpretation. FM-003, GRE Chapter 3, section 3.12, pp. 129–141, motivates the relation among diagnosis, action, feedback and repair; FM-002 preserves a separately supplied Chapter 3 variant whose chronological relationship remains unresolved. FM-007, Metamodel Part II, sections 7–12 and 16–19, informs distinctions among identity, occurrence, process history, retained description and institutional uptake. These are conceptual sources, not normative dependencies.

The proposed operationalization is recorded in ADR-0004. It requires attributable and scoped generative accounts rather than a universal metric. Separate histories are required where they affect interpretation; no fixed ontology of claim objects, universal clock or exhaustive branch tree is selected.

OPEN. The final minimum profile, recording burden, generativity-return operationalization, metadata subject to protection and interoperability bindings remain open to pilot evidence. Core, Standard and Deep/archival remain historical candidate names; this edition does not adopt their boundaries.

OPEN. Independent practice assessment, full presentation/access/conformance publications and a live institutional pilot remain future work. The example and compilation do not establish those results.

GENERATIVITY STANDARDS PROGRAM

GR-200

Epistemic Recording Framework

Standards-track Working Draft

Draft version 0.1

22 September 2026

WORKING DRAFT FOR REVIEW

This document is not adopted. Its requirement language expresses proposals for review and rehearsal. Preparation of this text does not establish programme governance, approve a formal standards project, or certify substantive truth, legal validity, or institutional legitimacy.

Publication class, scope, dependencies and unresolved decisions are stated in the document. No ISO, IEC or IEEE affiliation or endorsement is claimed.

Responsible editor: Unassigned.
Canonical source: `standards/GR-200-epistemic-recording/GR-200.tex`

Maturity: PREPARATORY; PROVISIONAL. This document contains candidate requirements for authoring and synthetic examination. It is not an adopted Standard, a formally initiated standards project, or an institutional or legal authorization. Formal initiation remains dependent on governance launch decisions and work-item approval. Requirement language is proposed for review.

9 Source trace and requirement rationale (informative) **8**

10 Open issues and specification needs **9**

1 Purpose and scope

This draft defines the minimum information needed to examine who asserts what about a target, through which observations and reasoning, on which material, within what scope, with what uncertainty, and with what history of assessment and revision. Its organizing problem is the separation of a convincing or authentic representation from a warranted account of the represented situation.

The requirements concern a declared *epistemic record package*, which can include records, claim references, source locators, assessments, and protected components. The package can be textual, tabular, or implemented in software. This draft does not choose between claims as separate objects, attributed assertions within records, or a hybrid. A claim reference can be a local label and locator; it need not be a globally registered identifier.

GR-100 version 0.1 supplies the draft vocabulary. GR-110 adds requirements for generative trajectories and practical consequences. GR-210 is intended to govern the practice of assessment, challenge, and disposition. This document records those activities when present; it does not substitute a complete adjudication process, guarantee an appeal right, or set an evidential sufficiency threshold for every domain. GR-160 and GR-400 are intended to elaborate protection and institutional use. None of these drafts creates jurisdiction, a legal duty, or factual certainty.

2 Conformance boundary and interpretation

The conformance subject is one named, versioned epistemic record package within a declared purpose, collection boundary, and access scope. Requirements apply to its included claims and assessments, with conditional requirements triggered by the relevant activity. An external source is not required to satisfy these rules merely because it is cited; the package's assertions about it and uses of it are within scope.

E200-001 The package shall declare its reference and version, responsible recording role, intended use, target and collection boundary, included claim set or selection rule, access scope, relevant descriptive regime, and the GR-200 draft version used. It shall identify exclusions and limits that materially affect interpretation.

E200-002 The package shall associate every requirement with an assessment result and an evidence locator. A claim of conformity to this draft shall identify its package boundary and applicable requirement set, and shall disclose failures, unassessed requirements, and restrictions that prevent assessment. It shall not represent technical or recording conformity as proof of factual truth, evidential sufficiency, ethical acceptability, or legal validity.

An assessment result is pass, fail, not assessed, or not applicable with a reason. Only requirements whose stated trigger is absent can be marked not applicable. A package with failures or unassessed applicable requirements can report partial assessment, but not full conformity. This draft has no certification or accreditation scheme.

"Material" in this document means capable of changing a reasonable examination of the declared claim, its warrant, or its consequential use. The package's selection rule states how materiality was judged. Unknown, not collected, withheld, lost, and inapplicable can be explicit informational states where a value is unavailable. They disclose a limitation rather than establish the unavailable value or a substantive negative conclusion.

3 Claims, attribution, method, and scope

E200-003 Each included claim shall have a reference that distinguishes its content and version within the package, stated assertion content, an identifiable target or an explicit unresolved target description, and a link to its recording context. Different assertions or versions shall remain separately referenceable where their attribution, grounds, or disposition differ.

E200-004 Each claim shall identify its represented originating actor or source and the role responsible for entering it into the package. Where these differ, the attribution chain shall distinguish origin from transcription, quotation, translation, summary, or adoption. Unknown, pseudonymous, restricted, or disputed attribution shall be explicit.

E200-005 Each claim shall state its epistemic mode and relevant perspective: for example observation report, testimony, inference, interpretation, retrospective reconstruction, hypothesis, simulation, or normative or institutional judgment. Combined modes shall identify the distinct contributions rather than present inferred content as directly observed. A claim about an occurrence or possibility shall distinguish its asserted actuality or modality from its epistemic basis; retrospective inference can concern an actual occurrence.

E200-006 Each claim shall identify its acquisition or reasoning method, material premises and assumptions, relevant method version when one is used, and known transformations from source material to assertion. Where this information is unavailable, the package shall state the limit and shall not claim reproducibility or direct observation on that basis.

E200-007 Each claim shall state the boundary, scale or level of aggregation, contextual conditions, and temporal horizon relevant to its interpretation. It shall identify known omissions or selection conditions that materially limit generalization. A narrowed scope shall not be silently presented as a claim about a broader target.

E200-008 Each claim shall distinguish target time from the times of observation or source acquisition, recording, and assessment where applicable. Time values shall carry their applicable meaning and known uncertainty or resolution. Unknown order shall remain distinguishable from asserted simultaneity and from recording order.

E200-009 A claim that reidentifies a target across appearances shall identify the identity criterion, the appearances linked, the responsible attribution, and the evidential basis or stipulation. A proposed split, merger, succession, or disputed match shall not silently merge record identity, target identity, and lineage.

Informative note. A testimony can be preserved without claiming its reporter is infallible. Requiring attribution does not require public disclosure of a protected person's name. A role or pseudonymous reference, its protection status, and an accountable custody arrangement can provide the appropriate recording context.

4 Material and evidential roles

E200-010 For each material item invoked in support of, against, or to qualify a claim, the package shall identify the item or pattern, its relevant portion, source or acquisition path, and availability status. It shall distinguish original material, copies, derived representations, and generated material where those differences affect the claimed use.

E200-011 Each assigned evidential role shall link the material to a specified claim and identify the assessor or attributing source, assessment time, role, and rationale addressing relevance, reliability limitations, and material alternative explanations. An item with no assessment shall be marked unassessed rather than silently represented as accepted support.

The role can be supportive, challenging, qualifying, non-discriminating, or another defined relationship. A single item can support one claim and challenge another. The package need not impose a ranking across all evidence forms.

E200-012 Where multiple items are used together as evidence, the assessment shall identify known material derivation or dependence among them and the basis for any asserted independence. Repeated copies, summaries, or citations of one source shall not be presented as independent corroboration solely by their count.

E200-013 A claim of absence or non-occurrence inferred from missing observations or records shall identify the expected observation or recording opportunity, coverage, detection or preservation limitations, and reasoning from the missing material to the claim. If those conditions are not established, the package shall preserve the weaker missingness statement and shall not treat it as established non-occurrence.

E200-014 Each claim assessment shall describe material uncertainty and its location, including relevant alternatives, assumptions, identification limits, measurement limits, temporal gaps, or boundary and model limitations. A numerical confidence quantity, if used, shall state what it measures, its method and assumptions, and the scope of its interpretation.

E200-015 The package shall record material competing claims or explanations known within its declared collection boundary, their attribution, their relationship to the target claim, and any recorded grounds for excluding or preferring them. If alternatives were not examined, this limitation shall be explicit; silence shall not be presented as evidence that no alternative exists.

An alternative need not receive equal evidential weight merely because it is recorded. Recording a disagreement does not mean that it remains unresolved after a reasoned assessment. The disposition and its grounds remain visible, and an attributed rejected interpretation can remain historically consequential.

5 Assessments, revision, and practical uptake

E200-016 Each assessment or determination shall identify its question, responsible assessor or decision role, criteria, material examined, result, date, limitations, and relationship to the assessed claim versions. Provenance/authenticity, factual warrant, institutional acceptance, normative evaluation, legal determination, and technical validation shall remain distinguishable assessment functions.

E200-017 A substantive revision shall link the prior and revised claim or assessment versions and record who revised it, when, why, and which content or scope changed. The reasons shall distinguish target change, evidence or assessment change, and descriptive-regime change, allowing combined reasons. Historical access shall preserve earlier meaning to the declared retention and protection extent; any unavailable earlier content shall have an explicit reconstruction limitation.

E200-018 A change of descriptive regime shall identify the prior and new definitions or methods, grounds for change, affected claim set, and any mapping or transformation used. It shall identify known non-comparability, lost distinctions, or unresolvable mappings; finer classifications shall not be reconstructed from insufficient earlier material as if evidenced.

E200-019 For a revised claim with known dependent assessments, claims, or consequential uses within the package boundary, the package shall identify those dependencies and record whether each was reviewed, updated, left unchanged with reason, or remains pending or unreachable. It shall not claim that external recipients or institutions have corrected their actions without evidence of that correction.

E200-020 Where the package records practical uptake of a claim, it shall distinguish the claim, its assessment, the institutional or other action, the actor responsible, and the asserted basis for acting. Recorded consequences and proposed remedies shall remain separately attributable from the original grounds and intended effects.

E200-021 For a challenge received within the package's declared collection boundary, the package shall record the challenged claim version, challenger or protected source reference, grounds and submitted material, receipt context, and current status. A disposition shall record the responsible role, response, reasons, date, unresolved disagreement, and resulting changes or the reason for no change. A challenge without disposition shall remain visibly pending or otherwise explicitly unresolved.

This clause addresses the record of a challenge. Fair routes for submission, notification, review independence, timeliness, appeal, and remedy are future procedural requirements in GR-210 and relevant institutional profiles. Merely supplying challenge fields does not demonstrate that a person can effectively contest a decision.

6 Machine mediation, protected material, and layered judgments

E200-022 Where computational mediation materially affects a claim's observation, classification, inference, reconstruction, or presentation, the package shall identify the system and available version, its task, supplied source material or its controlled reference, material transformations, output used, and the role responsible for uptake or review. Unavailable system details and resulting limits shall be stated. Generated output shall remain distinguishable from independent source evidence.

This requirement includes rules, statistical models, sensor processing, database transformations, and generative systems when material to the claim. It does not require exhaustive logs of unrelated operations or disclosure of private credentials. A vendor confidence score does not automatically measure the warranted confidence in the package's substantive claim.

E200-023 Where claim context or evidential material is restricted, the package shall identify the restriction and its asserted basis, responsible custodian or accountable role, assessment consequence, and any available route for authorized examination or challenge. A released view shall identify material omissions at a level permitted by the declared protection arrangement and shall not describe unavailable evidence as independently examined.

If even acknowledging an item is restricted, the released view can describe its assessed scope without exposing item-level existence. The protected package still needs an accountable restriction record. This clause supplies neither permission to disclose nor a legal retention rule. Where a reviewer cannot assess a required component, E200-002 requires an unassessed result; a protection reason does not turn missing verification into a pass.

E200-024 A normative or ethical assertion shall identify the evaluative question, attributed evaluator, stated criteria or values, affected parties and scope, and material acknowledged tradeoffs or disagreements. It shall remain distinguishable from the descriptive claims on which it relies and shall not treat a claimed generative effect as inherently desirable.

E200-025 A legal or jurisprudential assertion shall identify the asserted legal concept, source or rule relied upon, relevant institutional or jurisdictional context, attributed authority, temporal applicability, and procedural status, or explicitly state which are unresolved. It shall distinguish a descriptive legal analysis, party allegation, institutional determination, model rule, and policy proposal where applicable. Recording the assertion shall not be represented as creating or confirming its legal effect.

E200-026 When a package is selected, summarized, exported, or transformed and the resulting package is claimed to conform to this draft, it shall preserve the attribution, claim-version relationships, epistemic qualifications, material disagreement, and access/reconstruction limits required within the resulting declared boundary. Omitted or transformed content and the resulting limits shall be identified; a partial view shall not imply completeness of the source package.

This is an implementation-neutral requirement on the resulting package. Format negotiation, transport, identifiers, validation vocabulary, and machine-readable exchange behavior belong in Specifications prompted by the demonstrated need.

7 Worked example (informative; synthetic)

This invented case tests recording distinctions. It supplies no claim about an actual institution or applicable law.

Target. Whether request Q arrived before the deadline specified in a synthetic institution's internal rule R1. The asserted rule and whether it applies are separate claims.

C1 version 1. Clerk A reports that Q arrived after the deadline, inferred from entry log L1. Target time is the claimed receipt time; recording time is the later creation of C1. The method assumes entry time matches receipt time.

Evidence use. L1 supports that an entry occurred at the recorded time. Reviewer B records that its support for receipt time depends on the untested assumption about queue delay. Three copies of L1 are not independent corroboration.

Alternative C2. A protected participant reports earlier delivery; a receipt image R2 is available to an authorized reviewer. The public view identifies restricted evidence and the scope of examination without naming the participant.

Action D1. The institution records exclusion of Q using C1 and R1. This is an attributed institutional act. Its occurrence, justification, and any claimed legal effect remain separate.

Challenge CH1. The participant challenges C1 and provides R2. The record includes the challenged version and receipt time of the challenge; a pending challenge is not displayed as a completed review.

C1 version 2. Review establishes that the entry occurred later than the claimed delivery. The assessed receipt time changes; the entry event does not. The revision links its grounds to R2 and records the continuing uncertainty. C1 version 1 and D1 remain identifiable historical records.

Dependency review. D1 is marked for review. Until a later action is evidenced, correction of C1 is not displayed as restoration of Q's participation. The record can identify consequences of the interval of exclusion separately.

Regime change. If the institution later defines arrival by a different channel, the change of rule/category has its own effective interval. It does not silently recode earlier evidence or establish that earlier actors used the new meaning.

8 Candidate assessment matrix

The following evidence methods are proposed for future assessment. They specify discriminating checks and failure cases; this draft does not claim these cases have been implemented or passed. Each applicable requirement needs its own result even where several use the same dossier. Human review is necessary for meaning, rationale, and sufficiency of disclosure; structural field validation alone is inadequate.

Requirement	Candidate evidence and discriminating check
E200-001	Inspect package declaration and selected claim inventory. Check that a consequential excluded record is disclosed by the collection rule or limitation.
E200-002	Inspect result ledger and evidence locators. An inaccessible required component is not assessed; a syntax pass is not labeled a true fact.
E200-003	Retrieve two versions and two conflicting claims concerning Q. Their content and targets remain distinguishable.
E200-004	Follow testimony through a translator or summarizer. Originating source and recorder remain separate, including protected attribution.
E200-005	Inspect C1. Its late-arrival inference is not presented as direct observation merely because L1 was directly read.
E200-006	Recover the entry-time assumption and method for C1. A missing method produces a stated limit, not a reproducibility claim.
E200-007	Compare a single intake desk's coverage with an institution-wide assertion. A known unobserved delivery route remains a limitation.
E200-008	Recover receipt, acquisition, entry, and review times or their explicit uncertainty; out-of-order recording does not reorder events.
E200-009	Examine an organizational replacement using a reused name. An identity criterion and separate lineage prevent automatic merger.
E200-010	Locate the relevant L1 entry and R2 image or controlled locators; derived transcript and original are distinguished.
E200-011	Recover L1's separate evidential roles for entry time and delivery time, including rationale and assessor.
E200-012	Present three copies derived from L1. Assessment detects shared origin instead of counting three independent observations.
E200-013	Remove the log for one delivery channel. No receipt found remains distinct from evidence that no request arrived.
E200-014	Inspect uncertainty about queue delay and a confidence quantity if used. Its measured quantity and assumptions are explicit.
E200-015	Recover C2 and reasons for its disposition. If no alternative search occurred, the absence of search remains visible.
E200-016	Compare log authenticity check, receipt-time assessment, and D1 decision. Their questions, roles, criteria, and results are distinct.

Requirement	Candidate evidence and discriminating check
E200-017	Retrieve C1 versions and changed grounds. Target change, correction, and category change produce different stated reasons.
E200-018	Apply a category split to records lacking the finer information. Mapping records non-recoverability rather than invented categories.
E200-019	Follow C1 to D1. Pending action review is distinguishable from completed correction and from an unreachable external use.
E200-020	Recover D1, the claimed authority for action, and separately attributed consequences. No automatic remedy is inferred.
E200-021	Trace CH1 receipt through pending and disposed states. A closed status without response, responsible role, and reasons fails.
E200-022	Add a machine summary that invents a link. Recover input, system/version where available, output used, uptake role, and correction.
E200-023	Compare protected dossier and released view. Restriction basis and accountable route are recorded without unauthorized disclosure or a false independent-review claim.
E200-024	Inspect an assessment that exclusion was unfair. Criteria, affected parties, and descriptive premises are distinguishable.
E200-025	Inspect an allegation of unlawful exclusion. Asserted source, jurisdiction, authority, and procedural status are stated or unresolved; no legal effect follows from technical compliance.
E200-026	Examine a textual summary or exported dossier. Correction, dissent, attribution, scope, and protection limitations survive or omissions are explicit.

9 Source trace and requirement rationale (informative)

References are to the supplied local PDFs indexed in `foundation_manuscripts/MANIFEST.md`; page numbers are one-based PDF pages. Source passages provide conceptual grounds, not adopted requirements. No external compatibility or legal claim is made.

Source	Operational proposal and reason
FM-004, §4.2, pp. 11–14; §4.6, pp. 43–45	E200-003–008 distinguish target, manifestation, representation, and observation conditions. A single undifferentiated fact field cannot preserve these questions.
FM-005, §5.4, pp. 28–31	E200-010–013 assign evidence roles relative to claims and preserve trace paths, alternatives, and dependence. Material presence alone does not establish relevance or independent corroboration.
FM-005, §5.17, pp. 141–142	E200-014/015 preserve dimensional uncertainty and alternatives. A single mandatory confidence score was rejected for this draft because methods and uncertainty sources differ.
FM-007, §7, pp. 26–29	E200-009 separates record references, identity criteria, and lineage, permitting unresolved matches. Administrative identifier equality is insufficient as a universal criterion.

Source	Operational proposal and reason
FM-005, §5.20, pp. 168–174	E200-017–020 distinguish evidential, intervention-related, historical, and category revisions, and the historical effects of an earlier representation. Silent overwrite loses those distinctions.
FM-005, §5.19, pp. 160–161, 168	E200-021–023 make machine mediation and contestability inspectable while allowing differentiated access. A declaration that "AI was used" omits material epistemic conditions.
FM-003, §3.10.9, p. 115; §3.13, pp. 141–142	E200-024 separates generative attribution from ethical evaluation and records affected parties and criteria. No universal beneficialness or commensuration is assumed.
Programme Brief, §3A; repository jurisprudential discipline	E200-025 preserves the asserted basis and status of legal claims. This is a recording boundary proposed by the programme, not a legal conclusion derived from a manuscript.

The selected direction is an inspectable claim package with attributed relationships and scoped evidence. Alternatives included a single verified-fact flag, a mandatory new ontology class for every assertion, and a fully specified adjudication process inside this document. The first loses distinctions; the second prematurely fixes implementation architecture; the third conflicts with the planned separation of epistemic representation from GR-210 procedures. The present choice leaves representation and procedural elaboration open while producing requirements that a small synthetic dossier can test.

10 Open issues and specification needs

- **OPEN — Representation.** Whether claim identity is implemented through objects, qualified statements, wrappers, or hybrids requires disagreement, revision, protection, and exchange cases before a Specification decision.
- **OPEN — Burden.** Initial review needs to measure time and participant burden as well as field completeness. Shared context can reduce duplication, but a package-wide statement must not conceal claim-specific differences.
- **OPEN — Evidence assessment granularity.** The minimum useful rationale varies across testimony, measurement, historical interpretation, and routine record entries. Domain profiles need cases and relevant expertise.
- **OPEN — Challenge procedure.** GR-210 needs submission routes, standing, accessible participation, impartial assessment, notification, reasons, timing, appeals, and repair. E200-021 records their results without claiming these practices exist.
- **OPEN — Retention and restriction conflicts.** Historical reconstruction, deletion, protection, and procedural examination can conflict. Named institutional and jurisdictional profiles need explicit review; this draft imposes no universal retention period or disclosure priority.
- **OPEN — Technical needs.** Independently addressable versions, evidence-role links, dependency notifications, missingness states, controlled locators, and loss-aware transformations are candidate inputs to GR-SPEC-120/130/200. No encoding or transport protocol is adopted here.

- **OPEN — Conformance practice.** The matrix is a review design, not a completed validator or certification programme. Independent reviewers need to test whether the same package yields reproducible assessments and whether affected participants can recover its meaning.

GENERATIVITY STANDARDS PROGRAM

GR-210

Evidence, Interpretation, and Contestation

Standards-track Working Draft

Draft version 0.1

22 September 2026

WORKING DRAFT FOR REVIEW

This document is not adopted. Its requirement language expresses proposals for review and rehearsal. Preparation of this text does not establish programme governance, approve a formal standards project, or certify substantive truth, legal validity, or institutional legitimacy.

Publication class, scope, dependencies and unresolved decisions are stated in the document. No ISO, IEC or IEEE affiliation or endorsement is claimed.

8 Protection and retention 5

9 Conformance and assessment 5

10 Informative source rationale and open questions 6

1 Scope and authority

Responsible editor: UNASSIGNED. Canonical source: standards/GR-210-evidence-interpretation/GR-210.tex. Intended readers are procedure operators, affected people, reviewers and assessors.

This document proposes requirements for a bounded procedure through which people can question an attributed account, introduce evidence or an alternative interpretation, obtain a reasoned disposition and seek further review. Its subjects are the procedure operated by a named organization or recording practice and the associated case record.

An evidential assessment, a procedural disposition, an institutional action and an externally competent legal finding remain distinct. This draft provides no universal tribunal, evidentiary ranking or legal right to review. A conforming procedure can conclude that the available evidence does not resolve the dispute.

The document is preparatory standards-track authoring. It is not adopted and the work item is not represented as formally initiated. GR-100 Working Draft 0.1 supplies operational vocabulary. Material claims in a case record are assessed under GR-200 Working Draft 0.1. Both are draft dependencies. GR-110 concerns the broader recording package; full GR-300/310/400 profiles remain in development.

2 Procedure declaration

C210-001 The operator shall publish or otherwise provide an accessible procedure declaration identifying its purpose, eligible users, covered records or decisions, responsible roles, asserted authority, submission routes and exclusions.

C210-002 The declaration shall distinguish technical correction, evidential disagreement, procedural complaint, ethical or conduct complaint and an asserted legal claim, identifying their available handling routes and limits of authority.

C210-003 The operator shall declare response and review periods, their start events, permitted extensions, notice arrangements and the route available when a period is exceeded. The chosen periods shall be justified for the institutional context and affected users.

C210-004 The operator shall declare the information needed to submit a case, the support or alternatives available to users and how restricted evidence or protected identities can be handled. A demand for unnecessary public disclosure shall not be a condition of receipt.

Informative note. No universal period is selected here. The programme's own standards-development comments and appeals are governed by Directives Part 1 if adopted; an institution using records has its own declared procedure and legal context.

3 Receipt and scoping

C210-005 On receiving a submission, the operator shall create a distinguishable case reference and record receipt time, the target record or decision and version if available, the asserted issue and the submitter's attribution or protected-contact arrangement. Receipt shall not be reported as agreement with the submission.

C210-006 The operator shall acknowledge receipt through the declared route or record why acknowledgment is not possible. The response shall explain the next step, expected timing and any missing information needed for further action.

C210-007 Where a case is out of scope, incomplete, duplicated or directed to the wrong recipient, the operator shall record that procedural reason and any available correction or referral route. That outcome shall not be represented as factual refutation.

C210-008 Any restriction on repetitive or abusive submissions shall use declared criteria, record the reason and preserve a route to challenge the restriction. The operator shall not classify a submission as abusive solely because it criticizes an authoritative account or repeats an unresolved material concern.

4 Review responsibilities and participation

C210-009 Before substantive review, the operator shall identify the reviewer or review function, relevant competence, relation to the contested account and conflicts of interest. Material conflicts shall be handled through recusal, reassignment or a disclosed limitation with an appropriate further-review route.

C210-010 The reviewer shall identify the questions within the case, the relevant claim versions, evidence available, known limitations and decision criteria. Factual, normative, procedural and legal questions shall remain distinguishable.

C210-011 Affected parties shall be given an opportunity to respond to material grounds used in the disposition through a procedure consistent with protection and applicable institutional constraints. Where direct disclosure is restricted, the operator shall explain the permitted alternative and its limits.

C210-012 The operator shall record participation barriers known to affect the case, assistance or adjustments offered and material perspectives that could not be obtained. Absence of a response shall not automatically be represented as consent or admission.

Informative note. A reviewer cannot promise that every perspective will be available. The proposed obligation is to expose the evidential and procedural consequence of a material gap.

5 Evidence and interpretation

C210-013 An assessment shall identify the claim under examination, the evidence relied on, how that material bears on the claim, relevant method and assumptions, and known counterevidence or materially plausible alternatives.

C210-014 The reviewer shall distinguish the authenticity or integrity of a source from the warrant it provides for a particular claim. A signed assertion shall not receive an unqualified truth status merely because its signature validates.

C210-015 A conclusion based on missing evidence shall identify the expected trace-production, observation or preservation conditions supporting that inference. Where those conditions are not established, absence of the record shall remain distinguishable from non-occurrence.

C210-016 The assessment shall state uncertainty and its scope without inventing a common probability scale for heterogeneous judgments. Disagreement among assessors shall be attributed and retained where material and permitted.

C210-017 Where a category, method or institutional rule is challenged, the reviewer shall distinguish whether it was applied correctly from whether its adequacy or legitimacy is itself under review. A correct application shall not by itself dispose of a challenge to the rule.

C210-018 A material computational or AI-assisted contribution to the review shall be identified with the inputs or sources available for inspection, its role, relevant limitations and responsible human or institutional uptake. An inaccessible internal process shall not be replaced by an invented explanation.

6 Disposition and practical response

C210-019 The disposition shall state the questions decided, findings and their scope, evidence and reasons, responsible decision function, decision time, remaining disagreement and matters outside its authority.

C210-020 The disposition shall distinguish correction of a record, changed evidential assessment, maintained judgment, changed institutional action, inability to decide and procedural closure. Procedural closure shall not imply epistemic agreement.

C210-021 Where the procedure supports a remedy or practical response, the disposition shall identify the proposed or authorized action, its responsible executor, scope, timing and evidence needed to establish completion. Recording a proposed action shall not establish that it occurred.

C210-022 The operator shall notify the submitter and other relevant recipients through the declared, permitted routes, explain any further-review route and record delivery or known failure. Public notices shall respect the case's disclosure limits.

C210-023 A material correction shall be linked to the earlier account and known dependent views or decisions. The operator shall record which corrections or notices were performed and which downstream effects remain unresolved.

Informative note. A corrected classification can leave lost opportunities, costs or harm unremedied. The procedure records the distinction rather than declaring repair complete because a field changed.

7 Further review, reopening and continuity

C210-024 The procedure shall provide a declared route to request reconsideration of a material error, new evidence or procedural failure, with its scope, competent recipient and limitations. A reviewer of their own contested action shall not be described as independent.

C210-025 A reopened case shall identify the earlier disposition, trigger, changed evidence or criteria, reviewer and new outcome. Later interpretation shall not silently replace the record of what was known or decided earlier.

C210-026 If the operator lacks competence, authority or resources to complete a material step, it shall record the limitation and notify permitted recipients of the available alternative, postponement or closure basis. Passage of time alone shall not establish a finding on the substantive claim.

8 Protection and retention

C210-027 The operator shall specify access, retention, correction and disposal arrangements for submissions, evidence, reviewer notes, dispositions and notifications. Content and audit metadata shall be considered separately; history preservation shall not justify retaining prohibited sensitive material.

C210-028 Disclosure, redaction, access withdrawal or disposal affecting a case shall identify its authority, scope, executor and permitted evidence of the action. The operator shall state known limits concerning copies outside its control.

C210-029 A public summary shall distinguish the accessible grounds from material that cannot be disclosed, where that distinction is itself permitted. It shall not claim full independent inspectability when a material evidential restriction prevents it.

9 Conformance and assessment

C210-030 A conformance report shall identify the procedure or case record assessed, operator, institutional context, this draft and dependency versions, applicable requirements, reviewer relationship, evidence and results. It shall identify the case's material claims as a bounded GR-200 Working Draft 0.1 package and report its applicable requirement results, including package-level obligations. A case-record assessment alone shall not establish that unobserved procedural steps occurred.

C210-031 Each applicable requirement shall receive a supported result of fulfilled, not fulfilled or not assessed; a not-applicable result shall give its trigger-based reason. An unqualified claim of fulfillment shall not omit a failed or unassessed applicable requirement.

C210-032 A procedure assessment shall include an ordinary case and relevant failure cases concerning conflict, unavailable evidence, missed timing, restricted disclosure and correction propagation. A case-record-only assessment shall identify the supplied case and the procedural behavior it cannot establish. Reported success shall be limited to the cases and conditions actually exercised.

This edition defines no reduced case-record conformance profile. A case-only report is a partial documentary assessment. Performance obligations remain not assessed when only their records were examined; not applicable requires an absent stated trigger. A procedure claim covers all applicable requirements and the declared GR-200 package dependency. The multi-case rehearsal obligation in C210-032 is explicitly conditional on procedure assessment.

The following table provides informative methods for the initial rehearsal.

Requirements	Evidence	Failure case
C210-001–004	Procedure declaration and accessible submission exercise	Unstated period, inaccessible route, ungrounded authority.
C210-005–008	Receipt, acknowledgment and scope record	Receipt called acceptance; rejected submission called false.
C210-009–012	Reviewer assignment, conflict and response records	Original author silently decides their own procedural appeal.

Requirements	Evidence	Failure case
C210-013–018	Attributed assessment with evidence and alternatives	Missing metadata treated as proof of non-occurrence; AI summary treated as an observed fact.
C210-019–023	Reasoned disposition, action and notice records	Correction claimed complete without checking known dependent views.
C210-024–026	Further-review and reopening trace	New evidence cannot be submitted; timeout treated as agreement.
C210-027–029	Authorized and public views; scoped disposal trace	Restricted log reproduced in a public appeal report.
C210-030–032	Requirement register and rehearsal evidence	One synthetic case presented as independent live institutional assurance.

10 Informative source rationale and open questions

The synthetic funding case accompanying GR-110 supplies a common example. The procedure's record requirements can be implemented manually before a network protocol is needed. A later Specification would define message correlation, delivery, authorization, concurrent revision and failure semantics in response to demonstrated requirements.

Source and interpretation. FM-005, GRE Chapter 5, section 5.4, pp. 28–36, grounds the distinction between trace and evidence; sections 5.18–5.20, pp. 150–176, motivate participation, machine mediation and revisability. FM-003, GRE Chapter 3, section 3.12, pp. 129–141, motivates practical response and repair. FM-007, Metamodel Part II, sections 16 and 19, pp. 75–78 and 87–90, distinguishes factual warrant, institutional uptake and the evidence needed to evaluate a representation.

The design is a proposed operational procedure recorded in ADR-0004, not a claim that the source manuscripts prescribe this exact sequence. No external legal instrument is a normative dependency of this draft. The cross-domain programme identifies possible legal and policy sources for later contextual analysis.

OPEN. Service periods, independence arrangements, proof of authority, available remedies, costs and admissible disclosure depend on the institution and require a scoped profile. A synthetic procedure cannot establish their validity in a live jurisdiction.

OPEN. Abuse handling, protection of vulnerable participants, meaningful access under low resources and the burden of keeping case histories require review with affected users before live deployment.

GENERATIVITY STANDARDS PROGRAM

Programme Charter

Governance Working Draft

Version 0.2 2026-09-22

Standards Programme Charter

WORKING DRAFT FOR REVIEW

This document contains proposed provisions for technical and institutional review. It is not an adopted Standard or an operative governance instrument. Its scope, application conditions and publication status are specified in the text.

Prepared by the Generativity Standards Program. Reference to external publications does not imply endorsement by ISO, IEC, IEEE or any United Nations body.

Foreword

This document establishes proposed governance requirements for the Generativity Standards Program. It is a Governance Working Draft prepared for review, not an adopted Charter or technical Standard. Its authority depends on the founding procedure specified herein. The foundation manuscripts supply conceptual source authority; they do not constitute a governance adoption instrument.

Responsible editor: `UNASSIGNED`. Canonical source: `governance/standards_programme_charter.tex`. Intended readers are founding participants, administrators, reviewers, contributors, and affected people. Version 0.2 develops authority, participation, resources, oversight, transition, and assessment while retaining the requirement identifiers and obligations introduced in version 0.1.

This document is part of a coordinated draft governance package. Numerical development periods and ballot rules are specified in Directives Part 1. This Charter establishes the powers and accountability within which those rules operate.

Bibliography 14

Introduction

The programme responds to instability in the connections among representations, their referents, institutional classifications, and practical trust. Its purpose is to support warranted recognition, reasoned contestation, revision of judgment and action, and preservation of consequential generative trajectories. This includes the conditions under which people can produce evidence, inspect grounds, and influence practices that affect their future possibilities.

The programme's own decisions can shape which accounts are recognized and which infrastructures become authoritative. Governance therefore forms part of the programme's substantive task. Open documents alone do not demonstrate accessible participation; a recorded vote does not establish truth; and a maintained history does not by itself repair the consequences of a mistaken decision. The requirements below assign functions, make their exercise inspectable, and provide routes to correction within the programme's actual authority.

The initial model uses individual contributions and explicitly delegated functions. It permits a small organization without presuming that named committees, independent reviewers, funding, or institutional mandates already exist. A transition to another participation model remains subject to recorded amendment.

1 Scope

1.1 Subject and application

This Charter specifies requirements for the programme's founding, mission, publication authority, participation, appointments, decision accountability, resources, records, external relations, and institutional continuity. The assessed subject is the programme's governance arrangement and its exercise during a declared review period. A work item or publication can supply evidence of that exercise without itself constituting governance adoption.

1.2 Boundaries

The portfolio includes recording, preservation, exchange, presentation, assessment, contestation, revision, and accountable institutional use of generativity-related records. The Charter does not settle a complete metaphysics or create authority over external legal decisions. Its requirements concern decisions and resources within the recorded programme mandate.

2 Normative references

2.1 Coordinated draft dependencies

The following documents contain provisions needed to apply identified requirements of this Charter. The cited editions are Governance Working Drafts, version 0.2. Their listing establishes a draft dependency only. The founding instrument fixes the exact coordinated editions accepted for operation.

Directives Part 1 — Procedures for Development and Maintenance. `governance/directives_part_1.tex`. Provides development stages, review periods, dispositions, ballots, appeals, emergency action, and maintenance procedure.

Directives Part 2 — Structure and Drafting Rules. `governance/directives_part_2.tex`. Provides publication classification, provision structure, traceability, and production requirements.

GR/TC 1 Charter — Generativity Records and Infrastructure. `governance/technical_committee_charter.tex`. Defines committee scope, technical coordination, review, and pilot responsibilities.

Ethics, Conflict-of-Interest, and Contribution Rights Policy. `governance/ethics_ip_policy.tex`. Provides conduct, conflict, impact, contribution, and rights-handling requirements.

2.2 Use of references

CH-042 The founding or amending authority shall identify the exact coordinated governance editions, resolve conflicting provisions, and record the resulting allocation of authority before dependent decisions proceed. A later draft of a referenced document shall not replace the operative edition automatically.

External sources listed in the bibliography are informative. Their citation neither incorporates their procedures wholesale nor grants their institutional authority.

3 Terms and definitions

3.1 Programme authority

A person or constituted body with an expressly recorded mandate to decide specified programme matters. The term identifies the scope of decision power; it does not imply governmental authority or legal

personality.

3.2 Founding instrument

The record of actual signatories, capacities, express commitments, accepted governance editions, effective conditions, appointments, and limits by which the programme adopts its initial governance.

3.3 Delegation

A bounded assignment of a function by an authority entitled to assign it, together with responsibility, limits, duration or review point, and reporting obligations.

3.4 Affected interest

A person, group, practice, or condition materially affected by a proposed programme activity. An identified affected interest does not imply that a particular participant represents it.

3.5 Decision eligibility

Recorded authority to participate in a particular formal decision under announced criteria. It is distinct from the opportunity to contribute or comment.

3.6 Material governance change

A change affecting authority, decision eligibility, participation rights, appeal independence, publication powers, essential resources, or the ability to maintain operative obligations.

3.7 Reserved decision

A decision retained by the programme decision authority rather than assigned to an editor or administrator. Its classification concerns programme accountability and does not establish a legal classification.

3.8 Governance evidence

Records or observed actions supporting an assessment of a governance requirement, identified by version, custodian, access conditions, and relevant limitations.

4 Mission and programme commitments

4.1 Mission application

CH-006 Programme publications shall distinguish metamodel, record ontology, epistemic representation, normative assessment, jurisprudential status, institutional governance, political economy, and technical implementation wherever a requirement or claim depends on more than one of these layers.

CH-007 The programme shall preserve the distinction between theoretical GR concepts and scoped operational requirements. Intentional narrowing, operationalization, or departure shall identify its foundation sources, alternatives, rationale, and recorded architectural decision.

CH-008 Programme publications and public claims shall not present technical conformance, authentic provenance, a programme decision, or a recorded institutional finding as sufficient proof of factual truth, ethical legitimacy, legal validity, or international endorsement.

CH-009 The programme shall identify jurisdictional and institutional authority separately whenever a proposal concerns legal duties, rights, admissibility, liability, or public power. Unresolved applicability shall remain explicit.

CH-003 Each proposed programme work item shall identify the recognition or practical problem it addresses, its intended beneficiaries and affected interests, its anticipated contribution to the mission, and the evidence by which that contribution will be evaluated.

CH-004 Programme evaluations shall distinguish demonstrated improvements in recording, interpretation, contestation, or practical response from broader claims about restored trust, justice, or future generative capacity. A broader claim shall identify its evidence and limitations.

CH-005 The programme shall examine its own classification, recording, decision, and publication practices as potential sources of exclusion, dependency, and concentrated authority. Findings and corrective decisions shall enter the programme's maintained issue record.

CH-043 The programme decision authority shall maintain a current statement of objectives that links active work to the mission, identifies the practical capacities being developed, and distinguishes intended benefits from effects supported by evaluation. Each annual review shall examine whether the active portfolio still addresses those objectives.

4.2 Selection and review of work

CH-044 When prioritizing work, the programme decision authority shall record the relative need, affected interests, alternatives to new standardization, resource demands, dependencies, and consequences of delay. A priority based on available funding shall identify the resulting coverage gaps and influence conditions.

CH-045 Where evidence shows that a programme activity materially undermines participation, inspectability, contestation, or future access, the responsible authority shall examine revision, narrowing, suspension, or closure and record the chosen response and follow-up evidence. Publication volume shall not alone justify continuation.

5 Publication authority

5.1 Classes and approval boundaries

CH-010 Each publication shall declare its class, maturity, version, responsible editor, and decision authority. Specifications, adopted Standards, policy proposals, governance documents, Technical Reports, and manuals shall retain their distinct authority.

CH-011 The programme shall reserve the designation adopted Standard for an edition approved under its operative development procedure. A draft, schema, prototype, protocol, or technically normative Specification shall not acquire that designation through technical completion alone.

CH-012 Standards-track work shall begin with a stated normative problem, scope, terminology, intended requirements, conformance subjects, and relevant constraints. A dependent Specification work item shall identify the reusable technical need that motivates it. Draft requirements and Specifications may co-evolve through pilots and review.

CH-013 A policy proposal shall identify its intended institution or class of institutions, mandate assumptions, institutional alternatives, expected effects, safeguards, and evaluation approach. Its recommendations shall not amend technical conformance requirements outside the standards-development procedure.

CH-014 Formal work-item approval shall depend on the governance launch conditions in this Charter and Directives Part 1. Preliminary source research, draft preparation, synthetic examples, and technical exploration shall retain their preliminary status while those conditions remain unmet.

5.2 Reserved and delegated powers

CH-046 The programme decision authority shall reserve approval of governance amendments, creation or material alteration of committee mandates, formal work-item initiation, Standard adoption, substantive publication maintenance, and agreements creating programme commitments. A delegation of an operational step shall not transfer a reserved decision unless the operative founding or governance instrument expressly permits it.

CH-047 An editor or repository administrator shall exercise only recorded editorial or custodial powers. Technical ability to merge, publish, assign identifiers, change access, or remove material shall not substitute for authorization of a substantive decision.

CH-048 Before an authorized release, the release owner shall verify the applicable adoption or publication decision and the exact artifact set. If the intended public statement exceeds the recorded decision, the statement shall be corrected or referred for a new decision before release.

6 Participation and consideration

6.1 Entry and access

CH-015 The programme shall provide a documented route for interested individuals to contribute proposals and comments and to receive reasoned dispositions. Employment, institutional sponsorship, a proprietary tool account, payment, or travel shall not be a prerequisite for submitting a relevant comment.

CH-016 The participant register shall distinguish participation in an individual capacity from authorized institutional representation. It shall record relevant affiliations, interests, assigned roles, and any limits on a representation mandate, subject to justified protection of sensitive information.

CH-017 For each work item, the coordinator shall identify affected interests, reviewer competence needed, known participation gaps, outreach undertaken, and feasible measures for language, disability, time-zone, connectivity, and resource barriers. Unfilled gaps shall remain visible in progression decisions.

CH-018 The programme shall provide an asynchronous contribution route and a human-readable account of proposed substantive changes. A contribution requiring assistance with format shall be assessed for its substance after proportionate assistance or an accessible alternative has been offered.

CH-049 The coordinator shall publish the purpose and actual availability of each contribution route, the information needed to handle a submission, access and attribution choices, and the process for obtaining assistance. Failed contact, inaccessible material, or unmet accommodation shall be recorded and referred to the responsible review chair.

6.2 Consideration and protection

CH-019 Funding, institutional affiliation, authorship volume, technical access, or control of repository credentials shall not by itself confer decision rights or priority in comment disposition. The decision authority shall assess whether concentrated interests or unpaid-work burdens materially limit fair consideration.

CH-020 Any restriction on participation shall state the conduct or process reason, its scope, duration or review trigger, responsible decision maker, and available challenge route. Restrictions shall not be

imposed solely because a participant disputes a proposal or authoritative interpretation.

CH-050 Before closing a review, the review chair shall examine recorded access failures and participation gaps, determine their materiality to the decision, and document extension, targeted outreach, alternative access, narrowed claims, or deferral as appropriate. The absence of a complaint shall not alone establish adequate access.

CH-051 When an affected person cannot participate through the published format, the coordinator shall offer a feasible alternative or explain the resource limitation and a route to review it. An assisted submission shall preserve the contributor's intended meaning and identify substantive interpretation by the assisting person.

CH-052 The programme shall distinguish endorsement, consultation, contribution, representation, and assent in public accounts. A participant's name, affiliation, or contribution shall not be used as evidence of support for a decision without an established basis for that attribution.

6.3 Decision eligibility

CH-039 Before constituting a decision roster, the programme decision authority shall publish the proposed decision scope, nominations route, closing date, competence or affected-perspective criteria, expected review commitment, and conflict rules. Eligible individuals shall have an accepted bounded role, disclosed relevant interests, agreed applicable conduct terms, and a recorded capacity for the particular decision. Institutional representation shall require an identified mandate.

CH-040 Selection to or exclusion from a decision roster shall have recorded reasons against the announced criteria and an available procedural challenge. The authority shall assess concentrated interests and missing perspectives before fixing the roster. A roster shall not change during a ballot except through the correction and restart rules of Directives Part 1.

CH-053 A change in an eligible person's affiliation, capacity, or material interest shall be assessed before their next affected decision. The coordinator shall record whether the accepted role remains valid, requires a new mandate, or requires recusal or replacement under the operative procedure.

Eligibility establishes a bounded role. It does not give priority to a participant's factual assertion or make institutional status a substitute for reasons and evidence.

7 Organization and accountable appointments

7.1 Required functions

The minimum functional arrangement comprises founding authority, programme decision authority, coordinator and records custodian, committee convenor, editors or work-item leads, independent procedural review, ethics contact and alternate, rights review, release ownership, and maintenance ownership. All actual appointments are `UNASSIGNED` unless separately recorded.

The programme decision authority corresponds to the governance authority in Directives Part 1. The coordinator and records custodian performs the Secretariat function. The neutral procedural reviewer performs the independent appeal-review function. A review chair is assigned to a particular review. Functions can be combined where competence, capacity, and conflict controls permit.

CH-021 An appointment shall identify the person, appointing authority, accepted mandate, decision limits, relevant interests, start date, term or review date, alternate or vacancy arrangement, and removal or replacement procedure. An office shall not be treated as staffed until acceptance is recorded.

CH-022 The programme decision authority shall publish reasons for appointments, renewals, and

removals at a level compatible with necessary protection. A challenged appointment or removal shall have access to neutral procedural review under Directives Part 1.

CH-023 Where one person holds multiple functions, each decision record shall identify the capacity exercised and any resulting conflict. A person shall not conduct the neutral review of their own challenged decision.

CH-024 The programme shall not delegate a decision to an automated system. AI-assisted drafting, summarization, analysis, or validation shall retain an accountable human role responsible for checking the resulting material and recording consequential use.

CH-025 The programme shall not exercise a delegated function while its required responsible role is vacant or recused without an authorized substitute. Unaffected preliminary work may continue with its status declared.

7.2 Acceptance, performance, and replacement

CH-041 An appointment renewal or proposed removal shall receive a recorded grounds statement and an opportunity for the affected person and relevant participants to respond before a final decision. A non-conflicted authority shall decide the matter within its mandate and provide access to neutral procedural review. Urgent temporary protective measures shall follow the ethics policy and emergency procedure, with a stated review point.

CH-054 Before granting operational access for an appointed role, the appointing authority shall confirm the holder's accepted mandate, relevant competence or induction needs, conflict assessment, and knowledge of escalation and protection duties. Credentials shall be limited to the tasks actually assigned.

CH-055 Each role holder shall report inability to perform a material assigned duty, loss of required access, or a conflict preventing performance to the appointing authority. The authority shall assign an authorized substitute, narrow the activity, or defer dependent decisions and record the response.

CH-056 A role handover shall identify pending decisions, deadlines, records and access responsibilities, conflicts, accepted commitments, and unresolved risks. The outgoing and incoming custodians shall verify transferred access and the disposition of credentials; absence of an outgoing holder shall be recorded with recovery actions.

CH-057 Role performance review shall consider completion and quality of assigned duties, handling of objections, protection of records, influence concerns, and resource limits. An adverse assessment shall identify evidence and permit a response before a final appointment action, subject to time-limited protective measures.

8 Founding and decision accountability

8.1 Founding review and express adoption

CH-001 The programme shall identify this document as a Governance Working Draft until a founding adoption record identifies the adopting persons, their actual authority over programme resources and publications, the edition adopted, its effective date, and the scope of that authority.

CH-002 An adoption record shall distinguish the programme's own publication authority from any claim to represent a profession, institution, community, jurisdiction, or international constituency. Each representation claim shall identify its actual mandate and limits.

CH-036 Before founding adoption, the prospective founding signatories shall identify their actual capacities and proposed commitments, publish the exact governance package within cleared rights, identify

proposed appointments and decision-eligibility criteria, and announce a founding review that applies the public-review, comment-disposition, reply, and material-change periods in draft Directives Part 1 as explicit conditions of that founding process.

CH-037 The founding signatories shall execute an adoption instrument only after review dispositions, a governance rehearsal, accepted minimum appointments, and independent assessment of the founding process are recorded. The instrument shall identify each signatory's express agreement, scope of commitment, dissent, outstanding limits, and the exact texts adopted. A person or institution shall not be bound or represented by a signature that lacks actual authority.

CH-038 The founding instrument shall identify the first programme decision authority, its delegated limits, appointment and succession route, and review date. Founding adoption shall not itself approve GR/NWIP-001 or any technical Standard. Subsequent formal adoption and maintenance decisions shall use the applicable ballot and review rules of operative Directives Part 1, distinguishing substantive maintenance from editorial correction and confirmation.

CH-058 The founding review notice shall distinguish the proposed founding signatories from reviewers and commenters, identify the actual resources or functions they can commit, and explain how additional participation or an objection to authority will be considered. A claimed mandate disputed during review shall receive a reasoned disposition before reliance on that mandate.

CH-059 Execution of the founding instrument shall identify the exact agreement accepted by each signatory, any reservation and its agreed effect, verification of assent, and satisfaction of effective conditions. An unsigned field, synthetic signature, or recorded invitation shall not be treated as assent.

8.2 Readiness and decision evidence

CH-026 Each consequential progression, adoption, mandate, or appointment decision shall identify the operative procedure, authority, evidence considered, interests and recusals, alternatives, material objections, reasons, consequences, and review route.

CH-027 A claim of consensus shall include evidence that relevant concerns were considered and that remaining substantial objections received reasoned treatment. Silence, elapsed time, a vote total, or lack of a funded alternative shall not alone establish consensus.

CH-028 Before formal work-item initiation, the governance launch record shall identify the adopted Charter and Directives, committee mandate, ethics and contribution arrangements, public-review route, maintenance and records arrangements, accepted appointments, and an available neutral procedural review route. It shall include the results and dispositions of a governance rehearsal.

CH-029 If neutral review is unavailable for a consequential contested decision, the programme shall defer that disputed progression or adoption decision and record the capacity gap. The programme shall continue research and drafting that do not depend on the contested authority.

CH-060 The governance launch assessment shall classify each required capacity as available and evidenced, limited with a stated consequence, or unavailable. A rehearsal result shall be recorded separately from actual staffing, public review, permissions, and independent-review availability. Unmet mandatory launch conditions shall prevent formal work-item initiation.

CH-061 For a decision involving multiple functions, the decision record shall identify who prepared the evidence, who reviewed it, who decided, and who implements the result. Combined capacities shall be explicit, and the record shall identify which findings depend on independent consideration.

8.3 Amendment and interpretation

CH-030 An amendment to governance shall follow the change and review procedure in Directives Part 1, state its effective date and transition arrangements, and preserve the prior edition. A procedure shall not be changed retrospectively solely to validate a disputed decision.

CH-062 A request to interpret an operative governance provision shall identify the text, affected decision, competing readings, and practical consequences. The governance authority shall publish a reasoned interpretation within its mandate; an interpretation changing authority, eligibility, obligations, or minimum safeguards shall use the amendment procedure rather than operate as an editorial clarification.

CH-063 A governance amendment shall assess pending proceedings and identify the edition governing each transition. A pending participant's opportunity for reply or procedural review shall not be removed by an undisclosed change of rule.

9 Resources and infrastructure

9.1 Funding and expenditure authority

CH-031 The programme shall maintain an inspectable record of material funding, in-kind support, decision-related conditions, and control of essential infrastructure. Restricted details shall have a stated reason for restriction and an accountable reviewer.

CH-032 A funding or hosting arrangement shall not authorize a sponsor to suppress relevant criticism, require adoption of its preferred technical solution, or bypass review. Material changes in support shall trigger a capacity and continuity assessment.

CH-064 Before accepting material support or expenditure commitments, the authorized holder shall record the purpose, amount or nature of support, actual committing authority, conditions, expected benefit, duration, and effect on independence and continuity. A contribution shall not create an undisclosed priority or publication veto.

CH-065 The programme decision authority shall compare planned obligations with available financial, human, technical, and accessibility resources before authorizing an activity. An unfunded essential safeguard or maintenance duty shall be resolved by resourcing, scope reduction, or deferral rather than recorded as an assumed future capacity.

9.2 Custody and continuity

CH-066 The coordinator shall maintain an inventory of essential repositories, identifiers, contact routes, publication locations, build resources, and protected record stores, with accountable custodians, actual access, recovery arrangements, and dependencies on external providers. Sensitive recovery information shall be protected.

CH-067 The responsible custodian shall periodically exercise recovery of essential publication and decision records and record the recovered version, access limitations, failures, and corrective action. The review interval and extent shall reflect identified continuity risks and shall be included in the governance records schedule.

CH-068 Before a change of hosting or custody, the governance authority shall record preservation of identifiers, versions, access restrictions, permissions, and continuity of comment and review routes. Unrecoverable losses shall be disclosed with their effect on pending decisions and publication claims.

10 Records and external relations

10.1 Inspectable institutional history

CH-033 The records custodian shall maintain access to publication status, version history, work scopes, decision reasons, comment dispositions, and correction notices. Protection or deletion of underlying sensitive records shall retain a non-sensitive account of the action and its authority where permitted.

CH-069 The records custodian shall distinguish operative decisions from proposals, superseded decisions, implementation reports, and unresolved questions. Corrections shall link the changed account to the reason and authority, preserving prior material subject to the applicable protection and retention decision.

CH-070 Where a public account omits protected material, the custodian shall record the basis and scope of restriction and the availability of authorized review. The public account shall disclose its limitation without revealing protected existence, identity, or content where that disclosure would defeat protection.

10.2 Liaison, public statements, and agreements

CH-034 An external liaison, pilot, endorsement, submission, or agreement shall identify who is authorized to act, its purpose and limits, and any external institution's actual assent. Participation in the programme shall not be represented as institutional endorsement.

CH-071 An external agreement proposal shall identify the counterparty's actual mandate, authorized programme signatory, commitments and costs, control of resulting material, publication rights, protection duties, review and termination arrangements, and effects on programme independence. Unresolved authority or rights material to the agreement shall prevent execution of the affected commitment.

CH-072 An authorized spokesperson shall distinguish the programme's adopted position from personal analysis, a committee draft, or a policy option. An inaccurate public claim of adoption, affiliation, or representation shall receive a recorded correction through the same relevant communication route where feasible.

11 Oversight, transition, and closure

11.1 Programme review

CH-035 The programme decision authority shall review mission performance, participation gaps, concentrated influence, conflicts, unresolved appeals, review capacity, and maintenance resources at least annually with the programme account required by Directives Part 1 and after a material institutional change. The review shall record remedial actions, owners, and follow-up.

CH-073 The annual governance review shall identify open corrective actions, repeated procedural failures, unresolved capacity gaps, resource concentration, overdue maintenance, and the practical effects of earlier remedies. The authority shall assign owners, review points, and escalation conditions for actions it retains.

CH-074 A material governance failure shall receive an assessment of affected decisions and publications. The governance authority shall record whether renewed participation, independent review, correction, repetition of a stage, or suspension is required; correcting the administrative record shall not alone validate the original decision.

11.2 Transition and orderly closure

CH-075 A transition to institutional or hybrid participation shall identify representation mandates, decision eligibility, related-entity influence, existing participant treatment, resource needs, and appeal independence, and shall undergo Charter amendment before the new model governs decisions.

CH-076 A proposal to suspend or close programme operations shall identify the reason, actual deciding authority, current commitments, pending reviews and complaints, custodial destination of publications and protected records, rights limits, and feasible maintenance or withdrawal arrangements. The transition shall be reviewed under Directives Part 1 before permanent disposition.

CH-077 A closure or suspension notice shall state which activities stop, which publication statuses remain operative or change, the custodian and available contact route, and unresolved matters. It shall not represent loss of operational capacity as erasure of historical decisions or as retroactive cancellation of external uses.

12 Assessment

12.1 Subject, evidence, and findings

CH-078 A governance assessment shall identify the operative or experimentally assessed edition, review period, scope, assessor, interests, and evidence for each applicable Charter requirement. Results shall distinguish fulfilled, not fulfilled, not assessed, and not applicable, with reasons and corrective actions.

CH-079 An assessor shall examine actual records and demonstrated routes relevant to the claim, including appointments, decision authority, access, recusal, independent review, resources, and continuity. A blank template, announced intention, or unperformed rehearsal shall not be accepted as evidence of completed performance.

12.2 Response and follow-up

CH-080 The programme decision authority shall respond to material assessment findings with an action, owner, due or review date, and consequence for dependent decisions. A finding shall be closed only with recorded evidence of the action or a reasoned change of scope, while preserving any unresolved historical effect.

Annex A

(normative)

Minimum governance evidence records

A.1 Common record elements

CH-081 Each governance evidence record shall include a stable identifier, record type, responsible actor, relevant date or interval, applicable governance edition, subject and version, evidence location or access limitation, status, related records, and correction history. Unknown information shall be explicitly identified rather than supplied by inference without attribution.

A.2 Authority and appointment record

The authority and appointment record contains: actual person or body; source and scope of power; accepted capacity; reserved and delegated decisions; start and end or review conditions; interests and management; substitute or vacancy route; contact; and evidence of assent. Where public and protected versions differ, their relationship is identified through the access record.

CH-082 The appointing authority shall maintain the authority and appointment elements in this annex for each operative role and shall update the record when its holder, scope, interests, acceptance, or effective status changes.

A.3 Decision and review record

The decision record contains: question; authority; input editions; evidence and alternatives; participating capacities; conflicts and recusals; material objections and replies; procedure and any ballot reference; reasons; result; conditions; implementation owner; notice; and review route. The review record adds findings, limitations, corrective actions, follow-up dates, and verified completion.

CH-083 The responsible decision maker shall ensure that a consequential decision has the decision and review elements in this annex before it is relied on for progression. Where evidence is restricted, authorized review access and a safe public account shall be identified.

A.4 Continuity and transition record

The continuity record identifies essential resources, their custodians, recovery and access arrangements, test results, dependencies, and unresolved failures. The transition record identifies outgoing and incoming responsibility, transferred obligations, untransferred material, permission limits, notices, and acceptance of custody.

CH-084 The governance authority shall use the continuity and transition elements in this annex when authorizing a transfer, prolonged suspension, or closure and shall record material gaps and their disposition.

A.5 Selection of assessment evidence

CH-085 The assessor shall select evidence appropriate to the requirement using the minimum evidence families in Table A.1. An assessment based on sampling shall identify the population, selection rationale, excluded cases, and limits on conclusions. Documentary completeness shall not replace observation of a route whose actual availability is claimed.

Table A.1 – Governance evidence families and assessment limits

Function	Evidence and method	Limitation requiring separate treatment
Founding and delegation	Inspect actual commitments, mandates, accepted appointments, effective conditions, and edition references.	A signature or role name does not establish authority beyond the scope supported by its recorded basis.
Participation	Inspect notices and accommodation records; exercise public and protected routes with authorized test material.	A working contact route does not demonstrate that affected perspectives were reached or their concerns considered.
Decision and challenge	Trace input versions, objections, replies, reasons, conflicts, independent review, and implementation of remedies.	Procedural completeness does not establish substantive truth or agreement of an absent constituency.
Resources and independence	Inspect support conditions, essential resource control, actual staffing, and response to concentration findings.	Stated independence does not demonstrate that a reviewer is available or free of the relevant interest.
Continuity and records	Observe a permitted recovery exercise and compare restored versions, access controls, identifiers, and unresolved losses.	A successful copy does not establish preservation of meaning, rights, or the ability to resume a pending review.
Transition and closure	Inspect notices, accepted custodial transfer, unresolved commitments, status changes, and accessible contact.	A declared closure does not dispose of external rights or eliminate consequences of earlier programme decisions.

Annex B

(informative)

Application examples and design rationale

B.1 Funding concentration

A prospective host offers free infrastructure subject to exclusive control over publication access. The funding record exposes the condition, while the authority record shows that the host has no adoption power. Review examines an alternative host, portable copies, protected records, and continuity costs. Acceptance depends on resolving the condition consistently with programme independence; the price alone does not determine the result.

B.2 Founding capacity shortfall

Prospective signatories complete draft charters and a synthetic appeal exercise but have no available independent reviewer. The governance assessment records completed drafting and rehearsal separately from missing operational capacity. Source inquiry and document development continue. Formal work-item initiation remains pending until accepted appointments and the actual review route meet the launch requirements.

B.3 Changed representation

A committee participant changes employment during a ballot. The coordinator examines whether the accepted capacity was individual or institutionally mandated and whether the new interest affects recusal or the roster. The applicable Directives determine whether correction requires a restarted ballot. The participant's earlier contribution remains attributed even if their decision capacity changes.

B.4 Basis for the selected model

Open individual contribution lowers initial organizational barriers but can concentrate influence among people able to contribute unpaid time. Bounded appointments, explicit affiliations, assistance routes, and review of missing perspectives address that risk without claiming universal representation. Institutional membership and hybrid chambers remain alternatives requiring demonstrated mandates and administrative capacity.

B.5 Unresolved adoption decisions

OPEN ISSUE Founding signatories, organizational form, actual appointments, neutral-review capacity, operating resources, protected contact routes, and operative contribution terms remain unresolved. This draft supplies the requirements against which their proposed resolution can be reviewed.

OPEN ISSUE The minimum accessibility target, longer-term participation model, and evidence needed to assess societal effects remain subjects for governance and work-item review. The Charter does not assume that successful programme procedure demonstrates restored social trust.

Bibliography

Source and interpretation: Programme Brief, version 0.4; comprehensive development plan, version 0.1; cross-domain programme; foundation traceability map, particularly FT-01 and FT-06. Local paths: `PROGRAMME_BRIEF.md` and `docs/planning/`. These explain the mission and candidate operational direction.

Source and interpretation: Foundation manuscripts: FM-001, `GRE_Chapter_01.pdf`, section 1.14.2–1.14.5, pp. 79–83; FM-003, `GRE_Chapter_03.pdf`, section 3.12, pp. 129–132; FM-005, `GRE_Chapter_05_Complete_First_Draft.pdf`, section 5.18, pp. 150–153. Files are in `foundation_manuscripts/`. These ground the orientation to representational instability, revisable action, and unequal evidential capacities; they do not enact these governance clauses.

Source and interpretation: WTO, Principles for the Development of International Standards, Guides and Recommendations, official presentation of the 2000 TBT Committee decision, consulted 2026-09-22: https://www.wto.org/english/tratop_e/tbt_e/principles_standards_tbt_e.htm. Its treatment of transparency, participation, impartial consideration, relevance, coherence, and resource barriers informs process design. Local requirements and organization are programme proposals, not a claim of WTO recognition.

Source and interpretation: United Nations, National Quality Assurance Frameworks Manual for Official Statistics, 2019: https://desapublications.un.org/publications/united-nations-quality-assurance-frameworks-manual; official overview consulted 22 September 2026. The sector-specific quality-assurance approach informs examination of institutional capacity alongside outputs. Programme governance remains local and does not acquire a national-statistics mandate through this comparison.

Source and interpretation: ISO, Model International Standard, third edition, 2023: https://www.iso.org/iso/model_document-rice_model.pdf. Its formal document organization informs the distinction among front matter, provisions, and annex status. Local scope and authority remain those recorded in this Charter.

GENERATIVITY STANDARDS PROGRAM

Directives Part 1

Governance Working Draft

Version 0.2 2026-09-22

Procedures for Development and Maintenance

WORKING DRAFT FOR REVIEW

This document contains proposed provisions for technical and institutional review. It is not an adopted Standard or an operative governance instrument. Its scope, application conditions and publication status are specified in the text.

Prepared by the Generativity Standards Program. Reference to external publications does not imply endorsement by ISO, IEC, IEEE or any United Nations body.

Foreword

This document proposes an executable development procedure for the Generativity Standards Program. Its clauses govern the programme only after explicit governance adoption. It is a **PROVISIONAL Governance Working Draft**, not an adopted Standard, an approved project, or evidence that a committee exists. Its numbered requirements are proposed requirements. A rehearsal can test them without making them operative.

Responsible editor: `UNASSIGNED`. Canonical source: `governance/directives_part_1.tex`. Intended readers are founding participants, procedural administrators, editors, reviewers, affected people, and prospective implementers of the development procedure. The assessed subject is a particular project-development or maintenance procedure and its records, not the substantive truth of a resulting Standard.

This edition expands draft 0.1 while preserving the meaning of D1-001 through D1-058. The additional schedules specify evidence and handling responsibilities rather than constitute programme offices. Draft 0.1 remains a historical publication. The proposed local numerical defaults are unchanged.

Bibliography **22**

Introduction

The procedure supports inspectable, revisable recognition and practical action by preserving grounds, alternatives, objections, decisions, and subsequent changes in standards development itself. Its central object is a justified progression decision: who could contribute, what was considered, why a direction was selected, which disagreements remain, and how later correction can occur.

The programme examines standards-development practice without assuming the institutional resources or representative mandate of an established international standards body. Explicit work authorization, documented review, conflict-sensitive decision making, public scrutiny, and maintenance are adapted to actual available capacity. A short procedure can conceal an unavailable role just as easily as an elaborate organizational chart. These Directives consequently make vacancies and failures visible and prevent a document's apparent completeness from substituting for an operative institution.

Public participation and evidential adequacy are related but distinct. A numerical majority cannot establish a substantive fact, and a well-supported technical conclusion does not excuse exclusion from the prescribed process. Standards development can affect access, cost, classification, and future practical possibilities; review therefore examines these consequences alongside implementation and conformance.

1 Scope

1.1 General

These Directives specify development, review, decision, publication, maintenance, and appeal procedures for programme publications. They address officials, editors, contributors, reviewers, affected participants, and assessors. They do not determine the truth of recorded claims, settle GR theory by vote, or confer external legal authority. A procedure assessment identifies its project or decision scope and does not establish programme-wide fulfillment from a single dossier.

2 Normative references

2.1 Draft dependencies

The following companion Governance Working Drafts, version 0.2, provide proposed internal dependencies: the Standards Programme Charter, Directives Part 2, the GR/TC 1 Charter, and the Ethics, Conflict-of-Interest, and Contribution Rights Policy. Their source files are in `governance/`. References are dated to these draft editions for coordinated review; none is represented as adopted. The founding instrument identifies the exact adopted editions and applicable transition arrangements. A dependency change requires review of affected provisions and assessments.

External standards-development and United Nations system publications are informative comparison sources. No external voting rule, institutional mandate, or legal entitlement is incorporated by reference. The programme's own public-review periods and thresholds arise from its governance choice.

3 Terms and definitions

3.1 Operational procedural terms

Governance authority The body or bounded transitional authority constituted by the adopted Charter; its mandate determines which decisions it can take.

Technical committee An actually constituted committee with a bounded project mandate; not a label that itself establishes authority.

Substantive change A change that could alter scope, meaning, duties, permissions, conformance outcomes, interoperability, protection, or practical consequences.

Substantive objection A reasoned concern about technical adequacy, evidence, scope, procedure, rights, participation, harm, or feasibility relevant to the proposed decision.

Consensus assessment A documented assessment of participation, consideration of concerns, remaining disagreement, and grounds for progression. It is distinct from a ballot tally.

Eligible participant A person assigned decision rights under the Charter and recorded for the specific decision; authorship, payment, or attendance alone does not confer those rights.

Calendar day A day counted using the closing time and time zone stated in the notice. A notice states an exact closing timestamp.

4 Founding, responsibilities, and participation

4.1 General

D1-001 The programme shall apply the adopted Charter for decision authority and appointments, these Directives for development procedure, Directives Part 2 for drafting, and the adopted Ethics, Conflict-of-Interest, and Contribution Rights Policy for conduct, conflicts, and rights. A conflict between these instruments shall be referred to the governance authority and resolved before a dependent decision proceeds.

D1-002 Every procedural decision shall identify its accountable decision maker, operative authority and procedure versions, input document versions, grounds, outcome, date, and review or appeal route. Drafting, a repository merge, an ADR, or successful compilation shall not constitute governance adoption or Standard approval.

D1-003 An organizational function without an appointed holder and recorded mandate shall remain `UNASSIGNED`. Formal project initiation and adoption shall remain pending while required authority or an independent appeal route is unavailable. Preliminary research, drafting, and synthetic rehearsals may continue with explicit status labels.

D1-004 Before formal standards-project approval, the founding adoption record shall identify the founding basis, adopted governance texts and versions, participants and capacities, decision method, dissent, transitional limits, review date, and replacement route. Governance adoption shall follow the founding procedure recorded under the Charter, rather than assume that these draft Directives have already authorized themselves.

D1-005 The governance authority shall assign oversight, project progression, public-review administration, release, maintenance, conflict handling, and independent appeal functions. The assignment register shall identify holders, terms, delegated limits, substitutes, and contact routes. Combined roles shall be disclosed; an interested decision maker shall not determine their own procedural appeal.

D1-006 The Secretariat shall maintain an accessible work programme and participation route. A project notice shall identify the problem, scope, current status, available documents, contribution terms, comment routes, decision roles, and intended review dates. Public comment shall not require voting membership or endorsement of the proposal.

D1-007 The review chair shall document outreach to affected interests and relevant expertise, participation barriers, affiliations relevant to dominance, and remaining gaps. The chair shall provide an asynchronous contribution route and record requested accessibility or language accommodations and the response. Lack of response shall not be recorded as consent.

D1-008 Before a formal decision, the chair shall confirm current conflict declarations and apply the adopted recusal procedure. The record shall identify recusals and their effect on eligibility and quorum without disclosing protected details unnecessarily. If conflicts prevent a valid decision or impartial review, progression shall be deferred.

NOTE 1 Participant eligibility and appointment belong to the Charter; conduct and contribution permissions belong to the Ethics, Conflict-of-Interest, and Contribution Rights Policy. These Directives do not grant membership, impose a license, or establish a legal entity.

5 Project initiation and scope control

5.1 General

D1-009 A New Work Item Proposal shall identify purpose, intended users and affected people, publication class, bounded deliverables, exclusions, proposed conformance subjects, alternatives to new standardization,

source basis, dependencies, review expertise, pilot evidence, resource needs, and prospective maintenance responsibility.

D1-010 The proposal shall explain how the work addresses warranted recognition or generative trajectory and identify epistemic assumptions, ethical impacts, legal and institutional boundaries, public-policy implications, accessibility, protection needs, and distribution of recording and implementation burdens. A claimed institutional mandate shall identify its source and limits.

D1-011 The technical committee shall begin with the normative problem and assessment needs. A dependent Specification proposal shall identify the draft requirements requiring reusable technical infrastructure, the implementation alternatives, and intended tests. A protocol proposal shall additionally identify actors, interactions, states, transitions, outcomes, failure handling, and authority boundaries.

D1-012 The authorized project decision maker shall record accept, revise, defer, or reject, with reasons, scope, assigned responsibilities, dependencies, and review milestones. A coordinated proposal shall retain a separate bounded scope and progression record for each deliverable. A technical dependency shall not acquire Standard status through inclusion in a proposal.

D1-013 A proposed expansion beyond approved scope shall receive impact review and an explicit scope decision before dependent progression. A Specification intended for promotion to a Standard shall enter an explicit standards-track proposal and the applicable review stages; technical stability alone shall not authorize promotion.

5.2 Proposal handling and accountable capacity

D1-059 The Secretariat shall register a proposal with an identifier, receipt date, proposer, proposed class, scope version, and handling status. It shall acknowledge receipt within seven calendar days and identify the authority responsible for scheduling its consideration. An incomplete proposal shall receive a specific request for information or a reasoned deferral; registration shall not confer project approval.

D1-060 Before accepting a project, the decision authority shall verify that the editor and maintenance owner accept their responsibilities, required review competence can be obtained, the resource estimate includes participation and protection work, and the work plan states review dates and capacity limits. An unfilled essential role shall be resolved through assignment, a narrower scope, or deferral, rather than entered as an assumed resource.

D1-061 The project register shall distinguish proposed, active, suspended, closed, and completed work and retain the reason for a change of status. A proposer may withdraw a proposal before authorization; withdrawal shall preserve its record and relevant unresolved issues. Suspension or closure of approved work shall be authorized with affected-participant notice and a disposition of dependencies, contributions, and remaining records.

NOTE 1 Acceptance authorizes bounded work, not its expected conclusion. A negative pilot or a well-supported decision that standardization would add excessive burden can justify scope reduction or closure. A sponsor's preferred implementation remains an alternative to evaluate rather than the implicit criterion of success.

6 Stages and progression evidence

6.1 General

The following codes are the programme's local lifecycle. They retain the repository's grouping of review, revision, and withdrawal under stage 90. Specifications have separately declared maturity; stage 60 is reserved here for adopted Standards.

Table 1 – Local development stages and progression evidence

Stage	Local status	Evidence for progression
00	Preliminary	Need, preliminary sources, alternatives, and draft NWIP; no project authority presumed.
10	Proposal	Approved bounded scope, capacity, assignments, dependencies, and review plan.
20	Working Draft	Candidate clauses, source and decision traceability, assessment methods, and example or pilot design.
30	Committee Draft	Integrated requirements, review findings and dispositions, pilot evidence and limitations, proposed public-review package.
40	Public Review Draft	Versioned notice, accessible draft, comments and responses, material-change review, and remaining objections.
50	Final Approval Draft	Frozen approval package, consensus assessment, valid ballot, procedural checks, and appeal handling.
60	Published Standard	Recorded adoption and release authorization, verified publication package, maintenance owner and next review date.
90	Review / revision / withdrawal	Issue and impact evidence; recorded confirmation, correction, amendment, revision, supersession, or withdrawal.

D1-014 Each progression decision shall state the current and proposed stage, evaluate the relevant evidence, identify remaining limitations, and record approval, return for revision, deferral, or closure. A stage label shall not substitute for the decision record. No Standard shall skip public review or final approval by claiming that a prototype or pilot already establishes acceptance.

D1-015 The editor shall retain versioned drafts, a requirement-to-source and assessment map, an issue register, and substantive decision records identifying alternatives, selected direction, rationale, and affected artifacts. GR interpretation shall use relevant foundation manuscripts and preserve unresolved source differences; operational narrowing affecting architecture shall have an ADR.

D1-016 At committee review, named reviewers shall evaluate epistemic adequacy, practical usability, ethical and distributional effects, accessibility, preservation and protection, legal/institutional boundaries, and technical feasibility within declared competence. Missing expertise or evidence shall be reported and resolved, or the scope narrowed, before unsupported requirements advance.

D1-017 Pilot reports shall identify the tested versions, cases and negative cases, methods, participants' roles, failures, burdens, limitations, and resulting changes. Synthetic or author-operated tests shall be labelled accordingly. External institutional participation, access authority, independent validation, and legal validity shall not be inferred from a synthetic rehearsal.

6.2 Stage controls and project records

D1-062 The project lead shall assemble the entry and exit evidence specified in Annex A before requesting progression. The decision authority shall record its assessment of each applicable item, the evidence locator, responsible reviewer, result, and any required action. An inapplicable item shall have a scope-based reason; unperformed work or unavailable evidence shall not be recorded as fulfilled.

D1-063 A Working Draft shall identify open design alternatives and any unresolved requirements or dependencies. A Committee Draft shall integrate the selected proposal, source rationale, assessment method, and issue disposition sufficiently for a reviewer who did not participate in authoring. Neither designation shall imply that open issues have disappeared merely because the document has been renumbered.

D1-064 Before public review, the chair shall verify that applicable requirements have identified conformance subjects and assessment methods, examples are distinguished from obligations, material pilot failures are visible, and unresolved issues are bounded. A requirement whose interpretation depends on unavailable material or an unsettled contradiction shall be revised, narrowed, or withheld from the proposed normative scope.

D1-065 A coordinated package shall identify authoritative locations for shared requirements, exact dependency versions, change propagation responsibilities, and release sequencing. The responsible editors shall assess a material dependency change against affected scopes, tests, examples, and users before progressing any dependent release. Circular references shall not be used to conceal an unassigned obligation or unsupported conformance claim.

D1-066 A meeting used for a consequential decision shall have prior notice, an agenda and accessible materials, an assigned chair, identified participants and capacities, declared conflicts, and a decision record. A person unable to attend shall have the declared asynchronous opportunity to contribute before the decision closes. Meeting attendance alone shall not replace the prescribed ballot, public review, or reply period.

D1-067 The chair shall circulate a proposed decision record for correction of factual inaccuracies and attribute unresolved corrections before using it as progression evidence. An editorial correction to minutes shall not alter the decision taken; a proposed change to that decision shall use the relevant reconsideration or new-decision procedure. The register shall distinguish a proposal, recommendation, authorization, and completed action.

7 Public review and comment disposition

7.1 General

D1-018 Before opening public review, the chair shall freeze a uniquely identified draft and publish its scope, class, maturity, change summary, dependencies, known limitations, review questions, exact opening and closing times, submission routes, and intended treatment of commenter information. Required supporting material shall be accessible to reviewers under workable terms.

D1-019 Public review shall remain open for at least 60 calendar days. The chair shall record outreach, access interruptions, and accommodation needs; a material access failure shall receive an extension sufficient to restore meaningful opportunity, with reasons and revised closing time published.

D1-020 The Secretariat shall accept comments in an accessible free-text route as well as any structured template. It shall assign a stable identifier, record the affected version or topic, requested change if supplied, receipt date, and disclosure preference, and acknowledge receipt within seven calendar days. A comment shall not be rejected solely for lacking technical drafting expertise.

D1-021 The Secretariat shall offer a protected route for justified confidential submissions and explain its access limits. The chair shall arrange competent consideration and publish a safe summary of the issue and disposition where possible. If essential grounds cannot be exposed sufficiently for fair review, the chair shall record the limitation and defer or narrow the affected decision.

D1-022 The responsible review group shall give every in-scope comment a disposition of accepted, accepted with modification, not accepted, or deferred, with reasons and links to affected clauses or issues. Out-of-scope and duplicate comments shall retain identifiers and a reason or linked disposition. Deferral shall identify an owner, next action, and why the unresolved issue does not invalidate proposed progression.

D1-023 The chair shall target initial dispositions within 30 calendar days after review closes. If that target cannot be met, the chair shall publish reasons, interim status, and a new target before it expires. A

target extension shall not deem comments resolved. Commenters shall receive disposition notice and at least 30 calendar days to reply before final approval.

D1-024 The chair shall assess each reply and record remaining disagreement. Late comments shall be logged with reasons for current-cycle consideration or later referral; a newly identified material safety, rights, or validity defect shall receive assessment before adoption regardless of receipt date.

D1-025 A substantive post-review change shall undergo public re-review for at least 30 calendar days, showing the changed text, reasons, effects, and affected dependencies. The chair shall notify previous commenters and newly affected interests. A change that substantially alters the purpose, affected constituency, or conformance subject shall receive renewed scope approval and a full 60-day review.

D1-026 Re-review shall permit comments on changed material and its consequences for unchanged clauses. Further substantive changes shall repeat the applicable review. Editorial changes shall be logged with a reason why meaning and conformance remain unchanged.

7.2 Comment register and review administration

D1-068 The Secretariat shall maintain the comment and disposition register specified in Annex B. A combined response may address duplicate issues only if each original comment remains traceable and its distinct material grounds are considered. Splitting a submission into issues shall preserve the connection to its original meaning. Summary statistics shall not substitute for the disposition of an unresolved substantive concern.

D1-069 A review closure record shall identify the exact closing time, submissions received, submissions awaiting acknowledgement or clarification, late submissions, access failures, extensions, and next steps. The chair shall distinguish closure of intake from completion of dispositions. The count of unresolved comments shall not become zero merely because the public submission window has closed.

D1-070 For each proposed disposition, the review group shall identify the responsible respondent, material evidence, affected requirements, reason, resulting text or decision, and review required by the change. A not-accepted disposition shall address the substantive grounds rather than rely solely on lack of votes, institutional rank, drafting inconvenience, or an unsupported assertion that the issue was already settled.

D1-071 If a submission includes conduct allegations or protected information together with a technical objection, the Secretariat shall separate access and handling while retaining a safe cross-reference. The technical issue shall continue to receive consideration unless a recorded reason requires a stay. Protected reporting shall not confer permission to publish personal details in the public disposition register.

D1-072 When sending a disposition or re-review notice, the Secretariat shall record its intended recipients, authorized route, content version, dispatch time, and known delivery failures. Where a material failure prevents meaningful reply, the chair shall provide a workable alternative or extend the affected reply opportunity and record the resulting progression consequence. A failed delivery shall not be represented as silence by the recipient.

NOTE 1 A long review period does not demonstrate effective participation if a relevant person could not obtain the text, understand the submission route, or receive a response. Accessibility and outreach are assessed through the record of practical barriers and responses, not inferred from the existence of a public URL.

8 Consensus, ballots, and final approval

8.1 General

D1-027 Before recommending progression, the chair shall produce a consensus assessment identifying participation and gaps, objections, attempts at resolution, evidence and alternatives considered, remaining dissent, and reasons for the recommendation. Numerical approval shall not establish substantive truth or by itself dispose of an objection.

D1-028 A sustained substantive objection shall receive reasoned consideration and an opportunity for reply. It shall not automatically confer a veto. Unresolved defects in mandatory procedure, decision authority, rights to participate, or required evidence shall prevent progression until remedied. Other remaining disagreement shall be visible in the approval package and assessed by the authorized decision maker.

D1-029 For adoption, substantive maintenance decisions, and other decisions assigned a formal ballot by the Charter, the Secretariat shall circulate a frozen package and proposed resolution for at least 30 calendar days. It shall state eligible participants, recusals, closing time, threshold calculation, ballot options, and challenge route. Ballots shall be approve, disapprove, or abstain; nonresponse shall be recorded separately.

D1-030 The eligible non-recused roster shall be fixed before ballot opening. Each eligible person shall have one ballot in their declared capacity; proxies and duplicate capacities shall not count. Eligibility corrections or later recusals shall be recorded. A change materially affecting the electorate, quorum, or result shall require a new ballot; membership shall not be manipulated to obtain a desired outcome.

D1-031 Let N be the number of eligible non-recused participants, R valid returned ballots including abstentions, Y approvals, and D disapprovals. A ballot shall meet quorum only if $R \geq \lceil 2N/3 \rceil$. Approval shall also require at least three substantive ballots, $Y + D \geq 3$, and $Y \geq \lceil 2(Y + D)/3 \rceil$. Abstentions shall count for returned-ballot quorum but not the substantive-ballot minimum or approval denominator; nonresponses shall count for neither.

D1-032 The result shall include the frozen roster count, recusals, returned ballots, approvals, disapprovals, abstentions, nonresponses, calculation, minority grounds, and decision. Failure of quorum or threshold shall return the matter for further work or deferral, without deemed approval. A substantive change during ballot shall return to the applicable review stage.

D1-033 Final approval shall require a procedurally valid ballot, reasoned consensus assessment, completed dispositions and reply periods, resolved blocking findings, compatible normative dependencies, rights clearance, maintenance assignment, and an authorized adoption record. The Secretariat shall publish accessible decision notice, notify participants and commenters, and record when the appeal period starts. Release shall await that period and resolution of any appeal affecting adoption or publication.

OPEN ISSUE All numerical values in this draft are local proposals requiring author and participant review before governance adoption. They are not ISO/IEEE rules. A valid three-person ballot does not itself demonstrate stakeholder breadth or independent review capacity; the informative defaults annex identifies these participation-risk choices for explicit review.

8.2 Ballot administration and authorization

D1-073 The ballot notice shall include the exact resolution, frozen text and associated artifacts, consensus assessment, dispositions, remaining objections, eligibility basis, and required calculation. The Secretariat shall provide each eligible person a means to submit one attributable ballot without disclosing unnecessary personal information and shall identify a neutral route for challenges to ballot administration.

D1-074 A participant may replace their own ballot before the declared closing time; the Secretariat shall count only the latest valid submission and retain a protected audit of the replacement. An ambiguous or

unverifiable submission shall receive a clarification request and shall not be silently converted to approval or abstention. Ballot validity decisions shall identify the rule applied and the available challenge route.

D1-075 A ballot extension shall be announced before the original close, state the access or participation reason and new closing time, and apply equally to the eligible electorate. An extension shall not change the resolution or threshold or be used solely to solicit a desired result. A frozen package requiring substantive change shall be withdrawn from ballot and returned to applicable review.

D1-076 A non-conflicted person other than the person compiling the tally shall verify eligibility counts, duplicate or replacement handling, recusals, arithmetic, and the consistency of the declared result with the frozen resolution. The verification record shall identify any unresolved discrepancy. A numerical pass with an unresolved blocking procedural finding shall not authorize adoption.

D1-077 The adoption or release authorization shall identify the approved publication class and edition, resolution, vote result where required, consensus rationale, authority exercised, effective date, appeal notice, and conditions affecting release. The release owner shall distinguish this authorization from compilation, distribution, and commencement of an institution's use. An institution's uptake shall not be inferred from programme publication.

9 Procedural appeals and separate complaint routes

9.1 General

D1-034 A participant, commenter, or person directly affected by a programme decision may lodge a procedural appeal identifying the decision, alleged procedural failure, available evidence, and requested remedy. Membership or payment shall not be a condition. The ordinary filing period shall be 30 calendar days after accessible notice of the decision; lack of effective notice or newly discovered concealed procedural failure shall permit a reasoned extension by the independent reviewer.

D1-035 The Secretariat shall acknowledge an appeal within seven calendar days and refer it to an appointed reviewer independent of the disputed decision. The reviewer shall disclose relevant involvement and interests, consider conflict objections, and record independence. The decision's author, a materially interested participant, or a person deciding a related complaint about their own conduct shall not determine the appeal.

D1-036 The reviewer shall state scope, admissibility reasons, record access arrangements, and timetable; provide the appellant and responsible decision maker a meaningful opportunity to reply; and issue a reasoned determination. An initial determination shall be targeted within 30 calendar days of receipt, with reasoned extensions and updated dates notified before expiry. No response or elapsed time shall constitute rejection.

D1-037 An appeal concerning adoption, public-review exclusion, or authority shall pause the affected publication decision. Other appeals shall receive a recorded decision on whether a stay is necessary to prevent prejudice. If no independent reviewer is available, consequential contested progression shall remain pending while unaffected work continues.

D1-038 The reviewer may uphold the process, require disclosure or correction of records, set aside a procedurally defective decision, or remit the matter for renewed participation, review, or ballot. The reviewer shall not substitute a ruling on factual truth, external legal entitlement, or technical merit for procedural review. The accountable body shall record implementation of the remedy before renewed progression.

D1-039 Technical reconsideration, conduct complaints, record-specific access or correction requests, and external legal remedies shall have distinguishable routes. Misrouted submissions shall receive assisted referral rather than silent rejection. Protected conduct handling shall follow the adopted ethics policy;

disagreement alone shall not be treated as misconduct. Internal review shall not be presented as replacing external rights or remedies.

9.2 Appeal case management

D1-078 An appeal record shall identify the challenged decision, appellant or protected reference, grounds, requested remedy, receipt and notice dates, admissibility assessment, appointed reviewer, disclosed conflicts, participation opportunities, stay status, outcome, reasons, and implementation responsibility. Refusal to admit an appeal shall receive reasons and the same independence safeguards as a determination on its merits.

D1-079 The reviewer shall distinguish an objection to the substantive proposal from an allegation that the operative process was not followed. A submission containing both shall receive coordinated handling without forcing the appellant to abandon either ground. A procedural remedy shall identify which decision or stage is affected and what evidence is required before the stay can be lifted.

D1-080 A protected appeal shall give each affected party sufficient grounds and opportunity to respond for the determination being made. If disclosure limits prevent fair determination, the reviewer shall narrow the finding, obtain an authorized independent examination, or defer with stated reasons. Confidentiality shall not be described as proof that the undisclosed account is correct.

D1-081 The Secretariat shall track implementation of an appeal remedy and provide the appellant with its status through the permitted route. A remitted decision shall cite the appeal and demonstrate completion of the required reconsideration or repeated stage. Closing the appeal file shall not establish that a correction, new review, or practical remedy has been completed.

NOTE 1 Repeated submissions of the same disposed procedural point can be consolidated with an explanation and a preserved reference. Newly available evidence, a different material procedural failure, or alleged nonimplementation of a remedy requires an assessment of whether the case should be reopened; a previous closure is not a universal bar.

10 Publication and release integrity

10.1 General

D1-040 The release owner shall verify that the exact publication package implements the approved text and decision. The package shall identify edition, date, class, maturity, adoption authority, conformance scope, dependencies, licenses or permissions, known limitations, maintenance contact, next review date, and superseded publications where applicable.

D1-041 The release manifest shall identify authoritative source files, rendered publications, schemas or fixtures where included, their versions and integrity checks, build instructions and tool versions, and the approval record. A reviewer other than the final editor shall compare the rendered output with the approved source for omitted, altered, or unreadable requirements and record the result.

D1-042 The release owner shall resolve source/build discrepancies before release. Source corrections affecting meaning shall return to substantive review; a rebuild shall not silently change an adopted requirement. Public notices shall distinguish an adopted Standard, a Specification, an informative publication, and a policy recommendation and shall not claim ungranted endorsement or certification.

10.2 Release dependencies and distribution

D1-082 Before release, the owner shall complete the release register in Annex B, including dependency availability, permission basis, source/render verification, accessibility limitations, unresolved issues, appeal

status, distribution locations, and withdrawal contact. A dependency that is unavailable on usable terms shall trigger scope revision or deferral rather than an unsupported interoperability claim.

D1-083 A corrected build or accessible alternative representation shall identify its relationship to the approved edition and whether substantive content is unchanged. Where two representations disagree, the owner shall issue a notice, determine the approved content from the decision record, and correct the affected artifacts under the applicable change procedure. A hidden preference for the newest file shall not resolve normative disagreement.

11 Maintenance, review, and withdrawal

11.1 General

D1-043 Every release shall have an assigned maintenance owner, issue intake route, and next review date. The default review interval shall be two years, shortened by a recorded risk-based decision. Loss of ownership, serious defects, changed dependencies, inaccessible implementation rights, or evidence of material exclusion or harm shall trigger earlier review. An overdue review shall be publicly marked and escalated; silence shall not confirm continued suitability.

D1-044 The maintenance owner shall log reported issues, classify their effect, identify affected versions and dependencies, and publish disposition or investigation status. A correction request shall not be rejected merely because the reported behavior matches the current text.

D1-045 A corrigendum shall correct an error without introducing a new obligation, altering intended meaning, or changing a valid conformance outcome. It shall identify the affected text, corrected text, justification, reviewer, and authorization. If semantic effect is uncertain, the change shall use the amendment or revision route. Historical publications shall remain identifiable rather than silently overwritten.

D1-046 An amendment shall make a bounded substantive change to a named edition; a revision shall issue a consolidated new edition. Both shall receive scope approval, assessment of dependent artifacts and users, appropriate pilots, committee and public review, and final approval under these Directives. An incompatible change shall include migration, coexistence, and deprecation information without claiming lossless conversion absent evidence.

D1-047 Periodic review shall invite evidence from users and affected parties and record confirmation, correction, amendment, revision, supersession, or withdrawal with reasons. Confirmation shall require a maintenance report and an authorized decision; it shall not erase known limitations.

D1-048 Proposed withdrawal or supersession shall receive a public notice of reasons, dependencies, transition consequences, and alternatives for at least 60 calendar days, followed by comment disposition, reply, and formal approval. Withdrawn editions shall remain identifiable with status and date; withdrawal shall not retroactively change what a past conformance claim asserted. Necessary protection of underlying records shall follow D1-052, D1-053, and EIP-039.

11.2 Maintenance decisions and compatibility

D1-084 An issue assessment shall distinguish editorial error, conflicting requirements, implementation defect, changed external dependency, emerging misuse or harm, accessibility failure, and proposed new scope. The maintenance owner shall state the affected editions, current mitigation, evidence required, accountable next action, and review date. Classification shall be reconsidered when new evidence changes the issue's substantive effect.

D1-085 A proposed corrigendum shall be reviewed by a person other than its editor against examples and known conformance outcomes material to the correction. If the parties disagree whether meaning

changes, the owner shall preserve the disagreement and use substantive review unless the uncertainty is resolved with recorded grounds. Issuing a corrected file shall not erase the original published error and its applicability interval.

D1-086 An amendment or revision proposal shall assess current users, dependencies, historical records, version negotiation, migration losses, and coexistence needs. The approval record shall distinguish prospective requirements from statements about previous editions. A deprecated feature shall have a reason, affected scope, intended alternative, and transition notice; deprecation alone shall not retroactively change an earlier conformance result.

D1-087 A confirmation decision shall identify the review evidence, known limitations, current maintenance capacity, dependency status, and next review date. If review cannot establish continued suitability, the authority shall select further investigation, narrowing, revision, suspension of programme recommendations, or withdrawal rather than confirm by default. A dormant publication shall remain findable with its actual status.

12 Emergency safeguards and continuity

12.1 General

D1-049 An authorized governance or release holder may issue a time-limited warning or suspend programme distribution or programme recommendations for new use where a documented serious protection, rights, or integrity risk requires immediate action. The action shall state evidence, scope, authority, duration, contact, affected users, and safe public reasons. It shall remain within programme authority and shall not create or amend normative requirements or purport to invalidate external legal decisions.

D1-050 Emergency action shall receive independent review within seven calendar days and expire within 30 calendar days unless the governance authority records a justified extension, next review date, and remedy plan. Unavailable independent capacity shall not authorize emergency adoption. Permanent amendment or withdrawal shall follow the ordinary procedure; protective handling of unlawfully or improperly disclosed material remains governed by the applicable policy and context.

D1-051 A vacant role shall trigger recorded reassignment within the Charter's mandate or deferral of dependent decisions. A temporary substitute shall meet the same conflict and independence conditions. Emergency procedure shall not be used to avoid consultation because ordinary development is late or under-resourced.

12.2 Incident follow-up

D1-088 The owner of an emergency action shall maintain an incident record identifying the triggering evidence, protection decision, consultations, users notified, independent review, expiry or extension, and restoration criteria. At closure, the governance authority shall assess whether ordinary maintenance, a procedural amendment, or further support is needed and publish permitted reasons. Repetition of temporary measures shall not conceal an unresolved need for substantive review.

13 Records, transparency, and external liaison

13.1 General

D1-052 The Secretariat shall preserve linked proposal, draft, comment, disposition, decision, ballot-result, appeal-outcome, release, and maintenance records. Public readers shall be able to follow the grounds

and changes of a decision without mandatory access to private correspondence. Record corrections shall retain the prior account and correction relationship where lawful and appropriate.

D1-053 A records schedule shall state purpose, custodian, access category, retention period or trigger, restriction review, and authorized disposition for each record category. Public publication history and safe decision reasons shall be retained durably; sensitive submissions and personal data shall not be retained indefinitely by default. A restriction or deletion shall preserve a safe explanation when permitted, without revealing protected existence or identity.

D1-054 The governance authority shall publish an annual account of active work, decisions, unresolved objections, participation gaps, funding influence, overdue maintenance, and procedural incidents at a level that protects affected people. The account shall distinguish claimed representation from evidenced participation.

D1-055 External liaison shall have an explicit mandate identifying purpose, authorized speaker, commitments permitted, and reporting duties. A policy proposal shall identify its intended institution and review route and remain recommendatory. Liaison, use of external sources, and informal participation shall not imply affiliation, institutional endorsement, or adoption of another body's procedures.

13.2 Publication routes outside Standard adoption

D1-056 Before external release of a Specification or informative publication, the responsible authority shall approve a work-item review plan identifying publication class, maturity criteria, release authority, reviewers and needed competence, public-comment arrangements and period with rationale, objection disposition, appeal route, maintenance responsibility and rights clearance. The release record shall identify fulfillment and remaining limitations. Drafting alone shall not constitute that approval.

D1-057 A Specification release containing technical conformance requirements shall use the technical review, public review, disposition, ballot and appeal rules in this Part, while retaining Specification status and its declared maturity. Its release shall not use stage 60 or imply Standard adoption. Promotion shall require an explicit Standard work-item and adoption decision with review of changed scope, requirements and prior evidence.

D1-058 A Policy or Institutional Proposal shall receive a separate mandate-specific release decision identifying its intended addressee, institutional and affected-interest review, public-comment opportunity, considered alternatives and unresolved objections. Its review plan shall preserve a reasoned disposition and the procedural appeal route in this Part. An informative report or manual shall likewise identify its review and release decision without claiming technical Standard conformance authority.

13.3 Procedure assessment and continuing improvement

D1-089 An assessment against these Directives shall identify the procedure, project and decisions covered, operative or rehearsal editions, assessor and relationship, methods, evidence, and results for every applicable requirement. Documentary checks and observation of performed procedures shall be distinguished. An unobserved action shall remain not assessed when only a designed form or hypothetical record is available.

D1-090 The governance authority shall review procedural failures and participant feedback for recurring barriers, delay, concentrated influence, unavailable remedies, or unmanageable burden. The review shall identify corrective actions, owners, and follow-up evidence. A procedural amendment shall itself follow the Charter's review and transition rules and shall not retrospectively validate a defective decision.

Annex A

(normative)

Stage evidence and procedural schedule

A.1 General

This annex defines the evidence schedule invoked by D1-062. The stage labels apply to Standards-track development; D1-056 through D1-058 define how other publication classes use the applicable controls without acquiring Standard status. Evidence can be held in one coordinated dossier with references rather than duplicated in separate files.

D1-091 The stage dossier shall identify each scheduled evidence item, its location and version, custodian, access limitations, assessment result, and unresolved action. An item may be reused from an earlier stage when the responsible reviewer confirms that its scope and evidence remain applicable. Reuse shall not imply that a later change has been reviewed when it has not.

Table A.1 – Required stage-entry and exit evidence

Stage	Entry and work evidence	Exit and failure disposition
00	Identified problem, preliminary sources, affected interests, and alternatives, including reuse or no new publication.	A registered proposal with limitations; preliminary work retains that label if authority, need, or capacity is not established.
10	NWIP scope, class, conformance subjects, source questions, dependencies, impact and participation analysis, planned evidence and resources.	Authorized scope and accepted assignments, maintenance responsibility, review milestones, and decision rationale; incomplete capacity produces revise or defer.
20	Approved scope and candidate requirements, definitions, source map, ADRs for architectural choices, and assessment design.	Integrated Working Draft suitable for committee examination, with open issues, examples, and planned pilot; an editor's preference alone does not close an unresolved material issue.
30	Reviewer assignments and competence; integrated draft; pilot or other relevant evidence; dependency and rights review.	Committee findings and dispositions, horizontal review, known limitations, exact public-review package and outreach plan. Unsupported requirements return for revision or narrower scope.
40	Frozen Public Review Draft, available dependencies and evidence, notice, submission and protection arrangements.	Comment register, dispositions, replies, required re-review, remaining objections, and consensus assessment. A materially changed text does not advance on comments about its predecessor alone.
50	Frozen Final Approval Draft, eligibility and conflict records, completed review dossier, final resolution and maintenance proposal.	Verified valid ballot, authorized decision, notice and appeal record, resolved release blockers. A failed threshold returns to work or deferral rather than automatic withdrawal of the dissent.

Stage	Entry and work evidence	Exit and failure disposition
60	Release authorization and closed appeal conditions; exact source, render and artifact manifest; accessible status and terms.	Publication notice, maintenance route, next review date and archived decision trace. A build discrepancy prevents release until the applicable corrective process is complete.
90	Issue intake, usage and impact evidence, dependencies, maintenance capacity and review notice.	Reasoned confirmation, correction, amendment, revision, supersession or withdrawal. Substantive changes return through applicable stages; current limitations stay visible during investigation.

A.2 Timing and clock records

D1-092 Every notice governed by a period in Table A.2 shall state the starting event, time zone, closing timestamp, responsible function, extension rule, and next route if the period is missed. The period shall be measured from effective accessible notice or the specified receipt event. A changed closing time shall remain traceable to the prior notice and its reason.

Table A.2 – Local procedural periods and their effect

Action	Proposed period	Meaning and controlling requirement
Proposal, comment, appeal acknowledgement	Within seven calendar days of receipt	Receipt response; not acceptance of the substantive claim. D1-020, D1-035, D1-059.
Initial public review	At least 60 calendar days	Minimum opportunity; access failures can require extension. D1-019.
Material re-review	At least 30 calendar days	Full 60-day review when purpose, constituency, or conformance subject changes substantially. D1-025.
Initial comment disposition	Target 30 calendar days after close	Reasoned extension and updated target before expiry; no deemed resolution. D1-023.
Reply to dispositions	At least 30 calendar days before approval	Material reply assessed; renewed review where resulting change requires it. D1-023/024.
Ballot	At least 30 calendar days	Frozen resolution and roster; controlled extension or restart. D1-029/075.
Ordinary appeal filing	30 calendar days after accessible notice	Reasoned extension for ineffective notice or newly discovered concealed failure. D1-034.
Initial appeal determination	Target 30 calendar days from receipt	Independent handling and reasoned extensions; silence is not rejection. D1-036.
Maintenance review	Default two years	Earlier risk-based review; annual governance review remains separate. D1-043 and Charter.

Action	Proposed period	Meaning and controlling requirement
Withdrawal notice	At least 60 calendar days	Disposition, reply and formal approval follow; an emergency warning is distinct. D1-048.
Emergency review and expiry	Review within seven; expiry within 30 calendar days	Extension requires recorded reasons, next review, and remedy plan. D1-050.

D1-093 A missed acknowledgement or target date shall remain visible as a procedural event with reason, effect, corrective action, and notice to permitted recipients. An extension shall not erase the missed service obligation or cure exclusion retrospectively. An unresolved failure material to fair consideration shall prevent dependent progression until remedied.

Annex B

(normative)

Registers and minimum decision records

B.1 General

The schedule below defines record content, not a mandatory database schema. A protected locator can replace publicly identifying detail when the accountable custodian and basis remain available for authorized review. The applicable retention schedule determines what survives; the record of a disposition does not itself authorize indefinite preservation of its underlying sensitive evidence.

D1-094 The Secretariat shall maintain the registers in Table B.1 for applicable activities. Each record shall have a distinguishable reference, version or correction relationship, responsible custodian, creation time, and permitted access scope. A shared register may satisfy several functions if each required distinction remains retrievable.

Table B.1 – Minimum procedural register contents

Register	Required content in addition to common identification and custody
Work and scope	Need; proposer; class; current scope; exclusions; dependencies; status; assignments; resources; milestones; changes; decision and affected projects.
Roles and eligibility	Accepted capacity; mandate; term; criteria; nomination and selection reasons; interests; recusals; substitute; decision-specific eligibility; challenge and disposition.
Issues and alternatives	Source or trigger; affected clauses; materiality; alternatives; evaluation; selected direction; rationale; remaining uncertainty; affected artifacts; owner and next action.
Comments and dispositions	Submission and issue references; target version; grounds; requested change if supplied; receipt; protection preference; response; reasons; changed text; reply; remaining disagreement; re-review decision.
Consensus and decisions	Participants and gaps; substantial objections; resolution attempts; evidence; rationale; authority; operative procedure; outcome; date; limitations; notification and appeal route.
Ballots	Frozen package and resolution; roster and conflicts; valid and replacement ballots; exclusions and reasons; returned, yes, no, abstain and nonresponse counts; calculations; verification; final decision.
Appeals and remedies	Challenged decision; grounds; standing; notice; independent assignment; disclosures; replies; stay; determination; remedy; responsible executor; verification and unresolved implementation.
Releases	Publication class and edition; approval record; dependency versions; source and build manifest; rights and accessibility review; corrections; distribution; appeal status; owner; next review.
Maintenance and incidents	Affected editions; reported issue; classification; severity and limits; interim protection; users notified; review and expiry; compatibility consequences; final disposition and follow-up.

D1-095 A public decision view shall preserve enough permitted information to identify the issue, authority, reasons, outcome, status, and challenge route. An authorized assessor shall be able to locate

the underlying protected record when their mandate permits. A restriction that prevents assessment shall produce a stated assessment limitation rather than a presumed pass.

Annex C

(informative)

Proposed defaults and alternatives

C.1 General

These choices make the draft exercisable; they remain **PROVISIONAL** until explicit governance adoption. A future change to operative thresholds or minimum periods needs governance amendment and does not apply retrospectively to an open ballot or review.

Table C.1 – Local defaults, purposes, and alternatives

Proposed default	Purpose	Alternative and evidence needed
60-day public review; 30-day material re-review	Allow asynchronous participation while enabling bounded iteration.	Longer multilingual review or shorter narrow review; test notice reach, access, and actual response burden. Shortening minima needs prior governance amendment.
30-day disposition target and reply period; seven-day acknowledgement	Make receipt and delay visible while preserving substantive consideration.	Different service targets; test volunteer capacity and accessibility needs. A target is not an automatic closure rule.
30-day ballot and appeal periods	Give participants time to read a fixed package and challenge process.	Longer periods for complex work; test availability and remedy effectiveness.
Two-thirds returned-ballot quorum; three substantive votes; two-thirds approval	Prevent adoption based on one affirmative vote and abstentions; require substantial expressed support.	Larger minimum electorate or stakeholder balance conditions. Three voters do not demonstrate constituency breadth; assess actual participation and available competence.
Two-year maintenance review	Require periodic attention without continuous reballoting.	Annual or longer scope-specific review; evaluate dependency change, harms, issue volume, and maintenance resources.
Seven-day emergency review; 30-day expiry	Limit exceptional authority and expose delays.	Shorter periods for urgent privacy incidents; test reviewer availability and restoration of ordinary review.

Annex D

(informative)

Worked progression and rehearsal evidence

D.1 Worked progression

Consider a synthetic proposal for a record-correction protocol. Its first version assumes that only record custodians can challenge a classification. An affected-participant reviewer explains why that scope excludes people whose records are used in decisions. The editor proposes an accessible participant route and identifies the additional authentication and protected-contact infrastructure required. The Specification need follows the normative problem; it is not inferred from an available software library.

The committee records the competing alternatives: custodian-only correction, direct participant submission, and assisted representative submission. Its selected draft uses the latter two within a declared authority boundary. The decision retains the rejected alternative and reasons, including participation burden and risk of exposing identities. A public-review comment then demonstrates that the selected route still requires an unavailable identifier. Removing that prerequisite changes accepted inputs, requiring material re-review and corresponding changes to tests and explanatory examples.

Suppose the later ballot has five eligible non-recused people and four returns: two approvals, one disapproval, and one abstention. The numerical conditions pass because four returns meet the quorum, three substantive votes meet the minimum, and two approvals satisfy the two-thirds threshold. The objection still needs its disposition and consensus assessment. If the disapproving participant identifies a mandatory review omission, that blocking failure prevents approval despite the tally. The case distinguishes evidential reasons, consensus assessment, numerical support, and authority to progress.

A procedural appeal subsequently establishes that the affected reviewer never received the changed draft. The independent reviewer remits the decision for renewed notice and reply. The new decision cites the remedy and evidence that the opportunity was restored. No prior vote is silently relabelled as agreement with a text it did not consider. Publication then identifies the exact approved source, rendered edition, protocol artifact, and maintenance owner. Later correction of an example is evaluated for substantive effect before the owner chooses corrigendum or amendment.

This sequence is a design example only. Its people, comments, votes, appeal, and release have not occurred. The evaluated arithmetic cases in `examples/p0-governance-rehearsal.md` cover finite calculations, not the operational behavior described here.

D.2 Rehearsal method and evidence

A useful rehearsal records actors as fictional or unassigned, uses identified draft versions, and leaves a complete decision trail. It is not actual public review, proof of representativeness, or governance adoption.

Assessment uses an evidence register with a row for each applicable D1 identifier, the procedure or decision assessed, required record location, reviewer, result (fulfilled, not fulfilled, not assessed, or not applicable), and unresolved action. A not-applicable result identifies the absent trigger. Document inspection assesses notices, disclosures, reasons, and manifests; arithmetic recalculation assesses ballot results; observed exercises assess intake, recusal, reply, appeal, and restoration behavior. Independent procedural review assesses contested fairness and authority. Missing records or unperformed procedures are not counted as fulfillment.

1. Process a bounded NWIP through accept, revise, and defer alternatives. Identify an infrastructure need without presuming a Specification or Standard already exists.
2. Receive an accessible free-text comment, a protected submission, and a sustained minority objection. Show acknowledgement, reasoned disposition, reply, and safe publication.

3. Re-review a material change and demonstrate why a change of constituency restarts full review. Preserve unsuccessful alternatives and source uncertainty.
4. Recalculate a ballot after recusal: with five eligible people, four returns meet quorum; two approvals, one disapproval, and one abstention satisfy the approval threshold. Repeat with two returns and show deferral.
5. Test three returns consisting of one approval and two abstentions. Record failure of the three-substantive-vote minimum even though returned-ballot quorum can be met.
6. Appeal exclusion from review; document independent appointment, conflict challenge, stay, reply, remedy, and renewed decision. Repeat with no independent reviewer and show pending progression.
7. Compare approved source and rendered output, detect an omitted requirement, and prevent release. Distinguish typographic correction from a changed conformance result.
8. Simulate maintenance, incompatible revision, withdrawal, an urgent warning, and role vacancy. Demonstrate that an emergency cannot adopt a Standard.

The rehearsal report records failures, required staffing, elapsed effort, participation and confidentiality barriers, revised clauses, and remaining questions before the founding participants assess readiness.

Annex E

(informative)

Source tailoring and open decisions

E.1 Comparison and local choices

The programme's Brief and comprehensive plan supply the mission and local lifecycle. The comparative planning study supplies the alternatives examined. This draft proposes its own procedures and values; it does not claim ISO, IEEE, or WTO conformity, accreditation, or international representativeness. For the expansion decision and alternatives, see `decisions/ADR-0005-expanded-drafts-and-source-models.md`. The external-model comparison is maintained in `docs/references/drafting_models.md`; neither record substitutes for governance adoption.

ISO's model document informs the separation of foreword, introduction, scope, references, terminology, clauses, annexes, and bibliography. IEEE's procedural material informs the distinction between project supervision, review, ballot, and appeal functions. ITU-T's working-method and author guidance provide a United Nations system comparison for organized technical contributions and Recommendation preparation. These are comparisons of document and procedural functions; this programme has neither those organizations' constituencies nor their institutional powers.

The United Nations National Quality Assurance Frameworks Manual supplies a complementary comparison: attention to institutional environment, production processes, and outputs helps avoid evaluating only the finished publication. D1-060, D1-062, and D1-089 accordingly examine capacity, process evidence, and the limits of the resulting claim separately. This is a programme interpretation, not a declaration that the statistical framework governs generativity standards.

OPEN ISSUE The comparative study records an access gap for the full ISO/IEC Directives Part 1:2026 and Part 2 amendment text. This draft makes no clause-level claim about those unverified texts. Founding authority, actual appointments, contribution terms, neutral review availability, and numerical defaults need explicit resolution before governance adoption.

Bibliography

Source and interpretation: ISO, *International harmonized stage codes*, official webpage checked 22 September 2026, https://www.iso.org/stage-codes.html. The source distinguishes publication, review, and withdrawal; this programme retains its existing local stage 90 grouping. No ISO substage deadlines or voting rules are imported.

Source and interpretation: IEEE SA, *Standards Board Operations Manual*, clause 5, official webpage checked 22 September 2026, https://standards.ieee.org/about/policies/opman/sect5/. Its separation of project supervision, review, and appeals informs comparison. The programme's staffing, deadlines, eligibility, and remedies above are new local proposals, not statements of IEEE requirements.

Source and interpretation: WTO, *Principles for the Development of International Standards, Guides and Recommendations*, official presentation of the 2000 TBT Committee decision, checked 22 September 2026, https://www.wto.org/english/tratop_e/tbt_e/principles_standards_tbt_e.htm. Its process principles inform scrutiny of transparency, participation, relevance, and coherence; no determination of legal status under the TBT Agreement is made.

Source and interpretation: ISO, *Model document of an International Standard*, 2023, https://www.iso.org/iso/model_document-rice_model.pdf. Informative structural model, not a conformance dependency.

Source and interpretation: ITU-T, *Recommendation A.1: Working methods for study groups of the ITU Telecommunication Standardization Sector*, September 2019, official edition/status record: https://www.itu.int/itu-t/recommendations/rec.aspx?rec=a.1; and *Author's Guide*, June 2023, https://www.itu.int/dms_pub/itu-t/oth/0a/0f/T0A0F0000040005PDFE.pdf. Informative organizational and drafting comparisons; no ITU procedure is incorporated.

Source and interpretation: United Nations, *United Nations National Quality Assurance Frameworks Manual for Official Statistics*, 2019, https://unstats.un.org/unsd/methodology/dataquality/references/1902216-UNNQAFManual-WEB.pdf. Informative comparison of institution, process, and output quality; no statistical-system mandate is claimed. The programme's comparison record is `docs/references/drafting_models.md`.

GENERATIVITY STANDARDS PROGRAM

Directives Part 2

Governance Working Draft

Version 0.2 2026-09-22

Structure and drafting rules for programme publications

WORKING DRAFT FOR REVIEW

This document contains proposed provisions for technical and institutional review. It is not an adopted Standard or an operative governance instrument. Its scope, application conditions and publication status are specified in the text.

Prepared by the Generativity Standards Program. Reference to external publications does not imply endorsement by ISO, IEC, IEEE or any United Nations body.

Foreword

This document establishes the proposed editorial and document-engineering rules of the Generativity Standards Program. It is intended for document editors, technical reviewers, terminology maintainers, implementers of associated artifacts and publication assessors.

Responsible editor: `UNASSIGNED`. Canonical source: `governance/directives_part_2.tex`.

This second preparatory draft develops the requirements of Working Draft 0.1 into a publication architecture, drafting method and assessment procedure. Requirement identifiers D2-001 to D2-045 are retained. Additional identifiers designate new provisions. The earlier edition is preserved in the programme's source archive. Neither edition has been adopted as an operative governance instrument.

The foreword, introduction, notes, examples, informative annexes and bibliography provide information. Requirements in the main body and normative annexes are proposed requirements for the declared assessment subject. Their use in a rehearsal does not constitute programme adoption. The publication models consulted include ISO, IEEE and United Nations system materials; their institutional authority and proprietary presentation elements are not incorporated.

Introduction

A standardization programme requires documents whose provisions can be located, interpreted, implemented and assessed consistently. Length alone does not establish completeness. A short document can be complete for a narrow question, whereas a programme-wide recording or procedural document can require extensive definitions, conditions, assessment methods and interfaces.

The first publication cycle identified a recurring weakness: a list of requirements can state desirable outcomes without specifying how an implementer determines applicability, obtains the necessary evidence, handles exceptions or reports a failure. This edition requires those elements to be developed together. Formal drafting is used to increase precision and reviewability, while explanatory material retains a separate role.

The programme also requires distinctions that conventional technical documentation can leave implicit. A statement about a represented event differs from a claim about its evidence, an ethical evaluation, a legal allegation or an institutional decision. A manuscript can supply conceptual grounds without supplying normative authority. A schema can validate a representation without establishing its factual warrant. The drafting rules provide means to preserve these distinctions across publications.

The local publication profile draws selectively on established models. It uses decimal clauses, dated dependencies, separately identified annex status, controlled terminology and explicit assessment subjects. It does not reproduce another organization's foreword, approval process, legal status or branding. The detailed comparison and access record are maintained outside the normative provisions in `docs/references/drafting_models.md`.

1 Scope

This document specifies requirements for the structure, language, terminology, references, associated artifacts and editorial assessment of publications prepared within the Generativity Standards Program.

It applies to governance documents, Standards-track drafts, Specifications, Technical Reports, Manuals and Policy or Institutional Proposals. The applicable structural profile depends on publication class. The assessment subject is an identified publication package comprising the document source, rendered edition and explicitly associated artifacts.

This document does not prescribe a universal theory of generativity, select a technical interchange syntax, confer Standard status or determine the legal effect of a publication. Approval, review periods, release authority and maintenance decisions are governed by Directives Part 1 when adopted. Historical source manuscripts remain source records and are not retroactively edited to meet this document.

2 Normative references

2.1 Dated draft references

For coordinated assessment of this preparatory edition, the following programme drafts supply the provisions explicitly invoked in the text. References are dated to the stated draft version; later changes require dependency review.

- Standards Programme Charter, Working Draft 0.2: CH-010 and CH-011 on publication classes and the limits of Standard designation. Source: `governance/standards_programme_charter.tex`.
- Directives Part 1, Working Draft 0.2: D1-040 to D1-048 on exact-edition publication, correction, revision and maintenance, together with the procedure invoked for the applicable draft stage or publication class under D2-045. Source: `governance/directives_part_1.tex`.
- Ethics, Conflict-of-Interest, and Contribution Rights Policy, Working Draft 0.2: EIP-028 to EIP-031 on artifact-specific terms, source rights and intended distribution, and EIP-039 on custody and protected case information. Source: `governance/ethics_ip_policy.tex`.

These references form a proposed governance package. Listing them does not establish that they are operative. External drafting guides and foundation manuscripts are informative sources unless a particular requirement explicitly incorporates a separately identified technical provision. No ISO, IEEE or United Nations document is a normative dependency of this edition.

2.2 Bounded application and unavailable dependencies

D2-094 For coordinated assessment of this edition, the editor shall apply CH-010 and CH-011 to the publication-class and Standard-status statements required by D2-001 to D2-003; the applicable D1-040 to D1-048 provisions and the identified stage-specific procedure to the publication and change-control subjects invoked by D2-042 to D2-045; and EIP-028 to EIP-031 and EIP-039 to incorporated source material, intended distribution and protected case information where present. The dependency record shall identify the provisions triggered, exact editions, source locators and evidence. An unavailable or incompatible dependency shall leave the affected result not assessed pending resolution.

The incorporated scope concerns the named questions, not an assertion that this publication fulfils each governance instrument in its entirety. A draft without a release decision does not acquire adopted authority through editorial assessment. An absent distribution or case-information trigger can make the corresponding dependency provision inapplicable; missing rights evidence for an intended distribution is not an absent trigger. Programme authority, development procedure, rights and protection, and editorial

assessment remain distinct responsibilities. A conflict is recorded for the competent governance decision rather than resolved by treating a draft as already operative.

3 Terms and definitions

3.1 publication package

identified set of source texts, rendered documents and associated artifacts submitted for a stated review or release purpose

NOTE 1 A package can include a schema, assessment fixture or change record. Inclusion does not make every artifact normative.

3.2 provision

expression in a document that states a requirement, recommendation, permission or explanatory information

3.3 requirement

provision specifying an outcome or condition that is necessary to support the declared claim of fulfillment

3.4 conformance subject

identified object, practice, procedure, system or application against which requirements are assessed

3.5 applicability condition

stated circumstance that determines whether a requirement applies to the declared subject

3.6 normative reference

reference to an identified external provision whose fulfillment is necessary to fulfill an invoking requirement

3.7 informative reference

reference that supplies explanation, conceptual grounds, comparison or further information without adding a conformance obligation

3.8 profile

identified set of application conditions and permitted selections, additions or restrictions relative to specified parent requirements

3.9 editorial correction

change that corrects presentation without changing the meaning, applicability or assessment result of a provision

3.10 substantive change

change that can alter a provision’s meaning, applicability, authority, permitted behavior or assessment result

3.11 assessment evidence

material and recorded reasoning used to support a result for an identified requirement and subject

3.12 hanging paragraph

text attached directly to a clause that also contains numbered subordinate clauses, leaving its structural position ambiguous

4 Publication identity and document architecture

4.1 Identity and standing

D2-001 A publication shall identify its code or other identifier, title, publication class, maturity status, version, responsible editor or unassigned responsibility, and source location near its beginning.

D2-002 A draft shall state that it is not adopted and shall distinguish authoring progress from formally authorized project status. A publication shall not imply ISO, IEC, IEEE or governmental authority without a documented basis.

D2-046 A revision shall identify the preceding edition and summarize substantive changes. The publication package shall preserve a retrievable change relationship and the status of the earlier edition. A new rendering of unchanged text shall not be represented as a new normative decision.

The document identifier and the requirement identifier serve different purposes. A document identifier locates a publication family and edition. A requirement identifier supports the continuity of an obligation across editorial reorganization. A file name or page number is not sufficient to perform both functions.

4.2 Publication classes and audience

D2-003 An editor shall assign one principal publication class and state its intended readers, use and authority. A Standard, Specification, Technical Report, Manual, governance document and Policy or Institutional Proposal shall not be treated as interchangeable classes.

D2-004 A protocol description shall identify its containing publication class. Protocol behavior shall be distinguished from the institutional authority and procedure under which that behavior is used.

D2-005 A Policy or Institutional Proposal shall distinguish factual background, interpretation, objectives, options, mandate, implementation implications and unresolved questions. It shall not create technical conformance obligations through an unapproved policy recommendation.

D2-047 A document containing material of more than one publication class shall identify the principal class and separate the subsidiary material by a stated structural boundary. The editor shall state whether each part defines requirements, supplies guidance or proposes an institutional option.

Technical detail does not make a document an adopted Standard. A Specification can contain exact and testable provisions while retaining Specification status. A policy proposal can recommend adoption or experimentation without defining technical conformance. A protocol is a subject described within a publication, not an additional source of institutional authority.

4.3 Required structural components

D2-006 The scope shall identify the subject of conformance, intended use, relevant environment and exclusions. A claim of conformance shall be assessable within that stated boundary.

D2-007 Normative and informative material shall be distinguishable at clause, annex or artifact level. Notes, examples and informative annexes shall not introduce additional requirements.

D2-008 Every table, figure, annex and associated artifact shall have a stated role and, where interpretation depends on it, a stated authority status. A normative requirement represented in a diagram shall also have an identifiable textual formulation.

D2-048 A technical or governance draft prepared under this document shall contain a title and status statement, a foreword, a scope clause, a normative-reference clause, a terms-and-definitions clause, substantive provisions and an assessment or application clause. It shall identify the role of every annex and associated artifact. An informative bibliography shall be provided when informative external sources are cited.

D2-049 The foreword shall record publication history, responsible preparation and material edition changes without introducing technical requirements. The introduction, when present, shall explain the problem, approach and intended use without creating additional conformance obligations.

D2-050 The scope shall identify both inclusions and material exclusions. It shall not contain requirements that can be located only in the scope or imply applicability to environments for which the document supplies no assessment basis.

The principal body normally begins with Scope, Normative references and Terms and definitions, in that order. A document having no normative references states that fact. It does not populate the clause with a reading list. A vocabulary document can use a more extensive terminology structure, provided that definition entries and vocabulary-application requirements remain distinguishable.

4.4 Clause hierarchy and navigation

D2-051 The editor shall assign decimal clause and subclause numbers, use descriptive titles and place substantive text at an identifiable leaf of the hierarchy. If a clause has subclauses, introductory provisions belonging to that clause shall be placed in a General subclause or another identified subclause.

D2-052 A cross-reference shall identify a stable requirement, clause, table, figure or annex as appropriate. References such as above, below, elsewhere or the latest text shall not be the sole locator of content necessary for interpretation or assessment.

The depth of subdivision follows the complexity of the subject. Repeated one-sentence subdivisions can impair reading; long unstructured blocks can conceal distinct conditions. Editors select a hierarchy that permits a reviewer to identify the actor, trigger, action and evidence without reconstructing a paragraph's unstated scope.

5 Formulation of provisions

5.1 Requirement construction

D2-009 A requirement shall identify the responsible actor or object, the applicable condition, the required behavior or property, and an outcome or evidence by which fulfillment can be assessed.

D2-010 A requirement shall use a stable identifier independent of its displayed section number. An identifier shall not be reassigned to a different obligation after circulation; a withdrawn identifier shall remain traceable.

D2-011 A requirement shall not combine independent obligations whose applicability or assessment differs so materially that one result would conceal another. Related obligations can be grouped when their joint assessment is explicit.

D2-012 Terms such as adequate, appropriate, trustworthy or significant shall have a scoped criterion, declared decision responsibility or assessment procedure when they determine conformance. A broad aspiration alone shall not be presented as a testable requirement.

D2-053 Each requirement shall be linked to at least one discriminating assessment question. The question shall distinguish an acceptable outcome from a materially different outcome that would not fulfill the requirement.

D2-054 Where one identifier groups related obligations, the assessment schedule shall identify the components and record a result for each materially distinct component. Fulfillment of one component shall not conceal an unassessed or failed component.

An obligation normally identifies the responsible subject, any triggering condition, the required action or property and the information needed to determine fulfillment. A requirement can depend on a scoped judgment, but the judgment's criteria, decision responsibility and record are then part of the assessable arrangement. Formal drafting does not require every judgment to be reduced to a number.

5.2 Verbal forms

D2-014 The editor shall distinguish mandatory conditions, recommendations, permissions and capability statements consistently. A recommendation's non-fulfillment shall not be reported as failure of a requirement.

D2-055 The editor shall use shall and shall not for requirements and prohibitions, should and should not for recommendations, may for permission, and can for possibility or capability. Must shall not be used as an alternative requirement verb in programme-authored provisions.

D2-056 A statement of external necessity, including a stated legal constraint, shall identify its source and context. The editor shall distinguish that external constraint from an obligation created by the publication.

The grammatical present can describe a definition, process model or fact. It is not used to conceal an additional obligation. A statement that information can be recorded describes capability; it does not require the information to be retained in a particular record. Permissions are assessed in relation to mandatory limits, not as exceptions to them.

5.3 Conditions, exceptions and incomplete knowledge

D2-013 A permission shall not override a requirement implicitly. Exceptions shall identify the affected obligation, conditions, authority, required record and any limitation on the resulting conformance claim.

D2-015 A conditional requirement shall state its trigger and how applicability is determined. A result of not applicable shall include its reason; it shall not substitute for unavailable evidence or an unperformed assessment.

D2-016 When complete information is not realistically available, a recording requirement shall specify whether a justified unknown, limitation or restricted disclosure satisfies the obligation. It shall not require invented content to complete a mandatory field.

D2-057 A provision permitting an unknown value, unavailable source or restricted disclosure shall state the required declaration, responsible role and assessment consequence. The editor shall distinguish fulfillment of that declaration requirement from resolution of the underlying factual question.

D2-058 An exception shall state its eligibility condition, decision authority, permitted departure, duration or review trigger, required evidence and effect on the resulting claim of fulfillment. An exception shall not be implied solely by a resource limitation.

A conditional requirement remains mandatory when its condition is met. A requirement that has not been assessed is not made inapplicable by the absence of evidence. The document can require a justified declaration of uncertainty while leaving the substantive matter unresolved. It can also require access that the subject cannot provide, in which case the assessment reports the consequence rather than inventing an authorization.

5.4 Completeness and proportionality

D2-059 For each substantive topic in scope, the editor shall identify normal operation, material boundary cases, failure conditions and applicable interfaces. A topic shall not be treated as specified solely because it appears in a list of objectives.

D2-060 Where requirements can impose material recording, review or participation burdens, the document shall identify the intended operating scale and the evidence needed to assess that burden. A reduced profile shall state its limitations and shall not silently claim the coverage of the parent document.

Proportionality is expressed through explicit conditions, profiles and scope. It is not achieved by using undefined terms such as sufficient or appropriate as a substitute for deciding what an implementer records. Conversely, mandatory collection of every available detail can be inconsistent with purpose, protection and feasible participation.

6 Terminology and conceptual sources

6.1 Definition entries

D2-017 An operational definition shall state its scope and shall not imply that it exhausts a broader philosophical concept. A definition imported or adapted from a source shall identify that source, edition and the nature of the adaptation.

D2-061 A definition entry shall identify the preferred term, a unique term locator, the relevant domain where needed, and a definition that distinguishes the concept from adjacent concepts. Notes and examples shall remain separate from the definition.

D2-062 The editor shall use a defined term consistently within its declared scope. A synonym, abbreviated term, deprecated term or narrower profile-specific use shall be identified explicitly rather than introduced as an unexplained substitution.

Definitions describe concepts. They do not contain procedural obligations that belong in requirements. A definition can specify constitutive characteristics, while a later provision states when a conforming application has to record or satisfy those characteristics. Circular definitions and definitions consisting only of synonyms require revision unless the document explicitly identifies an unresolved terminology issue.

6.2 Foundation interpretation

D2-021 A draft shall distinguish occurrence claims, observations, evidence assessments, interpretations, normative evaluations, legal assertions and institutional determinations wherever conflation would strengthen a claim beyond its grounds or authority.

D2-018 For a substantive GR definition, the editor shall record the relevant foundation passage, alternatives, unresolved differences and the rationale for operational use. A material narrowing or departure shall have an Architecture Decision Record before the definition is stabilized for adoption.

D2-019 An operational definition of Entity, State, Event, Process, Relation or Property shall address admissibility, identity, temporal behavior, allowed relations, required and optional information, examples,

counterexamples and unresolved edge cases. A declaration that an item remains provisional shall identify the missing decisions.

D2-020 The editor shall not equate a formal state with an archival State, a mechanism with a Process, or formal change with an Event without an explicit argument and scoped decision. The six record roles shall not be presented as exhaustive constituents of reality.

D2-063 A source trace for a GR-specific operational definition shall identify the manuscript version, passage locator, interpreted distinction, operational narrowing, material alternative and affected provision. A source discrepancy shall remain visible until its disposition is recorded.

The foundation corpus supplies conceptual source authority. It does not determine the programme's approval procedure. A formal model's carrier, transition or mechanism does not automatically supply the identity or metadata of an archival State, Event or Process. A record ontology can support a practical distinction while leaving a deeper philosophical or mathematical question open.

6.3 Translations and mappings

D2-064 A translation or cross-vocabulary mapping used to determine conformance shall identify the source and target editions, responsible reviewer, correspondence asserted and known non-equivalences. An untranslated or unmapped distinction shall not be represented as preserved without supporting evidence.

Translations can be reviewed documents without being authoritative editions. The publication identifies which edition controls interpretation in the declared programme process. Disagreement over equivalence is recorded as a technical issue; an editor does not resolve it by silently changing the source term.

7 References and dependency management

7.1 Normative references

D2-022 An external reference used to support a normative or scholarly claim shall be verified against an identified primary source. Inaccessible text, uncertain edition, incomplete review and unverified compatibility shall be identified rather than reconstructed as fact.

D2-023 A normative reference shall identify the exact document and edition required to apply a requirement, the part relied on and a means of obtaining it. Informative motivation shall be listed separately from normative dependencies.

D2-065 Each normative reference shall be invoked by an identifiable requirement or application rule. The dependency record shall state the incorporated scope, required edition and assessment consequence of an unavailable or incompatible dependency.

The invocation can incorporate a whole profile or a bounded set of provisions. It does not automatically incorporate every recommendation, example or later amendment in the source publication. A draft dependency can be used for preparatory assessment if its status and exact edition are declared; it cannot supply an adopted authority that it does not possess.

7.2 Informative sources and external publication models

D2-024 A draft depending on another draft shall identify the dependency's version and status and the consequences of a change. It shall not imply the dependency has already been adopted.

D2-066 A bibliography entry shall provide enough information to distinguish the cited source and locate the relevant edition. Where an external model is used for drafting or comparison, the source record shall

distinguish directly inspected material from catalogue metadata, secondary description and unavailable text.

An organization's publication name does not establish that every document it issues has the same authority. For example, a technical Recommendation, a statistical manual and an institutional policy proposal can differ in their adoption procedure, audience and implementation effects. The programme therefore records the source's actual class before deriving a local design proposal.

7.3 Dependency review

D2-025 Before approval for publication, the editor shall produce a dependency review identifying incompatible versions, unavailable dependencies, circular requirements and licensing or access constraints material to implementation.

D2-067 A material dependency change shall identify affected requirements, definitions, assessment cases and associated artifacts. The editor shall record whether each affected element remains valid, requires revision or cannot yet be assessed.

A circular reference is not resolved by citing the two documents more precisely. Technical definitions and conformance conditions require a determinate interpretation. Governance instruments can be adopted as a coordinated package, but their allocation of authority, procedure and assessment still needs a documented reading order and conflict rule.

8 Conformance and assessment provisions

8.1 Subjects, scope and claims

D2-031 A draft shall state the limits of its conformance claims, including the distinction between record structure and factual truth, between source authentication and evidential warrant, and between technical conformance and legal or ethical judgment.

D2-026 A claim of equivalence, compatibility or interoperability with another model shall identify its direction, scope, tested cases, unsupported distinctions and known loss. Matching terminology alone shall not justify that claim.

D2-027 The conformance clause shall distinguish the assessed subject, publication edition, profile, applicable requirements, assessment method, assessor and result. It shall distinguish a record, producer, protocol participant, presentation, archive and organizational procedure when their obligations differ.

D2-068 A document allowing more than one conformance subject shall specify the requirement set applicable to each subject or state that the available assessment is partial. It shall distinguish examination of a record from observation of the practice or procedure represented by that record.

A statement about a completed institutional action requires evidence of that action. A narrative describing the action is evidence of an assertion and can be assessed as a record. It is not automatically sufficient evidence that the underlying action occurred or that an affected person received its result.

8.2 Assessment methods and results

D2-032 An automated check shall identify the constraints it actually assesses. A passing automated result shall not be presented as evidence of a human or institutional action that the check did not observe.

D2-028 Each requirement shall have at least one stated assessment method and evidence expectation. Structural checks, protocol tests, human interpretation and procedural review shall have separately identifiable results.

D2-029 A conformance report shall distinguish fulfilled, not fulfilled, not assessed and not applicable results. A missing assessment shall not be counted as fulfillment.

D2-069 An assessment method shall specify its objective, input conditions, procedure, relevant tools or competence, expected observations, result rule and material limitations. The method shall identify the conditions under which an inconclusive or not-assessed result is required.

D2-070 An assessment report shall retain failed and unassessed applicable requirements and their effect on the overall result. A summary shall not replace the underlying requirement-level evidence register.

Automated checks are suitable for such questions as syntax, identifier uniqueness or required structural elements. Evidential relevance, meaningful participation and the adequacy of a protected response can require competent judgment or observation. A document identifies these limits instead of describing every assessment as machine validation.

8.3 Profiles and optional features

D2-030 A profile shall state its parent requirements, additions, permitted restrictions, exclusions and intended users. It shall not silently weaken a parent requirement while claiming unqualified parent conformance.

D2-071 For an optional capability, a document shall state the condition under which associated obligations become mandatory. An implementation selecting that capability shall be assessed against the complete selected requirement set.

Optional selection and optional implementation quality are different questions. A subject can be permitted to omit a feature. If it claims to supply that feature, the relevant correctness, protection and failure-handling obligations apply according to the profile.

9 Information models, protocols and technical artifacts

9.1 Separation of semantics and bindings

D2-036 A schema, API or encoding choice shall be traceable to a stated requirement or interoperability need. Implementation convenience alone shall not be described as a philosophical necessity or universal institutional rule.

D2-072 A data dictionary shall distinguish semantic information requirements from serialization names, storage types and transport behavior. Each mandatory or conditional element shall identify its meaning, applicable subject and permitted absent or unknown states.

An abstract information requirement can be implemented in a narrative dossier, table or technical binding. The existence of a field in one implementation does not make its name or data type normative. When interoperability depends on that choice, a Specification work item provides the explicit binding and its assessment evidence.

9.2 Protocol behavior

D2-033 A protocol Specification shall define its participants, inputs, preconditions, state transitions, observable outputs, effects, refusal and failure cases, recovery behavior, version assumptions and authorization boundaries.

D2-034 An artifact package shall identify the relationship between its prose requirements and its schemas, examples, vocabularies, test fixtures and executable components. Conflicts shall have a documented resolution rule that does not silently amend an approved requirement.

D2-073 A protocol description shall distinguish sending, transport delivery, receipt, acknowledgment, acceptance for processing and substantive disposition when those states have different consequences. A transport success shall not imply institutional acceptance or completion of a remedy.

D2-074 Where concurrent updates or repeated messages are in scope, the protocol description shall specify correlation, version preconditions, duplicate handling, conflict disposition and recovery after interruption. If those behaviors are not specified, the interoperability claim shall identify that exclusion.

An institutional procedure can be implemented manually. A network protocol can support its exchanges but cannot itself assign legal competence, decide an evidential dispute or grant an institutional remedy. The document specifies the interface between technical behavior and the responsible institutional function.

9.3 Associated artifacts

D2-037 Executable validation or rendering shall not silently retrieve unpinned remote resources, disclose protected input or substitute a current external vocabulary for the edition declared in the package. Any required external processing shall be explicit.

D2-035 Examples intended to be valid shall identify the supported profile and expected result. Negative examples shall identify the intended defect. Synthetic evidence shall be labelled as synthetic.

D2-075 Each associated schema, vocabulary, executable example or test fixture shall identify its owner, version, publication class or role, controlling requirements and status. Its release manifest shall state whether the artifact is normative, informative or experimental.

D2-076 A discrepancy between prose and an associated artifact shall be recorded with affected conformance outcomes. The release package shall identify the controlling interpretation or remain pending resolution; implementers shall not be required to infer priority from file format.

10 Presentation, accessibility and contextual statements

10.1 Tables, figures and formulae

D2-077 Every substantive table and figure shall have a unique number, descriptive caption and an explicit reference or structural purpose in the surrounding text. Required information shall not be encoded solely by colour, shape or visual position.

D2-078 A formula used in a requirement or assessment method shall identify its variables, domain, units where applicable, assumptions and interpretation. Undefined quantities and unsupported numerical precision shall remain explicit limitations.

Table headings can state shared conditions, but a condition necessary for conformance is not left to typographic inference. Units and scales are attached to the represented quantity. A percentage without its denominator or a confidence score without an interpretation is insufficiently specified for a substantive assessment.

10.2 Examples and accessibility

D2-038 A publication shall use headings, table labels, link text and readable typography that expose its structure. Essential meaning shall not depend solely on color, visual position or a diagram.

D2-039 An editor shall provide a usable source or alternative reading representation and identify known accessibility limitations of the rendered document. Successful PDF compilation alone shall not establish accessibility conformance.

D2-079 An example shall state whether it is synthetic, adapted or empirical and identify any omitted material that affects its use. Expected behavior in an authored scenario shall remain distinguishable from observed behavior in an executed assessment.

D2-080 The publication assessment shall identify intended reading modes, known barriers and the evidence used to assess accessibility. Availability of source text, PDF text extraction or a successful build shall not alone establish accessibility conformance.

10.3 Legal, ethical and institutional assertions

D2-040 A legal or institutional assertion used in a requirement shall identify the context, asserted source of authority and scope. A proposed model rule or policy option shall be labelled as such rather than described as generally applicable law.

D2-041 The editor shall record cross-domain review findings relevant to scope, including epistemic, ethical, legal, institutional, political-economy, archival, security and accessibility questions. Unavailable competence or unresolved material objections shall remain visible in progression records.

D2-081 A policy or institutional recommendation shall identify the intended decision maker, asserted mandate, feasible alternatives, implementation conditions, affected interests and evaluation approach. Adoption of a technical requirement shall not be presented as resolving those policy choices automatically.

Contextual reviewers assess the questions within their competence. A legal statement identifies its jurisdiction and procedural status; an ethical statement identifies its evaluative grounds and affected interests. An unavailable review remains an identified gap rather than being replaced by a generic assurance sentence.

11 Versioning and publication production

11.1 Source and artifact control

D2-042 Each circulated edition shall identify its canonical source and rendered artifacts. Changes to proposed requirements shall be traceable through the change record, with superseded reasoning retained subject to justified access and retention rules.

D2-043 A release candidate shall be built from the declared source revision, with build instructions, required tooling and an artifact manifest sufficient to reproduce and compare its substantive content.

D2-044 The release check shall detect broken internal references, duplicate requirement identifiers, missing glyphs, visibly clipped material, mismatched status labels and disagreement between declared source and generated artifact. Unresolved defects shall be reported with their effect on use.

D2-082 The editor shall distinguish the canonical authoring source, any generated representation and the exact edition submitted for decision. A release manifest shall identify source and artifact integrity references, build instructions, tool versions and the associated review record.

Byte-identical rendering is not assumed. Compiler metadata and timestamps can change binary output without changing substantive content. Integrity references identify what was actually reviewed; comparison procedures identify whether the intended provisions, identifiers and status survived rendering.

11.2 Amendment and source preservation

D2-045 An editorial correction shall not silently change the substance of a requirement. A substantive change to an adopted normative edition shall use the amendment or revision procedure in Directives Part 1, including affected-artifact and compatibility review. A draft change shall follow the change-control and

re-review rules applicable to its current stage. Changes to a released Specification shall follow its declared maintenance procedure and promotion shall require a separate decision.

D2-083 A changed requirement shall retain its identifier when its continuity is defensible and identify the nature of the change. A withdrawn requirement shall remain traceable. Reorganization shall provide a correspondence map when clause numbering or placement changes materially.

D2-084 An archival source snapshot shall record the source set, edition and integrity references. A historical snapshot shall be marked as historical and shall not replace the current edition's status or dependency declarations.

12 Assessment of a publication package

12.1 Assessment declaration

D2-085 The assessor shall identify the publication package, assessed edition, applicable structural profile, assessment scope, assessor relationship and required competence before issuing an overall result. Missing expertise and unavailable artifacts shall be reported.

D2-086 The assessment shall use the record specified in Annex B and examine the structural schedule in Annex A. Each applicable requirement shall receive an individual supported result.

12.2 Disposition of findings

D2-087 A finding shall identify the affected provision or artifact, the observed defect, its effect on interpretation or assessment, the proposed disposition and the responsible action. A correction shall identify the revised edition and the evidence used to close the finding.

D2-088 An overall publication result shall distinguish structural checks, technical review, source interpretation, cross-domain assessment and authorization for release. Fulfillment of one category shall not be reported as fulfillment of an unperformed category.

Annex A

(normative)

Structural schedule for programme publications

A.1 Application

D2-089 The editor shall apply the structural schedule in Table A.1 according to the declared publication class. A departure shall identify its rationale, alternative location and effect on assessment. The schedule shall not require an empty clause to simulate completeness.

Table A.1 – Structural components and required treatment

Component	Technical or governance publication	Informative or policy publication
Identity and standing	Identifier, title, class, edition, date, responsible preparation and adoption status.	The same identity controls; identify recommendatory or informative authority.
Foreword	Preparation, edition history and principal changes; no technical requirements.	Publication context, responsibility and history where relevant.
Introduction	Optional problem and approach explanation; distinguish it from scope.	Purpose and context can be substantive, with recommendations distinguished from background.
Scope	Subject, intended use, operating environment and material exclusions.	Intended readers, question, context and limits of conclusions.
Normative references	Identify invoked dependencies or state that none apply.	Identify any incorporated requirements separately from a bibliography; no implied conformance authority.
Terms and definitions	Numbered operational definitions and referenced vocabulary.	Define terms needed to avoid ambiguity; do not restate an adopted vocabulary inconsistently.
Substantive body	Requirements, applicability, interfaces, exceptions and failure behavior.	Analysis, evidence, alternatives, recommendations and implementation implications.
Assessment or evaluation	Subjects, requirement sets, methods, result rules and limitations.	Evaluation questions and proposed evidence; distinguish proposed from measured results.
Annexes	Each annex designated normative or informative; references from the body.	Normally informative; any proposed normative model remains explicitly a proposal.
Bibliography	Informative sources and edition locators, distinct from dependencies.	Sources supporting analysis and recommendations, with access limits recorded.
Associated artifacts	Role, version, controlling requirements, integrity reference and maintenance owner.	Role and limitations; no implied normative priority from machine readability.

A.2 Minimum completion review

D2-090 Before submission for final approval, the package review shall determine whether each in-scope topic has a defined subject, required behavior or outcome, applicability rule and assessment basis. An unresolved topic shall be excluded explicitly, retained as an open issue preventing the affected claim, or returned for development.

Annex B

(normative)

Requirement assessment record

B.1 Record components

D2-091 The assessment record shall include the information specified in Table B.1. Protected evidence shall be referenced through a permitted locator and its examination limits shall remain explicit.

Table B.1 – Assessment record information

Component	Required information
Subject declaration	Publication, edition, source set, artifacts, profile, scope and exclusions.
Requirement locator	Stable identifier, containing clause and controlling edition.
Applicability decision	Trigger, determination, basis and any dependency affecting applicability.
Method	Inspection, recalculation, execution, competent review or user task; procedure and conditions actually used.
Evidence	Source or observation locator, relevant portion, acquisition date, access status and assessment rationale.
Result	Fulfilled, not fulfilled, not assessed or not applicable; component results where a clause groups obligations.
Attribution	Assessor, competence, relationship to the author or operator, and actual date.
Limitations	Unavailable evidence, unresolved interpretation, sampling scope and excluded conclusions.
Disposition	Required correction or additional evidence, responsible action, status and closure evidence.

B.2 Result rules

D2-092 Fulfilled shall be reported only when the stated assessment method and evidence support the applicable obligation. Not applicable shall identify an absent trigger. Unavailable evidence or an unperformed assessment shall be reported as not assessed unless another specified result rule applies.

D2-093 An unqualified claim of fulfillment of the declared publication profile shall not be issued while an applicable requirement is not fulfilled or not assessed. A partial result shall identify the assessed subset and excluded conclusions.

Annex C

(normative)

Publication self-assessment schedule

C.1 Method and applicability

D2-095 An assessment of this document or a publication prepared under it shall apply the topical checks in Table C.1 to every applicable D2 requirement, using the record in Annex B. Each requirement and each materially distinct grouped component shall receive its own result and evidence. A grouped table row shall not authorize one undifferentiated result for its identifiers.

The objective is to distinguish inspectable, correctly scoped provisions from plausible wording that loses a necessary distinction. Inputs are the declared source and rendered edition, dependency and source registers, associated artifacts, change history and actual review or build evidence. The assessor examines the identified passages, follows their references and applies the discriminating question in the table. Text searches and build checks support inspection; meaning, source interpretation and contextual authority require relevant review competence. Where execution or user examination is needed, a document describing that activity is not substituted for observing it.

The expected observation is the retained distinction or controlling evidence named in the check. A demonstrated contradiction or missing required component is not fulfilled; an unavailable examination or needed competence is not assessed; an absent stated trigger is not applicable. A fulfilled result requires evidence for every applicable component. The assessor may use a domain-equivalent check with its rationale and equivalent failure condition recorded. Results remain limited to the examined edition, artifacts, uses and procedures.

C.2 Topical checks

Table C.1 – Requirement groups, discriminating questions and evidence

Identifiers	Discriminating assessment question and evidence
D2-001, D2-002, D2-046	Compare title, foreword, metadata and preceding edition. Can a reader distinguish authoring revision from authorized initiation, adoption and an unchanged rebuild? Trace any authority assertion to its record.
D2-003, D2-004, D2-005, D2-047	Follow an implementation rule and a policy recommendation to their containing class and audience. Does a protocol or subsidiary policy passage silently acquire a different authority? Inspect structural boundaries.
D2-006, D2-007, D2-008, D2-048, D2-049, D2-050	Compare scope, body, annexes and associated artifacts. Is any necessary obligation present only in scope, a note, introductory narrative or an unclassified visual? Locate its controlling formulation.
D2-051, D2-052	Walk the clause tree and follow a substantive reference without surrounding conversation. Can its leaf, exact target and edition be identified, or does interpretation depend on an unlocated paragraph or latest text?
D2-009, D2-010, D2-011, D2-012, D2-053, D2-054	Apply a requirement to a normal and boundary case. Can the actor, trigger, criterion and outcome be determined? Compare grouped components with different results and check identifier continuity in the change record.
D2-014, D2-055, D2-056	Search modal verbs and inspect their contexts. Does an optional recommendation become a failure, a capability become an obligation, or an asserted legal necessity lack a scoped source?

Identifiers	Discriminating assessment question and evidence
D2-013, D2-015, D2-016, D2-057, D2-058	Apply an exception and an unknown value to a triggered obligation. Recover authority, permitted departure, review limit and result consequence; distinguish an absent trigger from an unavailable assessment.
D2-059, D2-060	Select a substantive topic and its failure case. Is behavior specified beyond an objective label, and can its burden be examined at the declared scale without assuming a reduced profile preserves full coverage?
D2-017, D2-061, D2-062	Trace a numbered term from definition to use and source. Do notes, synonyms or domain qualifications change its operative meaning without an explicit boundary? Compare an adjacent concept or counterexample.
D2-018, D2-019, D2-020, D2-021, D2-063	Compare an operational GR definition with its manuscript passage and decision record. Does a formal carrier become an archival class, or a source disagreement disappear, without a scoped argument and recorded disposition?
D2-064	Test a translation or mapping on a meaning that is narrower in one edition. Is the difference retained, with reviewer and editions, or silently described as equivalence?
D2-022, D2-023, D2-065	Follow an invoked dependency to the exact primary provision. Can a reader obtain the incorporated edition and determine what failure or inaccessibility means, rather than relying on a reading-list citation?
D2-024, D2-066	Compare the bibliography with access records and draft status. Does catalogue-only or unavailable material appear as directly inspected content, or a dated draft as an adopted authority?
D2-025, D2-067, D2-094	Examine an affected dependency version or unavailable source. Are incorporated clauses, impacted results and resolution recorded, including bounded Charter, Part 1 and ethics obligations? Check for circular or incompatible interpretations.
D2-026, D2-027, D2-031, D2-068	Compare a record-only result with a practice or interoperability claim. Is unobserved performance, lost meaning or legal/factual assurance incorrectly inferred from structure or vocabulary agreement?
D2-028, D2-029, D2-032, D2-069, D2-070	Reconstruct one assessment from its inputs, method and evidence. Can a failed or unavailable component be recovered from the summary, and does an automatic check claim only what it actually examined?
D2-030, D2-071	Select an optional feature and compare the profile to its parent. Are its triggered obligations assessed together, or is selecting the feature used to excuse a correctness or protection requirement?
D2-036, D2-072	Trace a mandatory data element to its semantic need and allowed missing states. Can another encoding preserve the meaning, or is a software convenience presented as a philosophical necessity?
D2-033, D2-034, D2-073, D2-074	Replay a refusal, duplicate or interrupted exchange where applicable. Can participants distinguish delivery, receipt and disposition, identify controlling text and recover without inventing institutional acceptance?
D2-035, D2-037, D2-075, D2-076	Run or inspect an associated fixture against its declared result and controlling edition. Are remote inputs or protected processing explicit, and does a prose/artifact conflict have a recorded resolution?
D2-077, D2-078	Read a table, figure or formula without relying on colour or position. Are role, variables, scale, units, assumptions and controlling textual requirements recoverable? Inspect unsupported numerical precision.
D2-038, D2-039, D2-079, D2-080	Examine source and rendered reading modes and available user evidence. Does an authored example appear as observed performance, or successful compilation as tested accessibility? Record barriers and unperformed examination.

Identifiers	Discriminating assessment question and evidence
D2-040, D2-041, D2-081	Follow a legal, ethical or policy assertion to its context and reviewer. Can mandate, affected interests, alternatives and evaluation be located without assuming technical adoption resolves the political choice?
D2-042, D2-043, D2-044, D2-082	Compare source, manifest and rendered artifact. Can the exact reviewed edition be rebuilt and inspected for omitted provisions, missing glyphs, clipped content, duplicate IDs and incorrect status?
D2-045, D2-083, D2-084	Compare an alleged editorial correction with prior permitted outcomes. If a single character changes an obligation, is substantive review triggered and the earlier edition still locatable?
D2-085, D2-086	Inspect the assessment declaration and its annex records. Are subject, profile, competence and unavailable artifacts identified before an overall result rather than supplied by a generic assurance?
D2-087, D2-088	Trace a finding to correction and closure evidence. Does closure identify the new artifact and actual recheck, and remain separate from unperformed technical review or release authorization?
D2-089, D2-090	Compare an in-scope topic against the structural schedule and final-approval evidence. Is an unresolved gap explicitly excluded, blocking or returned for work, rather than hidden by an empty heading?
D2-091, D2-092, D2-093	Inspect a mixed-result assessment record. Does unavailable evidence remain not assessed and prevent unqualified fulfillment, with protected evidence linked only through permitted locators?
D2-095	Compare this schedule with the completed requirement register. Does each applicable identifier and distinct component have evidence and a result, rather than inheriting a single group pass?

Annex D

(informative)

Drafting examples and discriminating assessments

D.1 A recording obligation

The sentence “The system should contain trustworthy information” does not identify a conformance subject, a meaning of trustworthy or an assessment method. An operational alternative is to require an attributed claim, its scope and version, the evidence role assigned to cited material, and the responsible assessment. The resulting assessment asks whether these distinctions are present and whether the stated evidential reasoning is inspectable. It does not infer that every recorded claim is true.

D.2 A conditional disclosure obligation

A requirement to publish the entire history would conflict with some legitimate protection and retention arrangements. A bounded provision can require the responsible practice to identify permitted public material, the basis of a restriction, its effect on examination and the available review route. The assessor then examines those decisions and the resulting view. The mere existence of a privacy statement is not equivalent to observing that access control was enforced.

D.3 A protocol acknowledgment

A message receipt and a favorable decision are different states. A technical specification can define a receipt identifier, correlation reference and retry behavior. A procedural document can define who determines admissibility and gives reasons. A test that confirms transport delivery establishes neither the substantive decision nor the legitimacy of the deciding body.

D.4 A numerical result

An assertion that an outcome has high confidence is ambiguous unless the assessed question and grounds are stated. Where a number is used, the document identifies the quantity, scale, method, assumptions and scope. Where heterogeneous uncertainties cannot be commensurated, separate descriptions are preferable to an unsupported aggregate score. This is a requirement to preserve meaning, not a prohibition on quantitative methods.

D.5 An editorial correction

Changing a misspelled word without altering meaning can be editorial. Changing a response period, required metadata element, exclusion rule or approval denominator changes permitted outcomes. The latter requires substantive change control even if it occupies only one character. The classification follows the effect of the change, not its visual size.

Annex E

(informative)

Editorial model, differences and unresolved matters

E.1 Selected local model

The programme combines a conventional standards-document structure with its own traceability identifiers and explicit publication classes. ISO's publicly available model provides an example of ordered preliminary elements, numbered requirements and labelled annexes. ITU's authoring guide distinguishes integral annexes from supplementary appendices. This programme instead labels each annex normative or informative, maintaining one alphabetic sequence. The source distinction is preserved in function without adopting two incompatible naming systems.

IEEE's published procedural guidance informs the separation of draft status, normative material and informative support. UN statistical quality guidance supplies a useful comparison for linking institutional arrangements, production processes, output quality and improvement evidence. Those functions are adapted to the programme's own subjects; a statistical quality framework does not supply a universal test of factual truth or generativity.

E.2 Implementation choices

The current authoring system uses TeX sources, a shared preamble and a manifest-driven LuaLaTeX build. Roman pagination distinguishes preliminary pages from the Arabic-numbered main body. Clauses run continuously; annexes have explicit status headings. No target page count, blank filler or enlarged type is used as a completeness criterion. The assessment includes substantive coverage, traceability, counterexamples and known limitations.

E.3 Open matters

The final accessibility target and a tested alternative reading representation remain open. The exact incorporation of licensed external terminology requires rights review. The full IEEE style-manual download and the complete ISO/IEC Directives edition identified in the external register were not retrieved during this revision; no conformity claim is made to unavailable text. Local participation and approval choices remain matters for programme governance rather than editorial styling.

GENERATIVITY STANDARDS PROGRAM

GR/TC 1 Charter

Governance Working Draft

Version 0.2 2026-09-22

Generativity Records and Infrastructure

WORKING DRAFT FOR REVIEW

This document contains proposed provisions for technical and institutional review. It is not an adopted Standard or an operative governance instrument. Its scope, application conditions and publication status are specified in the text.

Prepared by the Generativity Standards Program. Reference to external publications does not imply endorsement by ISO, IEC, IEEE or any United Nations body.

Foreword

This document specifies the proposed mandate and working obligations of GR/TC 1. It is a Governance Working Draft and does not constitute the committee or approve a work item. Version 0.2 retains the original TC requirement identifiers and develops the operational steps, review records, pilot controls, and readiness evidence required to exercise the mandate.

Responsible editor: `UNASSIGNED`. Canonical source: `governance/technical_committee_charter.tex`. Intended readers are the programme decision authority, prospective committee participants, editors, domain reviewers, affected people, implementers, and maintenance owners.

The Charter concerns committee performance and the evidence submitted for programme decisions. Programme authority, formal review periods, voting, and appeals remain governed by the companion programme Charter and Directives. Technical requirements are adopted through those procedures, not through this document's existence.

Bibliography **12**

Introduction

Developing infrastructure for warranted recognition requires coordination across several kinds of work. A coherent representation can remain evidentially weak; an accessible presentation can expose protected people; and a successful prototype can rely on an institutional authority that does not exist. Committee work therefore needs explicit responsibilities for source interpretation, requirements, practical procedures, implementation, multidisciplinary review, and evidence of effects.

The committee's organizing task is to preserve distinguishable histories of the situation under inquiry, evidence and judgment, and the categories or methods used to recognize it. Requirements begin with a bounded practical or normative problem. Specifications implement reusable infrastructure where that need is demonstrated. Pilots test the resulting practices and reveal costs, exclusions, loss, and failures as well as successful behavior.

One coordinated committee is proposed initially. Additional working groups are activated by actual scope and accepted participation rather than by a list of anticipated disciplines. Review of epistemic, ethical, institutional, legal, political-economic, archival, and technical issues remains distributed across competent and affected participants, with missing capacity reported.

1 Scope

1.1 Committee subject

This Charter specifies constitution, work-item control, assignment of functions, source and requirements discipline, multidisciplinary review, pilot management, publication progression, and maintenance coordination for GR/TC 1. The assessed subject is an identified committee activity or deliverable-development process within its recorded mandate.

1.2 Limits and portfolio

The proposed scope includes vocabulary, recording requirements, epistemic representation, evidence and interpretation, contestation and revision, institutional use, information models, exchange, presentation, preservation, access, and assessment.

2 Normative references

2.1 Internal dependencies

The following Governance Working Drafts, version 0.2, contain provisions required by this Charter. Their exact operative editions are fixed by the recorded programme adoption and committee mandate.

Standards Programme Charter. `governance/standards_programme_charter.tex`; authority, participation, appointments, resources, reserved decisions, and governance launch.

Directives Part 1. `governance/directives_part_1.tex`; work-item initiation, stages, public review, decisions, appeals, and maintenance.

Directives Part 2. `governance/directives_part_2.tex`; publication structure, normative drafting, dependencies, conformance, and production.

Ethics, Conflict-of-Interest, and Contribution Rights Policy. `governance/ethics_ip_policy.tex`; conflict, protection, substantive impact, and contribution-rights handling.

2.2 Edition control

TC-031 The convenor shall record the governance editions applicable to committee work and identify unresolved conflicts before dependent action. A new draft or external source shall not change an operative committee obligation by implication.

Foundation manuscripts and external documents cited in the bibliography provide informative sources. A technical publication's own normative references are assessed separately.

3 Terms and definitions

3.1 Work item

An authorized bounded activity with a problem, scope, intended outputs, responsibilities, dependencies, review plan, and expected evidence. A preliminary proposal is not an authorized work item.

3.2 Requirement baseline

An identified edition of candidate provisions and their associated source, decision, dependency, and assessment records used for a specified review or exercise.

3.3 Review finding

A recorded assessment of a stated question within a reviewer's competence, identifying evidence, reasons, limits, effect on progression, and requested disposition.

3.4 Blocking finding

A finding that a mandatory procedural, authority, protection, rights, or evidential condition for the proposed progression remains unmet. Its materiality is recorded against that progression, not asserted by a label alone.

3.5 Pilot

A bounded exercise of proposed practices or implementations under a declared purpose, case, authority, permissions, evaluation method, and stopping arrangements.

3.6 Independent evidence

Evidence produced or reviewed with the relevant organizational, authoring, financial, and practical dependencies declared and assessed for the particular independence claim.

3.7 Assessment method

A specified means of evaluating an applicable requirement, including its inputs, procedure, expected evidence, result categories, and limits.

3.8 Coordination issue

A disagreement or dependency spanning deliverables or domains whose resolution affects scope, meaning, implementation, assessment, or authority.

4 Mandate and work programme

4.1 Authorization and entry

TC-001 The committee shall become active only through a recorded mandate under the adopted programme Charter. The mandate shall identify its convenor, responsible decision authority, participating capacities, accepted work items, review resources, and mandate review date.

TC-002 The committee shall develop coordinated recording and practical procedures that support warranted, contestable, revisable recognition and preservation of consequential generative trajectories. Each accepted work item shall state its contribution to this purpose and the limits of its expected effects.

TC-003 Committee work shall distinguish changes in the situation under inquiry, changes in evidence and judgment, and changes in categories or methods of recognition. A technical representation connecting these histories shall preserve their distinguishable meaning.

TC-004 The committee shall retain the distinctions between theoretical metamodel, operational record ontology, epistemic representation, normative assessment, jurisprudential status, institutional governance, political economy, and implementation when defining scopes or allocating work.

TC-005 The committee shall not claim authority to certify substantive historical truth, resolve a complete metaphysics, determine legal rights across jurisdictions, endorse a political choice on technical grounds alone, or mandate unrestricted disclosure of recorded material.

TC-006 The committee shall preserve existing publication identifiers when refining scopes. A proposal to change a publication's class, merge or divide its scope, or introduce a new identifier shall record the reason, dependencies, alternatives, and authorizing decision before the change is treated as operative.

TC-007 A work-item proposal shall identify purpose, scope and exclusions, conformance subjects, affected interests, foundation sources and tensions, existing alternatives, related publications, anticipated Specifications, reviewer competence, practical evidence, and maintenance ownership.

TC-010 A proposed substantive scope expansion shall return to the responsible decision authority with its consequences for participation, sources, dependencies, review, and resources. Work outside the authorized scope shall remain exploratory pending a decision.

TC-032 On acceptance of a work item, the convenor shall create a project record linking the authorized proposal, actual decision, bounded outputs, accepted assignments, resources, milestones, dependencies, and unresolved conditions. The record shall distinguish preliminary drafting already performed from work formally authorized.

TC-033 Before scheduling a progression review, the convenor shall verify that the work remains within its mandate, that required responsibilities are staffed, and that necessary evidence is available. A scope or capacity defect shall receive correction, narrowing, or deferral rather than an unsupported stage label.

4.2 Programme coordination

TC-008 The committee shall record work-item dependencies and allocate requirements to their responsible publication before producing a normative technical binding. A shared requirement shall have one authoritative location, with versioned references from dependent work.

TC-009 Editors shall begin with the normative or procedural need and create a Specification proposal when reusable infrastructure is required to satisfy or assess it. A prototype shall not silently determine a theoretical definition or institutional obligation.

TC-034 The committee shall maintain a dependency register identifying each shared concept, requirement, interface, profile, or artifact; its responsible publication and owner; its exact version; and the consequence of change. Competing normative homes shall be resolved before the affected requirement is stabilized.

TC-035 For a coordination issue, the convenor shall identify affected editors and reviewers, record alternatives and semantic or institutional consequences, and seek an explicit decision within the appropriate authority. Technical convenience shall not resolve a normative, legal, or theoretical disagreement without that decision.

TC-036 A split, merger, pause, or termination of a work item shall identify the fate of requirement identifiers, comments, evidence, responsibilities, dependencies, and publication expectations. The programme decision authority shall authorize the revised scope before dependent formal progression.

4.3 Specification and protocol initiation

TC-037 A Specification proposal shall identify the candidate requirement it supports, the need for a reusable technical contract, implementation alternatives, version assumptions, and the evidence expected from a prototype. An institutional procedure shall identify its actual authority separately from protocol mechanics.

TC-038 Before treating a protocol draft as ready for implementation, its editor shall define participants, inputs, preconditions, state transitions, observable outcomes, refusals, failures, recovery, authorization boundaries, and responsibility for interrupted or conflicting operations. Unresolved behavior shall be marked and excluded from unsupported completeness claims.

5 Organization and conduct of work

5.1 Assignments and competence

TC-011 For each active deliverable, the committee shall record an accepted editor or lead, a maintenance contact, required review competence, available reviewers, and unfilled roles. Multiple roles held by one person shall be declared.

TC-012 A new working group shall have a bounded scope, actual willing participants, an accountable lead, dependencies, intended outputs, and review or closure conditions. Its formation shall not imply autonomous adoption authority.

TC-013 A reviewer shall identify the domain and scope of their assessment, relevant competence or situated knowledge, interests, material limitations, and whether they contributed to the material reviewed. A self-review shall not be labelled independent.

TC-014 Where required expertise or affected perspectives are unavailable, the committee shall record the gap and its material effect on progression. It shall narrow claims, seek additional review, or defer the affected decision when the gap prevents a justified assessment.

TC-039 An editor shall accept responsibility for the deliverable's current baseline, change record, source and requirement trace, pending comments, and progression evidence. A reviewer shall accept a bounded assessment assignment rather than an unspecified endorsement of the entire publication.

TC-040 The convenor shall compare each work item's planned drafting, review, accessibility, protection, and maintenance tasks with actual participant capacity. A shortage affecting mandatory evidence or a safeguard shall change the schedule or scope and be reported to the programme decision authority.

5.2 Meetings and asynchronous work

TC-041 For a substantive committee discussion, the convenor shall circulate the purpose, input versions, questions, expected output, access arrangements, and route for asynchronous contributions before the decision is taken. Participants unable to attend shall have the applicable opportunity to contribute under Directives Part 1.

TC-042 The discussion record shall distinguish persons present from represented institutions, information reported from findings accepted, and recommendations from authorized decisions. Material reasons, alternatives, objections, actions, owners, and affected baseline versions shall be recorded.

TC-043 Where new material changes the basis of a proposed decision during a meeting, the chair shall identify the change and apply the relevant further-review procedure. Attendance or an informal show of support shall not replace required notice, reply, or ballot.

5.3 Handover and group closure

TC-044 An editor or working-group handover shall provide the current baseline, requirement and source registers, unresolved comments and findings, dependencies, permissions, build or assessment instructions, and pending deadlines. The convenor shall verify receipt and record any gap before further reliance on the work.

TC-045 A working group that has no accepted lead or capacity to discharge its mandate shall be reported as inactive or pending reassignment. Its outputs shall retain their actual maturity, and unfinished responsibilities shall be reassigned or explicitly deferred.

6 Source interpretation and requirements

6.1 Foundation and external sources

TC-015 Before introducing or materially changing a GR definition, notation, ontology class, or compatibility claim, the responsible editor shall examine the relevant foundation manuscripts and record exact source locations, terminology, scope, historical differences, and the proposed operational translation.

TC-016 The committee shall preserve unresolved foundation differences rather than harmonizing them silently. A material operational narrowing or departure shall be recorded through an architectural decision with alternatives, rationale, affected publications, and remaining uncertainty.

TC-017 A candidate record-class definition shall identify its definition, admissibility conditions, identity criterion, temporal behavior, permitted relations, required and optional metadata, examples, counterexamples, and unresolved edge cases, or explicitly identify which elements remain under development.

TC-018 An external compatibility or reuse proposal shall identify the exact source and edition, verified relevant provisions, mapping assumptions, exclusions, and evidence needed to support the claimed relationship. Similar terminology shall not alone establish equivalence.

TC-046 The source register shall distinguish source wording, editorial paraphrase, historical variant, operational proposal, and accepted programme decision. Each material interpretation shall identify the relevant passage and version, verification status, and unresolved difference.

TC-047 When a source is revised, newly available, or found to have been misinterpreted, the editor shall identify affected definitions and requirements, assess the consequence, and submit necessary changes through the appropriate procedure. Earlier interpretations and the reason for revision shall remain traceable.

6.2 Requirement formation

TC-048 For each candidate requirement, the editor shall identify the responsible actor or subject, applicability condition, required outcome, assessment method, evidence expectation, source or operational rationale, and related issue or decision. A requirement with unresolved scope or testability shall retain a visible development issue.

TC-049 The editor shall separate independently assessable obligations where one result would conceal different applicability or failure. Recommendations, examples, and explanatory theory shall remain distinguishable from mandatory provisions.

TC-050 Before stabilizing a requirement baseline, the review group shall examine examples, counterexamples, unknown or unavailable information, restricted records, and relevant conflicting interpretations. Required uncertainty declarations shall not be replaced by invented information to complete a record.

6.3 Assessment design and claims

TC-026 A conformance proposal shall identify the assessed subject, edition, profile, applicable requirements, methods, evidence, unresolved findings, and limits of the resulting claim. Syntax checks, semantic interoperability, procedural compliance, usability, and substantive warrant shall receive distinguishable results.

TC-027 The committee shall substantiate an interoperability claim with independent implementation or exchange evidence appropriate to the claim. A single internally consistent prototype shall be reported as such.

TC-051 The requirement-to-assessment register shall identify which findings arise from automated checks, observed human tasks, documentary review, independent implementation, or substantive expert judgment. The reported result shall not claim evidence beyond what the chosen method establishes.

TC-052 A proposed profile shall identify inherited requirements, additions, permitted restrictions, applicability, and assessment consequences. The editor shall identify any divergence that prevents unqualified parent conformance and propose an appropriately bounded claim.

TC-053 An asserted external mapping shall identify direction, supported distinctions, unsupported cases, loss, and the exact tested source versions. An untested mapping shall be labelled proposed rather than interoperable.

7 Multidisciplinary review

7.1 Planning and scope

TC-019 At work-item scoping, before a real pilot, and before publication progression, the committee shall maintain a review dossier covering applicable epistemic, ethical, jurisprudential, institutional, political-economic, archival, privacy/security, accessibility, and technical questions. Each domain shall have findings or an explicit justified statement of non-applicability or unassessed scope.

TC-020 The review dossier shall identify evidence, reviewers and their capacities, affected perspectives, conflicts, alternative designs, findings, dispositions, owners of corrective action, and residual limitations. A metadata field or completed checklist shall not by itself count as domain assessment.

TC-054 The review plan shall state the questions, needed competence and affected perspectives, evidence, review independence sought, access arrangements, and decision points for each applicable domain. It shall distinguish non-applicability from unavailable review capacity.

7.2 Findings and disagreement

TC-055 Each domain reviewer shall classify a finding by the affected requirement or assumption, evidence and uncertainty, consequence for the proposed decision, and proposed disposition. A disagreement about values or policy shall be identified as such rather than converted into an unexplained technical defect.

TC-056 The editor shall respond to each material finding with acceptance, modification, reasoned non-acceptance, or deferral, linking the resulting text or action. A deferred finding shall retain an owner, next action, and explanation of whether progression is prevented.

TC-057 Where reviewers disagree across domains, the convenor shall preserve their respective questions, evidence, competence, and reasons and obtain a decision from the authority competent for the matter. A technical majority shall not substitute for an absent legal mandate or resolve a philosophical source conflict by assertion.

TC-058 Before recommending progression, the convenor shall verify that material findings and replies have been considered and that mandatory authority, evidence, rights, and protection conditions are satisfied. A decision to narrow scope shall identify the excluded behavior and prevent it from appearing in the resulting conformance claim.

7.3 Jurisprudential and policy interfaces

TC-021 A legal or institutional profile shall state its jurisdiction or forum, target action, relevant sources and status, claimed authority, temporal scope, unresolved conflicts, and reviewing competence. Generic technical conformance shall not replace assessment of actual applicability.

TC-022 A policy proposal arising from committee work shall follow the separate policy-publication route and compare plausible institutional options, including existing infrastructure or deferral when relevant. The committee shall not present participation in technical review as assent to a policy recommendation.

TC-059 A jurisdictional or institutional reviewer shall distinguish a party's assertion, an applicable source identified by the reviewer, an institution's operative decision, and an unresolved interpretation. The profile shall state the temporal and contextual limits of that review.

TC-060 For an institutional or international-policy proposal, the committee shall identify which technical findings are evidence for the proposal and which recommendations concern mandate, funding, distribution, oversight, or adoption choices. Unaccepted institutional participation shall remain prospective.

8 Pilot preparation and authorization

8.1 Protocol and evidence plan

TC-023 Before a pilot begins, its record shall identify the case and baseline, questions and success criteria, participants and actual authority, material and access permissions, resource burden, anticipated harms, challenge and correction routes, stop conditions, and responsible reviewers. Synthetic cases shall be labelled synthetic.

TC-024 The initial coordinated demonstration shall exercise a claim and its grounds, a consequential relation or contribution, an alternative or challenge, a reasoned response, a historical revision, a protected or unavailable record, and a presentation that makes their distinct status understandable.

TC-061 The pilot plan shall pin the requirement baseline, artifacts, scenario, input material, evaluation tasks, expected results, assessors, and comparison baseline before results are interpreted. A change during the exercise shall identify the reason and its effect on comparability.

TC-062 For a real pilot, the responsible authority shall verify participant and institutional permissions, rights to material, protection arrangements, accessible challenge routes, available remedy, and stopping authority before the affected activity starts. A planned safeguard shall not be reported as operational without evidence of implementation.

TC-063 A pilot relying on restricted evidence shall identify how authorized assessors can evaluate the relevant requirement and how a public result can communicate limitations safely. Lack of public access shall not be equated with absence of evidence or accepted as proof of adequacy.

8.2 Execution and interruption

TC-064 The pilot operator shall retain observations of performed tasks, relevant inputs and outputs, failures, participant assistance, departures from the plan, and protection incidents, within the approved access and retention conditions. Simulated events shall remain distinguishable from observed real behavior.

TC-065 When a stopping condition is met or an unanticipated material harm or authority defect is identified, the pilot operator shall pause the affected activity, notify the responsible authority, protect necessary evidence, and obtain a recorded disposition before restart. Unaffected activity may continue only within its existing authority and safeguards.

TC-066 A pilot restart shall identify the corrected condition, evidence that the response is operational, changed baseline or scope, required further permissions or notice, and the decision maker. A technically successful repair shall not alone establish restored participant protection.

9 Pilot evaluation and implementation evidence

9.1 Results and learning

TC-025 Pilot findings shall report failed tasks, missing or conflicting evidence, excluded participants, unmet assumptions, and burdens alongside successful behavior. The committee shall trace each material finding to a requirement change, retained decision with reasons, further inquiry, or scope limitation.

TC-067 The evaluator shall report the actual participant population, excluded or unavailable perspectives, resource burden, supported tasks, failed cases, assistance required, uncertainty, and limits on transfer to other contexts. A small cooperative exercise shall not be presented as evidence of general institutional adoption.

TC-068 The committee shall compare pilot results with the declared objectives and assessment criteria and trace each material finding to a requirement change, retained decision with reasons, further inquiry, or narrower claim. Unexpected benefits and harms shall be identified separately from the planned criteria.

TC-069 Where an outcome depends on later institutional action or effects on future capacity, the report shall state whether that action or effect was observed, is pending, or was outside the study period. A corrected record shall not be treated as evidence that downstream consequences were repaired.

9.2 Reproducibility and independence

TC-070 An implementation-evidence package shall identify source and artifact versions, configuration, test material, expected and actual outcomes, access or licence constraints, and instructions sufficient for an authorized reviewer to repeat the relevant assessment. Reproduction gaps shall be disclosed.

TC-071 For an independence claim, the convenor shall record who authored the requirements, implemented the artifacts, selected the cases, performed the assessment, and funded or controlled the work. The claimed degree of independence shall be limited to the separations actually evidenced.

10 Progression, maintenance, and publication

10.1 Readiness dossier

TC-028 For each requested progression decision, the convenor shall assemble the current draft, requirement and source trace, comment dispositions, unresolved objections, multidisciplinary findings, pilot or other assessment evidence, rights-clearance status, and maintenance proposal. The programme decision authority shall apply Directives Part 1.

TC-072 The progression dossier shall identify the requested decision and provide a requirement-by-requirement evidence status, unresolved finding register, dependency review, public-comment status where applicable, source and rights clearance, and implementation or pilot limitations. Missing evidence shall remain visible rather than being treated as tacit approval.

TC-073 Before forwarding a public-review or release package, an assigned reviewer shall check that the source, rendered document, associated artifacts, and declared status agree and that references, identifiers, and essential content remain usable. Material discrepancies shall be corrected through the applicable change procedure.

10.2 Change and maintenance

TC-029 The committee shall retain a link from a corrected or superseded requirement to the prior text, reason, decision, affected dependencies, and migration consequence. Historical decisions shall remain

distinguishable from the current authoritative edition.

TC-030 The committee shall submit scope, participation, resource, and outstanding-risk information at its mandate review and when material conditions change. An inactive or unstaffed work item shall receive an explicit status and continuity disposition.

TC-074 A substantive change shall identify affected requirements, interpretations, assessment fixtures, profiles, dependencies, existing users, and migration consequences. The maintenance owner shall distinguish a correction from an altered obligation and invoke the corresponding Directives route.

TC-075 On evidence of a serious defect or loss of a necessary dependency, the convenor shall notify the authorized maintenance or release holder with the affected versions, evidence, consequences, and proposed interim response. The committee shall not issue a permanent normative change through an informal implementation update.

11 Committee assessment

11.1 Assessment method

TC-076 An assessment of committee performance shall declare the activity, period, mandate and governance editions, assessor, interests, applicable TC requirements, evidence, and result for each requirement. Results shall distinguish fulfilled, not fulfilled, not assessed, and not applicable.

TC-077 The assessment shall include a trace from a selected material problem through source interpretation, candidate requirement, alternatives, assessment method, pilot or review evidence, disposition, and authorized decision. Breaks in the trace shall be recorded with their effect on the claimed readiness.

11.2 Correction and oversight

TC-078 The convenor shall assign owners and review dates for material performance findings and report unresolved scope, participation, capacity, or protection issues to the programme decision authority. Closing an action shall identify evidence of completion and any remaining limitation.

Annex A

(normative)

Committee dossier and record content

A.1 Work-item and baseline record

TC-079 The committee shall maintain a work-item and baseline record containing the authorized problem and scope, decision and mandate, output classes, accepted roles, sources, dependencies, versions, requirements, assessment methods, review milestones, permissions, resources, and remaining conditions. Each substantive update shall identify the responsible actor and reason.

A.2 Source and requirement trace

TC-080 The editor shall maintain a trace for each material requirement identifying its stable identifier, responsible publication, condition and subject, source passage or operational proposal, alternatives, decision rationale, assessment method, evidence, dependency versions, and unresolved question. Superseded interpretations shall remain linked to their replacements.

A.3 Domain finding record

TC-081 A domain finding record shall identify the question, scope, reviewer and competence, relevant interests, evidence and access limitations, assessed alternatives, finding and reasons, progression effect, response, reply, action owner, and closure evidence. A safe public account shall be linked where the full record is restricted.

A.4 Pilot and assessment record

TC-082 A pilot record shall identify its authorization, actual participants, baseline versions, scenario, data and permissions, evaluation tasks, expected and actual outcomes, failures, burdens, deviations, stopping or restart decisions, evidence limitations, and requirement dispositions. Synthetic and independent elements shall be explicitly identified.

A.5 Progression and handover index

TC-083 The convenor shall provide an index linking the current baseline, scope decision, review and comment dispositions, pilot evidence, blocking findings, rights status, artifact manifest, maintenance assignment, and requested decision. The index shall identify unavailable or incomplete elements and their proposed treatment.

Annex B

(informative)

Worked review and implementation cases

B.1 Missing evidence mistaken for non-occurrence

A synthetic institution records an uncalibrated instrument because no calibration field was present. A participant later supplies a restricted maintenance log. The exercise tests whether the representation distinguishes absent metadata from an occurrence claim, whether authorized review can consider the log, and whether the presentation exposes the changed basis without disclosing protected detail. Source and requirements review examine the inference; institutional review examines who can reconsider the consequential decision.

B.2 Technically successful but incomplete exchange

Two implementations exchange a current judgment successfully but omit its prior category and an unresolved objection. A syntax result can remain successful while trajectory and presentation requirements fail. The failure becomes evidence for a changed exchange requirement or an explicitly narrower profile, rather than being hidden by the successful parse.

B.3 Conflicting review considerations

An archival reviewer favors retaining an earlier attribution, while a protection reviewer identifies a risk in public release. Their findings address different questions. The committee examines preservation with restricted access, a safe public correction, and retention limits. A decision states the authority and evidence for each outcome without declaring either archival value or protection irrelevant.

B.4 Deferred theory and bounded implementation

A proposed mapping treats Property and the metamodel manuscript's Attribute as identical. The foundation register retains the difference and identifies the exact operational scope being proposed. An exploratory implementation can test one mapping with an experimental label. Stabilizing it requires the recorded interpretation and architectural decision; implementation convenience does not supply the missing conceptual argument.

B.5 Unresolved matters

OPEN ISSUE Committee appointments, accepted work items, domain-review capacity, actual independent implementers, and real institutional pilot mandates remain unassigned or unapproved. An exercise against this draft does not fill those roles.

OPEN ISSUE Property/Attribute interpretation, manuscript version precedence, and the relation between fixed-carrier semantics and broader emergence remain source questions. Their resolution is separate from the constitution of the committee.

Bibliography

Source and interpretation: Programme Brief, version 0.4; comprehensive development plan, cross-domain programme, protocol plan, and foundation traceability map in `docs/planning/`. These establish the local mission and proposed work architecture.

Source and interpretation: Foundation orientation: FM-001, Chapter 1, section 1.14, pp. 79–83; FM-003, Chapter 3, section 3.12, pp. 129–132; FM-005, Chapter 5, section 5.18, pp. 150–153. Exact files and unresolved source chronology are indexed in `foundation_manuscripts/MANIFEST.md`.

Source and interpretation: ITU-T Recommendation A.1 (09/2019), Working methods for study groups of the ITU Telecommunication Standardization Sector. Official edition and status page, consulted 22 September 2026: https://www.itu.int/itu-t/recommendations/rec.aspx?rec=a.1. The source concerns meetings, study management, coordination, rapporteurs, and contributions. It informs comparison of functional responsibilities; its membership and approval authority are not imported.

Source and interpretation: United Nations, National Quality Assurance Frameworks Manual for Official Statistics, 2019. Official publication overview, consulted 22 September 2026: https://desapublications.un.org/publications/united-nations-quality-assurance-frameworks-manual. It addresses assurance across national statistical systems and different data sources. This committee uses a narrower local comparison: quality questions belong throughout the development process and cannot be reduced to artifact syntax. No official-statistics mandate or UN endorsement is inferred.

GENERATIVITY STANDARDS PROGRAM

Ethics and IP Policy

Governance Working Draft

Version 0.2 2026-09-22

Ethics, Conflict-of-Interest, and Contribution Rights Policy

WORKING DRAFT FOR REVIEW

This document contains proposed provisions for technical and institutional review. It is not an adopted Standard or an operative governance instrument. Its scope, application conditions and publication status are specified in the text.

Prepared by the Generativity Standards Program. Reference to external publications does not imply endorsement by ISO, IEC, IEEE or any United Nations body.

Foreword

This document specifies proposed programme requirements for conduct, conflict management, ethical impact assessment, contribution rights, and implementation-rights concerns. It is a Governance Working Draft. Version 0.2 preserves the EIP identifiers from version 0.1, clarifies the distinction between the mandatory acknowledgement period and extendible determination target in EIP-014, and adds operational handling, assessment, and evidence requirements.

Responsible editor: `UNASSIGNED`. Canonical source: `governance/ethics_ip_policy.tex`. Intended readers are contributors, affected people, ethics and rights reviewers, project leads, custodians, and the programme decision authority.

Adoption requires the programme's actual authority and recorded procedure. This text is not a licence offer, copyright transfer, patent assurance, or legal determination. The specific organizational and jurisdictional context remains to be established for commitments that depend on it.

Bibliography 17

Introduction

The infrastructure being developed can affect whose experience becomes visible, whose evidence receives consideration, and who can challenge an authoritative account. Programme participation can reproduce unequal access, while publication and preservation can expose people or depend on rights the programme does not hold. Ethical assessment therefore concerns both development conduct and the effects of proposed practices.

This policy separates four inquiries: whether programme conduct meets its rules; whether an interest impairs a particular role; whether a design or pilot has unacceptable or unresolved effects; and whether a proposed use of material has an established basis. Evidence of one does not resolve another. A well-attributed contribution can remain inaccurate; an ethically desirable publication can lack distribution permission; and a contribution from an interested person can still contain relevant evidence.

The policy supplies procedures and records rather than a universal score of ethical adequacy or generativity. It retains value disagreement, limitations of inquiry, and the distinction between internal programme remedies and external legal proceedings.

1 Scope

1.1 Subjects and application

This policy applies to participants acting in programme functions, programme decisions about conduct and conflicts, impact review of work items and pilots, and intake or distribution of contributed material. Its assessed subject is a specified activity, decision, contribution, or handling process under a declared edition.

1.2 Authority boundary

Internal corrective measures concern participation, assigned functions, programme access, and programme publications. Financial compensation, enforceable legal duties, jurisdiction, and findings of legal liability require separately established authority. Contribution rights and legal applicability remain subject to their actual context.

2 Normative references

2.1 Internal provisions

The following Governance Working Drafts, version 0.2, supply provisions needed by this policy. Exact operative editions are fixed through recorded adoption.

Standards Programme Charter. `governance/standards_programme_charter.tex`; appointments, decision authority, participation, resources, reserved powers, and neutral review.

Directives Part 1. `governance/directives_part_1.tex`; handling periods, appeal, emergency measures, release, retention, and maintenance.

Directives Part 2. `governance/directives_part_2.tex`; source discipline, publication claims, dependencies, evidence, and production.

GR/TC 1 Charter. `governance/technical_committee_charter.tex`; domain review, pilot authorization, findings, and progression evidence.

2.2 Application of timing and sources

The mandatory acknowledgement period and the initial-determination target cited in EIP-014 apply the specified Directives provisions to conduct handling without changing its substantive route. Only the initial-determination target has the cited reasoned-extension provision. External sources in the bibliography are informative; no external treaty, recommendation, statute, or institutional policy is incorporated as a generally applicable legal obligation.

EIP-041 The responsible handler shall identify the operative policy and procedure editions for each matter and record any conflict affecting authority, timing, protection, or available remedy. A consequential dependent determination shall await resolution of a material conflict within actual authority.

3 Terms and definitions

3.1 Material interest

A financial, institutional, personal, authorship, funding, or infrastructure-control interest relevant to impartial performance of a specified programme function.

3.2 Conflict-management decision

A reasoned determination of whether an interest affects a particular function and what disclosure, oversight, separation, recusal, replacement, or deferral is required.

3.3 Report

Information submitted concerning possible conduct, protection, conflict, or rights problems. Receipt does not establish the allegation.

3.4 Reported person

A person whose programme conduct is the subject of a report or inquiry. The term does not imply a concluded finding.

3.5 Protective measure

A temporary action intended to limit an identified immediate risk while fair consideration remains incomplete. It is distinct from a final conduct finding or sanction.

3.6 Rights clearance

A scoped programme determination that an identified use of particular material is supported by recorded permissions or another reviewed basis, subject to stated limitations.

3.7 Contribution

Material submitted for a stated programme purpose, including prose, comments, schemas, software, examples, data, or source materials. Submission alone does not establish ownership or a licence for further uses.

3.8 Impact finding

An assessed actual or anticipated consequence of a proposed practice, identifying affected interests, evidence, uncertainty, values, alternatives, and proposed response.

3.9 Retaliation

Adverse programme treatment because a person raised a concern, gave relevant evidence, participated in review, or exercised a permitted challenge route. A reasoned response to independently established misconduct is assessed separately.

4 Responsibilities and readiness

4.1 Assignment and independence

EIP-001 The programme shall identify the adopted edition, effective scope, responsible ethics contact and alternate, protected reporting route, decision authority, and neutral-review route before treating this policy as operational. Until then it shall retain Governance Working Draft status.

EIP-002 The programme shall assess conduct, conflicts, substantive impacts, and contribution rights through distinguishable findings. A favorable finding in one area shall not be represented as clearance in

another.

EIP-042 The governance authority shall assign an ethics contact, an alternate, conflict-decision responsibility, competent rights review, record custody, and neutral procedural review before relying on those functions. Each holder shall accept a bounded mandate and declare interests; an unassigned function shall remain visibly unavailable.

EIP-043 The ethics contact shall receive and triage reports, arrange appropriate consideration, communicate status, and protect access. The investigator or assessor shall examine the stated question; the authorized decision maker shall determine programme findings and remedies. Where functions are combined, the record shall identify resulting limits and independent review needed.

EIP-044 Before opening a protected reporting route, the custodian shall verify restricted access, a safe alternate contact, retention arrangements, incident handling, and the information provided to reporters about confidentiality limits. If the route fails, the custodian shall publish or directly provide a safe alternative and prevent further avoidable disclosure.

4.2 Capacity and access to assistance

EIP-045 The responsible authority shall provide information on feasible assistance with language, access, or submission format and shall record unmet needs and their effect on fair consideration. A person shall not be required to expose protected information publicly to obtain assistance.

EIP-046 A material capacity gap in impartial handling, rights competence, or protection shall be reported to the governance authority with a proposed reassignment, narrower scope, or deferral. Continued drafting within existing permission shall remain distinct from approval of the affected use or finding.

5 Conduct and evidential integrity

5.1 Participation and attribution

EIP-003 Participants acting in programme roles shall not engage in harassment, threats, retaliation, discriminatory exclusion, or coercive disclosure of protected information. Critical disagreement about sources, methods, policy, and requirements shall remain eligible for reasoned consideration.

EIP-004 A participant presenting a factual or source-based claim shall distinguish observation, quotation, interpretation, inference, and proposal where that distinction affects review. Known material errors, fabricated evidence, or falsely attributed sources shall not be retained as support after discovery without correction or explicit disputed status.

EIP-005 Editors shall preserve attribution of material contributions and competing positions within actual permissions and protection needs. Authorship, acknowledgement, evidential reliability, ownership, and decision authority shall remain distinct.

EIP-047 A participant identifying a material error in their earlier contribution shall notify the responsible editor and supply the correction or known uncertainty. The editor shall assess affected arguments, decisions, and artifacts and retain an attributable correction record.

EIP-048 A claim that a contribution was deliberately fabricated or knowingly misattributed shall be assessed through the conduct procedure. A disputed interpretation, incomplete evidence, ordinary error, or unsubstantiated report shall not by itself establish intentional misconduct.

5.2 AI and external processing

EIP-006 A participant using AI assistance for a material draft, analysis, evidence synthesis, or disposition proposal shall identify the consequential assistance and the responsible human reviewer in the development record. The reviewer shall verify material sources and conclusions before relying on them.

EIP-007 Participants shall not submit protected, confidential, or third-party material to a tool or service without an established basis for that disclosure. Uncertainty about such a basis shall be resolved before the disclosure.

EIP-049 A consequential AI-use record shall identify the task, material source categories, transformations relied on, responsible human reviewer, verification performed, and known limits relevant to the resulting claim. Protected prompts or source contents shall not be exposed solely to demonstrate that assistance occurred.

EIP-050 When external processing terms or data handling change materially, the responsible user shall reassess permitted disclosure and reliance before further affected use. A tool's technical availability shall not establish permission to disclose material or confidence in its output.

6 Interests and influence

6.1 Disclosure and assessment

EIP-008 Before accepting a decision or review role and when relevant circumstances change, a participant shall disclose interests that could materially affect, or reasonably call into question, their impartial performance of that role. The disclosure shall include relevant financial, employment, funding, authorship, institutional, personal, and infrastructural-control interests.

EIP-009 The responsible coordinator shall record a conflict assessment, its author, the affected decision, the disclosed interest, protection limits, and the selected management action. Disclosure alone shall not be treated as resolving a conflict.

EIP-010 A person shall not determine the disposition of a complaint against themselves, act as neutral reviewer of their own decision, or independently assess a rights clearance in which they have an unresolved material interest. The alternate route shall be used.

EIP-011 Conflict management shall identify whether disclosure with oversight, separation of roles, partial recusal, replacement, or deferral is required. A recusal shall identify the decision scope and substitute authority without suppressing relevant technical evidence from the recused contributor.

EIP-012 The decision authority shall examine material concentration of funding, affiliation, available unpaid labor, infrastructure access, and agenda control when assessing fair consideration. If the concentration impairs review, it shall record corrective measures and reassess progression.

EIP-051 An interest disclosure shall identify the affected role or decision, nature and duration of the interest, relevant relationships, and protection needs. The conflict assessor shall distinguish an actual conflict, a reasonably perceived conflict needing management, and an interest not material to the stated role, with reasons.

EIP-052 Before the affected decision proceeds, the conflict assessor shall communicate the management decision to the role holder and responsible chair and record any objection. A challenged assessment involving the assessor's own interests shall be referred to the alternate or neutral route.

6.2 Recusal and control measures

EIP-053 A recusal arrangement shall identify prohibited decision participation, permitted factual or technical contribution, access limitations where justified, substitute authority, duration, and reconsideration trigger. The chair shall verify that the recusal was applied and record its consequence for eligibility or quorum.

EIP-054 If an undisclosed material interest is discovered after a decision, the governance authority shall assess the affected procedure and outcome, obtain independent consideration where needed, and record whether disclosure, renewed review, repeated decision, or another remedy is required. Retrospective disclosure shall not alone cure a defective process.

EIP-055 Measures addressing concentrated influence shall identify the actual mechanism, such as agenda control, dependence on one host, repeated affiliations, or unequal time resources, and the proposed response. The assessment shall not treat head count alone as evidence of balanced influence or stigmatize a contributor solely for an affiliation.

7 Report intake and triage

7.1 Receipt and route

EIP-013 The programme shall provide a reporting route to an ethics contact and an alternate independent of a reported person. Its notice shall explain receipt handling, who can access material, limits on confidentiality, possible outcomes, record retention, and the procedural-review route.

EIP-014 A report shall receive acknowledgement, triage, status communication, and a reasoned disposition. The seven-calendar-day acknowledgement requirement in D1-035 and the 30-calendar-day initial-determination target, with reasoned extensions notified before expiry, in D1-036 shall apply to report handling without converting the report into a procedural appeal. An extension of the determination target shall not extend the acknowledgement requirement. Triage shall distinguish immediate protection needs, conduct issues, procedural appeals, substantive technical objections, and record-specific correction or access requests.

EIP-015 A report shall not be rejected solely because its author requests protected handling or lacks a formal role. The reviewer shall record whether limited identity or unavailable evidence constrains investigation and what fair assessment remains possible.

EIP-056 At intake, the ethics contact shall assign a stable identifier, record the reported concern and relevant programme connection, acknowledge the requested protection, identify immediate risk, and explain the next handling step. Requests for additional information shall be limited to what is needed for that step.

EIP-057 Triage shall identify scope, required authority and competence, potential conflicts, available evidence, immediate protection needs, and whether another programme or external route is relevant. A referral shall preserve the original receipt history and explain what the programme will and will not determine.

EIP-058 When a report contains both a technical objection and a conduct allegation, the handler shall provide linked but distinct handling records. The technical concern shall not lose consideration because the conduct allegation is unsubstantiated, and a conduct concern shall not be dismissed solely because the technical proposal is accepted.

7.2 Protected, anonymous, and repeated submissions

EIP-059 The handler shall assess an anonymous or partly identified report to the extent supported by available information and record limits on verification, reply, and remedy. Identity disclosure shall not be demanded without a stated handling need and consideration of a less intrusive alternative.

EIP-060 A repeated submission shall be linked to earlier handling and assessed for new evidence, unaddressed grounds, or changed circumstances. Limits on repetitive or abusive contact shall state the conduct basis, safe route for materially new information, scope, review date, and challenge route. Mere persistence in disagreement shall not establish abuse.

8 Inquiry and fair response

8.1 Scope and evidence plan

EIP-016 Before an adverse conduct finding, the responsible reviewer shall provide the affected person a sufficient account of the concern and an opportunity to respond, using redaction or a protected intermediary when necessary. Where protection prevents a fair determination, that limitation shall remain explicit.

EIP-061 Before a substantive inquiry, the appointed assessor shall state the questions, applicable programme rules, scope, evidence sources, access arrangements, opportunities to respond, intended timetable, and decision authority. A material expansion shall be notified to affected participants with an adequate response opportunity.

EIP-062 The assessor shall distinguish direct information, testimony, contemporaneous records, inference, hearsay, and disputed interpretation where that distinction affects the finding. Relevant contrary evidence and plausible alternative explanations shall be examined; source status alone shall not determine credibility.

EIP-063 The assessor shall document evidential gaps and the reasons material may be unavailable, including protection, loss, or lack of access. An unavailable record or a person's inability to participate shall not automatically be treated as proof of the alleged conduct or its absence.

8.2 Opportunity to respond and protection

EIP-064 A response invitation shall identify the material concern and grounds sufficiently for a meaningful reply, the response route and deadline, available assistance, and the proposed decision scope. If safe disclosure cannot support a fair finding, the limitation shall prevent an unsupported adverse determination.

EIP-065 The assessor shall avoid unnecessary repeated disclosure of sensitive experiences and shall record how protected testimony can be tested fairly through safe summaries, questions, or an authorized intermediary. A summary materially interpreted by another person shall retain that mediation and any confirmation or dispute by its source.

EIP-066 The handler shall obtain an appropriate rights and protection assessment before disclosing case material to an external institution. A claimed obligation to disclose shall identify the competent authority, context, basis, and unresolved questions; the policy itself shall not be treated as creating that obligation.

9 Protective measures and determinations

9.1 Interim action

EIP-017 A temporary protective measure shall identify the immediate risk, authority, limited scope, review point, and route to challenge. It shall be distinguished from a concluded misconduct finding.

EIP-067 The authority issuing a protective measure shall identify less restrictive feasible alternatives, the effect on participation and evidence access, the person responsible for review, and the conditions for ending or modifying the measure. The D1-050 controls shall apply to temporary protective measures under this policy, including participation restrictions: independent review within seven calendar days and expiry within 30 calendar days unless the governance authority records a justified extension, next review date, and remedy plan. Continued restriction shall retain renewed reasons and an available challenge route; temporary protection shall not become a permanent sanction through elapsed time alone. These controls shall not expand the programme's substantive authority.

EIP-068 A person subject to a protective measure shall receive its scope, safe reasons, duration or review point, and challenge route to the extent consistent with immediate protection. Any delayed notice shall be justified and reviewed rather than omitted indefinitely.

9.2 Findings and evidential criterion

EIP-018 A final conduct disposition shall identify the applicable rule, assessed evidence and limits, conflicts and recusals, finding, reasons, proportionate remedy, responsible implementer, and review route. Available programme remedies include correction, facilitated participation, role reassignment, limited access, suspension, or removal under the Charter.

EIP-020 If a fair, sufficiently independent review cannot be provided, the programme shall record that limitation, preserve appropriate protections, and defer the affected consequential determination. It shall not represent inability to investigate as proof that a report is false or established.

EIP-069 For an internal conduct finding, the decision maker shall distinguish substantiated, not substantiated on available evidence, outside mandate, and resolved by an agreed measure without a conduct finding. A substantiated finding shall explain why the alleged conduct is more likely than not on the assessed evidence, address material contrary information and plausible alternatives, and identify limits. A numerical probability shall not be required. Where the assessment does not favor the alleged conduct over its non-occurrence, including an unresolved balance, the allegation shall not be classified as substantiated. This criterion shall not override EIP-016, EIP-020, or EIP-064 concerning fair response and sufficiently independent consideration, and shall not be represented as an external legal finding or burden of proof.

EIP-070 The decision maker shall distinguish the conduct established, any intention or effect separately supported, the rule engaged, and the resulting programme consequence. A serious remedy shall be supported by reasons addressing severity, impact, recurrence, context, and feasible alternatives within programme authority.

EIP-071 A disposition based on an agreed measure shall record the actual agreement, its scope, responsible parties, review point, and treatment of unresolved allegations. Agreement shall not be presumed from silence or obtained by making access to the ordinary complaint route conditional on acceptance.

9.3 Remedies and review

EIP-019 The programme shall monitor agreed remedies and potential retaliation and shall publish a non-sensitive account sufficient to inspect procedural handling. Confidential material shall not be published merely to demonstrate transparency.

EIP-072 A remedy plan shall identify required actions, owners, practical resources, dates or triggers, completion evidence, and consequences of non-performance. Correcting a record, restoring participation, changing a role, and addressing downstream effects shall be distinguished.

EIP-073 The disposition notice shall explain the finding and safe reasons, the operative procedure, available procedural review, and the basis for any restricted evidence. A request concerning substantive reconsideration shall be distinguished from an appeal alleging procedural failure.

EIP-074 A material new fact or demonstrated handling error shall trigger an assessment of reopening, revised remedy, or referral. The record shall retain the original determination and reasons for changed status; reopening shall not silently erase prior reliance or its consequences.

EIP-075 Monitoring for retaliation shall identify a safe contact and review trigger without imposing unnecessary surveillance on participants. A reported adverse response shall receive separate assessment of its connection to protected participation and any independently stated reason.

9.4 Scoped substantive reconsideration

EIP-099 A reporter or reported person may request substantive reconsideration through the ethics contact or non-conflicted alternate on grounds of material new evidence, an identified material error in assessment or application of the conduct criterion, or a remedy materially unsupported by the stated findings. The request shall identify the disposition, grounds, available evidence, and requested change. Mere repetition without identified grounds may receive a reasoned refusal; disagreement shall not itself constitute misconduct. The disposition notice shall explain this scoped route separately from the procedural appeal route.

EIP-100 The ordinary filing period for substantive reconsideration shall be 30 calendar days after accessible notice of the disposition. The non-conflicted reconsideration reviewer may extend that period with recorded reasons for ineffective notice, newly available material evidence, or a previously concealed assessment defect. The ethics contact shall acknowledge receipt within seven calendar days and arrange an initial admissibility or substantive determination targeted within 30 calendar days of receipt, with reasoned extensions and revised dates notified before expiry. Silence shall not constitute rejection.

EIP-101 The governance authority shall assign substantive reconsideration to a competent person or function that did not determine the challenged finding and has no unresolved material conflict, with a mandate identifying the issues and available programme remedies. The reviewer shall give an admissibility decision with reasons and provide affected parties an opportunity to respond to material new grounds before a consequential outcome. An admitted request shall have a notified timetable for replies and reasoned disposition; a change shall have reasons and notice before the affected target expires. If sufficiently independent competence is unavailable, EIP-020 shall govern deferral; reassessment by the original decision maker shall not be presented as independent reconsideration.

EIP-102 The reconsideration reviewer shall identify the record examined, grounds admitted, evidence and replies considered, criterion applied, reasons, outcome, and implementation responsibility. Within the recorded mandate, the reviewer may uphold, qualify, set aside, or remit a conduct finding or remedy for renewed consideration; a remedy outside that mandate shall be referred to its authorized decision maker. The record shall preserve the earlier finding and explain any changed effect, notice, or practical action. Substantive reconsideration shall not determine external legal liability or replace access to procedural appeal under Directives Part 1.

EIP-103 On a substantive reconsideration request, the responsible authority shall record whether an existing remedy requires a stay, modification, or continued operation within programme powers, considering protection, participation, evidence, and consequences. The decision shall have reasons, a review point, and permitted notice. Neither an automatic stay nor automatic continuation shall be inferred solely from the request. Any temporary restriction retained shall remain subject to EIP-067, and implementation of a reconsideration remedy shall be monitored under EIP-072.

10 Ethical impact assessment

10.1 Question, affected interests, and alternatives

EIP-021 Each work item shall assess whose experiences become visible, who can challenge classifications, who bears recording and review burdens, and who gains control or access through the proposed infrastructure. Assessment shall consider relevant alternatives, evidence, and residual uncertainty.

EIP-022 An impact assessment shall distinguish observed effects, predicted effects, value commitments, and institutional choices. It shall identify material tradeoffs involving recognition, privacy, autonomy, unequal participation, maintenance labor, ecological conditions, and future capacities where relevant to the use case.

EIP-024 A proposal involving contribution or generativity return shall distinguish descriptive attribution, normative evaluation, and any proposed allocation of benefits or responsibilities. It shall not infer a monetary amount, entitlement, or contractual obligation solely from a generativity record.

EIP-076 The impact reviewer shall identify the proposed use, affected interests and absent perspectives, decision context, baseline, foreseeable benefits and harms, evidence and uncertainty, and alternatives including reduced collection, restricted access, different institutional arrangements, or deferral where relevant.

EIP-077 Where values conflict, the assessment shall state the values and affected people, reasons for the proposed priority, alternatives rejected, expected distribution of benefits and burdens, and conditions requiring reconsideration. A single aggregate score shall not replace those reasons.

EIP-078 A participation or recognition proposal shall assess whether people can refuse optional recording, challenge an attribution, or obtain an explanation without disproportionate burden. A claimed exception shall identify its actual institutional basis and consequences rather than present coercion as technical necessity.

10.2 Authorization, monitoring, and intervention

EIP-023 Before a real pilot or consequential expansion, the responsible authority shall record its purpose, actual participants and mandate, permitted material, accessible notice and challenge routes, protection measures, monitoring, stop conditions, and capacity to implement correction or repair.

EIP-025 A material unresolved ethical or participation finding shall receive a recorded disposition before the affected publication or pilot decision. Completion of a form shall not alone establish that an impact is acceptable or a remedy effective.

EIP-079 Before relying on mitigation to authorize a pilot or use, the responsible authority shall verify its owner, resources, operational status, and assessment method. Unimplemented mitigation shall remain a condition or limitation and shall not be counted as an achieved safeguard.

EIP-080 Monitoring shall identify observations capable of challenging the intervention rationale, emerging burdens or exclusions, and stopping or revision triggers. Findings shall distinguish absence of observed harm from evidence of absence of harm within a sufficiently examined scope.

EIP-081 After a material protection or ethical failure, the responsible authority shall assess immediate containment, affected people and uses, correction or repair, continued-use conditions, and lessons for requirements. Restart shall depend on recorded evidence addressing the failure, not solely on a revised description.

11 Contribution intake and permission

11.1 Artifact identity and intended uses

EIP-026 For contributed material proposed for incorporation or distribution, the rights register shall identify the artifact and version, contributor and stated capacity, claimed rights holder, source, intended uses, asserted permission or licence, restrictions, third-party components, evidence of authority, and unresolved questions.

EIP-027 A contribution record shall distinguish permission to examine material from permission to incorporate, edit, redistribute, sublicense, or publish it. Repository access, submission of comments, acknowledgement, or the absence of a licence notice shall not alone be treated as permission for those further uses.

EIP-028 The programme shall keep terms for prose, schemas, software, examples, datasets, and foundation manuscripts separately identifiable. A licence applying to one artifact class shall not be presumed to cover the others.

EIP-029 Foundation manuscripts and third-party sources shall retain their recorded source terms. Incorporating a source in the foundation manifest, citing it, extracting concepts from it, or placing it in the repository shall not be represented as relicensing the source.

EIP-082 The contribution handler shall identify the submitted version, source and included components, contributor's stated capacity, intended examination or incorporation, and the scope of any assertion about rights. A claim of ownership or permission shall retain its source and verification status.

EIP-083 Before incorporating material, the editor shall determine whether its intended modification, combination, publication, implementation, or retention is within the reviewed basis. New uses or components shall receive renewed clearance rather than inherit approval from an earlier narrower purpose.

11.2 Clearance and unresolved rights

EIP-030 Before public distribution of an artifact, the designated rights reviewer shall record that the intended distribution and included material are covered by identified permissions or another reviewed basis. Unclear rights shall block the affected distribution, while drafting and review within established permissions may continue.

EIP-031 Where an intended use exceeds available permission, the editor shall obtain suitable permission, replace or remove the material, narrow the use, or retain the affected artifact as restricted. The disposition shall preserve the source and reason without exposing restricted content.

EIP-032 A change in contribution or publication terms shall identify the artifacts and versions affected, authority for the change, contributor acceptance needed, and transition treatment. A new licence shall not be represented as retrospectively covering existing contributions without an established basis.

EIP-084 A clearance decision shall identify the artifact and exact intended use, claimed rights holder and authority evidence, applicable terms and version, third-party components, review competence, restrictions, unresolved issues, and expiry or reconsideration triggers. Clearance shall be limited to that recorded use.

EIP-085 If a rights claim or permission dispute arises after incorporation, the rights contact shall record affected material and uses, preserve appropriate evidence, seek competent assessment, and notify the authorized release holder of any needed restriction or correction. The programme shall not declare the claim valid or invalid solely from its receipt.

EIP-086 A contributor's request to withdraw or change permission shall be assessed against the actual terms, prior uses, downstream distributions, protection concerns, and relevant authority. The response

shall distinguish feasible programme action from uses or rights outside programme control.

12 Terms, implementation rights, and publication

12.1 Selection and acceptance of terms

EIP-033 Before offering contribution terms or choosing publication licences, the programme shall record its organizational and jurisdictional context, intended rights and obligations, artifact classes, alternatives, implementation consequences, and review by a person competent for the relevant rights questions.

EIP-034 The programme shall make operative contribution terms available before requesting assent to them and shall retain the accepted version and scope. A record of assent shall not assert that the contributor holds rights that remain unverified.

EIP-087 The terms-selection record shall compare rights needed for the intended artifact use, contributor interests, implementation and redistribution conditions, attribution, modified versions, translation, dependency compatibility, and maintenance. Prose, code, schemas, datasets, examples, and manuscripts shall receive distinct treatment where their requirements differ.

EIP-088 An acceptance record shall identify who assented, their stated authority, the exact terms and covered contribution, date, and evidence of assent. A form submission or repository action shall count as assent only where the announced process clearly established that meaning and actual acceptance is evidenced.

12.2 Implementation-rights concerns

EIP-035 A participant aware of a potentially material rights obstacle to implementing a proposed requirement shall report the known concern and its basis to the designated rights contact. The report shall distinguish actual knowledge, an asserted claim, and unresolved inference; it shall not be presented as a legal determination.

EIP-036 The programme shall record a material implementation-rights concern, affected requirements, available public information, review competence needed, feasible alternatives, and its disposition before approving an implementation claim that depends on the concern.

EIP-037 No programme participant shall make a licensing promise, patent assurance, rights waiver, or financial commitment on behalf of another person or institution without documented authority. A declaration under another organization's process shall not be represented as a programme agreement without review of its actual scope.

EIP-038 Where implementation rights remain materially unresolved, the responsible decision authority shall narrow the claim, select a reviewed alternative, or defer the affected normative adoption. An empty concerns register shall not be described as proof that implementation is free of third-party rights.

EIP-089 The handling of a potential essential-rights concern shall distinguish notification, factual clarification, specialist assessment, exploration of alternatives, and an authorized decision. A request for information shall not be phrased as a programme licensing commitment or as a determination of validity or essentiality.

EIP-090 Where a technical alternative is proposed to address a rights concern, the committee shall assess whether it satisfies the affected requirement and whether it introduces other material constraints. Selecting an alternative shall not be reported as resolving all implementation rights without the corresponding evidence.

13 Records, oversight, and assessment

13.1 Custody and publication of case information

EIP-039 Ethics, conflict, and rights records shall identify an accountable custodian, access rules, retention or review basis, correction route, and treatment of protected information. Public decision evidence shall avoid unnecessary disclosure while making authority, procedure, and unresolved limits inspectable.

EIP-091 The custodian shall separate public disposition information from protected evidence, restrict access to accepted roles with a handling need, and retain access and disclosure decisions. Changes in custodianship shall verify transfer of restrictions and pending response or retention duties.

EIP-092 Before releasing a case summary, the responsible handler shall assess whether combinations of facts disclose protected identity, existence, or content. The summary shall state material limits on public inspection without creating a false impression that an allegation or rights assertion was conclusively established.

13.2 Review and performance

EIP-040 The programme shall review this policy with the governance review cycle and after a material complaint, rights dispute, change of legal or organizational context, or change in publication arrangements. A revision shall preserve the prior edition and unresolved cases' transition treatment.

EIP-093 An assessment against this policy shall identify the subject, period, edition, assessor and interests, applicable EIP requirements, evidence, and results as fulfilled, not fulfilled, not assessed, or not applicable. Unperformed handling steps and blank templates shall not demonstrate fulfillment.

EIP-094 The governance authority shall review repeated complaints, unresolved conflicts, rights-clearance delays, protection failures, unequal burdens, and remedy effectiveness using protected or aggregated information as appropriate. Corrective actions shall have owners, review points, and evidence of completion.

Annex A

(normative)

Handling records and state transitions

A.1 Minimum case record

EIP-095 A case record shall contain identifier, scope and applicable editions, receipt history, requested protection, roles and conflicts, alleged issue distinguished from findings, evidence and limits, notices and replies, interim measures, decision and reasons, remedy, review route, access and retention basis, and current state. Changes of state shall identify their actor, date, grounds, and linked evidence.

A.2 Case states

EIP-096 The handler shall use the case states in Table A.1, or an explicitly mapped equivalent, so that receipt, examination, pending capacity, determination, remedy, and closure remain distinguishable. A transition shall preserve linked prior states and shall not imply completion of an unperformed step.

Table A.1 – Case state meanings and transition evidence

State	Meaning	Evidence supporting a transition
Received	Submission logged; no finding.	Receipt identifier, safe contact, requested protection, acknowledgement.
Triaged	Scope and route assessed.	Authority, conflicts, immediate risk, referral or inquiry decision.
Under consideration	Evidence and replies being assessed.	Questions, responsible assessor, evidence plan, notices, replies.
Pending capacity or information	A stated limitation prevents the next step.	Missing item or role, action owner, review date, protection retained.
Determined	Authorized finding or scoped disposition recorded.	Reasons, evidence limits, response consideration, remedy and review route.
Remedy under implementation	Agreed or directed action remains open.	Owners, resources, deadlines or triggers, follow-up evidence.
Closed or referred	Programme handling completed or assigned elsewhere.	Closure grounds or referral acceptance, residual limits, reopening/contact route.

A.3 Conflict and impact records

EIP-097 A conflict record shall identify the interest, affected function, assessor and independence, materiality reasons, management action, objection and response, implementation evidence, and review trigger. An impact record shall identify affected interests, evidence, values, alternatives, distributional effects, safeguards, authority, monitoring, and unresolved limitations.

A.4 Rights decision and acceptance records

EIP-098 A rights record shall identify artifact and version, source and components, contributor and asserted authority, intended uses, terms or other reviewed basis, competent assessment, restrictions, decision, acceptance where needed, and reconsideration triggers. Public licence statements shall be checked against that record before release.

A.5 Assessment of timing, findings, and reconsideration

EIP-104 An assessment claiming fulfillment of conduct-handling procedure requirements shall exercise the applicable conditions in Table A.2, identify the tested edition, input and expected outcome, and record performed actions, results, and limitations. A documentary assessment shall distinguish a complete specimen record from evidence that acknowledgement, independent consideration, notice, or remedy actually occurred. Unobserved performance shall remain not assessed rather than fulfilled.

Table A.2 – Conduct-review assessment conditions and limits

Condition	Relevant provisions and evidence	Discriminating result
Receipt and extended inquiry	EIP-014; actual receipt and acknowledgement, determination target, extension reason and notice.	A timely determination extension does not turn an acknowledgement later than seven days into timely performance.
Temporary participation restriction	EIP-017, EIP-067/068; authority, alternatives, independent review, expiry or justified extension and next review.	A restriction cannot continue indefinitely through a missing expiry or be relabelled a final sanction without determination.
Unresolved evidential balance	EIP-016/020/064/069; assessed grounds, contrary material, response opportunity and competence.	An unresolved balance does not substantiate the allegation; a numerical score is unnecessary; the outcome does not assert that the report was false.
Material reassessment request	EIP-099–102; identified grounds, receipt, admissibility, independent assignment, timetable, response and outcome.	A reasoned finding can change within mandate; the original decision maker is not described as independent; mere silence does not reject the request.
Unavailable reviewer or continuing action	EIP-020, EIP-072, EIP-101/103; capacity gap, stay assessment, protection, remedy ownership and verification.	Missing capacity remains visible and the consequential determination deferred; a planned remedy is not reported as completed.

Annex B

(informative)

Worked applications and unresolved choices

B.1 Interested expertise and neutral decision

An implementer funds an editor who proposes an exchange feature. The editor's evidence remains relevant, while the funding and implementation interest require assessment against the decision role. Oversight or separation can preserve the contribution while preventing the editor from determining a complaint about suppression of alternatives. The record shows which capacities were retained and which decisions were reassigned.

B.2 Protected testimony and limited finding

A participant reports exclusion but cannot safely publish identifying details. Intake records the protection need and available evidence. A neutral assessor considers whether a safe summary permits a meaningful reply. If the material cannot be tested sufficiently for an adverse finding, the result remains limited; it is not converted into a conclusion that the account is false. Feasible access improvements can still be considered without pretending that an allegation was proved.

B.3 Rights to read and rights to publish

A manuscript is available to project members for background reading. An editor proposes attaching it to a public package. The contribution record distinguishes examination from redistribution. The proposed attachment awaits a reviewed basis; source interpretation and new drafting continue within actual permission. A licence selected for the new programme prose does not automatically cover the manuscript.

B.4 Record correction and consequential repair

A synthetic pilot corrects an inaccurate attribution after a challenge. The correction record establishes that the current account changed. A separate remedy record asks whether excluded participation, lost access, or other practical consequences were addressed. Where those effects were not examined, the report states the limitation rather than claiming that the corrected text restored the affected person's position.

B.5 Local choices requiring review

The internal evidential criterion for conduct findings is a programme proposal that makes decisions reviewable; it does not purport to prescribe a court's procedure. Remedies remain bounded by actual programme authority. Different organizational contexts could justify revised procedures through the governance amendment process.

The proposed criterion requires a reasoned comparison of the assessed grounds, not a compulsory probability calculation. Alternatives include a more demanding internal threshold for particular findings or leaving the criterion to case-specific choice. The present draft selects an explicit common criterion, alongside fair-response and independence conditions, so that participants can examine its application and request scoped reconsideration. The choice, its error and participation risks, and the local reconsideration periods require review before governance adoption; see `decisions/ADR-0005-expanded-drafts-and-source-models.md`. No finding becomes valid merely because its author asserts that the threshold was met.

OPEN ISSUE Organizational and jurisdictional context, operative contribution agreements, publication licences, patent policy, named contacts, protected infrastructure, and specialist rights-review capacity remain unresolved. The policy supplies conditions for reviewing those choices without making the commitments itself.

OPEN ISSUE Procedural rehearsal needs to test handling burden, neutral-review availability, language and disability access, protected evidence, recusal, rights disputes, and remedy follow-up. Synthetic success does not establish capacity for a live consequential case.

GENERATIVITY STANDARDS PROGRAM

GR-100

Standards-track Working Draft

Version 0.2 2026-09-22

Foundations and Vocabulary

WORKING DRAFT FOR REVIEW

This document contains proposed provisions for technical and institutional review. It is not an adopted Standard or an operative governance instrument. Its scope, application conditions and publication status are specified in the text.

Prepared by the Generativity Standards Program. Reference to external publications does not imply endorsement by ISO, IEC, IEEE or any United Nations body.

Foreword

Responsible editor: UNASSIGNED.
Canonical source: `standards/GR-100-foundations-vocabulary/GR-100.tex`

This document is a standards-track Working Draft of the Generativity Standards Program. Its maturity is **PREPARATORY; PROVISIONAL**. It is available for substantive review and experimental assessment. It is not an adopted Standard, evidence of formal project initiation, or approval of GR/NWIP-001. Appointment of an editor, adoption of the governance instruments, work-item approval, review and final adoption require their own recorded decisions. Draft requirement language has no programme adoption or independent legal effect.

Edition 0.2 replaces edition 0.1 as the active authoring text; the earlier edition remains historical material. Existing requirement identifiers V100-001 to V100-012 retain their meanings. The body supplies candidate normative definitions and requirements. Annex A is a normative assessment schedule. The remaining annexes and bibliography are informative. No informative example or note adds a requirement.

The publication structure separates scope, dated references, numbered terms, requirements, conformance and annexes. Structural resemblance to another organization's publications establishes no affiliation, endorsement or compliance with its development procedures. Foundation manuscripts provide conceptual sources rather than adopted normative authorities.

Bibliography 24

Introduction

The programme responds to instability in the connection between representations, their targets, institutional classifications and practical trust. An authentic or fluent account can be mistaken for a warranted account of what happened. Correction can also erase the history of an earlier claim's influence. Inspectable recording requires these differences to remain expressible before a technical model standardizes interchange.

Reality is not reduced to what a recording institution recognizes. Manifestations, traces, accounts and judgments can disclose a target partially; they can also enter subsequent action and change conditions of further generation. A mistaken classification can remain historically important after its evidential warrant has been rejected. Its occurrence, interpretation and practical effects require distinguishable descriptions.

The foundation manuscripts distinguish abstract metamodel concepts from richer analytical categories and distinguish ontological questions from evidential access. This document uses those distinctions without turning six record roles into ultimate kinds of being. Its operational definitions do not exhaust GR theory. They support partial knowledge, contested identity, overlapping roles, changing categories and revisable interpretation.

Interoperability requires more than shared spelling. One institution can use evidence for an accepted document, another for material bearing on a claim and another for a procedural exhibit. Similarly, a numerical property can be a category code, an ordinal rating or a measurement. A common format does not make their operations equivalent. Vocabulary application therefore includes scope, source, transformation and assessment duties.

1 Scope

1.1 General

This document supplies a bounded operational vocabulary for recording and examining claims about generative histories. It addresses a practical problem: a record can accurately preserve an assertion while the assertion is mistaken, an authentic document can contain an unsupported inference, and a later correction can conceal the historical consequences of an earlier judgment. Inspectable practice requires distinctions among what is claimed to have happened, how it became accessible, what was recorded, what was inferred, and how the account was used.

The scope includes vocabulary use, the separation of levels of description, identity and temporal distinctions, and a candidate description of six record roles. It does not define truth, a complete metaphysics, a universal theory of evidence, legal validity, a universal generativity score, or a machine-readable schema. Domain methods can provide stronger criteria within a declared scope.

GR-110 develops trajectory recording requirements. GR-200 develops the epistemic record package. GR-120 and associated Specifications are intended to resolve technical representation after requirements and cases expose a reusable need. GR-210 is intended to address assessment and contestation procedures. References to these publications identify coordinated draft work; none is an adopted normative dependency.

2 Normative references

2.1 General

There are no external normative references in this edition. All requirements needed for assessment are contained in its body and Annex A. Foundation manuscripts and programme documents in the bibliography are informative sources for interpretation and drafting rationale, not supplementary conformance requirements.

2.2 Dated applications and mappings

An application can identify an additional dated domain vocabulary or profile in its declaration. That source becomes part of the application's own commitments, not a normative dependency of GR-100. The assessment distinguishes fulfillment of this document from fulfillment of that additional source. A current online resource does not silently update the meaning used in an assessed edition.

3 Terms and definitions

3.1 General

The following definitions apply within this document's recording scope. Capitalized Entity, State, Event, Process, Relation and Property name the operational record roles in Clause 5. Lowercase ordinary uses remain possible when their meaning is evident. Terms concerning uncertainty and missingness describe an inquiry rather than settle the truth values of the underlying world.

These definitions support linked descriptions, not a mandatory class hierarchy. Several terms can concern one activity: observation can involve interpretation and inference, and its result can become evidence for another claim. The application identifies these functions rather than treating their coexistence as an error.

3.2 Target

That about which a claim is made.

NOTE 1 A target can be a situation, participant, occurrence, relation, condition, possibility, record, or another claim. Its identification can remain partial or contested. A target reference is an act of reference; it does not establish existence or identity.

3.3 Manifestation

For recording purposes, an identified way in which a difference becomes available to encounter, registration, measurement, expression, or classification under specified conditions.

NOTE 2 This is a limited operational use informed by FM-004; it does not exhaust that manuscript's account of manifestation.

3.4 Representation

A description or arrangement of signs used to describe, classify, model, or otherwise stand for a target.

NOTE 3 Representations can themselves become targets of inquiry and participants in later action.

3.5 Record

An identified retained representation, together with the context needed to interpret its declared recording purpose.

NOTE 4 A record can contain several claims, and several records can concern one target. Retention need not mean public disclosure or indefinite preservation.

3.6 Record package

A declared collection of records and contextual references presented together for a specified purpose and version.

NOTE 5 A package can contain protected components and a restricted or public view. A view's limitations are part of its declared scope.

3.7 Claim

An attributed assertion with identifiable content and target, expressed under a stated scope.

NOTE 6 The assertion can concern an occurrence, a possibility, an interpretation, a value judgment, or institutional or legal status. Recording it does not endorse it. Several parties can assert the same content with different grounds.

3.8 Attribution

A recorded association between a claim or activity and the person, institution, system, or source represented as originating or performing it.

NOTE 7 Attribution can be pseudonymous, unknown, disputed, or mediated through another source.

3.9 Observation

A situated activity of attending to or registering a manifestation through a stated method.

NOTE 8 An observation report is a claim about that activity or its result; "direct" does not mean free of mediation or interpretation.

3.10 Inference

A step that relates identified premises or material to a conclusion under a stated method or reasoning.

NOTE 9 An inferred claim has a different epistemic role from the claim that its premises were recorded.

3.11 Interpretation

An attributed assignment of meaning, classification, or significance within a stated context.

NOTE 10 Interpretation can participate in observation and inference; these terms do not partition human or machine activities into exclusive kinds.

3.12 Judgment

An attributed assessment or determination made using identified grounds and criteria.

NOTE 11 A judgment can assess evidential warrant, ethical acceptability, legal status, or institutional action. These functions carry different bases of authority.

3.13 Assessment

A recorded examination of a specified question using identified criteria and material, with a result and limitations.

NOTE 12 In GR-200 an evidence assessment concerns a claim-relative evidential role. A syntax check concerns a different assessment target.

3.14 Uncertainty

Specified unresolved limitations or alternatives affecting a claim's content, identification, observation, method, interpretation, timing, boundary, or warrant.

NOTE 13 An uncertainty description is itself attributed and scoped. A numerical quantity is one possible representation, not a mandatory universal measure.

3.15 Trace

Material, behavior, testimony, inscription, or another manifestation identified as a remainder or consequence relevant to a target inquiry.

NOTE 14 The proposed connection to its generative conditions is a claim with its own grounds; calling an item a trace does not establish the proposed origin.

3.16 Evidence

A role assigned to identified material in assessing a specified claim, with an account of relevance, reliability, and alternative explanation.

NOTE 15 The material can support, challenge, limit, or fail to discriminate the claim. Evidence is not an intrinsic status permanently attached to a file or person.

3.17 Evidential warrant

The grounds offered for accepting, qualifying, or rejecting a specified claim under stated methods, assumptions, and scope.

NOTE 16 This draft records those grounds without imposing one universal sufficiency rule.

3.18 Provenance

A recorded account of origins, attribution, derivation, custody, or transformations of an identified item.

NOTE 17 Provenance can be incomplete or disputed. Provenance of a claim's expression differs from evidence for the claim's content.

3.19 Authenticity assessment

An assessment of whether an item is what it is represented to be, within a specified question and method.

NOTE 18 Authenticity of an utterance or document does not establish truth of its substantive claims.

3.20 Missingness

A stated condition in which information sought for a recording purpose is absent or unavailable.

NOTE 19 Not observed, not recorded, lost, withheld, unknown, inapplicable, and disputed describe different conditions and are not interchangeable with a zero, false value, or non-occurrence claim.

3.21 Record reference

A designation sufficient to distinguish a record or a particular version within a declared context.

NOTE 20 A reference scheme does not itself determine the identity of the represented target.

3.22 Identity criterion

A stated basis for treating two appearances or descriptions as concerning the same target within an inquiry.

NOTE 21 Identity claims can be contested and criterion-dependent. Similar behavior, equal content, shared names, and common descendants do not alone establish target identity.

3.23 Lineage

A directed account of derivation, succession, or continuation.

NOTE 22 Lineage can branch or merge. Its use does not automatically assert that predecessors and successors are one identical target.

3.24 Target time

The time or interval a claim concerns, including an explicitly unknown or uncertain temporal location.

3.25 Observation time

The time at which an observation or acquisition is represented as occurring.

NOTE 23 It can differ from target time and recording time.

3.26 Recording time

The time at which a record or identified version was made or entered into a recording context.

NOTE 24 It does not automatically date the target occurrence.

3.27 Assessment time

The time of a stated assessment or judgment, distinct from the time to which that judgment applies.

3.28 Descriptive regime

The declared categories, definitions, methods, scales, or boundary choices used to describe a target within an inquiry.

NOTE 25 This is an operational term; it does not require a fixed family of regimes or a particular mathematical construction.

3.29 Revision

An identified change to a representation, claim, assessment, or descriptive regime, with its relationship to an earlier formulation and the stated reason.

NOTE 26 Revision of an account of the past does not itself change the past occurrence.

3.30 Trajectory

A scoped account linking conditions, occurrences, continuations, alternatives, and consequences over a declared temporal or ordering frame.

NOTE 27 A reconstructed trajectory can remain partial and contested; it need not be a single fully ordered sequence.

3.31 Generativity-related claim

In this operational vocabulary, a claim about how relations, conditions, or activity generate, sustain, transform, restrict, or destroy subsequent states, capacities, relations, distinctions, or possibilities.

NOTE 28 This defines the programme's recording subject; it is not a comprehensive definition of GR generativity.

3.32 Generative condition

A condition claimed to enable, constrain, or shape a specified trajectory or possibility.

NOTE 29 Its role needs attribution and grounds; contemporaneous presence alone does not establish contribution.

3.33 Possibility claim

A scoped claim that a continuation was or is available, feasible, blocked, lost, or conjectured under identified conditions.

NOTE 30 An unchosen proposal differs from an evidenced feasible alternative, and each differs from a later imagined counterfactual.

3.34 Contribution

An attributed participation or influence in a specified trajectory or outcome.

NOTE 31 Contribution, credit, causal responsibility, entitlement, and legal liability remain distinct questions.

3.35 Practical uptake

An identified use of a representation or judgment in action, classification, allocation, or institutional decision.

NOTE 32 Its consequences can become new recording targets.

3.36 Generativity return

A research and recording topic concerning claimed return pathways through which generated effects alter conditions of further generation.

NOTE 33 Its operational measurement, evaluative meaning, and any allocation rule remain **OPEN**; no universal quantity or entitlement is defined here.

3.37 Vocabulary application

A named and versioned use of specified terms within a declared document, record package, profile, register or implementation description.

NOTE 34 Its boundary identifies which uses are claimed to follow this document and which belong to external or ordinary-language vocabularies.

3.38 Vocabulary extension

An additional term, narrower operational meaning or application-specific relationship introduced for a declared purpose.

NOTE 35 An extension does not change the meaning of this document's terms in other applications or become a programme term merely through local use.

3.39 Term correspondence

An attributed and scoped relationship between meanings in identified vocabularies or editions.

NOTE 36 Correspondence can be equivalent for a particular use, narrower, broader, overlapping, conditional or unresolved. Similar labels do not establish equivalent meanings.

3.40 Record-role correspondence

An explicit relationship between descriptions using different record roles or different boundaries within one role.

NOTE 37 It identifies which targets or occurrences the descriptions concern and which information is retained, added, omitted or unresolved.

3.41 Actuality or modality statement

A statement of whether a target is claimed as actual, attempted, planned, possible, hypothetical, counterfactual, unrealized or unresolved within a specified frame.

NOTE 38 These qualifications are not a universal exclusive enumeration. An attempted action can have occurred while its intended result remained unrealized.

3.42 Epistemic mode

The way a claim is presented as known, reported, inferred, interpreted, reconstructed, hypothesized or stipulated.

NOTE 39 Epistemic mode differs from actuality or modality and from assessed warrant. An inference can concern an actual occurrence; a direct observation report can be disputed.

3.43 Definedness condition

A condition determining whether a characteristic, classification or operation has an applicable value for a subject under its definition.

NOTE 40 Inapplicability differs from unavailable evidence about an applicable value. A representation can require both a definedness condition and a missingness reason.

4 Vocabulary application and semantic safeguards

4.1 General

V100-001 A vocabulary application shall identify this document and version, its own boundary and version, the terms it uses, and any local extensions or narrower domain meanings. It shall describe departures explicitly and shall not claim unqualified GR-100 vocabulary conformity for a conflicting use of a defined term.

4.2 Reality, manifestation, and representation

The foundation's ontological, relational, and manifestational registers concern different analytical questions. They are not exclusive categories of objects or a mandatory temporal sequence. A practice can operate before its recognition, and a classification can subsequently change the practice. This document does not require every target to receive a philosophical register label.

V100-002 A vocabulary application shall distinguish a represented target, an identified manifestation or trace, a retained record, and a claim wherever it uses those roles. It shall not treat a record identifier, representation, or manifestation as establishing the existence, complete nature, or identity of its target solely by being recorded.

4.3 Claim, observation, inference, and judgment

V100-003 A vocabulary application shall distinguish assertion, observation report, inference, interpretation, and assessment where those functions occur. Where one item performs several functions, it shall identify the functions and their scopes rather than infer one function's warrant from another.

4.4 Trace, evidence, and provenance

V100-004 A vocabulary application shall represent an evidential role relative to an identified claim. It shall keep provenance or authenticity results, evidential assessments, technical conformance, institutional acceptance, and normative or legal judgments distinguishable. It shall not describe success in one of these assessments as success in another without a separately stated argument.

4.5 Identity, time, and history

V100-005 A vocabulary application shall distinguish record reference, target identity, and lineage. A stated identification of targets across appearances shall identify its criterion and the scope in which it is used. Unresolved identity shall remain expressible without forced merger.

V100-006 A vocabulary application shall distinguish target, observation, recording, and assessment times wherever it uses them. It shall preserve uncertainty about time or order rather than derive occurrence order solely from record entry order.

V100-007 An application that represents revision shall distinguish change in the target situation, change in evidence or assessment, and change in the descriptive regime. It shall allow more than one reason to apply and shall not silently replace the earlier formulation with a later one. Where earlier content cannot be retained or disclosed, it shall identify the resulting limit on historical reconstruction.

These are three linked histories rather than three mutually exclusive event types. Publication of a revised classification can change a target situation as well as its description. A later assertion that the earlier situation differed is an epistemic revision; it does not backdate the physical act of correction.

4.6 Generativity and practical consequences

V100-008 An application using generativity-related terms shall identify the claimed change or continuation, affected target or participants, relevant conditions, and scope. It shall distinguish a generative attribution from a value judgment and shall not infer beneficialness, entitlement, or legitimacy from the term “generative” alone.

5 Six operational record roles

5.1 General

These role descriptions are standards-specific proposals, informed by FM-007 and earlier programme vocabulary. They describe how a target is represented for an inquiry. They neither exhaust reality nor require exclusive schema classes. The term Property is retained from the programme; FM-007 uses Attribute. No equivalence between them is asserted.

In the descriptions below, *minimum metadata* means the information required when the role is applied under V100-009. V100-025 distinguishes structural designations and criteria from contextual factual values that permit an explicit unknown or restriction. Common metadata means record reference and version, role, described target, recording responsibility and time, and links to relevant claims and their epistemic context. Referenced context can be shared across a package without duplication.

V100-009 An application of a six-role description shall identify the applied role, its admissibility and identity criteria, the common metadata, and the role’s minimum metadata below. It shall disclose unresolved boundaries and use the temporal meaning associated with the role. Missing information shall retain its stated reason rather than be converted to a substantive negative claim.

V100-010 An application shall allow a target to be described through more than one applicable record role without treating role overlap as evidence of inconsistency. A restriction in an application profile shall state its recording purpose and information limits. A Relation whose own identity, state, properties, or history matters to the declared inquiry shall remain independently referenceable.

V100-025 The application shall supply its reference and version, applied term labels and definition locators. Each applied role shall have an identified role, record reference and version, target designation and responsible recording role; an unresolved target designation shall state the target question or description. These structural designations shall not be replaced by an unknown value. An unavailable contextual factual value may be represented by an explicit unknown, disputed, lost or restricted state, with the stated reason, attributing role and assessment limitation. Required admissibility or identity criteria shall be stated; a provisional assignment with unresolved criteria shall not receive a fulfilled result for a criterion-dependent obligation.

A target designation can identify an unresolved historical subject without establishing its identity. An accountable role can use a protected reference without public disclosure of a person's name. These are supplied designations with declared limits, not empty values. Conversely, a known absence of a required criterion is a recording defect; unavailable evidence for deciding whether an identified criterion is met is an assessment limitation. A fulfilled declaration of unknown context does not resolve the underlying fact.

5.2 Entity

Definition and admissibility. A record role for a focal subject tracked across appearances under a declared continuity criterion. Admissible when the inquiry needs cross-context or cross-time reference; use does not require an unchanging substance.

Identity. The stated reidentification criterion and evidence determine the claim of continuity. A database key identifies a record, not automatically the represented subject. A disputed criterion can remain unresolved.

Temporal behavior. Properties, membership, and relations can change while continuity is asserted. Formation, dissolution, replacement, or uncertain duration can be recorded separately.

Relations to other roles. Participation in Events and Processes; possession of described States or Properties; participation in Relations; lineage links to other Entity descriptions. These are candidate meaningful links, not an exhaustive edge schema.

Minimum metadata. Focal subject and appearances in scope; continuity criterion; temporal scope; attributed identity judgment or unresolved status.

Optional metadata. Names, identifiers assigned by other systems, formation history, known predecessors and successors.

Example and counterexample. An association tracked across a change of premises under a stated organizational continuity criterion. Two unrelated associations sharing a name are not thereby one Entity.

OPEN edge. A split into two successors can preserve lineage while leaving continuity with the predecessor disputed.

5.3 State

Definition and admissibility. A record role for a scoped description of conditions of a target at a stated time or interval. Admissible when the question concerns those conditions rather than an exhaustive inventory of reality.

Identity. Same target, temporal scope, and descriptive regime identify the intended condition description; record versions and conflicting accounts remain distinct. Equality of observed values alone does not establish equality of target conditions.

Temporal behavior. A condition can persist over an interval or be known only at an observation time. Persistence between observations requires a claim. Predictive sufficiency is relative to specified questions and continuations.

Relations to other roles. Conditions of Entities or Relations; preconditions and results of Events; intermediate descriptions in Processes; values articulated through Properties.

Minimum metadata. Target; time or interval; description boundary and regime; conditions described; observation or inferential basis.

Optional metadata. Supported queries, omitted conditions, comparison horizon, warranted persistence interval.

Example and counterexample. A committee's recorded membership on a given date. A timestamped snapshot alone does not establish every member's continuing participation throughout a month.

OPEN edge. A reduced state adequate for a current report can omit historical memory needed for a later operation.

5.4 Event

Definition and admissibility. A record role for an individuated happening or attempted happening under a declared occurrence criterion. Hypothetical, planned, or reconstructed events remain admissible as explicitly qualified targets of claims.

Identity. An occurrence criterion distinguishes event tokens; a description can refer to one event in several records. Repetition of the same operation or outcome does not merge occurrences.

Temporal behavior. Duration, boundaries, sequence, or overlap can be exact, interval-based, partial, or unknown. Failure or interruption does not imply non-occurrence of an attempt.

Relations to other roles. Participants represented as Entities or Relations; changes between States; steps of Processes; Properties of the occurrence.

Minimum metadata. Proposed happening; occurrence and individuation criteria; claimed actuality or modality, such as occurred, attempted, planned, hypothetical, or unresolved; separate epistemic basis, such as reported, observed, or retrospectively inferred; temporal scope; participating targets where known. A retrospectively inferred event can be claimed to have actually occurred.

Optional metadata. Place, before/after conditions, attempted purpose, completion status, links to repeated occurrences.

Example and counterexample. Two separately evidenced permission issuances with the same final status. A formula for the effect of an issuance does not establish that either occurred.

OPEN edge. Different temporal resolutions can treat one prolonged happening as an Event, Process, or several Events; the segmentation rationale matters.

5.5 Process

Definition and admissibility. A record role for activity linked by a declared ordering and criterion of unity. Admissible for goal-directed, recurrent, interrupted, branching, or otherwise connected activity; achievement of an intended endpoint is not required.

Identity. The stated grouping and boundary criterion individuates the process. Equal endpoints or equal modeled composite effects do not establish the same process history.

Temporal behavior. Ordering can be partial; duration and completion can be uncertain. Alternative possible paths remain distinct from the reconstructed actual path.

Relations to other roles. Comprises or links Events and intermediate States; involves Entities and Relations; has scoped Properties; connects to dependent Processes.

Minimum metadata. Unity and boundary criterion; activity in scope; supported ordering; claimed actuality or modality, distinguished from its observational or reconstructive basis; time scope and completion/continuation status.

Optional metadata. Intended purpose, branches, interruptions, excluded steps, retained intermediate conditions.

Example and counterexample. A proposal–revision–authorization sequence with a recorded failed earlier attempt. A factorization of an outcome into mathematically possible operations is not evidence of that history.

OPEN edge. Overlapping practices can belong to several processes; no universal segmentation rule is proposed.

5.6 Relation

Definition and admissibility. A record role for an identified connection, arrangement, or dependence among specified targets or conditions within a stated context. Admissible when its incidence, formation, continuity, or effects are relevant. Potential efficacy requires a further claim.

Identity. A stated criterion distinguishes a continuing arrangement from a renewed or separate one. Equal participants and equal current effects do not alone establish the same relation.

Temporal behavior. Formation, persistence, dormancy, change of terms, and ending are separately attributable. A relation can change while participants remain identified.

Relations to other roles. Participants can be targets described by any relevant role, including other Relations; Events can form or change it; Processes describe its history; States and Properties describe its conditions.

Minimum metadata. Relation reference; participant or condition references with roles; context; relation criterion and temporal scope; stated identity basis.

Optional metadata. Formation history, dependency claims, terms, changing states, prospective effect comparisons.

Example and counterexample. Two separately identified agreements between the same parties, each with its own renewal history. Co-occurrence in a table alone does not establish cooperation, trust, or dependence.

OPEN edge. Uncertain or changing participants can prevent a complete incidence description without eliminating the recorded relation claim.

5.7 Property

Definition and admissibility. Provisionally, a record role for an attributed characteristic or value of a specified subject under a stated definition, time, and context. Admissible when the meaning and subject of the attribution are explicit. This operational use does not resolve the broader Property/Attribute relationship.

Identity. A property assertion is distinguished by subject, characteristic definition, contextual and temporal scope, attribution, and version. A type of characteristic differs from a particular assignment of its value.

Temporal behavior. A value can change with the subject; a later correction can instead revise knowledge of an earlier value. The two histories remain distinguishable.

Relations to other roles. Describes a target represented through any role; measurement or classification can be linked to an Event or Process; multiple conflicting assignments can concern one subject.

Minimum metadata. Subject; characteristic definition; value or explicit missingness state; time and context; method or attribution; scale and unit when used.

Optional metadata. Measurement uncertainty, valid domain, derivation, calibration reference, alternatives.

Example and counterexample. A reported resource quantity for an organization at a specified time. A numbered nominal category is not a measurement permitting arithmetic solely because its code is numeric.

OPEN edge. FM-007's Attribute has explicit domain, interpretation, scale, and definedness conditions. Equivalence to Property, separation, or renaming needs source comparison and a recorded decision.

5.8 Role boundaries and admissibility decisions

Admissibility concerns whether a description can perform the stated recording role. It does not establish the claim about its target. A proposed historical Entity can be admissible as the subject of inquiry while its identity is contested. A hypothetical Event can support counterfactual analysis while its modality excludes it from the asserted actual history. Role metadata and epistemic context preserve both distinctions.

A role's minimum metadata is semantic information, not a prescribed collection of database columns. Shared references can supply context when their version and scope are clear. A narrative dossier can supply information through identified passages. An empty field, unexplained code or link to a changing resource does not necessarily supply an inspectable meaning.

An unknown value can satisfy a duty to disclose unavailable context where a requirement permits it. It does not satisfy a duty to demonstrate continuity, observed occurrence or contribution. A protected identity can use a stable reference without publishing a name; protection does not establish that two references identify one person.

An agreement can be a Relation while tracked as an Entity for continuity. Its negotiation can be a Process; its signing an Event; its operative terms at a time a State described through Properties. These descriptions coordinate different questions. They need not assert six independently existing objects or duplicate a single occurrence six times. A technical profile that restricts overlap needs a route for retaining the distinctions relevant to its declared use.

6 Boundaries between layers

6.1 General

V100-011 A vocabulary application shall distinguish operational record roles from metamodel concepts. It shall not identify a formal carrier state with a record State, a mechanism with a Process, or formal change with an Event without an explicit scoped mapping and argument.

V100-012 A vocabulary application shall keep descriptive, epistemic, evaluative, legal, institutional, and technical assertions distinguishable by their stated question and grounds. It shall not represent technical conformance as automatically creating factual truth, rights, duties, liability, admissibility, jurisdiction, or institutional authority.

The same dossier can connect these assertions. For example, an institutional decision can cite an evidential assessment and an asserted rule, while each remains separately attributable and open to the appropriate

form of review. This is separation of questions and authority, not a requirement for independent databases.

7 Vocabulary management and correspondences

7.1 General

Vocabulary management concerns inspectable meaning across local uses, languages, profiles and versions. A register can be a small table or a documented specification mapping. It need not duplicate a dictionary, but an exact definition and its application scope need to be recoverable. When a source is unavailable, the adopted local wording and that limitation remain visible.

7.2 Terms, sources and local extensions

V100-013 The application shall maintain a term-use register identifying the terms used, their definitions or dated definition references, their recording scope, their source status and the role responsible for interpreting local use. An imported label shall not establish equivalence without an identified correspondence and rationale.

V100-014 A local extension shall identify its purpose, definition, admissibility conditions, relation to existing terms, affected uses and limitations. A conflicting meaning shall use a distinct qualification or label and shall not be presented as an unchanged GR-100 definition.

An extension can address a specialized institutional process without claiming that its categories are universal. For example, a profile can define a reviewed submission within its own procedure. It identifies the relationship to Record and Claim, the criterion for entering the review category and the information the category omits. The label does not imply that the submission is true or that every recording context has the same procedure.

7.3 Languages, editions and mapping

V100-015 A term correspondence across languages, domains or editions shall identify the source and target meanings, direction, scope, responsible attribution and known non-equivalence. A narrower, broader, partial or conditional correspondence shall not be represented as unrestricted equivalence.

A translation can preserve an operational distinction even when ordinary words carry additional meanings in one language. The operational definition travels with the label. Where a translation is contested, alternative formulations and grounds remain available. A terminology register need not require every language to borrow the same word or every application to create a universal dictionary.

Renaming a field does not by itself change meaning. Retaining the same label while changing its definition can change the descriptive regime. The register identifies both situations. A mapping that loses information describes the uses for which the mapped representation remains adequate and the uses it no longer supports. Switching to a finer vocabulary does not recreate distinctions absent from the source material.

7.4 Modality, epistemic function and status expressions

V100-016 An application describing an occurrence or possibility shall distinguish its asserted actuality or modality, the epistemic mode of the assertion and the assessment disposition. It shall preserve combinations such as an actual occurrence inferred retrospectively and a directly reported observation whose accuracy is disputed.

V100-017 Where an application uses fact, verified, valid, confirmed or an equivalent status expression, it shall state the question resolved, applicable criterion, attributed assessor and grounds or assessment

reference. An unspecified status expression shall not erase known uncertainty, an unresolved identity question or the limited scope of a check.

Recorded fact can mean a statement treated as settled by an institution, an asserted occurrence, or a database entry. This document does not make these meanings interchangeable. A historical account can preserve that a claim was institutionally accepted without endorsing its substantive content. Similarly, a valid structure can contain a false claim; a verified signature can authenticate a mistaken statement.

7.5 Correspondence between roles and levels

V100-018 A relied-on correspondence between record roles or descriptive levels shall identify the linked descriptions, intended relationship and use, retained distinctions and known losses or unresolved links. A transformation shall not silently create target identity, occurrence multiplicity or historical detail unsupported by its source.

Table 1 – Role correspondences and distinctions requiring attention

Correspondence	Recording question	Distinction at risk
Event–Process	One prolonged occurrence examined through internal activity; a process treated as a bounded episode	Segmentation, attempts, partial order and intermediate conditions.
Relation–Entity	An agreement or dependence tracked across renewal	Continuity criterion, incidence context and whether renewal creates a separate arrangement.
State–Property	Conditions described through characteristic assignments	Domain, time, omitted conditions and observational or inferential basis.
Process–State	Activity summarized by a resulting condition	Different histories can share an endpoint; the endpoint does not establish the path.
Entity–type	Subjects classified by a shared characteristic	Type equality does not establish token identity or continuity.
Record–target	Several reports linked to a proposed occurrence	Record multiplicity differs from occurrence multiplicity; linkage can remain disputed.

Table 1 is a boundary guide, not an exhaustive allowed-edge schema. A profile can add relationships with stated meanings. An Event description can aggregate several occurrences only when that aggregation is explicit and does not purport to preserve individual occurrence counts or intermediate history. Conversely, decomposing an Event into a possible Process does not establish that the proposed steps occurred.

7.6 Missingness and definedness

V100-019 An application shall distinguish missingness and definedness states material to its use, including zero or false values, unknown values, non-observation, non-collection, inapplicability, disputed assignment and restricted access where present. A mapping that combines these states shall state the loss and shall not infer a substantive negative claim from the combined code.

Unknown is an epistemic condition rather than a third truth value imposed on the world. Inapplicable means the stated characteristic lacks an applicable value under its definition. Not measured means an

applicable measurement was not performed. Withheld concerns access and can coexist with a known value in a protected view. Disputed can describe incompatible assignments with available evidence. These differences affect later counting, assessment and revision.

An application need not claim knowledge of why a value is absent. Unknown reason is legitimate when supported. It also need not reveal protected material's existence to an unauthorized audience. A reduced view can state its collection and access scope while a protected accountable record retains a more specific explanation where permitted.

7.7 Properties, scales and aggregates

V100-020 A numerical Property description shall identify its characteristic definition, applicable domain, scale meaning and unit where relevant. Any arithmetic, weighting or aggregation relied on shall state its interpretation, included population or components and material limitations. Numerical labels alone shall not establish the validity of the operation.

A nominal code supports differentiation, not automatically addition. An ordinal rating supports ordering under its interpretation, not automatically meaningful distances or averages. A measurement with a unit still depends on an instrument, boundary and procedure. The distinctions remain relevant when values have the same software numeric datatype.

An aggregate can change because underlying values change, because composition or weights change, or because a classification rule changes. These are different interpretive questions. A rate can require its numerator, denominator, inclusion criteria and period for interpretation. A pooled increase does not establish improvement for every group; a pooled decrease does not by itself establish causal deterioration in practice. The inference needs its own grounds.

7.8 State sufficiency and retained history

V100-021 An assertion that a State description is sufficient shall identify the question or operation family, comparison horizon, relevant observations, assumptions and known omitted distinctions. Sufficiency for a current report or specified prediction shall not be represented as historical completeness or sufficiency for undeclared continuations.

Two subjects can have the same current reported flag while retaining different conditions that affect a future response. Conversely, a reduced description can predict a selected response while omitting whether the condition arose by agreement or imposition. Predictive and historical purposes need different evidence. A statement of adequacy identifies the question answered, rather than converting that question into a universal account of the subject.

7.9 Identity decisions

V100-022 A relied-on identity judgment shall state whether the proposed relation is identity, similarity, identifier correspondence, succession or another defined relation, and shall preserve material competing criteria and unresolved cases. Automated matching or shared lineage shall not be promoted to target identity without the stated criterion and its supporting attribution.

Organizational registration, membership continuity, operational practice and historical self-description can support different identity inquiries. Agreement under one criterion need not resolve another. A split or merger can be represented by directed lineage without identifying each successor with every predecessor. A shared name does not decide which relation is intended.

Identity also differs from access. Redaction can hide information needed to assess a match while a custodian retains it. A public view can report a scoped assertion and its limits without claiming independent external verification. Lack of disclosure does not justify inventing either identity or non-identity.

8 Conformance

8.1 General

The conformance subject is a declared vocabulary application at an identified edition and boundary. Requirements concerning extensions, numerical Properties, transformations or particular roles are conditional on those features being present. An absent feature can make its specific requirement not applicable. It does not exempt a general safeguard already used elsewhere in the application.

8.2 Declaration and assessment boundary

V100-023 A conformance statement shall identify the application, edition, boundary, GR-100 edition, applied terms, applicable requirements, assessor and evidence. It shall distinguish full fulfillment of applicable requirements from partial assessment and shall not imply assessment of excluded uses or unavailable evidence.

A scope can be small without being vague. A short profile using only Record, Claim, Trace and Evidence identifies those uses and definitions. It does not need examples for an unused Process role. A profile using a numerical Property and an aggregate triggers V100-020 even when its label is score rather than Property. Applicability follows meaning and use, not convenient field spelling.

8.3 Results and mandatory schedule

Fulfilled means that the required evidence was examined and met the check within scope. Not fulfilled means examined evidence demonstrates a failure. Not assessed means necessary evidence, access or method was unavailable or the check was not performed. Not applicable means the triggering feature is absent, with a documented reason. Lack of access is not non-applicability.

V100-024 The assessment shall follow Annex A and retain a result, evidence locator, assessor and reason for every requirement. A failed or unassessed applicable requirement shall prevent an unqualified conformity claim for the declared application. Each not-applicable result shall identify the absent trigger.

V100-026 Where one requirement groups obligations whose results can differ materially, the assessment shall retain a result and evidence for each such component. The overall requirement shall be fulfilled only when every applicable component is fulfilled. A failed or unassessed component shall remain visible in the requirement-level and overall application result.

A vocabulary result does not establish factual truth, philosophical exhaustiveness, effective institutional participation or legal validity. Syntactic checking can assist assessment, but cannot determine whether a term is coherently applied to a contested case. The report distinguishes automatic checks from substantive examination of meaning.

8.4 Maintenance of an assessment

A change in definition, scope, role criterion, correspondence or assessment-relevant use changes the assessed subject. The application identifies the affected edition and results requiring review. Correcting spelling alone need not change semantics; an unchanged label does not prove semantic stability.

An implementation can retain multiple vocabulary editions for historical records. Assessment identifies which meaning governed each record and which mappings support a combined view. A later interpretation does not retrospectively give earlier actors access to the newer vocabulary. If the historical definition cannot be recovered, that is a reconstruction limitation rather than permission to silently substitute the current one.

Annex A

(normative)

Vocabulary assessment schedule

A.1 General

This schedule specifies required assessment checks for applicable features; it does not report executed tests. The assessor examines the declared subject and reports fulfilled, not fulfilled, not assessed or not applicable for each requirement, with an evidence locator. Not applicable requires an absent trigger, not an inconvenient result. Unavailable examination evidence or an unperformed check receives a not-assessed result. A review cannot establish an external fact merely from compliant vocabulary.

Table A.1 – Vocabulary assessment checks

Requirement	Evidence and discriminating check
V100-001	Declaration names version, boundary, terms, extensions. Compare a local "fact" label against its stated meaning; detect an undisclosed conflicting use.
V100-002	Trace a target, manifestation, record, and claim in the subject. An authentic but incorrect report remains representable.
V100-003	Inspect a summary combining observation and inference. Recover which content was registered and which was inferred, by whom.
V100-004	Inspect one material item used differently for two claims. A successful authenticity check does not become a truth result.
V100-005	Inspect a merger, split, or disputed identification. Recover identity criterion and directed lineage without an automatic merger of targets.
V100-006	Inspect a late-entered report. Target time, observation time, recording time, and review time remain distinguishable or explicitly unknown.
V100-007	Compare target change, corrected report, and changed category. Prior meaning and reasons remain recoverable to the declared retention/access extent.
V100-008	Inspect a generative attribution. Scope and affected targets are present; description of expanded capacity is separate from its evaluation.
V100-009	For each applied role, locate admissibility, identity, temporal meaning, and required metadata; inspect a missing value's explicit reason.
V100-010	Inspect a relation with changing terms and an event analyzed as a process. Relevant identity/history and overlapping views remain expressible.
V100-011	Inspect any metamodel mapping. Identify additional premises; absence of a mapping means the conditional check is not applicable.
V100-012	Compare event report, institutional determination, legal assertion, ethical judgment, and technical check. Their distinct grounds remain visible.
V100-013	Inspect the term-use register, source status and dated definitions; a reused label has an argued correspondence.
V100-014	Examine a local extension's definition, admissibility, scope and limits; it does not silently replace a core meaning.
V100-015	Examine an inter-language or inter-edition mapping; partial correspondence is not represented as unrestricted equivalence.

Requirement	Evidence and discriminating check
V100-016	Compare actuality/modality, epistemic mode and assessment disposition, including an actual but retrospectively inferred occurrence.
V100-017	Inspect uses of fact, verified, valid and confirmed; recover the question, criterion, assessor and grounds.
V100-018	Inspect a correspondence between roles; retained references and stated losses prevent invented identity or occurrence detail.
V100-019	Compare zero, false, unknown, disputed, withheld and inapplicable values before and after a mapping.
V100-020	Examine numerical meaning, units, scale and aggregation; recover included population and weighting interpretation.
V100-021	Examine a sufficiency claim; recover the supported question, operations, horizon and omitted history.
V100-022	Examine an identity decision with alternative criteria; distinguish identifier matching, similarity, lineage and identity.
V100-023	Check the conformance statement's edition, boundary, terms and evidence; excluded uses do not acquire a result.
V100-024	Check the complete assessment register; every exclusion has an absent-trigger reason and every fulfilled result has evidence.
V100-025	Check mandatory designations and criteria separately from unavailable contextual facts; an unknown declaration does not resolve a criterion or replace a reference.
V100-026	Inspect a grouped requirement with one unassessed or failed component; its other fulfilled components do not produce an overall fulfilled result.

A.2 Execution and evidence record

The assessor first identifies the application and term-use register, then the feature-triggered requirements. For an applicable check, the evidence includes the definition or dated reference and an actual use. A boundary case is included when needed to distinguish alternative meanings. A documented equivalent case is acceptable when it tests the same distinction in the application's domain. An empty template or undocumented expert understanding is insufficient evidence of actual vocabulary use.

The register records subject version, requirement identifier, applicability, evidence locator, observed result, assessor, date and unresolved limitation. Component results follow V100-026. One evidence item can support several requirements, but their results remain separate. Assessor disagreement identifies whether it concerns meaning, factual material, scope or the assessment method. Restricted evidence receives a scope statement; unavailable required examination evidence receives a not-assessed result rather than an inferred pass. Assessment of an allowed unknown-context declaration follows V100-025 and remains separate from assessment of the unresolved fact.

Annex B

(informative)

Worked vocabulary cases

B.1 Initial distinction cases

1. A clerk records that a request arrived late. An attributed entry record can support a reported recording time, subject to the relevant clock, integrity and acquisition-context checks. Whether the request itself arrived late requires identifying the receipt-time source, applicable deadline and inference. The record, target event and deadline assessment remain distinguishable.
2. A later witness report changes the assessment of the arrival time. That is a revision of the account. A later extension of the deadline changes a governing condition. A new definition of "arrival" changes the descriptive or institutional rule. One dossier can contain all three histories without conflating them.
3. Two administrations reuse an office name. An application follows their records under the same catalogue heading while recording replacement and disputed institutional continuity. Shared cataloguing does not decide Entity identity.
4. A new procedure reduces review time and makes some participants unable to contest an error. A generativity record can preserve both the increased processing capacity and the restricted capacity for correction; an ethical judgment states its own affected parties and criteria.

B.2 One agreement and several roles

A fictional agreement links a cooperative and a laboratory. It is a Relation for questions of commitments and access and is tracked as an Entity for continuity after personnel changes. Negotiation and amendment form a Process, signing is an Event, operative terms on a date form a State description and a reported access limit is a Property assignment. These descriptions need not compete for a single exclusive class.

Renewal creates a boundary question. The parties and title continue while terms change substantially. Participants can describe the same agreement, an archive can retain a new document and a legal analyst can ask a separate continuity question. The application retains the criteria and their grounds rather than deriving a universal identity resolution from the shared title. A technical edge that records only an active connection can support a current-status query while losing formation and dispute history.

B.3 Changing composition in an aggregate

A programme reports participation rates for two groups. Both groups improve in a later period, while the population contains a larger share of the initially lower-rate group. The pooled rate can decline despite each group's improvement. This is a stipulated comparison problem, not evidence about a real programme.

The Property description retains population, denominator, definitions, weights and periods. A question about the same people over time additionally needs identity linkage. A question about institutional composition can instead treat entry and exit as part of the process. The scalar alone does not establish which question is relevant or whether the outcome is fair.

B.4 Missing, withheld and inapplicable

One form records a zero reading, another says no measurement was performed, another withholds an existing value, and another concerns a subject for which the characteristic is inapplicable. A conversion maps every case to an empty cell. That table can have a limited use, but it cannot claim preservation of the distinctions or support a count of zero readings.

A finer vocabulary can recover an omitted value only where retained or newly obtained evidence supports it. Changing notation does not create missing observations. Authorized examination can use a protected source while a public view remains incomplete. The correspondence records the different routes and resulting limitations.

Annex C

(informative)

Foundation trace and drafting rationale

C.1 General

Page numbers below are one-based pages in the supplied PDFs. FM identifiers are those in `foundation_manuscripts/MANIFEST.md`. The definitions here are operational proposals rather than quotations or claims that the manuscripts prescribe this recording model.

Table C.1 – Foundation passages and operational decisions

Source	Preserved distinction and draft application
FM-004, §4.2, pp. 11–14; §4.6, pp. 43–45	Registers answer different questions; manifestation is broader than representation, and recognition need not precede relational reality. Basis for V100-002; no exclusive philosophical register schema.
FM-005, §5.4, pp. 28–31	Trace, target relation, and evidence differ; evidential force is target-relative. Basis for V100-003/004 and GR-200 evidence-role requirements.
FM-005, §5.17, pp. 141–142	Uncertainty concerns several dimensions and need not have one scalar measure. Basis for the uncertainty definition and GR-200.
FM-005, §5.20, pp. 168–174	New evidence, intervention, historical revision, and category revision differ. Basis for V100-006/007; three linked histories are an operational organizing proposal.
FM-007, p. 2; §7, pp. 26–29; §8, pp. 32–33	Roles overlap; identity criterion, lineage, participant incidence, and relation continuity require distinct information. Basis for V100-005/009/010 and Entity/Relation proposals.
FM-007, §9, pp. 37–38, 43; §12, pp. 56–57	Occurrence differs from effect; histories differ from endpoints and possible factorizations. Basis for Event/Process proposals.
FM-007, §10, pp. 43–44; §11, pp. 52–53, 56	Attribute domain/scale and State sufficiency are scoped. Basis for Property/State proposals, with Property/Attribute unresolved.
FM-003, §3.10.9, p. 115; §3.13, pp. 141–142	Generativity has no fixed normative sign; effects vary across subjects and time. Basis for V100-008, without a universal measure. Both Chapter 3 variants remain independently preserved.

The main alternatives were a complete philosophical definition, an exclusive six-class schema, or a limited operational vocabulary. This draft selects the third provisionally because initial cases need distinguishable claims and histories before a technical model can be justified. A programme decision record accompanies this drafting choice; adoption and technical realization remain separate decisions.

C.2 Additional analysis in edition 0.2

FM-007, sections 10.4–10.10, PDF pages 45–50, distinguishes partial definedness, overlapping classifications, scale interpretation, aggregate behavior and changing composition. V100-019/020 preserve these meanings without importing the formal constructions or equating Attribute with Property. The manuscript's arithmetic examples are stipulated constructions, not empirical validation of this vocabulary.

FM-007, sections 17.1–17.2, PDF pages 78–80, distinguishes within-regime consistency from cross-regime alignment and explains the inability of a coarse description to recover omitted distinctions by relabeling. V100-015/018 preserve correspondence limits without claiming that a fixed regime catalogue anticipates every future distinction.

FM-005, sections 5.4.4–5.4.8, PDF pages 32–35, distinguishes observation, inference, latency, hiddenness and negative evidential warrant. V100-016 distinguishes a target's claimed actuality from its inferential accessibility. Missing evidence is not proof of concealment, and inference is not a weaker kind of reality. Sections 5.18.1–5.18.5, pages 152–156, examine visibility, classification power and institutional legibility. The extension requirements make classifications inspectable without assuming that maximal visibility is desirable.

The provisional term Generativity return identifies a programme recording topic, not an asserted equivalence with a manuscript-defined quantity. FM-005, section 5.17.3, PDF page 145, discusses uncertainty in recirculation claims, including conversion or transfer, return pathways and effects on later generative conditions. That passage supports questions to record, while the terminology's wider definition, measurement and evaluative interpretation remain unresolved.

Annex D

(informative)

Unresolved issues and development evidence

D.1 General

- **OPEN — Property/Attribute.** Compare FM-007 with sustained programme usage and test conflicting value assignments, undefined values, and nominal scales before deciding equivalence, separation, or a terminology change.
- **OPEN — Claim representation.** Compare independently identified claims, attributed assertions within records, and hybrids using disagreement, revision, restricted access, and round-trip examples. This draft requires distinguishability, not a seventh ontology class.
- **OPEN — Role overlap and profiles.** Test overlapping Event/Process and Entity/Relation descriptions. No exclusive schema typing or full cross-role relation vocabulary has been adopted.
- **OPEN — Identity.** Domain-specific criteria and disputed linkage need examples beyond names and administrative identifiers; branching continuity does not have a universal resolution.
- **OPEN — Generativity and return.** Test possibility, foreclosure, contribution, and return pathways without presuming a universal metric or a normative entitlement.
- **OPEN — Source chronology.** Chapter 3 editorial precedence remains unresolved. This draft cites particular passages without declaring one variant authoritative over the other.

GENERATIVITY STANDARDS PROGRAM

GR-110

Standards-track Working Draft

Version 0.2 2026-09-22

Generativity Recording Requirements

WORKING DRAFT FOR REVIEW

This document contains proposed provisions for technical and institutional review. It is not an adopted Standard or an operative governance instrument. Its scope, application conditions and publication status are specified in the text.

Prepared by the Generativity Standards Program. Reference to external publications does not imply endorsement by ISO, IEC, IEEE or any United Nations body.

Foreword

This document specifies proposed requirements for generativity record packages and the practices that create, use, and maintain them. It is a preparatory Standards-track Working Draft. It is not an adopted Standard and does not establish that a formal standards project has been initiated.

Responsible editor: `UNASSIGNED`. Canonical source: `standards/GR-110-recording-requirements/GR-110.tex`. Intended readers are recording practitioners, participants in inquiry, record custodians, institutional users, implementers, and assessors.

Version 0.2 retains R110-001 through R110-034 and updates their dated draft dependency to GR-200 version 0.2. It develops operational planning, capture, attribution, alternatives, practical response, custody, presentation, and assessment. Normative annexes specify semantic information and assessment schedules. Informative annexes provide authored examples and a source-to-proposal explanation.

The proposed requirements are available for review and controlled exercises while programme governance develops. Their fulfillment concerns the stated recording practice and evidence. It does not certify factual truth, beneficial generativity, complete history, or external legal validity.

Introduction

A final output can survive while the relations, judgments, alternatives, and conditions that made it possible become inaccessible. An account of a current result can also conceal mistaken assessments, changing categories, unrecognized contributions, or the loss of capacities elsewhere. This document addresses those problems through bounded and revisable recording.

A generativity package connects three distinguishable histories: changes in the situation being investigated; changes in evidence, interpretation, and judgment; and changes in categories, methods, or institutional recognition. A classification can enter the situation and alter access or action. Its practical effect does not establish that its description was warranted, and its later correction does not demonstrate repair of earlier consequences.

The recording objective is therefore more specific than accumulating observations. A reader needs to identify the asserted transformation, whose account it is, how earlier conditions are said to connect to it, which grounds support that connection, and what remains unavailable or disputed. A practice needs arrangements for proportionate collection, protection, challenge, correction, custody, and intelligible presentation.

The foundations support several forms of generative inquiry. A relation can enable, constrain, maintain, amplify, mediate, or stabilize an effect, and its role can change over time. A generative trajectory can cross several relations and carriers rather than follow one persistent object. The clauses below operationalize the recording of such accounts; they do not impose one causal theory, universal measurement scale, or exhaustive graph of possible futures.

1 Scope

1.1 Included subjects

This document specifies requirements for an identified generativity record package and the responsible recording practice. It covers purpose and boundary, material claims, record identity, time, generative accounts, contributions, alternatives, changes in distinctions, practical uptake, revision, protection, custody, and presentation.

The package contains the retained representation and its declared limits. The practice includes people or institutions, methods, assigned responsibility, collection and review actions, custody, and user-facing behavior. Full assessment of the declared scope examines both documentary material and applicable practice obligations. A package-only examination is a partial assessment under this edition; no reduced package-conformance profile is defined.

1.2 Excluded claims and implementations

The document does not require an exhaustive world history, unrestricted observation, a particular database, cryptographic mechanism, interchange format, common metric, or mandatory category-theoretic semantics. Narrative dossiers, tables, and technical systems can satisfy the same semantic obligations where the required distinctions and behavior remain inspectable.

It does not establish ownership, a compensation entitlement, a legal duty to disclose, or the authority of an external institution. Contextual legal and policy assertions are recorded with their grounds and status. Full GR-120, GR-130, GR-140, GR-150, GR-160, and GR-400 publications are not prerequisites for applying the bounded manual assessment in this draft.

2 Normative references

2.1 Dated draft dependencies

The following Standards-track Working Drafts supply provisions invoked by this document:

GR-100, Foundations and Vocabulary, version 0.2. `standards/GR-100-foundations-vocabulary/GR-100.tex`. The incorporated scope is Clause 3's terms, Clause 5's record-role meanings when used, and the result-category meanings in 8.3. This reference does not impose a separate claim of GR-100 vocabulary-application conformity.

GR-200, Epistemic Recording Framework, version 0.2. `standards/GR-200-epistemic-recording/GR-200.tex`. Provides the applicable requirements for the bounded epistemic record package required by R110-005, including package-level obligations.

These are draft dependencies, not adopted Standards. An assessment identifies their exact versions and the incorporated requirements. A later change requires dependency review.

2.2 Related documents

GR-210, Evidence, Interpretation, and Contestation, version 0.2, provides a complementary procedural draft. It is not a blanket dependency of this document. A claim to fulfill a GR-210 procedure requires a separate assessment. Programme governance controls publication development and adoption; it does not automatically supply the mandate of an institution using a package.

3 Terms and definitions

3.1 Generativity record package

An identified collection assembled for a stated inquiry or practical purpose, with a scope, inventory, responsible recording practice, attributable material claims, and history relevant to that purpose.

3.2 Recording practice

The responsible people or organization, methods, decisions, and custody arrangements used to assemble, assess, present, and maintain a package.

3.3 Material claim

An assertion relied on to explain a consequential relation, generative effect, decision, classification, assessment, or revision within the declared purpose. Materiality is determined by that reliance and the selection rationale; it is not a truth status.

3.4 Generative account

An attributed account of how conditions or relations enabled, maintained, transformed, or constrained subsequent capacities, relations, distinctions, constraints, or possibilities. This operational term permits recording an account whose substantive warrant remains disputed.

3.5 Generative contribution role

The asserted target-relative function of a relation, actor, or configuration in an account, such as enabling, triggering, mediating, amplifying, stabilizing, substituting, or constraining. Roles can overlap and change; they are not new record-ontology classes.

3.6 Generative carrier account

An account of a persisting or transmitted condition through which an earlier contribution is connected to a later effect, including any transformation of that condition. This is a recording expression informed by FM-005, Definition 5.100, rather than a new mandatory class.

3.7 Possibility-field account

A bounded account of the alternatives or pathways represented as accessible, constrained, opened, or foreclosed for specified subjects under stated conditions. It does not claim to enumerate the complete possibility field of reality.

3.8 Practical uptake

Reliance on an identified claim, classification, or assessment in a stated action or decision, distinguished from mere receipt or availability of the information.

3.9 Recording horizon

The period covered by collection or reconstruction. It can differ from the period over which a claimed effect is expected or assessed.

3.10 View

A selected or transformed presentation of package content for an identified purpose and audience, with declared relation to source versions and material limitations.

3.11 Declared limitation

An explicit account of a collection, knowledge, access, method, temporal, or assessment constraint. Declaring a limitation does not automatically satisfy an obligation requiring evidence that remains missing.

4 Planning and responsibility

4.1 Purpose, boundary, and selection

R110-001 A package shall identify its purpose, intended users, subject matter, boundary, relevant time horizon, recording practice and package version.

R110-002 The recording practice shall state the selection criteria for included material and identify known omissions material to the purpose, including unavailable perspectives, uncollected information and limits of reconstruction.

R110-003 The package shall distinguish an inventory of retained records from an assertion that the underlying history is complete. The existence of a record shall not be used as proof of its represented content.

R110-035 Before systematic capture or reconstruction, the recording practice shall identify the questions the package is intended to support, the decisions or uses anticipated, and the information needed to examine them. The collection plan shall distinguish necessary detail, conditional detail, and material excluded from collection with reasons.

R110-036 The plan shall identify temporal horizon and resolution, observational boundary and scale, included perspectives, source types, expected gaps, and relevant relations outside the boundary treated as context. A change of boundary or scale material to interpretation shall be versioned and explained.

R110-037 The practice shall assess feasible recording, assessment, protection, and participation effort for the declared purpose. If essential work exceeds available capacity, it shall narrow the scope, obtain capacity, or report an unmet requirement; resource limits shall not justify invented content or an unqualified assessment claim.

The selection plan makes the account usable and bounded. An inquiry into a maintenance collaboration can require the work that sustained access without documenting every interaction among its participants. Selection becomes misleading when exclusions material to the stated account disappear from view.

4.2 Responsible functions and operating conditions

R110-004 The recording practice shall assign responsibility for capture, assessment, custody, access decisions and correction, recording combined roles and relevant conflicts. An automated component shall not substitute for an unassigned responsibility.

R110-038 Each assigned function shall identify the responsible person or organization, accepted task, authority and access needed, relevant interests, and a contact or continuity arrangement. Where a function cannot be performed, the practice shall record the limitation and its consequence for current use or assessment.

R110-039 The recording plan shall identify when capture is contemporaneous, retrospective, automated, or assisted and how consequential selections or transformations will be checked. Automated output shall retain its relationship to source material and accountable review.

R110-040 A material expansion of purpose, audience, source collection, or practical use shall receive renewed scope and protection assessment before the affected activity begins. The package shall identify the change and distinguish earlier permission and evidence from authority for the new use.

R110-041 The practice shall maintain the package inventory, current responsible functions, known dependencies, and active review or correction routes through the declared maintenance period. A decision to stop maintenance shall identify its date, reason, custodial disposition, and consequences for users.

5 Capture, identity, and epistemic integration

5.1 Intake and trace preservation

R110-042 On incorporating material, the practice shall record its source, acquisition or creation time, received version or identifying characteristics, method of capture, relevant production context, and permitted use. Unverified source assertions shall remain attributed rather than represented as established provenance.

R110-043 A transcription, translation, summary, selection, annotation, or reconstruction shall identify the source material, responsible transformer or method, material changes, and known loss or uncertainty. A derived account shall remain distinguishable from its source.

R110-044 When several materials derive from a common source, the package shall retain known derivation relationships relevant to evidential independence. Multiple copies or repeated citations shall not be presented as independent corroboration without additional grounds.

R110-045 The practice shall identify collection or extraction errors that can materially affect interpretation, including temporal aggregation, omitted context, unresolved attribution, and unsupported precision. Correction of an extraction shall not silently alter the underlying source record.

5.2 Package and claim dependency

R110-005 The package shall identify its material claims and assessments as a bounded epistemic record package assessed against GR-200 Working Draft 0.2, including that draft's package-level obligations. It shall identify the assessed claim set, dependency versions, applicable requirements, evidence, exceptions and results; a claim-level check alone shall not establish fulfillment of the package dependency.

R110-046 The assessed material-claim set shall include claims relied on for generative connections, identity, alternatives, category change, and practical consequences, not only claims supported by convenient evidence. Exclusion of a relied-on claim shall be identified as a limitation of the assessment rather than omitted from the declared set.

R110-047 The package shall link each material claim and relevant assessment to the applicable GR-200 records and results. The dependency assessment shall cover all applicable obligations for that bounded epistemic package; successful individual claim checks shall not substitute for package-level evaluation.

5.3 Identity and temporal meaning

R110-006 Each retained record and version shall be distinguishable within the package, and a reference shall identify its intended target sufficiently for the declared use. A record identifier shall not itself establish identity of the represented person, event or relation.

R110-007 A continuity or identity judgment material to the trajectory shall identify its criterion, responsible source, supporting grounds and known dispute. Merger, succession and common labels shall not silently be treated as identity.

R110-008 The package shall distinguish the represented occurrence or validity time from observation, recording and later assessment times when their difference is relevant. Uncertain intervals and unsupported ordering shall remain explicit.

R110-009 Represented observations, actions, relations, states and properties shall retain the information needed to distinguish their operational roles. A relation with a material history, status or properties of its own shall be identifiable as a recordable subject.

R110-048 A disputed identification, apparent duplicate, split, merger, or succession shall retain the alternative interpretation and the decision or uncertainty governing linkage. The practice shall distinguish correction of a record identifier from revision of a judgment about the represented subject.

R110-049 The temporal account shall identify relevant ordering, interval, resolution, and uncertainty, including where observations leave gaps. A claimed continuous relation shall state its continuity criterion and evidence; continuity of a label, manifestation, or file shall not alone establish continuity of the relation.

R110-050 When a reconstruction uses categories or evidence unavailable to earlier actors, it shall identify that retrospective basis and retain the earlier terminology or a supported account of it where material. The reconstruction shall not attribute later knowledge or intended outcomes to earlier actors without grounds.

6 Generative accounts and attribution

6.1 Target and connection

R110-010 For each generative account, the package shall identify the target capacity, relation, constraint, distinction or possibility; the relevant actors or configuration; the comparison or earlier condition; and the temporal and contextual scope.

R110-011 The account shall state how the proposed enabling, maintaining, transforming or constraining contribution connects earlier conditions to the target, with grounds, method and limitations. Temporal precedence or a diagram edge alone shall not be presented as establishing that connection.

R110-012 An account shall distinguish the asserted occurrence or modality of an effect, such as realized, intended, possible, unrealized or disputed, from its epistemic basis, such as observed, reported, inferred or reconstructed. A realized past effect can be retrospectively inferred. The recording practice shall not manufacture an observed outcome where follow-up evidence is absent.

R110-014 When an enabling encounter, decision or judgment is material to the account, the package shall identify its represented role, relevant conditions and the claim connecting it to subsequent developments.

R110-051 A generative account shall distinguish the existence or occurrence claim about its target from the attribution claim connecting candidate contributors to that target. The role, boundary, scale, time horizon, and evidential limits of the attribution shall remain inspectable even when the target change is well supported.

R110-052 Where association, sequence, or co-occurrence is used as support, the account shall state that evidential role and assess material alternative explanations, such as selection, common conditions, reverse influence, or changing definitions, or identify their unresolved status. Association shall not be relabelled as a demonstrated mechanism.

R110-053 A mechanism account shall identify the intermediate changes proposed to carry the contribution, their connection to available evidence, and any unobserved or assumed link. Restating the final

outcome as an intermediate step shall not be presented as additional evidence.

The meaning of a contribution depends on the target. A network can be associated with income while the stated generative question concerns access to knowledge or a new collaboration. The account identifies the level at which the asserted contribution operates. Different methods can provide different kinds of support without being reduced to one confidence number.

6.2 Alternative contributors and counterfactual reasoning

R110-054 When a counterfactual supports attribution, the account shall identify the focal change, connected conditions allowed to vary, background conditions provisionally held stable, target comparison, time horizon, evidence for plausibility, and material uncertainty. A modeled counterfactual shall remain distinguishable from an observed comparison.

R110-055 Where multiple or distributed contribution is material, the account shall identify the supported roles or organizational pattern, relevant complementarities, substitutions, or feedback, and the limits of allocating effects among participants. Failure to isolate a single contributor shall not force an unsupported sole attribution.

R110-056 A claim of emergent or configurational contribution shall identify the interaction, organization, or dependency said to matter and the evidence supporting its relevance to the target. The label emergent or systemic shall not replace the account of the proposed connection.

6.3 Carriers, delay, and long trajectories

R110-057 For a delayed contribution, the account shall identify the persisting or transmitted condition proposed to connect the earlier relation to the later effect, known transformations of that condition, intervening influences, and the limit of useful attribution. A long interval alone shall not establish either continuity or disconnection.

R110-058 A trajectory containing several generative links shall preserve link-specific contributors, target, grounds, modality, and uncertainty where these differ materially. Evidence supporting one link shall not automatically validate downstream links or the whole trajectory.

R110-059 Where available evidence ceases to support a downstream attribution, the account shall identify that boundary and classify further development as unassessed, conjectured, or separately supported as appropriate. A diagram or narrative shall not hide that change of status.

R110-060 A path-dependence or lock-in claim shall identify the sequence-sensitive condition said to alter later alternatives, its carrier or feedback, and grounds distinguishing historical dependence from persistence under current conditions. Claimed irreversibility shall state the relevant horizon and alternatives considered.

6.4 Branches and contributions

R110-013 Material participants and contributions shall be attributed with their basis and uncertainty. The recording practice shall provide a means to record disputed, collective, indirect or unknown contribution without forcing attribution to one actor.

R110-061 An account of branching shall distinguish opening or constraining a pathway, selecting a branch, and stabilizing a later outcome when those contributions differ. Earlier enabling conditions shall not receive the whole realized history's attribution solely because they preceded it.

R110-062 A contribution record shall distinguish descriptive attribution from acknowledgement, authorship, compensation, ownership, institutional credit, or legal responsibility. Any asserted entitlement or

allocation shall identify its separate source, authority, evaluative basis, and disputed or operative status.

7 Alternatives, distinctions, maintenance, and loss

7.1 Alternative and possibility accounts

R110-015 A recorded alternative shall state whether it was considered at the time, inferred retrospectively, modeled or merely proposed, and identify the grounds for any claim of feasibility. Recorded alternatives shall not be presented as exhaustive or equally feasible without supporting grounds.

R110-063 A historical alternative shall identify whether it was evidenced as available to relevant actors at the time, proposed then but infeasible under identified conditions, or introduced retrospectively for analysis. A later technology, category, or institutional option shall not be represented as historically available without grounds.

R110-064 A possibility-field account shall identify the subjects or positions concerned, the selected pathways, the relevant conditions and horizon, and the change alleged in accessibility, cost, probability, or viability. Unenumerated possibilities and limits of comparison shall remain explicit; a bounded list shall not imply exhaustion.

R110-065 Where an option is represented as available, the account shall distinguish formal availability from practical access under material resources, authority, knowledge, timing, or participation conditions. A declared permission alone shall not establish that the affected person could exercise the option.

R110-066 A comparison of earlier and later possibilities shall state whether the compared categories, boundaries, and subjects remain sufficiently consistent for the claimed comparison. If the process generating change or the available distinctions changed, that change shall be represented rather than forced into an unchanged scale.

Alternatives are recorded for their relevance to the inquiry. No branch tree is required. A package can retain evidence of one abandoned option and explicitly state that other pathways were not reconstructed. A possibility claim is stronger than a statement that an observer imagined an option, and its grounds are recorded accordingly.

7.2 Categories and historical reinterpretation

R110-016 A material change in categories, available distinctions or methods shall identify the earlier and later formulation, the reason for change and its effect on interpretation. A new description shall not automatically be represented as a newly existing underlying object.

R110-067 A material classification or method change shall identify its responsible source, effective or asserted period, definitions or rules changed, and consequences for reading earlier records. A later harmonized dataset or view shall preserve a route to the distinctions lost or identify that loss.

R110-068 A retrospective interpretation shall distinguish correction of an earlier error, expansion using later evidence or categories, and subsequent transformation of the represented relation. Where more than one applies, the package shall preserve their separate grounds rather than choose one merely for a simpler history.

The same word can refer to changing institutional arrangements, and different words can describe related practices. A genealogy can therefore connect heterogeneous predecessors without claiming one continuous identity. The package identifies the type of historical account and the limits of the continuity or formation claim.

7.3 Maintenance, depletion, and restriction

R110-017 Known maintenance, depletion, restriction, exclusion or loss material to the declared generative account shall be recorded alongside creation or expansion, or have an explicit collection or protection limitation under R110-002 and R110-026. The account shall distinguish descriptive effects from their evaluation for particular people or values.

R110-069 Where maintaining a capacity or relation is material, the account shall identify the recurring work or conditions asserted to sustain it, the relevant period, and evidence or uncertainty about deterioration in their absence. Lack of a novel final output shall not be used to omit a supported maintenance contribution.

R110-070 A loss account shall distinguish loss in the represented situation from loss of records, visibility, access, institutional recognition, or interpretability. The package shall identify which kind is asserted, its basis and affected subject, without inferring one solely from another.

R110-071 An enabling or constraining effect that differs by participant, position, scale, or horizon shall be scoped accordingly. A short-term benefit shall not erase a recorded longer-term dependency or cost, and a loss to one participant shall not be concealed by aggregate expansion.

R110-072 A normative evaluation of maintained, created, or lost conditions shall identify the evaluator, relevant values, affected interests, grounds, and disagreement. Descriptive generativity and the desirability of its consequences shall remain distinguishable.

7.4 Generativity return

R110-018 Where generativity return is assessed or proposed, the package shall identify the asserted concept, intended recipients, scope, grounds and evaluative basis. Where it is not assessed, that limitation shall be stated without inventing a quantity or entitlement.

R110-073 A generativity-return account shall distinguish the proposed concept and evaluation from any observed transfer, practical response, or legally asserted entitlement. If a quantity is used, the account shall state its meaning, units or scale, calculation or judgment method, horizon, assumptions, and limits on comparability.

An account can state that generativity return was not assessed. The record of that limitation is assessed separately from any substantive claim about return. No universal distribution rule or monetary equivalent is prescribed.

8 Practical uptake, feedback, and revision

8.1 Decision and intervention accounts

R110-019 When a represented claim or classification informs a decision within scope, the package shall identify the claim version relied on, the decision, the asserted decision authority, its stated grounds and known subsequent response.

R110-074 A practical-uptake record shall distinguish availability or receipt of a claim from actual reliance, the decision communicated, and the action implemented. Each asserted step shall identify its source and evidence or uncertainty; a delivery acknowledgement shall not establish that a judgment was accepted.

R110-075 When an intervention rationale is within scope, the package shall identify the immediate action, intended generative effect, target relations or conditions, relevant assumptions, beneficiaries and affected interests, and evidence expected to support or challenge the rationale. It shall identify the asserted authority rather than derive that authority from the recording Standard.

R110-076 Where monitoring or feedback is part of the assessed practice, the practice shall identify questions, observations, review points or triggers, responsible recipients, and the decisions that feedback can inform. A collection schedule without a route to consideration shall not be represented as an operative feedback arrangement.

The practical sequence depends on context. A retrospective archive need not operate the intervention it describes. Its package can record an institution's asserted action and the evidence available about it. A practice claiming to provide an operational feedback route needs evidence that the route works within its authority.

8.2 Learning and consequences

R110-077 The package shall distinguish evidence that an action was implemented as intended from evidence that the anticipated transformation followed. Unexpected, delayed, mixed, or unobserved effects shall retain those statuses rather than being treated as success or failure solely from implementation completion.

R110-078 A material feedback record shall identify the observation or testimony, its relation to the intervention rationale, the person or function considering it, and any maintained or revised action with reasons. Where the practice cannot observe consideration or action, that limit shall be reported.

R110-079 When feedback leads to a changed target, method, boundary, objective, or evaluative criterion, the package shall preserve the change and its rationale. Later success criteria shall not be presented as though they governed the original action unless that earlier status is evidenced.

R110-080 An account of withdrawal, reversal, or repair shall distinguish ending an activity, attempting to restore an earlier condition, and addressing residual consequences. It shall identify responsible authority, planned and performed actions, observed effects, and known limits; restoring a rule shall not alone establish restoration of the prior situation.

R110-081 Where a corrective decision has known downstream consequences within the declared scope, the practice shall record follow-up evidence or its absence, including whether affected access, participation, capacity, or dependence changed. A corrected description alone shall not be reported as completed practical repair.

8.3 Revision and challenge

R110-020 A revision shall identify its actor or responsible source, time, target, reason and affected records, distinguishing a change in the represented situation, evidence or interpretation, and descriptive regime. More than one reason can apply.

R110-021 The recording practice shall preserve the intelligible relationship between earlier and later accounts, subject to stated retention and access rules. It shall not retrospectively present earlier actors as possessing evidence or categories first available later.

R110-022 A correction shall identify dependent records or presentations known to the practice, actions taken to correct them and any limits on propagation. The practice shall not assert that uncontrolled external copies were corrected or deleted without evidence.

R110-023 The practice shall provide a declared route for questions, contested attribution and correction requests, identify the responsible recipient and maintain permitted request/disposition records. Availability of the route shall not imply a legal entitlement or a promise of agreement.

R110-082 The declared correction route shall explain how to identify the disputed material, contact the responsible function, request protected handling, and learn the status or disposition. The practice shall test the route within its claimed operating conditions and record failures and remedies.

R110-083 Conflicting correction requests shall remain separately attributable and linked to the affected versions. The practice shall record the responsible determination or unresolved disagreement and shall not silently overwrite one account merely because another was received later.

9 Protection, custody, and preservation

9.1 Authority and proportionate collection

R110-024 The recording practice shall declare the purpose and authority basis for collecting, retaining, accessing and disclosing material within the package, including the applicable policy or institutional context and unresolved constraints. It shall limit collected detail to that justified by the declared purpose.

R110-025 Access and retention decisions shall distinguish content, metadata, derived views and audit traces. Preservation of history shall not automatically require public disclosure or indefinite retention of sensitive material.

R110-084 Before collecting or disclosing sensitive material, the practice shall identify the intended use, actual authority or permission basis, audience, relevant restrictions, and feasible less intrusive information sufficient for the purpose. If the intended use lacks an established basis, that use shall not proceed merely to complete the package.

R110-085 Protection decisions shall consider whether identifiers, relationships, timing, summaries, or combinations of metadata disclose restricted identity, existence, or content. The resulting access arrangement shall distinguish material that can be retained, examined by authorized reviewers, or presented to a particular audience.

9.2 Unavailable information and retention

R110-026 Where material is unavailable, the package shall distinguish known non-collection, loss, destruction, restriction and an unknown reason to the extent that doing so is supported and permitted. It shall not disclose a protected fact merely to label an absence.

R110-086 An unavailable-information declaration shall state only what is supported and permitted, identify its effect on interpretation or assessment, and indicate a review or future-access route where one exists. A protected omission shall not be filled with a false factual explanation.

R110-087 The practice shall identify the custodian, retention period or event-based trigger, access-review point, and authorized disposition for material whose retention or disclosure is controlled. Expiry or withdrawal of access shall trigger review of affected claims, views, and assessment limitations.

R110-088 When interpretability depends on a vocabulary, method, software environment, codebook, or external resource, the package shall identify the relevant version and preservation or availability arrangement. A broken reference or obsolete tool shall be assessed for semantic loss rather than treated only as a display defect.

9.3 Transfer and migration

R110-027 A transfer, migration or custody change performed by the practice shall identify the source and destination versions or custodians, its authority, relevant transformation and known information loss. Unsupported finer distinctions shall not be invented during conversion.

R110-089 Before a transfer or migration, the responsible custodian shall identify the authorized source and destination, material and versions in scope, rights and restrictions to carry forward, transformation rules, expected losses, acceptance criteria, and responsibility if the operation fails.

R110-090 After a transfer or migration, the practice shall compare the resulting material against the declared acceptance criteria, including identity, attribution, versions, temporal distinctions, generative links, uncertainty, access restrictions, and known losses. A successful byte transfer shall not alone demonstrate preservation of meaning.

R110-091 An interrupted or unsuccessful custody operation shall retain a record of completed and incomplete steps, authoritative copies, protection status, recovery actions, and unresolved loss. The practice shall not claim that destination custody is complete before acceptance is evidenced.

9.4 Correction, restriction, and disposal

R110-028 An authorized correction, restriction, retention or disposal action shall have a scoped disposition and an accountable executor. The practice shall record permitted evidence of its result and known limitations without retaining prohibited content solely to prove deletion.

R110-092 An authorized restriction or disposal shall identify the affected content and derived views, permitted evidence of execution, known copies or dependents, and limits of control. The practice shall review public statements and assessment claims that relied on material no longer available, without retaining prohibited information merely to document the action.

10 Presentation and accessible examination

10.1 View identity and mediation

R110-029 A presentation supplied as part of the assessed practice shall identify its source package/version and disclose material selection, reconstruction, uncertainty, disagreement and restriction within the permitted audience. It shall distinguish an attributed claim, an assessment and an institutional determination.

R110-030 A public or reduced view shall not imply that it contains the entire retained package. A validation or provenance result shall state what was checked and shall not be presented as certification of substantive truth or normative legitimacy.

R110-093 Each supplied view shall identify its audience and purpose, source package and version, generation or preparation method, material selection and transformations, and update status. A cached or exported view shall not imply that it reflects later corrections without evidence of refresh.

R110-094 A view of a generative account shall distinguish the status of the asserted effect, the evidential basis for it, and the evaluation of its desirability. A visual edge, color, badge, or position shall not be the sole means of expressing a distinction necessary for interpretation.

R110-095 Navigation from a public or reduced view shall respect the access limits of linked evidence and metadata. Where a material link cannot be exposed, the view shall communicate the permitted limitation without suggesting that the source does not exist or that unrestricted inspection is available.

10.2 User tasks and support

R110-031 The practice shall provide enough accessible explanation for intended users to locate the grounds of a material claim and the relevant review route. A practical assessment shall record observed comprehension barriers and the alternatives or limitations offered.

R110-096 The practice shall assess whether intended users can identify a material claim and its source, distinguish assessment from institutional decision, find relevant uncertainty or alternatives, recognize

revision and view limits, and locate the permitted challenge route. Assessment shall record tasks, users or representative role, observed barriers, assistance, and limits.

R110-097 Where a presentation fails a material intended task, the practice shall provide an accessible alternative, correct the presentation, narrow the supported use, or report an unresolved limitation. Successful file rendering or text extraction shall not be reported as demonstrated user comprehension.

11 Assessment and claims

11.1 Declaration and subject coverage

R110-032 A report shall identify the assessed subject, versions of this draft and its dependencies, purpose/profile, applicable requirements, assessor, method, evidence, results and unresolved limitations. Package-only results shall not be presented as assessment of unobserved practice.

R110-033 The report shall distinguish fulfilled, not fulfilled, not assessed and not applicable results for each requirement, with reasons for exclusions. A failed or unassessed applicable requirement shall prevent an unqualified claim that the declared scope satisfies this draft.

R110-034 The report shall distinguish structural or documentary checks from tests of understanding, evidential warrant and institutional performance. It shall not infer truth, complete historical recovery, beneficial generativity or legal validity from structural fulfillment.

R110-098 Before assessment, the assessor shall identify the package baseline, recording practice, purpose, period and environment, applicable requirements, incorporated GR-100 and GR-200 versions, protection limits, assessor competence and interests, and the methods in Annex B to be used. The declaration shall distinguish planned from completed assessment.

R110-099 An unqualified claim for the declared GR-110 scope shall require evidence for all applicable package and practice obligations, including the full applicable GR-200 package dependency. A successful documentary subset or absence of reported failures shall not establish that unobserved practice was performed.

R110-100 A package-only or otherwise partial assessment shall identify the exact assessed subset, methods and evidence, excluded practice claims, and dependency limitations. It shall not use an unqualified label suggesting that the complete recording practice or a reduced conformance profile was assessed.

11.2 Methods and result rules

R110-101 The assessor shall use requirement-level evidence and discriminating cases under Annex B. Where one identifier contains materially distinct obligations, component results shall be retained so that a fulfilled component does not conceal failure or non-assessment of another. A requirement shall be fulfilled only if every applicable component is fulfilled; any failed or unassessed applicable component shall prevent overall fulfillment of that requirement.

R110-102 Fulfillment shall require evidence of the stated obligation under its applicability condition. A missing required declaration shall be reported as not fulfilled; inability to examine whether a represented action occurred shall be reported as not assessed unless adequate permitted evidence supports a result. Non-applicability shall identify the absent trigger.

R110-103 Where assessment uses sampling, the report shall identify the population, selection method, covered risks, excluded cases, and limits on extension of the findings. Cases selected only because they already appear complete shall not support a general claim about an unexamined practice.

R110-104 A dependency mismatch, unavailable required evidence, or unresolved interpretation affecting the result shall be recorded with the affected requirements and claim consequence. The assessor shall not substitute a newer dependency silently or count an unsupported exception as fulfillment.

11.3 Reassessment and change

R110-105 A material change to purpose, claim set, generative account, category, protection, custody, presentation, or dependency shall trigger review of affected assessment results. The new report shall identify what was reassessed, what remains supported by prior evidence, and what can no longer be claimed.

The assessment concerns the declared scope. It does not establish that the package contains every important historical fact or that every recorded interpretation is correct. A requirement to preserve uncertainty can be fulfilled while the underlying generative attribution remains contested.

Annex A

(normative)

Semantic information schedule

A.1 Application

R110-106 The recording practice shall provide the semantic information in Table A.1 when its stated trigger applies, by content in the package or a permitted reference to identified material. The schedule shall be implemented without treating its labels as mandatory serialization field names or ontology classes.

R110-107 For each scheduled information group, the package shall identify its applicable subject, version, source or responsible actor, temporal scope where relevant, access status, and relationship to the material claims it supports. Information shared across records may be referenced when the intended scope and target remain unambiguous.

A.2 Information groups

The table specifies semantic content rather than a database schema. An embedded document can supply several groups, but their meanings and responsible sources remain distinguishable.

Table A.1 – Semantic information and applicability

Group	Trigger and subject	Required meaning and relationships
Package context	Each package.	Identity/version; purpose and intended users; subject and boundary; horizon; inventory; selection and omissions; responsible practice; declared dependencies and assessment status.
Source and capture	Material incorporated or transformed.	Source and received form/version; acquisition or creation; capture method; production context; derivation; transformation and known loss; permitted use and verification limits.
Material claim	Reliance within the declared purpose.	Attributed assertion, target, scope and status; grounds, method, alternatives, uncertainty and revision through the applicable GR-200 package; link to the relied-on version.
Identity and time	Identity or timing material to interpretation.	Record/version identity separate from subject identity; continuity criterion and grounds; competing identification; occurrence, observation, capture and assessment times with supported resolution and uncertainty.
Generative account	A generative connection is represented.	Target; candidate configuration and contribution role; earlier or comparison condition; proposed link and grounds; scale/horizon; modality; alternative contributors; known unobserved links and limits.

Group	Trigger and subject	Required meaning and relationships
Carrier and branch	Delay, transmission, or branching is material.	Carrier or persisting condition and transformations; intervening influences; pathway opening, selection and stabilization where distinct; branch-specific evidence and uncertainty.
Alternative and possibility	Alternative or changed accessibility asserted.	Whose option; relevant period and conditions; contemporaneous, retrospective or modeled basis; feasibility grounds; changes in access, cost or viability; unexamined options and comparison limits.
Category or method change	A change alters interpretation.	Earlier/later formulations, author or authority, effective period, rationale, correspondence and loss; distinction among new knowledge, revised description and a changed situation.
Maintenance and loss	Material sustaining work or loss within scope.	Capacity or relation sustained/depleted; continuing conditions/work; affected subjects and horizon; kind and evidence of loss; permitted collection limits; evaluation separately attributed.
Practical uptake	Decision or action relies on represented material.	Relied-on version; receipt versus reliance; authority assertion; decision and reasons; intended versus implemented action; anticipated versus observed effects; feedback and disposition.
Revision and challenge	Correction, reinterpretation or request occurs.	Target and prior version; actor/time; reason; permitted request and reply; revised or maintained assessment; known dependents; notification/propagation limits; separate practical remedy.
Protection and custody	Each maintained package and controlled operation.	Purpose and authority basis; custodian; content/metadata/view controls; retention/review triggers; unavailable-information status; transfers, losses, disposal and permitted execution evidence.
View and assessment	A view or assessment is supplied.	Source baseline; audience and purpose; selection/mediation; limits and update status; assessor/method; applicable requirement and component results; dependency status; excluded claims.

A.3 Absence, uncertainty, and restrictions

R110-108 An absent scheduled element shall be distinguished as not applicable with a trigger-based reason, unknown, not collected, lost, destroyed, restricted, or otherwise unavailable only where that status is supported and permitted. An unavailable contextual factual value, including historical capture time or source-production context, may be represented by such a typed declaration identifying the responsible or attributing role, known reason, and effect on interpretation or assessment. Package and record references

and versions, purpose and scope, accountable recording role, and relationship locators needed to identify asserted claims, contributions, assessments, and revisions shall not be replaced by unknown values. Required reasoning, criteria, and results of the package's own assessment shall remain explicit. Fulfillment of a contextual declaration obligation shall not establish the unavailable fact or fulfillment of an examination or action that could not be performed.

Annex B

(normative)

Requirement assessment schedule

B.1 Method and evidence register

R110-109 The assessor shall maintain a register for every applicable requirement, including R110-106 through R110-111, with subject/version, trigger, method, evidence locator, assessor and competence, component results, overall result, limitations, and needed action. The register shall use the discriminating assessment families in Table B.1 and identify any justified equivalent method.

Inspection examines the actual package and controlled records. A competent content review examines the grounds and distinctions asserted; it does not certify all historical truth. An observed task tests what the practice or user actually does under identified conditions. A lifecycle exercise uses authorized fixtures to assess access, revision, transfer, or disposal. Synthetic exercise results remain separate from evidence of live institutional action.

B.2 Assessment families

Table B.1 – Assessment families and discriminating outcomes

Requirements	Method and evidence	Outcome distinguishing fulfillment from failure
001–004, 035–041	Inspect scope, selection, inventory, accepted roles, resources, and maintenance record.	Boundary and omissions are explicit; no complete-history claim or automated substitute for missing responsibility.
042–045	Trace captured and derived material to its source and inspect transformations.	A summary and repeated copies remain distinguishable from the source and independent corroboration.
005, 046–047	Reconcile material-claim inventory with the complete applicable GR-200 package assessment.	Relied-on claims and package obligations are covered; isolated claim checks do not stand for the dependency.
006–009, 048–050	Compare disputed identity, an uncertain interval, and a historical category against their records.	Record identity, continuity judgment, time uncertainty and retrospective interpretation remain distinct.
010–012, 014, 051–056	Review a target and attributed contribution with an alternative explanation or unobserved link.	Occurrence, mechanism, association, counterfactual and model-based grounds retain their respective strength and limits.
057–060	Follow a delayed or multi-link account and examine a claimed persistence mechanism.	Uncertain carriers or downstream links remain uncertain; persistence alone does not establish lock-in.
013, 061–062	Examine collective/disputed attribution, branch contributions, and a separate credit or rights claim.	No forced sole attribution or automatic ownership/entitlement; branch formation and realization remain distinct.

Requirements	Method and evidence	Outcome distinguishing fulfillment from failure
015, 063–066	Compare a contemporaneous alternative and a retrospective proposal, including practical access.	Historical availability, imagination, permission and feasible access are not conflated.
016, 067–068	Reconstruct a change of category and an earlier account under its original information.	A revised description does not silently create a past object or erase the prior semantics.
017, 069–072	Review sustained capacity, record loss, and different effects across groups or horizons.	Maintenance remains visible; loss kinds and normative evaluations are separately grounded.
018, 073	Inspect any return account and its measurement or entitlement basis.	Concept, observed transfer, evaluation and legal assertion remain distinct; non-assessment is explicit.
019, 074–081	Trace decision, implementation, intended effects, feedback and a corrective action.	Receipt is not reliance; implementation is not beneficial effect; record correction is not completed repair.
020–023, 082–083	Exercise the permitted challenge route and inspect linked revisions and requests.	Earlier grounds survive within retention limits; conflicting requests remain attributable; propagation claims have evidence.
024–026, 084–088	Inspect authority, purpose, permissions, protected views, retention and unavailable information.	Required distinctions remain interpretable without disclosing protected content or inventing an absence reason.
027–028, 089–092	Exercise an authorized migration or lifecycle action and compare source/destination meaning.	Loss, failed steps, access control, disposal evidence and uncontrolled copies are correctly reported.
029–031, 093–097	Perform stated reader tasks using the actual view and available assistance.	Users can locate grounds and challenge routes; untested comprehension and inaccessible features remain limitations.
032–034, 098–111	Inspect the scope, complete result register, dependencies, methods and change review.	Failed/unassessed obligations prevent an unqualified claim; package-only and synthetic evidence remain bounded.

B.3 Execution and result integrity

R110-110 An exercised assessment shall record initial conditions, input and output versions, relevant permissions, performed steps, expected discriminating outcome, observed result, interruptions, and limitations. A described fixture or expected outcome without execution shall be recorded as a planned test rather than observed fulfillment.

R110-111 The assessor shall state the requirement-level consequence of each material failed task, inconsistent record, unavailable evidence item, or unresolved dependency. A remedied result shall retain the earlier finding, corrective action, new evidence, and remaining limit; a favorable summary shall not

conceal it.

Annex C

(informative)

Worked recording cases

C.1 Contested funding decision

This synthetic case concerns a public research fund that rejects an application after an AI-assisted summary treats missing calibration metadata as evidence that calibration did not occur. The community applicants later provide testimony and a restricted maintenance log. The package contains the initial claim and its grounds, the inference from missing information, the decision that relied on it, the challenge, authorized examination of the log, and the subsequent assessment.

The revised factual assessment is distinct from the institution's decision whether to reconsider funding. A separate classification review examines whether the original scoring categories excluded relevant knowledge. The public view identifies permitted limits on the log without publishing protected content. A reader can distinguish the old judgment, current assessment, policy question, and pending practical response.

A documentary check can assess these distinctions in an authored package. Testing the practice additionally requires observing the contact route, authorized access, notifications, and reader tasks. The synthetic case does not establish that a real institution changed its decision or that interrupted research capacity was restored. The existing fixture is `examples/p1-contested-decision.md`.

C.2 Maintenance, delay, and distributed contribution

A synthetic laboratory collaboration produces little new output during a year of instrument maintenance, training, and preserving shared access. A later discovery relies partly on those capacities. The account separates evidence that the maintenance occurred, its role in sustained capacity, the later discovery, and the attributed connection between them.

Training, functioning equipment, and retained procedures are possible carriers in the account. Their supported roles can differ, and the discovery can also depend on later collaborators or changed methods. No mandatory percentage allocation follows. An earlier contributor's loss of access remains visible even if the aggregate output increases. Recognition or compensation proposals require their own evaluative and institutional grounds.

C.3 An alternative that became visible later

An archive contains a proposal rejected under historical eligibility rules. Years later, a new category makes its significance easier to recognize. The reconstruction preserves the earlier categories and decision context, the later interpretive method, and evidence concerning options actually available at the earlier time.

The new account can be better supported without implying that the earlier actors possessed the later concept. An alternative technologically imaginable today is labelled retrospective unless period-specific evidence supports historical availability. A claim that the original choice caused lock-in needs evidence of changed transition conditions, such as accumulated dependencies or switching costs, rather than the persistence of the chosen arrangement alone.

C.4 Migration and loss of interpretation

A synthetic custodian exports a package into a format that preserves current claims but omits former versions and uncertainty in temporal ordering. The files transfer successfully. Assessment nevertheless

identifies loss relevant to reconstruction and treats the destination as a reduced representation.

A repair can preserve the missing relationships in an accompanying dossier without requiring one prescribed schema. The migration record identifies the source, transformed representation, remaining loss, and accepted custody. If the earlier source cannot be retained under applicable permission, the package states the resulting limitation rather than implying lossless preservation.

Annex D

(informative)

Foundation interpretation and unresolved issues

D.1 Source-to-proposal relationship

FM-005 section 5.13, pp. 105–113, develops target-relative generative attribution through association, mechanism, counterfactual reasoning, multiple contribution, distributed organization, delay, branching, and emergence. R110-051–R110-062 translate this into attributable recording of a proposed connection and its limits. The standard does not turn every account into a warranted attribution merely because the required information is present.

FM-005 section 5.14, pp. 113–122, distinguishes relational continuity from chains of generative contribution and treats path dependence, genealogy, historical evidence, alternatives, and re-epistemization. R110-049–R110-050, R110-057–R110-060, and R110-063–R110-071 preserve those distinctions operationally. The term possibility-field account denotes a bounded representation; it does not redefine the broader theoretical possibility field.

FM-003 section 3.12, pp. 129–141, treats praxis through diagnosis, enabling and constraining conditions, intervention, downstream tracing, feedback, adaptation, withdrawal, reversal, and repair. R110-074–R110-081 record the corresponding distinctions where they occur within scope. The source's sequence is heuristic; this draft does not impose one intervention lifecycle on every archive or practice.

D.2 Open conceptual and implementation questions

OPEN ISSUE The programme has not established a universal measure of generativity or generativity return, a mandatory causal-identification method, or exhaustive minimum historical coverage. Purpose-specific burden and usefulness require pilot evidence.

OPEN ISSUE The relation of Property to the metamodel manuscript's Attribute and the chronology of the two Chapter 3 files remain unresolved. This draft retains operational terminology without claiming that the variants are identical or that one supersedes the other.

OPEN ISSUE No common serialization, permanent identifier service, certification scheme, or full presentation/access profile is selected here. Reusable implementation needs enter separate Specification work items; limited assessment does not acquire full conformance by naming a future profile.

OPEN ISSUE The required evidence for effective practical repair, independent implementation, and sustained human comprehension remains use-context dependent. An initial synthetic exercise can expose missing procedures but cannot demonstrate those outcomes generally.

GENERATIVITY STANDARDS PROGRAM

GR-200

Standards-track Working Draft

Version 0.2 2026-09-22

Epistemic Recording Framework

WORKING DRAFT FOR REVIEW

This document contains proposed provisions for technical and institutional review. It is not an adopted Standard or an operative governance instrument. Its scope, application conditions and publication status are specified in the text.

Prepared by the Generativity Standards Program. Reference to external publications does not imply endorsement by ISO, IEC, IEEE or any United Nations body.

Foreword

Responsible editor: UNASSIGNED.
Canonical source: `standards/GR-200-epistemic-recording/GR-200.tex`

This document is a standards-track Working Draft of the Generativity Standards Program. Its maturity is **PREPARATORY; PROVISIONAL**. It contains proposed requirements for review and experimental assessment, not an adopted Standard, a formally initiated project or an institutional or legal authorization. Governance adoption, editor appointment, work-item approval, review and final publication require separate recorded decisions.

Edition 0.2 develops the initial framework into a fuller requirements document. Existing identifiers E200-001 to E200-026 retain their meanings; additional requirements specify claim structure, evidential context, uncertainty, revision, mediated use and assessment. Annexes A and B are normative within the proposed draft. The remaining annexes and bibliography are informative. Historical edition 0.1 is preserved rather than rewritten.

The publication follows a structured requirements format with scope, dated references, numbered terms, operational requirements, conformance and annexes. It does not claim ISO, IEEE, ITU or United Nations approval or affiliation. Conceptual sources inform the distinctions; resemblance of publication structure does not establish conformance with another body's development procedure.

Bibliography 26

Introduction

A representation can be authentic while its substantive content is mistaken. A classification can be applied consistently while failing to represent the situation relevant to a decision. A corrected record can improve current knowledge while leaving practical consequences of the earlier judgment unresolved. These are different problems, and a single verified-fact status cannot preserve their differences.

This document addresses the recording conditions for examining such problems. The epistemic record package links assertions, attributed sources, observations and reasoning, material, evidence roles, assessments, uncertainty, challenges and revisions. It supports inquiry into actual, possible, hypothetical and disputed targets without assigning all of them the same epistemic status. It records grounds for an assessment without prescribing one universal method of reaching substantive truth.

The programme's wider purpose concerns generativity: how relations and activity create, maintain, transform or restrict subsequent conditions and possibilities. The existence of a relation and an outcome does not establish the contribution linking them. Similarly, institutional uptake does not establish evidential warrant, and the ability to record a challenge does not establish effective access to review. Requirements for representation and requirements for institutional practice therefore remain connected but distinct.

The framework is deliberately independent of serialization. A small narrative dossier can distinguish claim versions and evidential roles through stable local references. A larger implementation can use structured objects or qualified statements. Choosing an encoding does not justify erasing an alternative, merging an unresolved identity or hiding an assumption. Specifications are developed when reusable implementation needs emerge from these requirements.

1 Scope

1.1 General

This draft defines the minimum information needed to examine who asserts what about a target, through which observations and reasoning, on which material, within what scope, with what uncertainty, and with what history of assessment and revision. Its organizing problem is the separation of a convincing or authentic representation from a warranted account of the represented situation.

The requirements concern a declared *epistemic record package*, which can include records, claim references, source locators, assessments, and protected components. The package can be textual, tabular, or implemented in software. This draft does not choose between claims as separate objects, attributed assertions within records, or a hybrid. A claim reference can be a local label and locator; it need not be a globally registered identifier.

GR-100 version 0.2 supplies the draft vocabulary. GR-110 adds requirements for generative trajectories and practical consequences. GR-210 is intended to govern the practice of assessment, challenge, and disposition. This document records those activities when present; it does not substitute a complete adjudication process, guarantee an appeal right, or set an evidential sufficiency threshold for every domain. GR-160 and GR-400 are intended to elaborate protection and institutional use. None of these drafts creates jurisdiction, a legal duty, or factual certainty.

2 Normative references

2.1 Dated draft reference

The following referenced document supplies this edition's operational meanings: Generativity Standards Program, *GR-100 — Foundations and Vocabulary*, Standards-track Working Draft, version 0.2, available at `standards/GR-100-foundations-vocabulary/GR-100.tex`. The incorporated scope is Clause 3's terms, Clause 5's record-role meanings when used, and the result-category meanings in 8.3. This reference does not impose a separate claim of GR-100 vocabulary-application conformity. It is a dated draft dependency, not an adopted Standard. If an incorporated meaning is unavailable or incompatible, the affected assessment is not assessed until the dependency is resolved. A later GR-100 edition does not silently change the meanings used here.

2.2 Other publications

There are no external normative references. GR-110 and GR-210 identify coordinated recording and procedural work, but their requirements are not imported into GR-200. A report claiming conformity to more than one publication identifies and assesses each dependency separately. Foundation manuscripts and external drafting models in the bibliography are informative.

3 Terms and definitions

3.1 General

The terms in GR-100 Working Draft 0.2 apply. The following terms specify their use for this document. These information structures are semantic recording units; they do not introduce new metaphysical classes or determine whether an implementation uses objects, wrappers or attributed statements.

3.2 Epistemic record package

An identified and versioned collection of claim content and linked context assembled for a declared inquiry, practical use and collection boundary, with an inventory or selection rule, responsible role and access scope.

3.3 Included claim

A claim designated as part of the assessed package, rather than merely occurring within an external source cited by it.

NOTE 1 Assertions attributed to another source remain assertions to be examined, not endorsements by the package owner.

3.4 Material information

Information capable of changing a reasonable examination of the declared claim, its warrant or its consequential use.

NOTE 2 Materiality is relative to the declared purpose; its selection rationale is inspectable and does not establish truth.

3.5 Claim reference

A designation that distinguishes an assertion and its version within the package.

NOTE 3 It supports links to evidence and assessment without itself establishing target identity or prescribing a globally registered identifier.

3.6 Material item

An identified source, portion, pattern or result proposed for use in an inquiry.

NOTE 4 It can be a trace, testimony, observation, record, comparison or intervention result. Its inclusion does not establish an accepted evidential role.

3.7 Evidence-role assignment

An attributed relationship between identified material and a specified claim, together with an assessment of relevance, limitations and alternatives.

NOTE 5 Supporting, challenging, qualifying and non-discriminating roles concern that relationship rather than an intrinsic status of the material.

3.8 Assessment record

An identified account of a question examined, the criteria and material used, the responsible assessor, timing, result, uncertainty and limitations.

NOTE 6 An assessment record can itself become a target of a later claim or challenge.

3.9 Dependency

A stated relationship through which a claim, assessment, representation or action relies on another identified item or version.

NOTE 7 Derivation, inferential reliance, shared-source dependence and practical uptake have different meanings and are identified separately where material.

3.10 Coverage statement

An account of the scope within which observation, collection, source examination or assessment was performed, including known omissions and exclusions.

NOTE 8 Coverage does not necessarily coincide with the scope of a substantive target claim.

3.11 Negative-evidence claim

A claim whose grounds include nonappearance of an expected trace.

NOTE 9 Its warrant depends on stated production, detection, coverage and preservation conditions; a missing value alone does not establish non-occurrence.

3.12 Transformation record

An account of a material change between a source representation and a resulting representation, identifying the input, output, operation, responsible role and known preservation or loss of meaning.

3.13 Released view

A representation selected from a package for a specified audience and purpose under stated access and disclosure conditions.

NOTE 10 Its completeness and inspectability are assessed against its declared boundary, not assumed from its source package.

3.14 Epistemic context

The attributed observations, methods, assumptions, evidential roles, uncertainty, perspective and temporal and descriptive scope required to interpret a claim.

NOTE 11 Shared context can apply to several claims when the inheritance and any exceptions are explicit.

4 Package declaration and recording boundary

4.1 General

The conformance subject is one named, versioned epistemic record package within a declared purpose, collection boundary, and access scope. Requirements apply to its included claims and assessments, with conditional requirements triggered by the relevant activity. An external source is not required to satisfy these rules merely because it is cited; the package's assertions about it and uses of it are within scope.

E200-001 The package shall declare its reference and version, responsible recording role, intended use, target and collection boundary, included claim set or selection rule, access scope, relevant descriptive regime, and the GR-200 draft version used. It shall identify exclusions and limits that materially affect interpretation.

E200-002 The package shall associate every requirement with an assessment result and an evidence locator. A claim of conformity to this draft shall identify its package boundary and applicable requirement set, and shall disclose failures, unassessed requirements, and restrictions that prevent assessment. It shall

not represent technical or recording conformity as proof of factual truth, evidential sufficiency, ethical acceptability, or legal validity.

An assessment result is fulfilled, not fulfilled, not assessed or not applicable with a reason. Only requirements whose stated trigger is absent can be marked not applicable. A package with failures or unassessed applicable requirements can report partial assessment, but not full conformity. This draft has no certification or accreditation scheme.

"Material" in this document means capable of changing a reasonable examination of the declared claim, its warrant, or its consequential use. The package's selection rule states how materiality was judged. Unknown, not collected, withheld, lost, and inapplicable can be explicit informational states where a value is unavailable. They disclose a limitation rather than establish the unavailable value or a substantive negative conclusion.

4.2 Semantic units and shared context

E200-027 The package shall provide the applicable information in Annex A for its declaration, included claims, material items, evidence-role assignments and assessments. Information supplied through shared context shall have an identifiable scope and version, with claim-specific exceptions explicit. A reference shall resolve within the declared assessment arrangement or carry an availability limitation.

These units need not be separate software objects. A table row can contain a claim and refer to shared acquisition context; a narrative passage can identify an assessment and its sources. E200-027 requires an inspectable association without reliance on undocumented assumptions. Reusing one context statement is acceptable when it actually applies to the linked claims. A package-wide uncertainty statement cannot conceal a material difference between a direct observation and a distant reconstruction.

External sources do not enter the assessed claim set merely because every sentence in them is quoted or stored. The package distinguishes the source material, the claim that the source contains a statement and any adopted substantive assertion. The resulting collection boundary is finite and declared. It is not a requirement to reproduce or assess every upstream publication, every possible objection or the entire history of an institution.

An assessment of this document can be recorded in a linked report outside the substantive claim set under examination. The report identifies the exact subject package and edition. Its statements about conformity do not automatically become evidence for the package's substantive claims.

5 Claim content, attribution and method

5.1 Claim identity and content

E200-003 Each included claim shall have a reference that distinguishes its content and version within the package, stated assertion content, an identifiable target or an explicit unresolved target description, and a link to its recording context. Different assertions or versions shall remain separately referenceable where their attribution, grounds, or disposition differ.

5.2 Attribution

E200-004 Each claim shall identify its represented originating actor or source and the role responsible for entering it into the package. Where these differ, the attribution chain shall distinguish origin from transcription, quotation, translation, summary, or adoption. Unknown, pseudonymous, restricted, or disputed attribution shall be explicit.

5.3 Modes and modality

E200-005 Each claim shall state its epistemic mode and relevant perspective: for example observation report, testimony, inference, interpretation, retrospective reconstruction, hypothesis, simulation, or normative or institutional judgment. Combined modes shall identify the distinct contributions rather than present inferred content as directly observed. A claim about an occurrence or possibility shall distinguish its asserted actuality or modality from its epistemic basis; retrospective inference can concern an actual occurrence.

5.4 Method and reasoning

E200-006 Each claim shall identify its acquisition or reasoning method, material premises and assumptions, relevant method version when one is used, and known transformations from source material to assertion. Where this information is unavailable, the package shall state the limit and shall not claim reproducibility or direct observation on that basis.

5.5 Boundary and scale

E200-007 Each claim shall state the boundary, scale or level of aggregation, contextual conditions, and temporal horizon relevant to its interpretation. It shall identify known omissions or selection conditions that materially limit generalization. A narrowed scope shall not be silently presented as a claim about a broader target.

5.6 Temporal scope

E200-008 Each claim shall distinguish target time from the times of observation or source acquisition, recording, and assessment where applicable. Time values shall carry their applicable meaning and known uncertainty or resolution. Unknown order shall remain distinguishable from asserted simultaneity and from recording order.

5.7 Target identity

E200-009 A claim that reidentifies a target across appearances shall identify the identity criterion, the appearances linked, the responsible attribution, and the evidential basis or stipulation. A proposed split, merger, succession, or disputed match shall not silently merge record identity, target identity, and lineage.

NOTE 1 A testimony can be preserved without claiming its reporter is infallible. Requiring attribution does not require public disclosure of a protected person's name. A role or pseudonymous reference, its protection status, and an accountable custody arrangement can provide the appropriate recording context.

5.8 Compound claims and qualifiers

E200-028 Where one expression contains assertions with materially different targets, attribution, temporal scope, modality or evidential grounds, the package shall distinguish the components and their qualifications sufficiently for separate assessment and revision. A conjunction or summary shall not silently transfer warrant from one component to another.

The expression "the meeting occurred and secured lasting cooperation" contains an occurrence claim and a claim about a later relational effect. Evidence for attendance might support the first while leaving the second unresolved. The components can remain in one document if their references and qualifications are distinguishable. The requirement does not demand logical atomization of every sentence; it applies where shared wording would otherwise conceal a material difference.

5.9 Relayed speech, quotation and translation

E200-029 Where a claim is quoted, translated, paraphrased or relayed, the package shall distinguish the attributed source expression from the recorder's rendition or interpretation, identify the available source context and material transformations, and state uncertainty about attribution or meaning. A quotation's presence shall not be treated as endorsement by its recorder.

A testimony can identify an experience available to a situated participant while leaving causes or other participants' intentions unresolved. A summary can be accurate for one question while omitting qualifications needed for another. Selection, transcription, translation and interpretation can each affect the path from source to assertion. The package records the relevant path instead of claiming that the reported wording is an unmediated view of the target.

5.10 Observation and acquisition context

E200-030 For an observation or measurement claim, the package shall identify the observer or acquisition system, observed feature, method, relevant instrument or procedure version, observation window and conditions materially affecting recognition, detection or recording. Known limitations in coverage, resolution or calibration shall be stated where relevant to the claim.

This requirement is proportional to the claim. A report that an inscription was seen can cite the observer and inspection context without manufacturing a quantitative measurement protocol. A measurement claim can require units, resolution and an instrument procedure. The package does not imply that a larger dataset removes selection effects or that an automated observation lacks an observer position.

5.11 Inference and reconstruction

E200-031 For a material inference or reconstruction, the package shall distinguish its asserted premises, adopted assumptions, inferential steps needed to examine the conclusion and material unresolved alternatives. An assumed premise shall not be represented as an observed input, and a mathematically possible history shall not be presented as an evidenced occurrence sequence without additional grounds.

An inference can be qualitative, historical, comparative, statistical, computational or mixed. The requirement is an inspectable connection between premises and conclusion, not a universal proof calculus. A researcher can identify a plausible contribution while remaining unable to establish causal sufficiency. A formal model can show consistency under its assumptions without establishing that its stipulated subjects and operations describe the actual case.

6 Material, evidence and uncertainty

6.1 Material identification

E200-010 For each material item invoked in support of, against, or to qualify a claim, the package shall identify the item or pattern, its relevant portion, source or acquisition path, and availability status. It shall distinguish original material, copies, derived representations, and generated material where those differences affect the claimed use.

6.2 Claim-relative evidential roles

E200-011 Each assigned evidential role shall link the material to a specified claim and identify the assessor or attributing source, assessment time, role, and rationale addressing relevance, reliability limitations, and material alternative explanations. An item with no assessment shall be marked unassessed rather than silently represented as accepted support.

The role can be supportive, challenging, qualifying, non-discriminating, or another defined relationship. A single item can support one claim and challenge another. The package need not impose a ranking across all evidence forms.

6.3 Dependence and corroboration

E200-012 Where multiple items are used together as evidence, the assessment shall identify known material derivation or dependence among them and the basis for any asserted independence. Repeated copies, summaries, or citations of one source shall not be presented as independent corroboration solely by their count.

6.4 Absence and non-occurrence

E200-013 A claim of absence or non-occurrence inferred from missing observations or records shall identify the expected observation or recording opportunity, coverage, detection or preservation limitations, and reasoning from the missing material to the claim. If those conditions are not established, the package shall preserve the weaker missingness statement and shall not treat it as established non-occurrence.

6.5 Uncertainty

E200-014 Each claim assessment shall describe material uncertainty and its location, including relevant alternatives, assumptions, identification limits, measurement limits, temporal gaps, or boundary and model limitations. A numerical confidence quantity, if used, shall state what it measures, its method and assumptions, and the scope of its interpretation.

6.6 Competing explanations

E200-015 The package shall record material competing claims or explanations known within its declared collection boundary, their attribution, their relationship to the target claim, and any recorded grounds for excluding or preferring them. If alternatives were not examined, this limitation shall be explicit; silence shall not be presented as evidence that no alternative exists.

An alternative need not receive equal evidential weight merely because it is recorded. Recording a disagreement does not mean that it remains unresolved after a reasoned assessment. The disposition and its grounds remain visible, and an attributed rejected interpretation can remain historically consequential.

6.7 Formation, selection and survival of material

E200-032 Where the production, selection, custody or survival of material affects an assigned evidential role, the assessment shall record the relevant known conditions and gaps, including selective preservation or inaccessible channels. A hypothesis of concealment shall have stated grounds and shall not be inferred solely from missing evidence.

An archive contains what was produced, captured, retained, made accessible and recognized as relevant. Failure at any stage can alter the evidential field. A missing complaint has different implications when a reporting route was usable, when it was dangerous to use, or when submissions were not retained. The package records what is known about those conditions rather than assigning one universal evidential weight to silence.

6.8 Transformation and derived material

E200-033 A material transformation relied on in an assessment shall identify its source and output versions, operation, responsible role and known effects on meaning or inspectability. Extraction, redaction, normalization, deduplication, imputation and generation shall remain distinguishable where their differences affect the claim. Supplied or inferred values shall not be represented as original observations.

A copy can preserve substantive content while changing its custody context. A redaction can protect a person while removing context important to interpretation. A transcript can make a recording searchable while introducing uncertain wording. None of these operations is inherently disqualifying. Their role and limits need to be visible to the assessment that relies on them.

6.9 Combination, aggregation and independence

E200-034 Where a claim relies on combined or aggregated material, the assessment shall state the included units, inclusion and exclusion rules, relevant denominators or weights, and known changes of composition. A claim about independent corroboration, stable population or comparable periods shall identify its basis rather than follow solely from a count, common label or shared format.

Several individually weak traces can jointly constrain a claim when their production paths differ in relevant ways. The opposite is also possible: many records can reproduce the same source, coding rule or institutional selection effect. Neither volume nor diversity of file formats establishes independent evidential pathways. Known dependence remains visible even when its precise quantitative effect cannot be estimated.

6.10 Comparability of uncertainty statements

E200-035 A comparison, aggregation or transfer of confidence quantities or qualitative grades shall state the meanings, assessed claims, scopes, methods and assumptions that support comparability. Incomparable dimensions shall not be silently combined into a universal score. Strong warrant in one dimension shall not erase a material unresolved limitation in another.

Confidence in an occurrence can exceed confidence in a causal attribution or long-term consequence. A numeric model score can concern a prediction conditional on its training and observation regime, while an assessor's confidence concerns a broader institutional claim. Shared numerical range does not establish shared meaning. A package can retain dimensional qualitative assessments without inventing probabilities or forcing all disagreements onto one scale.

6.11 Alternatives and limits of examination

E200-036 The assessment shall distinguish an alternative examined and rejected with grounds, an alternative retained as plausible, and an alternative not examined. Where a conclusion depends materially on boundary, scale, population, method or descriptive-regime choice, the assessment shall identify that dependence and any comparison actually performed. An unperformed sensitivity or alternative analysis shall not be described as completed.

Alternatives can compete for the same explanatory role or concern different parts of a composite process. A rule, network and resource condition can each contribute without being interchangeable explanations. Recording them does not require equal weighting or an exhaustive catalogue. It requires the package to disclose the comparison it actually makes and where a claim exceeds that comparison.

7 Assessment, revision and practical use

7.1 Assessment questions and criteria

E200-016 Each assessment or determination shall identify its question, responsible assessor or decision role, criteria, material examined, result, date, limitations, and relationship to the assessed claim versions. Provenance/authenticity, factual warrant, institutional acceptance, normative evaluation, legal determination, and technical validation shall remain distinguishable assessment functions.

7.2 Substantive revision

E200-017 A substantive revision shall link the prior and revised claim or assessment versions and record who revised it, when, why, and which content or scope changed. The reasons shall distinguish target change, evidence or assessment change, and descriptive-regime change, allowing combined reasons. Historical access shall preserve earlier meaning to the declared retention and protection extent; any unavailable earlier content shall have an explicit reconstruction limitation.

7.3 Descriptive-regime change

E200-018 A change of descriptive regime shall identify the prior and new definitions or methods, grounds for change, affected claim set, and any mapping or transformation used. It shall identify known non-comparability, lost distinctions, or unresolvable mappings; finer classifications shall not be reconstructed from insufficient earlier material as if evidenced.

7.4 Dependent records and actions

E200-019 For a revised claim with known dependent assessments, claims, or consequential uses within the package boundary, the package shall identify those dependencies and record whether each was reviewed, updated, left unchanged with reason, or remains pending or unreachable. It shall not claim that external recipients or institutions have corrected their actions without evidence of that correction.

7.5 Practical uptake

E200-020 Where the package records practical uptake of a claim, it shall distinguish the claim, its assessment, the institutional or other action, the actor responsible, and the asserted basis for acting. Recorded consequences and proposed remedies shall remain separately attributable from the original grounds and intended effects.

7.6 Challenge and disposition records

E200-021 For a challenge received within the package's declared collection boundary, the package shall record the challenged claim version, challenger or protected source reference, grounds and submitted material, receipt context, and current status. A disposition shall record the responsible role, response, reasons, date, unresolved disagreement, and resulting changes or the reason for no change. A challenge without disposition shall remain visibly pending or otherwise explicitly unresolved.

This clause addresses the record of a challenge. Routes for submission, notification, review independence, timeliness, appeal and remedy are procedural matters addressed in the coordinated GR-210 draft and relevant institutional profiles. Their effectiveness requires separate assessment. Merely supplying challenge fields does not demonstrate that a person can effectively contest a decision.

7.7 Criteria, status and temporal validity of an assessment

E200-037 An assessment shall identify the version and scope of its criteria and distinguish the date of examination, the evidential state examined and any stated period or condition of applicability. A later change of criteria or available evidence shall not silently change the recorded meaning of an earlier result.

Supported, rejected, qualified, unresolved and not examined have different meanings when applied to a claim. A procedural status such as closed concerns the case process rather than the claim's truth. An institution's acceptance can authorize an internal action while the underlying evidential assessment remains qualified. The package records these distinctions instead of using one status field as a substitute for them.

7.8 Version identity and concurrent interpretation

E200-038 Where more than one revision or interpretation of the same earlier item is retained, the package shall identify their predecessor relationships, responsible sources and whether a preferred current version has been designated within a stated scope. It shall preserve material unresolved branches and shall not treat latest recording time alone as evidential precedence.

Version history can branch. Two reviewers can correct different parts of a description, or disagree about the interpretation of the same material. A later administrative designation can select one version for use without establishing that every competing claim has been factually disproved. The designation, its authority and its grounds remain separately identifiable.

An editorial correction that preserves meaning can be recorded as such. A changed target, evidential ground, qualification, criterion or scope requires the substantive revision context of E200-017. Replacing an artifact for formatting does not automatically create a new historical occurrence or erase the earlier asserted content.

7.9 Intervention and reflexive effects

E200-039 Where intervention, publication, observation or classification is claimed to have changed the target situation, the package shall distinguish pre-change observations, the intervention or uptake, subsequent observations and the claim connecting them. An improvement in observation shall not automatically be represented as creation of a new relation, and an intervention-produced change shall not automatically be used as evidence of the earlier unchanged situation.

Discovery and creation can coexist. A new reporting route can reveal previously unrecorded practice and alter that practice by making it visible. A revised eligibility category can change both available distinctions and subsequent access. The package can record combined reasons while preserving their different temporal and evidential bases. It does not require a counterfactual causal experiment where none exists; it records the stated method and limits of attribution.

8 Mediation, protection and layered assertions

8.1 Computational mediation

E200-022 Where computational mediation materially affects a claim's observation, classification, inference, reconstruction, or presentation, the package shall identify the system and available version, its task, supplied source material or its controlled reference, material transformations, output used, and the role responsible for uptake or review. Unavailable system details and resulting limits shall be stated. Generated output shall remain distinguishable from independent source evidence.

This requirement includes rules, statistical models, sensor processing, database transformations, and generative systems when material to the claim. It does not require exhaustive logs of unrelated operations

or disclosure of private credentials. A vendor confidence score does not automatically measure the warranted confidence in the package's substantive claim.

8.2 Protected material

E200-023 Where claim context or evidential material is restricted, the package shall identify the restriction and its asserted basis, responsible custodian or accountable role, assessment consequence, and any available route for authorized examination or challenge. A released view shall identify material omissions at a level permitted by the declared protection arrangement and shall not describe unavailable evidence as independently examined.

If even acknowledging an item is restricted, the released view can describe its assessed scope without exposing item-level existence. The protected package still needs an accountable restriction record. This clause supplies neither permission to disclose nor a legal retention rule. Where a reviewer cannot assess a required component, E200-002 requires an unassessed result; a protection reason does not turn missing verification into a pass.

8.3 Normative and ethical assertions

E200-024 A normative or ethical assertion shall identify the evaluative question, attributed evaluator, stated criteria or values, affected parties and scope, and material acknowledged tradeoffs or disagreements. It shall remain distinguishable from the descriptive claims on which it relies and shall not treat a claimed generative effect as inherently desirable.

8.4 Legal and jurisprudential assertions

E200-025 A legal or jurisprudential assertion shall identify the asserted legal concept, source or rule relied upon, relevant institutional or jurisdictional context, attributed authority, temporal applicability, and procedural status, or explicitly state which are unresolved. It shall distinguish a descriptive legal analysis, party allegation, institutional determination, model rule, and policy proposal where applicable. Recording the assertion shall not be represented as creating or confirming its legal effect.

8.5 Selected and transformed packages

E200-026 When a package is selected, summarized, exported, or transformed and the resulting package is claimed to conform to this draft, it shall preserve the attribution, claim-version relationships, epistemic qualifications, material disagreement, and access/reconstruction limits required within the resulting declared boundary. Omitted or transformed content and the resulting limits shall be identified; a partial view shall not imply completeness of the source package.

This is an implementation-neutral requirement on the resulting package. Format negotiation, transport, identifiers, validation vocabulary, and machine-readable exchange behavior belong in Specifications prompted by the demonstrated need.

8.6 Computational observation and inferred completion

E200-040 Where computational processing affects evidential coverage, identity, category assignment or missing values, the package shall identify the relevant selection, linkage, classification and completion operations and their known limitations. A generated or imputed relation shall not be presented as an independently observed relation solely because it appears in a structured output.

The term machine-mediated includes a rule-based pipeline or database transformation as well as a learned model. A system can record extensive interactions while excluding people or activities outside its infras-

tructure. A link-prediction result can be a useful candidate for inquiry while remaining an inference. An embedding similarity is not itself evidence that two people collaborated or that two records concern one target.

8.7 Reproduction and availability claims

E200-041 A claim that a material computational result is reproducible or independently reviewable shall identify the available inputs, system or method version, relevant configuration and output, and the procedure supporting that claim. Unavailable internals, changing services, inaccessible data or nondeterministic behavior shall be disclosed where they limit the asserted reproduction or examination.

This requirement does not demand secret credentials, unrelated conversation logs or an invented explanation of a model's internal reasoning. It requires a truthful account of what can be inspected and repeated. A person can review a generated summary against its cited documents without reconstructing every internal operation, but that limited review is described as such. Reproducing the same output does not by itself establish its factual warrant.

8.8 Protected context and accountability

E200-042 Where protected references or substitutes are used, the package shall state the examination they permit, the accountable custody or review role, and their known limits for source identification, context and challenge. A custodian's assurance, an assessor's direct examination and an unavailable source shall remain distinguishable.

Restricted evidence can be handled through an authorized reviewer, an excerpt or a statement of examined scope. Those arrangements can support different questions. A public summary cannot claim full independent inspectability when its readers cannot examine a decisive source. The protected package need not reveal a source's identity to every audience; the restriction and the resulting assessment limitation remain accountable within the authorized arrangement.

8.9 Loss of access and historical reconstruction

E200-043 Where deletion, restriction, loss or a failed reference materially affects later examination of a retained claim, the package shall record the known change, its scope, responsible role or explicit unknown, and the resulting assessment or reconstruction limit. Evidence of a permitted disposal action shall not retain prohibited content solely to prove its removal.

Historical assessment and present inspectability can diverge. An assessor might have examined a source that is no longer available to a later reader. The historical result can remain recorded with the evidence then cited, while the later reader's ability to reassess it is limited. Neither automatic erasure of the earlier examination nor an unsupported assertion of continuing inspectability follows.

8.10 Evaluative scope and policy proposals

E200-044 Where an ethical or policy assessment compares effects across people, groups or periods, it shall identify the compared effects, evaluative criteria, aggregation or tradeoff method if any, and material effects left outside the comparison. A recommendatory institutional or policy proposal shall remain distinguishable from an adopted requirement, an authorized decision and a descriptive finding.

The same intervention can expand one group's capacity while reducing another's access to review. An assessment can favor the intervention under stated values while preserving the adversely affected group's account. Describing a generative effect does not settle its normative sign. A proposal addressed to an international organization also requires a stated intended institution and mandate context when those affect its recommendation; technical recording conformity does not confer that mandate.

9 Conformance

9.1 General

The conformance subject is one declared epistemic record package at a fixed edition, purpose and boundary. This document specifies recording requirements, not proof that every described activity occurred or that an institution's procedure was fair. A package can faithfully record an unsupported or rejected claim when its attribution, status and grounds are clear. Whether a substantive inference is warranted remains an assessment question with its own scope.

9.2 Applicable requirements and information schedules

E200-045 A conformity assessment shall use the semantic schedules in Annex A and the checks in Annex B, documenting the applicable requirements, evidence, assessor, date, result and limitations. Each requirement shall receive a result; an omitted field or unavailable source shall not be treated as an absent trigger for a requirement whose subject is present.

E200-049 Where one requirement groups obligations whose results can differ materially, the assessment shall record the result and evidence for each such component. The requirement shall be fulfilled only if every applicable component is fulfilled. A failed or unassessed component shall remain visible in the requirement-level and overall package result.

General package requirements apply to every assessed package. Claim requirements apply to every included claim. Requirements concerning measurements, legal assertions, machine mediation, transformations, restrictions, revisions or practical uptake apply when those features occur within scope. A package without a legal assertion can mark E200-025 not applicable. A legal allegation lacking a known jurisdiction instead invokes that requirement and records the jurisdiction as unresolved.

9.3 Extent of examination

E200-046 The assessment shall state the extent of examination, including any sampling, inaccessible components and checks performed only automatically. A sampled or partial assessment shall not be represented as exhaustive examination of the package. An unqualified conformity claim shall require a supported fulfilled result for every applicable requirement throughout the declared subject.

Automatic checks can verify presence, reference integrity or structural combinations. They cannot alone establish appropriate inference, meaningful scope, adequacy of an explanation or the source of institutional authority. A larger assessment can use justified sampling to discover defects, but its report remains explicit about the claim that the sample supports. Narrowing the subject to examined cases does not justify describing the result as institutional assurance.

9.4 Result categories and reassessment

The result categories are fulfilled, not fulfilled, not assessed and not applicable with a reason. They have the meanings stated in GR-100, 8.3. A blocked review receives a limitation and an unassessed result; an authorized restriction is not itself evidence of fulfillment of an unexamined requirement.

E200-047 A change to an assessed package, its claimed scope or an applicable dated dependency shall identify the prior assessment, affected requirements and evidence, and any reassessment performed or pending. Previous results shall not silently transfer to materially changed claims, methods, access conditions or transformations.

A report identifies whether it concerns the retained protected package, a released view or both. A view can receive its own bounded assessment if it preserves the requirements applicable to that view and does not

imply access to withheld material. Where a required component cannot be examined, its result remains not assessed. No certification, accreditation or legal evidentiary status is created by these categories.

Annex A

(normative)

Semantic information schedules

A.1 General

This annex specifies the semantic information required by E200-027. It does not prescribe a serialization, field name, datatype or new ontology class. Information can be directly recorded or supplied by a stable contextual reference whose meaning and applicable edition are inspectable. E200-048 distinguishes mandatory structural information from unavailable contextual factual values and identifies the assessment consequence of the latter.

E200-048 The package shall supply its reference and version, declared purpose and boundary, included claim references and content, target designations, accountable recording role, and relationship locators needed to identify each asserted evidence role, assessment or revision. These structural components shall not be replaced by an unknown value. A required contextual factual value that is unavailable may be represented by a typed unknown, uncollected, lost, disputed or restricted declaration identifying the responsible or attributing role, known reason and assessment limit. Such a declaration shall not establish the unavailable fact, replace required reasoning or criteria for the package's own assessment, or produce a fulfilled result for an examination that could not be performed.

An unresolved target designation states what the claim concerns or the identification question under examination, as allowed by E200-003. It is not an invented identity. A protected actor or material can have a controlled reference whose disclosure scope is stated. The structural requirement is an identifiable relationship in the authorized arrangement, not publication of protected identifying information.

For the tables below, unknown contextual values include the actual source person's identity, target time, instrument details, an upstream actor's method, external legal context or unavailable historical content where these cannot be established. The package's own declared assessment method, criterion, inference and result describe what its assessor actually used or determined. An unperformed evidential examination is recorded as not examined; fulfillment of the duty to disclose that state remains separate from any claim that the examination occurred. A known omission of required structural content or assessment reasoning is a recording defect rather than an unknown-context exception.

A.2 Package, claim and material information

Table A.1 – Core semantic information and its governing requirements

Component	Required information when the component is present	Governing requirements
Package	Reference and version; purpose; recording responsibility; target and collection boundaries; included claims or selection rule; access scope; descriptive regime; exclusions; assessment results.	E200-001/002/027/045.
Claim	Distinguishable content/version and target; origin and recording attribution; epistemic mode and relevant modality; method; material assumptions; scope; temporal context; identified unavailable context.	E200-003–008/028–031.

Component	Required information when the component is present	Governing requirements
Identity assertion	Appearances linked; stated criterion; responsible attribution; grounds or explicit stipulation; material dispute; distinction from lineage and record references.	E200-009.
Material item	Reference or controlled locator; relevant portion or identified pattern; source/acquisition path; availability; distinction between original, copy and derived or generated representation.	E200-010/032/033.
Evidence-role assignment	Material and claim-version links; assessor/source; time; evidential role; relevance rationale; reliability limits; material alternatives and known dependence.	E200-011/012/034.
Assessment	Question; assessor or decision role; criteria and version; material examined; result; date; claim versions; uncertainty and limitations; available alternative analysis.	E200-014–016/035–037.

A.3 Conditional information

Table A.2 – Information activated by conditional recording subjects

Trigger	Information required for the triggered subject	Governing requirements
Negative evidence	Expected trace opportunity; production, detection, coverage and preservation conditions; inference and limitations.	E200-013/032.
Revision	Prior/resulting versions; responsible source; time and reasons; changed content/scope; history limits; known dependents and disposition.	E200-017–019/038.
Regime change	Earlier/new definitions or methods; reasons; affected claims; mapping used; non-comparability or lost distinctions.	E200-018.
Practical uptake	Relied-on claim/version; assessment; action and actor; asserted authority or grounds; intended effects; separately attributed consequences or remedy.	E200-020/039.
Challenge	Challenged version; protected or open source attribution; grounds/material; receipt context; status; disposition responsibility, reasons and resulting changes.	E200-021.
Machine mediation	System and available version; task; inputs and outputs used; material operations; uptake/review role; unavailable detail; limits on claimed reproduction.	E200-022/040/041.

Trigger	Information required for the triggered subject	Governing requirements
Protected or lost material	Restriction or loss; asserted basis; accountable role; examination route where available; effect on assessment and later reconstruction.	E200-023/042/043.
Ethical or policy assessment	Evaluative question; attribution; values/criteria; affected parties; comparisons and tradeoffs; limits; recommendatory or operative status.	E200-024/044.
Legal assertion	Legal concept; asserted source; institutional/jurisdictional context; authority; temporal applicability and procedural status, including explicit unresolved components.	E200-025.
Transformed view	Source/resulting versions; selection/transformation; retained attribution, qualification and history; omitted content and limitations; declared audience and boundary.	E200-026/033.

A.4 Link interpretation and unavailable context

A claim reference identifies the asserted version, not merely a mutable latest view. A material reference identifies the portion used where that distinction affects the inference. A criteria reference identifies the governing edition. A shared-context reference identifies which claims inherit it and which exceptions apply. An ambiguous reference does not provide an inspectable link merely because it opens a document.

If the package cannot determine a material value, it records whether the value is unknown, not collected, not applicable, disputed, lost or restricted to the extent supported and permitted. A reason recorded by another source remains attributed to that source. This annex does not require the package to accept an assertion of completeness or authority merely because a custodian supplied it.

Annex B

(normative)

Assessment schedule

B.1 General

This normative schedule specifies the minimum evidence methods for assessing this draft. They specify discriminating checks and failure cases; this draft does not claim these cases have been implemented or passed. Each applicable requirement needs its own result even where several use the same dossier. Human review is necessary for meaning, rationale, and sufficiency of disclosure; structural field validation alone is inadequate.

Table B.1 – Epistemic recording assessment schedule

Requirement	Required evidence and discriminating check
E200-001	Inspect package declaration and selected claim inventory. Check that a consequential excluded record is disclosed by the collection rule or limitation.
E200-002	Inspect result ledger and evidence locators. An inaccessible required component is not assessed; a syntax pass is not labeled a true fact.
E200-003	Retrieve two versions and two conflicting claims concerning Q. Their content and targets remain distinguishable.
E200-004	Follow testimony through a translator or summarizer. Originating source and recorder remain separate, including protected attribution.
E200-005	Inspect C1. Its late-arrival inference is not presented as direct observation merely because L1 was directly read.
E200-006	Recover the entry-time assumption and method for C1. A missing method produces a stated limit, not a reproducibility claim.
E200-007	Compare a single intake desk's coverage with an institution-wide assertion. A known unobserved delivery route remains a limitation.
E200-008	Recover receipt, acquisition, entry, and review times or their explicit uncertainty; out-of-order recording does not reorder events.
E200-009	Examine an organizational replacement using a reused name. An identity criterion and separate lineage prevent automatic merger.
E200-010	Locate the relevant L1 entry and R2 image or controlled locators; derived transcript and original are distinguished.
E200-011	Recover L1's separate evidential roles for entry time and delivery time, including rationale and assessor.
E200-012	Present three copies derived from L1. Assessment detects shared origin instead of counting three independent observations.
E200-013	Remove the log for one delivery channel. No receipt found remains distinct from evidence that no request arrived.
E200-014	Inspect uncertainty about queue delay and a confidence quantity if used. Its measured quantity and assumptions are explicit.
E200-015	Recover C2 and reasons for its disposition. If no alternative search occurred, the absence of search remains visible.
E200-016	Compare log authenticity check, receipt-time assessment, and D1 decision. Their questions, roles, criteria, and results are distinct.

Requirement	Required evidence and discriminating check
E200-017	Retrieve C1 versions and changed grounds. Target change, correction, and category change produce different stated reasons.
E200-018	Apply a category split to records lacking the finer information. Mapping records non-recoverability rather than invented categories.
E200-019	Follow C1 to D1. Pending action review is distinguishable from completed correction and from an unreachable external use.
E200-020	Recover D1, the claimed authority for action, and separately attributed consequences. No automatic remedy is inferred.
E200-021	Trace CH1 receipt through pending and disposed states. A closed status without response, responsible role, and reasons fails.
E200-022	Add a machine summary that invents a link. Recover input, system/version where available, output used, uptake role, and correction.
E200-023	Compare protected dossier and released view. Restriction basis and accountable route are recorded without unauthorized disclosure or a false independent-review claim.
E200-024	Inspect an assessment that exclusion was unfair. Criteria, affected parties, and descriptive premises are distinguishable.
E200-025	Inspect an allegation of unlawful exclusion. Asserted source, jurisdiction, authority, and procedural status are stated or unresolved; no legal effect follows from technical compliance.
E200-026	Examine a textual summary or exported dossier. Correction, dissent, attribution, scope, and protection limitations survive or omissions are explicit.
E200-027	Compare supplied semantic components with Annex A. Resolve shared context and exceptions without inferring undocumented values.
E200-028	Inspect a compound occurrence-and-effect claim. Separate components can receive different assessments and revisions.
E200-029	Follow a translated or relayed statement to its available source context; distinguish quoted content from the recorder's interpretation.
E200-030	Inspect an observation's window, method, observer and detection limits; a broader claim does not acquire unobserved coverage.
E200-031	Recover premises, assumptions and consequential inferential steps; a stipulated process is not mislabeled an observed history.
E200-032	Examine selective preservation and any concealment hypothesis. Missing evidence alone does not establish concealment.
E200-033	Trace an extraction, redaction or imputation to its source and effect; a completed value remains distinguishable from observation.
E200-034	Inspect aggregate populations, denominators, weights and changed composition; repeated or recoded items do not become independent observations.
E200-035	Compare confidence statements across targets or methods; unsupported commensuration and hidden unresolved dimensions are detected.
E200-036	Distinguish rejected, retained and unexamined alternatives; an unperformed sensitivity analysis is not described as completed.
E200-037	Reconstruct assessment criteria and evidence at the time; later rules do not silently change an earlier result.

Requirement	Required evidence and discriminating check
E200-038	Follow two revision branches. Latest entry order alone does not establish evidential precedence or erase disagreement.
E200-039	Separate pre-intervention evidence, intervention, later evidence and effect attribution; discovery differs from creation.
E200-040	Inspect generated links, imputed values and computational selection; structured output is not treated as independent observation.
E200-041	Test a stated reproduction or inspection claim against available inputs, method and configuration; unavailable detail limits the result.
E200-042	Compare custodian assurance, direct authorized examination and unavailable source; their scopes remain distinct.
E200-043	Inspect a formerly accessible source after loss or restriction; the historical assessment and current access limit remain distinguishable.
E200-044	Recover affected parties, evaluative comparisons and omitted effects; a recommendation is not reported as an adopted rule.
E200-045	Check every requirement's result and evidence against both normative annexes; absence of required information is not a missing trigger.
E200-046	Inspect coverage, sampling and automatic checks; partial examination does not acquire an exhaustive claim.
E200-047	Compare a revised package with its prior assessment; affected results are reassessed or explicitly pending.
E200-048	Inspect unknown-context declarations alongside mandatory references/content and reasoning; a missing structural component or unperformed examination does not acquire a fulfilled result.
E200-049	Inspect a grouped obligation with mixed component results; an unassessed or failed component remains visible and prevents overall fulfillment.

B.2 Assessment sequence and retained result

The assessor fixes the package edition, access arrangement and claim inventory before applying the schedule. The assessor identifies present conditional subjects, locates the Annex A information and examines the semantic checks in Table B.1. The result register records the requirement, trigger, evidence locator, observed result, assessor, date and limitation. A domain-equivalent case can test the same distinction when the package does not concern the illustrative delivery case.

One material item can support several checks, but every applicable requirement receives a separate result and materially distinct component results follow E200-049. A counterexample establishes a defect only within the tested scope; a passing case does not establish universal institutional performance. If assessor disagreement concerns the meaning of a claim, its material, criteria or scope, the report identifies that point rather than averaging incompatible conclusions into a numerical result.

Annex C

(informative)

Worked epistemic cases

C.1 A late-recorded delivery

This invented case tests recording distinctions. It supplies no claim about an actual institution or applicable law.

Target. Whether request Q arrived before the deadline specified in a synthetic institution's internal rule R1. The asserted rule and whether it applies are separate claims.

C1 version 1. Clerk A reports that Q arrived after the deadline, inferred from entry log L1. Target time is the claimed receipt time; recording time is the later creation of C1. The method assumes entry time matches receipt time.

Evidence use. L1 supports that an entry occurred at the recorded time. Reviewer B records that its support for receipt time depends on the untested assumption about queue delay. Three copies of L1 are not independent corroboration.

Alternative C2. A protected participant reports earlier delivery; a receipt image R2 is available to an authorized reviewer. The public view identifies restricted evidence and the scope of examination without naming the participant.

Action D1. The institution records exclusion of Q using C1 and R1. This is an attributed institutional act. Its occurrence, justification, and any claimed legal effect remain separate.

Challenge CH1. The participant challenges C1 and provides R2. The record includes the challenged version and receipt time of the challenge; a pending challenge is not displayed as a completed review.

C1 version 2. Review establishes that the entry occurred later than the claimed delivery. The assessed receipt time changes; the entry event does not. The revision links its grounds to R2 and records the continuing uncertainty. C1 version 1 and D1 remain identifiable historical records.

Dependency review. D1 is marked for review. Until a later action is evidenced, correction of C1 is not displayed as restoration of Q's participation. The record can identify consequences of the interval of exclusion separately.

Regime change. If the institution later defines arrival by a different channel, the change of rule/category has its own effective interval. It does not silently recode earlier evidence or establish that earlier actors used the new meaning.

C.2 Generated relationship and shared-source dependence

A fictional analysis receives three documents: an intake entry, its automated summary and a report that cites the summary. The summary adds a claim that two named organizations coordinated their decisions. The intake entry only records that messages were exchanged. The package keeps the communication occurrence, the inferred coordination and the later report as distinct claims.

The three documents share a derivation path. Their number does not supply independent corroboration. The generated relation has a source and method reference, but that provenance does not establish its content. A reviewer can reject the unsupported coordination inference while retaining evidence of the messages. A later independent account could change the assessment; its independence and target relevance would still need examination.

If a public graph displays only the generated edge, the reduced view needs its inferential qualification and relevant limitation. A caption that describes the edge as observed would lose the distinction. No universal

graph schema is needed to expose this failure; a reader can compare the graph's statement with the source material and assessment.

C.3 Reclassification, intervention and later evidence

A fictional institution broadens its participation category after reviewing evidence that earlier records omitted some forms of contribution. Existing archived material supports reclassification of some earlier cases, while others lack the necessary detail. The new category also changes later access to institutional resources.

The dossier retains three linked changes. The category changed; knowledge of some earlier contributions changed through re-examination; and later resource access changed through practical uptake. The unresolved earlier cases do not acquire a finer classification merely because the vocabulary now provides one. Nor does increased later participation prove that identical opportunities were available earlier.

An ethical assessment can favor the new arrangement while recording its additional reporting burden and effects on different groups. A policy proposal can recommend wider adoption without claiming institutional authority to impose it. The package records these positions and their criteria separately from evidence concerning participation and from the decision that implemented the change.

Annex D

(informative)

Source trace and drafting rationale

D.1 General

References are to the supplied local PDFs indexed in `foundation_manuscripts/MANIFEST.md`; page numbers are one-based PDF pages. Source passages provide conceptual grounds, not adopted requirements. No external compatibility or legal claim is made.

Table D.1 – Foundation passages and recording requirements

Source	Operational proposal and reason
FM-004, §4.2, pp. 11–14; §4.6, pp. 43–45	E200-003–008 distinguish target, manifestation, representation, and observation conditions. A single undifferentiated fact field cannot preserve these questions.
FM-005, §5.4, pp. 28–31	E200-010–013 assign evidence roles relative to claims and preserve trace paths, alternatives, and dependence. Material presence alone does not establish relevance or independent corroboration.
FM-005, §5.17, pp. 141–142	E200-014/015 preserve dimensional uncertainty and alternatives. A single mandatory confidence score was rejected for this draft because methods and uncertainty sources differ.
FM-007, §7, pp. 26–29	E200-009 separates record references, identity criteria, and lineage, permitting unresolved matches. Administrative identifier equality is insufficient as a universal criterion.
FM-005, §5.20, pp. 168–174	E200-017–020 distinguish evidential, intervention-related, historical, and category revisions, and the historical effects of an earlier representation. Silent overwrite loses those distinctions.
FM-005, §5.19, pp. 160–161, 168	E200-021–023 make machine mediation and contestability inspectable while allowing differentiated access. A declaration that “AI was used” omits material epistemic conditions.
FM-003, §3.10.9, p. 115; §3.13, pp. 141–142	E200-024 separates generative attribution from ethical evaluation and records affected parties and criteria. No universal beneficialness or commensuration is assumed.
Programme Brief, §3A; repository jurisprudential discipline	E200-025 preserves the asserted basis and status of legal claims. This is a recording boundary proposed by the programme, not a legal conclusion derived from a manuscript.

The selected direction is an inspectable claim package with attributed relationships and scoped evidence. Alternatives included a single verified-fact flag, a mandatory new ontology class for every assertion, and a fully specified adjudication process inside this document. The first loses distinctions; the second prematurely fixes implementation architecture; the third conflicts with the planned separation of epistemic representation from GR-210 procedures. The present choice leaves representation and procedural elaboration open while producing requirements that a small synthetic dossier can test.

D.2 Additional foundation analysis for edition 0.2

FM-005, sections 5.4.4–5.4.8, PDF pages 32–35, distinguishes observation, inference, latency, hiddenness and negative evidence. E200-030–032 require an inspectable observational and inferential path and do not infer concealment from silence. Sections 5.17.3–5.17.8, pages 145–150, distinguish generative linkage, boundary, scale, time, model and competing-explanation uncertainty. E200-034–036 preserve those dimensions without a compulsory scalar score.

FM-005, sections 5.18.1–5.18.5, PDF pages 152–156, explains why visibility and institutional legibility are uneven and why greater visibility can itself cause exposure. E200-042/043 separate accountable examination from unrestricted publication. These recording duties do not claim to complete the manuscript's broader account of epistemic justice.

FM-005, section 5.19, PDF pages 162–164, distinguishes computational observation, classification, inference and generated representation. E200-033/040/041 preserve transformations and limits on inspection. A generated description can aid inquiry without becoming an independent source of authority.

FM-007, section 10, PDF pages 45–50, distinguishes partial attributes, numerical scales and changing composition; section 17, pages 78–80, distinguishes regime alignment and recovery of omitted information. E200-034–038 adapt these distinctions to inspectable records without importing a formal model or declaring Property equivalent to Attribute.

D.3 External drafting models

The ISO model document and ITU-T author's guide inform the organization of scope, dated references, terms, clauses and normative or informative annexes. The United Nations National Quality Assurance Frameworks Manual provides a useful comparison for distinguishing institutional conditions, processes and outputs in a quality framework. Here, package recording, assessment performance and institutional effects remain separate subjects. No UN statistical quality indicator or external conformance rule is incorporated through this comparison.

Annex E

(informative)

Unresolved issues and specification needs

E.1 General

- **OPEN — Representation.** Whether claim identity is implemented through objects, qualified statements, wrappers, or hybrids requires disagreement, revision, protection, and exchange cases before a Specification decision.
- **OPEN — Burden.** Initial review needs to measure time and participant burden as well as field completeness. Shared context can reduce duplication; E200-027 addresses the preservation of claim-specific exceptions.
- **OPEN — Evidence assessment granularity.** The minimum useful rationale varies across testimony, measurement, historical interpretation, and routine record entries. Domain profiles need cases and relevant expertise.
- **OPEN — Challenge procedure.** The effective operation of submission routes, standing, accessible participation, impartial assessment, notification, timing, appeals and repair in GR-210 and institutional profiles needs evidence from actual practice. E200-021 records results without establishing that these practices exist or work.
- **OPEN — Retention and restriction conflicts.** Historical reconstruction, deletion, protection, and procedural examination can conflict. Named institutional and jurisdictional profiles need explicit review; this draft imposes no universal retention period or disclosure priority.
- **OPEN — Technical needs.** Independently addressable versions, evidence-role links, dependency notifications, missingness states, controlled locators, and loss-aware transformations are candidate inputs to GR-SPEC-120/130/200. No encoding or transport protocol is adopted here.
- **OPEN — Conformance practice.** The matrix is a review design, not a completed validator or certification programme. Independent reviewers need to test whether the same package yields reproducible assessments and whether affected participants can recover its meaning.

GENERATIVITY STANDARDS PROGRAM

GR-210

Standards-track Working Draft

Version 0.2 2026-09-22

Evidence, Interpretation, and Contestation

WORKING DRAFT FOR REVIEW

This document contains proposed provisions for technical and institutional review. It is not an adopted Standard or an operative governance instrument. Its scope, application conditions and publication status are specified in the text.

Prepared by the Generativity Standards Program. Reference to external publications does not imply endorsement by ISO, IEC, IEEE or any United Nations body.

Foreword

Responsible editor: UNASSIGNED. Canonical source: standards/GR-210-evidence-interpretation/GR-210.tex. Intended readers are procedure operators, affected people, reviewers and assessors.

This is a **PROVISIONAL Standards-track Working Draft**. It is not adopted, and preparation does not formally initiate a standards project, authorize an institutional procedure, or establish a legal entitlement. Its requirements are proposals for review and experimental assessment. Draft 0.2 preserves the meaning of C210-001 through C210-032 and extends the procedure declaration, case handling, protection, and assessment schedules. Draft 0.1 remains historical material.

Bibliography 20

Introduction

An account can be authentic, widely repeated, or institutionally accepted and still lack adequate grounds for its substantive conclusion. A person affected by that account also needs a usable route to question it. This document connects the examination of evidence with the practical organization of receipt, response, review, revision, and action. It keeps those functions distinct so that a successful correction of text is not mistaken for a completed remedy and an inclusive procedure is not mistaken for proof of truth.

The foundation manuscripts distinguish trace from evidence, evidential adequacy from epistemic justice, and current knowledge of the past from the past and its historical representations. They also identify unequal capacities to produce, preserve, interpret, and contest evidence. The procedures proposed here operationalize a bounded part of those concerns. They do not claim to exhaust the philosophical concepts or prescribe a single institutional model.

The procedure can be operated with documents and accountable people before a machine protocol is needed. Technical infrastructure becomes useful when case correlation, controlled exchange, version tracking, notification, or concurrent action requires interoperable behavior. Such infrastructure remains subordinate to declared authority and protection. A complete state log cannot establish that a reviewer actually considered the grounds or that an affected person could use the route.

1 Scope

1.1 General

This document proposes requirements for a bounded procedure through which people can question an attributed account, introduce evidence or an alternative interpretation, obtain a reasoned disposition and seek further review. Its subjects are the procedure operated by a named organization or recording practice and the associated case record.

An evidential assessment, a procedural disposition, an institutional action and an externally competent legal finding remain distinct. This draft provides no universal tribunal, evidentiary ranking or legal right to review. A conforming procedure can conclude that the available evidence does not resolve the dispute.

The scope includes a procedure declaration, accessible receipt, case scoping, reviewer assignment, evidential and interpretive examination, participation, reasoned disposition, notification, further review, correction propagation, practical response, closure, and protected retention. It excludes a universal evidentiary ranking, mandatory probability scale, cross-jurisdiction legal remedy, and a claim that procedural conformity proves the underlying facts. Institutional profiles determine the contextual service periods and authority within these boundaries.

2 Normative references

2.1 Dated draft dependencies

For experimental assessment against this edition, GR-100, *Foundations and Vocabulary*, Working Draft 0.2, supplies operational terms; GR-200, *Epistemic Recording Framework*, Working Draft 0.2, supplies the package and claim requirements invoked by C210-030. The source locations are `standards/GR-100-foundations-vocabulary/GR-100.tex` and `standards/GR-200-epistemic-recording/GR-200.tex`. Both are draft dependencies, not adopted Standards. Their relevant requirements remain applicable to the bounded claim package; a field-level check does not satisfy package-level obligations.

A dependency revision requires review of affected procedure declarations, claim packages, and assessment results. GR-110 concerns the broader generativity recording package and is a related informative publication here, not a blanket additional conformance dependency. Full GR-300/310/400 profiles remain in development. Directives Part 1 governs the programme's own development procedure after adoption; its periods are not universal periods for institutions using GR-210.

No external legal instrument or United Nations publication is a normative dependency of this edition. Comparative sources in the bibliography inform drafting and assessment architecture without importing institutional powers or policy commitments.

3 Terms and definitions

3.1 Operational procedure terms

The following terms narrow the procedural use in this document without redefining the broader GR concepts supplied by GR-100.

Operator The accountable organization, person, or arrangement that declares and provides the procedure within its stated authority.

Case A distinguishable collection of issues, submissions, review actions, dispositions, and follow-up concerning identified records or decisions.

Case record The retained representation of a case, including its boundaries, versions, access scope, and

known missing material. Its existence does not prove that every represented action occurred.

Issue A question capable of receiving a scoped response, such as whether a date is wrong, evidence supports a claim, a category is adequate, or the declared procedure was followed.

Reviewer The assigned person or accountable review function that examines specified issues within declared competence and authority.

Disposition The reasoned procedural outcome for an issue or case. It can maintain a judgment, support revision, record unresolved evidence, refer the matter, or close a procedure without settling the substantive question.

Practical response An authorized or proposed action following review, distinct from recording the disposition and from evidence that the action was completed.

Further review Reconsideration, a procedural appeal, or another declared examination of a previous handling or disposition, with the route's authority and independence stated.

Material grounds Evidence, assumptions, criteria, or reasons capable of changing a reasonable assessment of the issue, its disposition, or its consequential use within the declared scope.

Case state A procedural status indicating completed and pending handling. It is not a truth value, a probability, or an institutional judgment on the underlying claim.

4 Procedure declaration

4.1 General

C210-001 The operator shall publish or otherwise provide an accessible procedure declaration identifying its purpose, eligible users, covered records or decisions, responsible roles, asserted authority, submission routes and exclusions.

C210-002 The declaration shall distinguish technical correction, evidential disagreement, procedural complaint, ethical or conduct complaint and an asserted legal claim, identifying their available handling routes and limits of authority.

C210-003 The operator shall declare response and review periods, their start events, permitted extensions, notice arrangements and the route available when a period is exceeded. The chosen periods shall be justified for the institutional context and affected users.

C210-004 The operator shall declare the information needed to submit a case, the support or alternatives available to users and how restricted evidence or protected identities can be handled. A demand for unnecessary public disclosure shall not be a condition of receipt.

NOTE 1 No universal period is selected here. The programme's own standards-development comments and appeals are governed by Directives Part 1 if adopted; an institution using records has its own declared procedure and legal context.

4.2 Declared authority and service conditions

C210-033 The declaration shall have an identifier, version, effective interval, accountable owner, and accessible change history. It shall identify the normative dependencies and any institutional profile applied, the intended users and languages, and the procedure functions actually available. A named but unstaffed function shall be identified as unavailable rather than presented as an operative review route.

C210-034 For each kind of issue, the declaration shall identify who can receive it, examine evidence, determine a disposition, authorize action, and conduct further review. It shall distinguish an operator's

internal policy from a claimed external legal mandate and identify the source, scope, and uncertainty of the latter. Receipt by one function shall not transfer authority belonging to another.

C210-035 The operator shall maintain the service schedule in Annex A, including receipt, acknowledgement, clarification, review, reply, disposition, notification, further-review requests, action follow-up, and closure. The schedule shall identify clock starts, responsible roles, expected periods or deadlines, permitted pauses and extensions, and escalation when service cannot be provided.

C210-036 The operator shall make submission and further-review routes available without requiring a person to accept the challenged account, withdraw an unrelated complaint, or expose unnecessary protected information. Any eligibility limitation, fee, identity requirement, representative arrangement, or technological prerequisite shall have a declared purpose, authority, proportionality rationale, and available alternative or challenge route.

C210-037 Before changing the procedure, the operator shall assess effects on open cases, participation, protection, and remedies. The change notice shall state the new version, effective date, reasons, transition treatment, and how affected users can question the change. A later rule shall not be applied silently to make an earlier handling appear compliant.

C210-038 A profile shall identify its institutional setting, covered actions, authority limits, service periods, available resources, review competence, protection basis, and assessment scope. It shall identify any requirement not met rather than claim full GR-210 fulfillment through a profile that silently removes an applicable obligation.

C210-039 The operator shall assess whether its declared channels and staffing can support the expected cases and urgency. Material capacity gaps shall produce a documented mitigation, narrower service declaration, referral arrangement, or postponement with notice. A backlog shall not be concealed by classifying unexamined submissions as resolved.

NOTE 2 An institution can distinguish a clerical correction desk from a merits-review panel and an external legal forum. A single contact can assist routing, but that convenience does not make it competent to decide each type of question. A profile's named institution is part of the authority claim to verify, not evidence of authority by itself.

5 Receipt and scoping

5.1 General

C210-005 On receiving a submission, the operator shall create a distinguishable case reference and record receipt time, the target record or decision and version if available, the asserted issue and the submitter's attribution or protected-contact arrangement. Receipt shall not be reported as agreement with the submission.

C210-006 The operator shall acknowledge receipt through the declared route or record why acknowledgment is not possible. The response shall explain the next step, expected timing and any missing information needed for further action.

C210-007 Where a case is out of scope, incomplete, duplicated or directed to the wrong recipient, the operator shall record that procedural reason and any available correction or referral route. That outcome shall not be represented as factual refutation.

C210-008 Any restriction on repetitive or abusive submissions shall use declared criteria, record the reason and preserve a route to challenge the restriction. The operator shall not classify a submission as abusive solely because it criticizes an authoritative account or repeats an unresolved material concern.

5.2 Intake, triage, and issue separation

C210-040 The operator shall accept enough information to identify a concern without requiring the submitter to supply a complete evidentiary case or technically correct amendment at receipt. If the target or issue is unclear, the operator shall seek clarification and offer the declared assistance before closing for incompleteness, unless contact is unavailable or a stated protection constraint prevents it.

C210-041 Triage shall identify immediate protection or irreversible-consequence risks, the covered question, required routing, known deadlines, and whether temporary preservation or action review is available within the operator's authority. Triage shall not be presented as a concluded evidential finding. Any urgent measure shall have a responsible actor, scope, reason, review point, and notice appropriate to protection needs.

C210-042 A submission containing several kinds of issue shall be divided into distinguishable questions with linked handling routes and a coordinating contact. A referral shall identify what is sent, on what authority, to whom, and whether receipt or acceptance has been confirmed. The operator shall not describe sending a referral as evidence that the recipient has assumed the case.

C210-043 The intake record shall preserve the submitted meaning and relevant original formulation within protection limits. Translation, transcription, summarization, or assisted reformulation shall identify its responsible role, method, version relationship, and material uncertainty. The submitter shall have a practicable opportunity to correct a material misunderstanding through the permitted contact arrangement.

C210-044 A duplicate-case decision shall identify the related case and explain which issues are shared and which remain distinct. Consolidation shall retain separate attribution, protection preferences, and individual practical consequences where material. A previous disposition shall not automatically dispose of new evidence or a newly identified defect in the previous handling.

C210-045 A request for further information shall specify the missing information, why it matters, who is expected to supply it, available assistance or alternatives, the response period, and the effect of nonresponse. The operator shall not shift responsibility for evidence within its own declared control to a person who lacks access without explaining and addressing that access problem.

C210-046 A case placed on hold shall identify the reason, affected work, responsible owner, next review date, and clock treatment. A hold shall not remove the case from pending-work reporting or imply acceptance, rejection, or abandonment. The operator shall reassess the hold at the stated review point and notify permitted recipients of a material change.

C210-047 When a submitter withdraws a request, the operator shall record its scope, distinguish withdrawal of participation from withdrawal of an evidential assertion, and explain any continuing handling under a separate declared responsibility. Withdrawal shall not be described as proof that the original claim was false or that the person agreed with the challenged decision.

C210-048 Case transitions shall conform to the semantic controls in Annex B. The operator shall record the previous and new state, trigger, responsible actor, time, reason, and next action. Local status labels may differ if their mapping preserves the distinctions between receipt, review, disposition, action pending, and closure.

6 Review responsibilities and participation

6.1 General

C210-009 Before substantive review, the operator shall identify the reviewer or review function, relevant competence, relation to the contested account and conflicts of interest. Material conflicts shall be handled through recusal, reassignment or a disclosed limitation with an appropriate further-review route.

C210-010 The reviewer shall identify the questions within the case, the relevant claim versions, evidence available, known limitations and decision criteria. Factual, normative, procedural and legal questions shall remain distinguishable.

C210-011 Affected parties shall be given an opportunity to respond to material grounds used in the disposition through a procedure consistent with protection and applicable institutional constraints. Where direct disclosure is restricted, the operator shall explain the permitted alternative and its limits.

C210-012 The operator shall record participation barriers known to affect the case, assistance or adjustments offered and material perspectives that could not be obtained. Absence of a response shall not automatically be represented as consent or admission.

NOTE 1 A reviewer cannot promise that every perspective will be available. The proposed obligation is to expose the evidential and procedural consequence of a material gap.

6.2 Assignment, competence, and meaningful response

C210-049 The reviewer assignment shall state the questions delegated, relevant domain competence or situated knowledge, decision limits, availability, and accepted responsibility. Where several reviewers supply different expertise, the record shall identify who integrates findings and who is accountable for the disposition. Unavailable competence shall narrow the finding or trigger additional review, referral, or deferral.

C210-050 The operator shall provide a route to raise a conflict concern and assign its assessment to a person not deciding a complaint about their own interest. The conflict disposition shall identify the concern, relevant evidence, management action, and effect on the case. Disclosure alone shall not be represented as independent handling.

C210-051 An author of the challenged account may explain its sources or participate in a disclosed initial reconsideration, but shall not be described as an independent reviewer of that account. A material unresolved conflict shall not support an unqualified independent-review claim; the available further-review arrangement and its limits shall remain explicit.

C210-052 Before a consequential disposition, the operator shall give affected parties notice of the questions, material grounds proposed for reliance, applicable criteria, response route, and response period to the extent permitted by protection. A later-added material ground shall receive a further response opportunity unless a declared urgent measure requires temporary action with prompt subsequent review.

C210-053 An opportunity to respond shall be assessed in relation to actual access, language, disability, resources, time, and the form of the material. The operator shall record requested adjustments, its response, and unresolved barriers. Merely making a complex dossier available shall not establish that an affected person could meaningfully address the proposed grounds.

C210-054 Where direct participation is unsafe or impracticable, the operator shall assess the declared alternatives, including protected contact, assisted submission, representative participation, or controlled independent examination. The record shall identify the chosen arrangement, its authority and limitations, and any material perspective it cannot provide. Representation shall not be inferred without a basis.

C210-055 A reviewer shall assess testimony in relation to the source's access, claim scope, method, and material limitations rather than institutional status alone. Relevant experience and technical expertise shall remain distinguishable. Giving a person an opportunity to speak shall not be reported as showing that their grounds influenced the decision unless the disposition records how they were considered.

C210-056 If the reviewer and decision authority are different, the authority shall identify the review findings received, any departure from them, the grounds and competence for that departure, and the

additional response opportunity required by new material grounds. A managerial instruction shall not silently replace an evidential assessment while retaining the reviewer's attribution.

C210-057 The operator shall provide a protected route to report retaliation or interference linked to participation and shall record available protective responses within its authority. Such a report shall remain distinct from the factual merits of the original case. A person shall not have to publish the protected allegation to obtain triage or an explanation of the available route.

7 Evidence and interpretation

7.1 General

C210-013 An assessment shall identify the claim under examination, the evidence relied on, how that material bears on the claim, relevant method and assumptions, and known counterevidence or materially plausible alternatives.

C210-014 The reviewer shall distinguish the authenticity or integrity of a source from the warrant it provides for a particular claim. A signed assertion shall not receive an unqualified truth status merely because its signature validates.

C210-015 A conclusion based on missing evidence shall identify the expected trace-production, observation or preservation conditions supporting that inference. Where those conditions are not established, absence of the record shall remain distinguishable from non-occurrence.

C210-016 The assessment shall state uncertainty and its scope without inventing a common probability scale for heterogeneous judgments. Disagreement among assessors shall be attributed and retained where material and permitted.

C210-017 Where a category, method or institutional rule is challenged, the reviewer shall distinguish whether it was applied correctly from whether its adequacy or legitimacy is itself under review. A correct application shall not by itself dispose of a challenge to the rule.

C210-018 A material computational or AI-assisted contribution to the review shall be identified with the inputs or sources available for inspection, its role, relevant limitations and responsible human or institutional uptake. An inaccessible internal process shall not be replaced by an invented explanation.

7.2 Evidence plan and material examination

C210-058 The reviewer shall maintain an issue-to-evidence plan identifying the question, claim versions, relevant criteria, material available, material sought, expected access, alternatives to examine, and known gaps. A change in the plan that materially affects the scope or burden of review shall be recorded and communicated to permitted affected participants.

C210-059 An evidence item used in a disposition shall have a locator or controlled reference, source attribution, acquisition context, relevant version, and any known transformation or custody limitation material to the inference. An unavailable original shall be distinguished from an examined copy, excerpt, testimony about the item, or generated reconstruction.

C210-060 For each material item, the assessment shall state its role relative to the specified claim: support, challenge, qualification, non-discrimination, or another explained relationship. The reviewer shall not give the item a universal reliability status that silently transfers across different claims, times, or contexts. A role assigned by a party shall remain distinguishable from the reviewer's assessment.

C210-061 Where several items are treated as corroboration, the reviewer shall examine known derivation and dependence material to that claim. Copies, summaries, translations, model outputs, and repeated

citations of one source shall not count as independent observations solely because they are separately stored or differently worded. Any asserted independence shall have a stated basis and limits.

C210-062 The reviewer shall identify material alternatives that fit the accessible evidence and state why an alternative is retained, weakened, rejected, or outside the assessed scope. An alternative need not receive equal weight merely because a party proposes it. Failure to examine alternatives shall remain a limitation rather than be reported as evidence that none exists.

C210-063 When an identity, temporal order, measurement, classification, or causal link is contested, the review shall identify the relevant criterion or method and assumptions. Agreement on a record identifier, timestamp, endpoint, or category label shall not by itself resolve the corresponding underlying identity, chronology, trajectory, or causal question.

C210-064 An assessment of a generative contribution shall state the capacity, relation, distinction, constraint, or possibility at issue, the comparison condition, temporal horizon, proposed connection, and evidential limits. A change following an intervention shall be examined for whether it reveals an earlier condition, creates a new condition, or combines both; later observation shall not silently become direct evidence of the earlier configuration.

C210-065 If a rule or category is challenged, the operator shall separate the case-specific application question from the rule-review question and identify the competent recipient for each. A referral of the rule question shall leave its status visible. Rejection under the existing rule shall not be represented as a finding that the rule is adequate, fair, or legally valid.

C210-066 A change in evaluative criteria during review shall identify the earlier and revised criteria, authority, reasons, affected issues, and transition effects. The operator shall provide a response opportunity where the change materially affects a party's case. Historical acts shall retain the criteria actually relied on at the time, even when the present assessment uses a later framework.

C210-067 A numerical score, confidence estimate, or model recommendation used materially in review shall identify what it measures, relevant inputs, method and version where available, assumptions, uncertainty, and role in the decision. A threshold chosen for operational action shall remain distinguishable from an estimate of factual warrant. Unavailable technical details shall qualify the assessment rather than be fabricated.

C210-068 The reviewer shall document the planned examination actually performed, material steps not performed, reasons, and effects on the conclusion. An evidence request sent, an access permission obtained, or a tool available shall not be reported as an examination completed. A finding shall remain bounded by the material and methods actually used.

8 Disposition and practical response

8.1 General

C210-019 The disposition shall state the questions decided, findings and their scope, evidence and reasons, responsible decision function, decision time, remaining disagreement and matters outside its authority.

C210-020 The disposition shall distinguish correction of a record, changed evidential assessment, maintained judgment, changed institutional action, inability to decide and procedural closure. Procedural closure shall not imply epistemic agreement.

C210-021 Where the procedure supports a remedy or practical response, the disposition shall identify the proposed or authorized action, its responsible executor, scope, timing and evidence needed to establish completion. Recording a proposed action shall not establish that it occurred.

C210-022 The operator shall notify the submitter and other relevant recipients through the declared, permitted routes, explain any further-review route and record delivery or known failure. Public notices shall respect the case's disclosure limits.

C210-023 A material correction shall be linked to the earlier account and known dependent views or decisions. The operator shall record which corrections or notices were performed and which downstream effects remain unresolved.

NOTE 1 A corrected classification can leave lost opportunities, costs or harm unremedied. The procedure records the distinction rather than declaring repair complete because a field changed.

8.2 Reasons, notification, and action tracking

C210-069 Each disposition shall address every scoped material issue or state why it remains deferred, referred, withdrawn, or unresolved. The record shall distinguish the parties' positions, the reviewer's assessment, the authorized determination, and any minority or competing assessment retained within protection limits. A single closed-case label shall not conceal different outcomes for different issues.

C210-070 A maintained judgment shall explain why the challenge does not warrant the requested change, including treatment of material contrary grounds. An inability-to-decide disposition shall identify the limiting evidence, authority, or method and any conditions for further review. Neither outcome shall rely solely on institutional acceptance of the original account.

C210-071 An action plan shall distinguish proposed, authorized, assigned, initiated, completed, verified, failed, and no-longer-pursued actions where those differences are material. It shall identify the executor, authority, affected records or persons, due or review date, completion evidence, and route when execution fails. A reviewer lacking implementation authority shall identify the required decision recipient rather than promise completion.

C210-072 When immediate action is taken before full review, the operator shall record the urgency, authority, limited purpose, expected consequences, duration or review point, notice limits, and later examination required. The temporary action shall not be presented as a final evidential finding or remove the remaining opportunity to challenge material grounds.

C210-073 The notification record shall identify the permitted recipient, route, exact disposition or summary version, dispatch time, known delivery status, and any protected information withheld. The operator shall distinguish dispatch, delivery, receipt acknowledged, and substantive response. A delivery failure material to a review opportunity shall trigger the declared alternative or timing correction.

C210-074 A notice of disposition shall give an accessible account of the outcome, material reasons and limitations, action status, further-review route, relevant deadline and starting event, and assistance available. If the full record cannot be shared, the notice shall explain the permitted way to examine or challenge the grounds without overstating the completeness of the summary.

C210-075 Correction planning shall identify known dependent claims, assessments, records, presentations, and decisions within the operator's control or declared notification relationships. For each, the operator shall record correction performed, review pending, no change with reason, notification sent, unreachable recipient, or another explained status. It shall not assert universal propagation beyond the evidenced boundary.

C210-076 A correction shall preserve a distinguishable relationship between the prior and revised account, its reason and authority, and the time of each formulation, subject to protection and retention. The corrected view shall not present earlier decision makers as having used evidence or categories acquired later. A removed sensitive detail shall not be retained in the public history solely to illustrate the correction.

C210-077 A consequential action or remedy shall be evaluated separately from record correction. The follow-up shall identify the intended practical change, evidence of what occurred, unresolved costs or losses, affected perspectives obtained, and limits on causal attribution. An apology, amended field, or scheduled meeting shall not be recorded as restoration of an opportunity without supporting evidence.

C210-078 A case closure shall identify which issues are disposed, which actions remain pending, who owns continuing follow-up, and the conditions for reopening. Where the declared procedure requires action verification before closure, unavailable verification shall prevent that closure claim. Administrative closure shall not erase outstanding obligations, remaining disagreement, or unavailable evidence.

C210-079 If a disposition is itself corrected, the operator shall identify the earlier disposition and notice versions, the error, authority for correction, affected deadlines or actions, and renewed notifications or response opportunities. A substantive change shall receive the review warranted by its effect, rather than be hidden as a typographic correction.

9 Further review, reopening and continuity

9.1 General

C210-024 The procedure shall provide a declared route to request reconsideration of a material error, new evidence or procedural failure, with its scope, competent recipient and limitations. A reviewer of their own contested action shall not be described as independent.

C210-025 A reopened case shall identify the earlier disposition, trigger, changed evidence or criteria, reviewer and new outcome. Later interpretation shall not silently replace the record of what was known or decided earlier.

C210-026 If the operator lacks competence, authority or resources to complete a material step, it shall record the limitation and notify permitted recipients of the available alternative, postponement or closure basis. Passage of time alone shall not establish a finding on the substantive claim.

9.2 Reconsideration, procedural appeal, and reopening

C210-080 The declaration shall distinguish reconsideration of evidence or judgment, review of procedural failure, conduct handling, and an external legal route where one is asserted. It shall state who can request each route, the grounds and scope, responsible recipient, available remedies, timing, and independence arrangements. Routing assistance shall preserve the submitted concern rather than require technical knowledge of the operator's organization.

C210-081 A further-review request shall receive a linked reference, acknowledgement, admissibility decision with reasons, reviewer assignment, timetable, and notice of any effect on action or closure. A refusal to admit the request shall not be represented as substantive refutation and shall identify any remaining challenge route or explicit limit.

C210-082 A person who made the challenged decision shall not be described as independent when reviewing it. An independent-review claim shall identify the reviewer's separation from the disputed handling and relevant interests. If the declared independent function is unavailable, the operator shall disclose the limitation and refrain from claiming that an independent appeal occurred.

C210-083 The further-review authority shall assess whether disputed action needs a stay, temporary qualification, preservation measure, or other protection within its mandate. The decision shall identify urgency, consequences for affected parties, duration or review point, and reasons. Requesting review shall not be assumed either to stop every action or to leave every action unaffected.

C210-084 Further review shall identify the record and criteria reviewed, new material admitted, opportunities for response, questions determined, reasons, remedy, and implementation responsibility. A procedural reviewer acting outside authority to decide factual merits shall remit the appropriate question rather than relabel a procedural finding as a final factual conclusion.

C210-085 Where a remedy requires renewed notice, evidence examination, reassignment, reconsideration, or action, the operator shall record completion evidence before asserting the remedy fulfilled. The renewed disposition shall link the earlier decision and further-review grounds. Repeating the earlier conclusion without performing the required remedy shall not constitute compliance with the review outcome.

C210-086 A reopening assessment shall distinguish newly available evidence, a material error, changed target conditions, changed categories or criteria, procedural defect, and unimplemented remedy. It shall state whether these grounds affect the past assessment, current action, or both. A later event shall not automatically prove that an earlier claim was mistaken under the evidence then available.

C210-087 A reopened case shall preserve the earlier scope, evidence state, disposition, and consequential uses to the permitted extent and identify the new review boundary. New and prior issues may be linked or separated when the reason is recorded. Reopening shall not silently reset an overdue action or delete the history of a missed response.

C210-088 When a service period is exceeded, the operator shall record the missed event, cause, effect, notice, revised target or authorized extension, and available escalation. An extension shall identify who authorized it and why it is consistent with the declared procedure. Repeated extensions shall trigger capacity review and a reasoned alternative, rather than indefinite pending status without accountability.

C210-089 A handover, operator closure, or loss of a responsible function shall identify open cases, pending actions, permitted successor access, affected notices, and continuity limits. Transfer shall require a stated authority and custody record. Where no successor can accept responsibility, users shall receive the available permitted explanation and alternatives; an unavailable service shall not continue to be advertised as operational.

10 Protection and retention

10.1 General

C210-027 The operator shall specify access, retention, correction and disposal arrangements for submissions, evidence, reviewer notes, dispositions and notifications. Content and audit metadata shall be considered separately; history preservation shall not justify retaining prohibited sensitive material.

C210-028 Disclosure, redaction, access withdrawal or disposal affecting a case shall identify its authority, scope, executor and permitted evidence of the action. The operator shall state known limits concerning copies outside its control.

C210-029 A public summary shall distinguish the accessible grounds from material that cannot be disclosed, where that distinction is itself permitted. It shall not claim full independent inspectability when a material evidential restriction prevents it.

10.2 Differentiated access and protected case handling

C210-090 The operator shall distinguish submission content, identity and contact information, evidence, internal working material, disposition, public summary, and audit information in its access and retention schedule. Access shall correspond to an identified purpose and authority. Permission to examine one component shall not be presumed to authorize onward publication or unrestricted reuse of the case.

C210-091 Before relying on protected grounds for a consequential adverse disposition, the reviewer shall assess whether affected parties can receive a sufficient account or a credible authorized alternative examination. If protection prevents fair examination of a material issue, the operator shall narrow the finding, defer it, or state the unresolved limitation rather than claim fully contestable determination.

C210-092 A controlled view shall identify its source case and disposition version, intended audience, material selection or transformation, and permitted limitations. If acknowledging a particular item's existence is restricted, the view shall state its scope at a safe level without exposing that existence. The protected accountability record shall remain available only within its authorized boundary.

C210-093 A suspected unauthorized disclosure, misdirected notification, or compromise of protected evidence shall receive recorded triage, containment within authority, affected-case assessment, permitted notice, and review of whether the evidence or procedure remains usable. Correction of the public copy shall not be described as recall of copies beyond the operator's control.

C210-094 A retention or disposal decision shall assess ongoing review, action, and reconstruction needs against the applicable protection basis, authority, and schedule. The record shall state what is retained or disposed of, when, by whom, and the permitted verification method. It shall not retain prohibited content merely because a review might theoretically occur in the future.

C210-095 An assessor denied access to material required for an applicable finding shall state the resulting limitation. A protected assessment by another authorized competent person may be cited with its scope and independence limits, but shall not be represented as the first assessor's direct examination. Confidentiality shall not convert an unassessed obligation into fulfillment.

11 Conformance and assessment

11.1 General

C210-030 A conformance report shall identify the procedure or case record assessed, operator, institutional context, this draft and dependency versions, applicable requirements, reviewer relationship, evidence and results. It shall identify the case's material claims as a bounded GR-200 Working Draft 0.2 package and report its applicable requirement results, including package-level obligations. A case-record assessment alone shall not establish that unobserved procedural steps occurred.

C210-031 Each applicable requirement shall receive a supported result of fulfilled, not fulfilled or not assessed; a not-applicable result shall give its trigger-based reason. An unqualified claim of fulfillment shall not omit a failed or unassessed applicable requirement.

C210-032 A procedure assessment shall include an ordinary case and relevant failure cases concerning conflict, unavailable evidence, missed timing, restricted disclosure and correction propagation. A case-record-only assessment shall identify the supplied case and the procedural behavior it cannot establish. Reported success shall be limited to the cases and conditions actually exercised.

This edition defines no reduced case-record conformance profile. A case-only report is a partial documentary assessment. Performance obligations remain not assessed when only their records were examined; not applicable requires an absent stated trigger. A procedure claim covers all applicable requirements and the declared GR-200 package dependency. The multi-case rehearsal obligation in C210-032 is explicitly conditional on procedure assessment.

11.2 Assessment plan, results, and limitations

C210-096 Before assessment, the assessor shall define the procedure version, operator and institutional scope, period observed, cases selected, relevant failure conditions, methods, evidence access, and inde-

pendence or author involvement. A sample of cases shall have an explicit selection rationale and limit; a favorable sample shall not be generalized to unexamined settings without supporting grounds.

C210-097 The assessment register shall give each applicable requirement its own result, evidence locator, method, assessor, and unresolved action, distinguishing documentary adequacy from actual performance where both are required. A grouped test may support several results only when its evidence supports each obligation separately.

C210-098 A procedure assessment shall use the minimum coverage schedule in Annex C and justify any additional failure cases arising from the declared context. A synthetic exercise shall identify fictional actors and unperformed external actions. A demonstration of software behavior shall not establish competent human review, meaningful participation, legal authority, or practical remedy.

C210-099 Assessment shall include an intended user's attempt to locate the route, identify the issue, understand the notice and reasons, and determine the next available action under permitted conditions. The report shall record assistance, barriers, failures, and participant relationship to the design. Author familiarity shall not be reported as independent evidence of ordinary-user comprehension.

C210-100 An assessment finding that results in a corrected procedure, case record, or implementation shall identify the changed version, affected requirements, corrective action, and reassessment scope. Results for unchanged material may be reused only with a recorded reason that the change does not invalidate the evidence. A prior pass shall not automatically transfer across a material change.

C210-101 A public assessment summary shall identify the assessed scope, dependency versions, methods, failures and unassessed requirements, protected-evidence limitations, and whether actions were observed or merely documented. It shall not use a certificate, badge, or concise status to imply factual truth, institutional legitimacy, or full procedure fulfillment beyond the evidence.

Annex A

(normative)

Procedure declaration and service schedule

A.1 General

This schedule specifies the information needed to operate and assess the declared procedure. It does not set universal numerical deadlines. The operator supplies actual values, their justification, and the corresponding authority under C210-003/035. An unspecified period is an incomplete declaration, not an unlimited permission to delay.

C210-102 For every applicable service event in Table A.1, the schedule shall specify the responsible role, starting event, period or deadline, notification, allowed pause or extension, and escalation recipient. If institutional constraints impose a different controlling deadline, the declaration shall identify the asserted source and conflict treatment. A service extension shall not be represented as altering an external deadline beyond the operator's authority.

Table A.1 – Procedure declaration and service-event schedule

Event or arrangement	Required declared treatment
Receipt and acknowledgement	Submission routes; minimum intake content; time of receipt; distinction between receipt and agreement; acknowledgement channel and alternative when contact fails.
Clarification and scoping	Assistance; information requested and purpose; response period; inactivity treatment; routing of separate issues; decision on scope with reasons.
Urgent triage	Risks assessed; available temporary protection; authority; duration or review point; notice and later examination; limits on irreversible action.
Review assignment	Accepted reviewer role; competence; conflicts and challenge route; substitute or unavailable-capacity treatment; intended completion or status-update events.
Grounds and reply	Material grounds disclosed or authorized alternative; response period; adjustments; treatment of new material; consequence of failed notice.
Disposition and notice	Decision responsibility; required reasons; delivery arrangements; action plan; notice of further-review scope, deadline, and starting event.
Further review and reopening	Permitted grounds; recipient; independence; admissibility and response events; stay decision; remedy; new-evidence and closure rules.
Action and closure	Executor; due and review points; verification; dependent corrections; remaining action ownership; closure criteria and later contact.
Protection and continuity	Access categories; retention and disposal basis; incident handling; handover authority; limitations when evidence or operators become unavailable.

Annex B

(normative)

Case-state and transition controls

B.1 General

The states below define procedural meaning rather than mandatory serialized values. A procedure can use local terminology or several parallel issue tracks if the mapping remains explicit. State changes concern handling, while claim assessments and institutional actions have separate versions and statuses.

C210-103 A transition shall identify the prerequisite evidence, authorizing role, permitted notification, and continuing work in Table B.1. Skipping a named state shall be permitted only when its underlying obligations are either fulfilled together with another step or inapplicable for a recorded reason. A state label alone shall not serve as evidence that its prerequisite action occurred.

C210-104 Where a case contains multiple issue or action tracks, the overall state shall identify unresolved tracks and their owners. Disposition of one question shall not close another without an explicit reason. Reopening or remitting an issue shall preserve the earlier disposition and its procedural context while identifying the newly pending work.

Table B.1 – Semantic case states and transition conditions

State	Evidence and permitted transition	Meaning not established by the state
Received	Distinguishable submission and receipt time; move to clarification, scoping, or urgent triage with an accountable owner.	Agreement with the assertion or completeness of evidence.
Awaiting clarification	Specific missing information, support, response opportunity, and review point; proceed on receipt or give a reasoned scope or closure disposition.	Falsity, abuse, or abandonment inferred solely from delay.
Scoped / assigned	Questions, target versions, authority, reviewer and conflicts identified; proceed to material examination or a reasoned referral.	Jurisdiction outside the declared mandate or independent review by title alone.
Under review	Examination plan and performed work; material grounds and reply opportunity; pauses remain recorded with review dates.	That every source is authentic or every planned check has occurred.
Awaiting response	Specified grounds and usable response route; proceed after the declared opportunity, addressing barriers and newly raised issues.	Consent, admission, or waiver inferred from nonresponse.
Disposed	Reasoned issue outcomes, limitations, action and further-review notice; proceed to action, review, or permitted closure.	Action completion, truth certification, or agreement by the submitter.

State	Evidence and permitted transition	Meaning not established by the state
Action pending	Authorized executor, action and review point, dependency and verification record; close or escalate under declared criteria.	Remedy completed because it was ordered or scheduled.
Closed / withdrawn	Recorded basis, disposed and unresolved issues, continuing follow-up and reopening route; later reopen with a linked trigger.	Erasure of remaining disagreement, past consequences, or obligations owned elsewhere.
Reopened / remitted	Earlier outcome, trigger, scope, assigned reviewer, and required remedy identified; return to the affected review step.	Retrospective disappearance of the earlier decision or evidence state.

Annex C

(normative)

Minimum procedure-assessment coverage

C.1 General

This schedule applies to a procedure assessment under C210-032/098. For a case-record-only assessment it identifies behavior that the supplied record cannot establish; it does not turn unobserved performance into a not-applicable result. Cases can combine several conditions when each relevant obligation is separately examined.

C210-105 The procedure assessment shall cover each applicable condition in Table C.1, record the input and expected behavior, observe the action claimed, and retain permitted outcome evidence. It shall identify conditions not exercised and their effect on the assessment claim. A fulfilled result shall not be assigned merely because a specimen record contains the expected fields.

Table C.1 – Minimum assessment conditions and discriminating evidence

Condition	Required assessment focus
Ordinary material challenge	Exercise accessible receipt through reasons, notification and stated next action. Trace claim versions and GR-200 package results. Distinguish completed handling from a template showing intended steps.
Conflict or missing competence	Raise an assignment concern; inspect its independently handled assessment, reassignment or limitation, and effect on progression. A title alone does not prove independence.
Unavailable or dependent evidence	Supply a missing original and several derived copies. Observe scope qualification and treatment of dependence rather than invented verification or independent corroboration.
Missed timing or failed notice	Cross a declared target or introduce a delivery failure. Verify status, extension or escalation, renewed opportunity where needed, and absence of deemed substantive agreement.
Restricted material	Compare authorized and permitted reduced views. Check meaningful response alternatives, audit access, and the stated limit where examination cannot be provided.
Category or rule challenge	Separate application from adequacy or authority; trace referral and its acceptance status. Correct application does not alone dispose of a challenge to the rule.
Correction and practical action	Follow a revised assessment to known dependencies and an executor. Distinguish notification, correction, action completion, verification, and unresolved loss.
Further review and reopening	Exercise a procedural or evidential request, stay decision where relevant, reasoned outcome and remedy, and reopening on a distinct trigger. Preserve prior meanings and time boundaries.

Annex D

(informative)

Worked cases and interpretation

D.1 Missing attachment and changed classification

The following case elaborates the synthetic dossier in `examples/p1-contested-decision.md`. None of its actors, notices, decisions, or remedies represents a live institution. A fictional research fund rejects a water-monitoring application after a generated summary states that the equipment was never calibrated. Its intake extract shows only that a calibration attachment was absent. A technician later supplies testimony and a maintenance-log excerpt, while the protected original contains contact details.

Intake creates a case with three questions: whether calibration occurred, whether the application met the existing documentary rule, and whether that rule gives appropriate recognition to maintenance evidence. The first requires claim-relative assessment. The second requires application of the declared rule version. The third is referred to the function authorized to review the rule. None of these operations alone determines a legal claim or an award of funding.

The reviewer distinguishes the absent attachment from non-occurrence, the generated summary from source evidence, and the log excerpt from independent examination of its original. Testimony and a log can share a source; their number does not establish independence. The protected original receives controlled handling with a safe account of the grounds available for response. If the reviewer cannot examine calibration quality or instrument identity, the disposition preserves those limits even while revising the overbroad statement that no calibration occurred.

The record correction links the old and revised claims. A later rule change records its own effective interval rather than making the earlier decision appear to have used the new rule. Scheduling a renewed eligibility review creates an action-pending state, not an award or restoration of lost training opportunities. Practical follow-up investigates the reported interruption, the scope of attribution, and the actual effect of any later response.

D.2 Protected grounds and unavailable independent review

In a second synthetic case, a person disputes an adverse classification based partly on restricted testimony. The operator cannot safely disclose the witness's identity. It provides a redacted account of the material allegation and explores controlled examination by an independent reviewer. The distinction between protection and warrant matters: hiding an identity does not establish the allegation, while the need to test an allegation does not itself authorize publication of the identity.

Suppose the only available reviewer authored the classification. They can explain their original sources and conduct a disclosed reconsideration, but the operator cannot label that work independent. If a credible alternative examination cannot be arranged, the disposition identifies the unresolved procedural and evidential limits. A narrow temporary protective action can be separately considered within actual authority; it does not convert the disputed allegation into a final finding.

The relevant assessment results remain granular. A documented restriction basis can fulfill a documentary obligation. An unperformed independent review remains not assessed. A case record describing a desired notice does not establish delivery or a meaningful response opportunity. The case can close administratively under declared limits without claiming that the underlying factual disagreement has been resolved.

D.3 Outage, deadline, and later reopening

A third synthetic case concerns a challenge received during a service outage. The original timestamp and failed acknowledgement remain recorded. An extension notice identifies the operational cause, responsible

role, revised target and escalation route. If a separate institutional deadline applies, the operator states its asserted source and whether it has authority to alter it; a service notice is not treated as changing external law.

Later material reveals that the original classification depended on a mistaken identity link. Reopening identifies this evidential trigger and the affected past assessment, while preserving the decision and its consequences during the intervening period. The remedy includes checking known dependent views and actions. An unreachable external recipient is recorded as unreachable rather than silently treated as corrected.

Annex E

(informative)

Source rationale and unresolved profile decisions

E.1 Operational interpretation

The synthetic funding case accompanying GR-110 supplies a common example. The procedure's record requirements can be implemented manually before a network protocol is needed. A later Specification would define message correlation, delivery, authorization, concurrent revision and failure semantics in response to demonstrated requirements.

The initial operational direction is recorded in ADR-0004. This expanded procedure remains a programme proposal, not a claim that the foundation manuscripts prescribe these case states, deadlines, or institutional functions. Chapter 5 treats evidence as a role relative to an epistemic target and distinguishes just participation from evidential adequacy. Those distinctions motivate separate assessment of access, method, warrant, disposition, and consequences. The record preserves both a supported conclusion and the limits of the procedure that produced it. For the expansion decision and alternatives, see `decisions/ADR-0005-expanded-drafts-and-source-models.md`. The comparison record is `docs/references/drafting_models.md`.

The choice of explicit schedules follows the need to make a procedure exercisable by someone other than its author. Alternatives include a general right-to-comment statement, a fixed software workflow, or a single universal adjudication model. The first leaves response and remedy underspecified; the other two impose technical or institutional commitments beyond this draft's scope. The selected approach fixes inspectable obligations while profiles specify contextual authority and service arrangements.

The United Nations National Quality Assurance Frameworks Manual provides an informative comparison for separating institutional capacity, process quality, and output quality. Here, the operator and authority declaration, observed review behavior, and resulting case record receive distinct assessment evidence. This translation is a programme design choice; it does not assert that an official-statistics framework creates rights or governs the review procedure. ISO's model document and ITU-T drafting guidance inform publication structure rather than the evidential meaning of a finding.

OPEN ISSUE Service periods, independence arrangements, proof of authority, available remedies, costs and admissible disclosure depend on the institution and require a scoped profile. A synthetic procedure cannot establish their validity in a live jurisdiction.

OPEN ISSUE Abuse handling, protection of vulnerable participants, meaningful access under low resources and the burden of keeping case histories require review with affected users before live deployment.

OPEN ISSUE No reduced profile, universal evidential threshold, legal admissibility rule, or machine protocol is adopted. Domain-specific proof standards, representative arrangements, protected disclosure mechanisms, and independently feasible remedies require their own competent review and recorded authority.
